**Response Structure**

- *(dict)* –

  Describes the settings for a configuration set.

  - **SolutionStackName** *(string)* –

    The name of the solution stack this configuration set uses.

  - **ApplicationName** *(string)* –

    The name of the application associated with this configuration set.

  - **TemplateName** *(string)* –

    If not null, the name of the configuration template for this configuration set.

  - **Description** *(string)* –

    Describes this configuration set.

  - **EnvironmentName** *(string)* –

    If not null, the name of the environment for this configuration set.

  - **DeploymentStatus** *(string)* –

    If this configuration set is associated with an environment, the `DeploymentStatus` parameter indicates the deployment status of this configuration set:

    - `null`: This configuration is not associated with a running environment.

    - `pending`: This is a draft configuration that is not deployed to the associated environment but is in the process of deploying.

    - `deployed`: This is the configuration that is currently deployed to the associated running environment.

    - `failed`: This is a draft configuration, that failed to successfully deploy.

    * `null`: This configuration is not associated with a running environment.
* pending: This is a draft configuration that is not deployed to the associated environment but is in the process of deploying.
* deployed: This is the configuration that is currently deployed to the associated running environment.
* failed: This is a draft configuration that failed to successfully deploy.

- **DateCreated** *(datetime)* –
  The date (in UTC time) when this configuration set was created.

- **DateUpdated** *(datetime)* –
  The date (in UTC time) when this configuration set was last modified.

- **OptionSettings** *(list)* –
  A list of the configuration options and their values in this configuration set.

  * *(dict)* –
    A specification identifying an individual configuration option along with its current value. For a list of possible option values, go to Option Values in the AWS Elastic Beanstalk Developer Guide.

  - **ResourceName** *(string)* –
    A unique resource name for a time-based scaling configuration option.

  - **Namespace** *(string)* –
    A unique namespace identifying the option’s associated AWS resource.

  - **OptionName** *(string)* –
    The name of the configuration option.

  - **Value** *(string)* –
    The current value for the configuration option.

### create_environment(**kwargs)**
Launches an environment for the specified application using the specified configuration.

**Request Syntax**

```python
response = client.create_environment(
    ApplicationName='string',
    EnvironmentName='string',
    Description='string',
    CNAMEPrefix='string',
    Tier={
        'Name': 'string',
        'Type': 'string',
        'Version': 'string'
    },
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ],
    VersionLabel='string',
    TemplateName='string',
    SolutionStackName='string',
    )
```
OptionSettings=[
    {
        'ResourceName': 'string',
        'Namespace': 'string',
        'OptionName': 'string',
        'Value': 'string'
    },
  ],
OptionsToRemove=[
    {
        'ResourceName': 'string',
        'Namespace': 'string',
        'OptionName': 'string'
    },
  ]

Parameters

- **ApplicationName** *(string) – [REQUIRED]*
  
The name of the application that contains the version to be deployed.

  If no application is found with this name, `CreateEnvironment` returns an `InvalidParameterValue` error.

- **EnvironmentName** *(string) – [REQUIRED]*
  
  A unique name for the deployment environment. Used in the application URL.

  Constraint: Must be from 4 to 23 characters in length. The name can contain only letters, numbers, and hyphens. It cannot start or end with a hyphen. This name must be unique in your account. If the specified name already exists, AWS Elastic Beanstalk returns an `InvalidParameterValue` error.

  Default: If the CNAME parameter is not specified, the environment name becomes part of the CNAME, and therefore part of the visible URL for your application.

- **Description** *(string) –* Describes this environment.

- **CNAMEPrefix** *(string) –* If specified, the environment attempts to use this value as the prefix for the CNAME. If not specified, the CNAME is generated automatically by appending a random alphanumeric string to the environment name.

- **Tier** *(dict) –* This specifies the tier to use for creating this environment.
  
  - **Name** *(string) –* The name of this environment tier.
  
  - **Type** *(string) –* The type of this environment tier.
  
  - **Version** *(string) –* The version of this environment tier.

- **Tags** *(list) –* This specifies the tags applied to resources in the environment.
  
  - *(dict) –* Describes a tag applied to a resource in an environment.
    
    - **Key** *(string) –* The key of the tag.
    
    - **Value** *(string) –* The value of the tag.
- **VersionLabel** *(string)* – The name of the application version to deploy.

  If the specified application has no associated application versions, AWS Elastic Beanstalk `UpdateEnvironment` returns an `InvalidParameterValue` error.

  Default: If not specified, AWS Elastic Beanstalk attempts to launch the sample application in the container.

- **TemplateName** *(string)* – The name of the configuration template to use in deployment. If no configuration template is found with this name, AWS Elastic Beanstalk returns an `InvalidParameterValue` error.

  Condition: You must specify either this parameter or a `SolutionStackName`, but not both. If you specify both, AWS Elastic Beanstalk returns an `InvalidParameterCombination` error. If you do not specify either, AWS Elastic Beanstalk returns a `MissingRequiredParameter` error.

- **SolutionStackName** *(string)* – This is an alternative to specifying a configuration name. If specified, AWS Elastic Beanstalk sets the configuration values to the default values associated with the specified solution stack.

  Condition: You must specify either this or a `TemplateName`, but not both. If you specify both, AWS Elastic Beanstalk returns an `InvalidParameterCombination` error. If you do not specify either, AWS Elastic Beanstalk returns a `MissingRequiredParameter` error.

- **OptionSettings** *(list)* – If specified, AWS Elastic Beanstalk sets the specified configuration options to the requested value in the configuration set for the new environment. These override the values obtained from the solution stack or the configuration template.

  – *(dict)* –

    A specification identifying an individual configuration option along with its current value. For a list of possible option values, go to Option Values in the AWS Elastic Beanstalk Developer Guide.

    - **ResourceName** *(string)* –
      A unique resource name for a time-based scaling configuration option.

    - **Namespace** *(string)* –
      A unique namespace identifying the option’s associated AWS resource.

    - **OptionName** *(string)* –
      The name of the configuration option.

    - **Value** *(string)* –
      The current value for the configuration option.

- **OptionsToRemove** *(list)* – A list of custom user-defined configuration options to remove from the configuration set for this new environment.

  – *(dict)* –

    A specification identifying an individual configuration option.

    - **ResourceName** *(string)* –
      A unique resource name for a time-based scaling configuration option.

    - **Namespace** *(string)* –
      A unique namespace identifying the option’s associated AWS resource.
OptionName (string) –
The name of the configuration option.

Return type  dict

Response Syntax

```
{
  'EnvironmentName': 'string',
  'EnvironmentId': 'string',
  'ApplicationName': 'string',
  'VersionLabel': 'string',
  'SolutionStackName': 'string',
  'TemplateName': 'string',
  'Description': 'string',
  'EndpointURL': 'string',
  'CNAME': 'string',
  'DateCreated': datetime(2015, 1, 1),
  'DateUpdated': datetime(2015, 1, 1),
  'Status': 'Launching'|'Updating'|'Ready'|'Terminating'|'Terminated',
  'AbortableOperationInProgress': True|False,
  'Health': 'Green'|'Yellow'|'Red'|'Grey',
  'HealthStatus': 'NoData'|'Unknown'|'Pending'|'Ok'|'Info'|'Warning'|'Degraded'|'Severe',
  'Resources': {
    'LoadBalancer': {
      'LoadBalancerName': 'string',
      'Domain': 'string',
      'Listeners': [
        {
          'Protocol': 'string',
          'Port': 123
        }
      ],
    },
    'Tier': {
      'Name': 'string',
      'Type': 'string',
      'Version': 'string'
    }
  }
}
```

Response Structure

- *(dict)* –
  
  Describes the properties of an environment.
  
  - **EnvironmentName (string)** –
    
    The name of this environment.
  
  - **EnvironmentId (string)** –
    
    The ID of this environment.
  
  - **ApplicationName (string)** –
    
    The name of the application associated with this environment.
  
  - **VersionLabel (string)** –
    
    The application version deployed in this environment.
  
  - **SolutionStackName (string)** –
The name of the SolutionStack deployed with this environment.

- **TemplateName** *(string)* –
  The name of the configuration template used to originally launch this environment.

- **Description** *(string)* –
  Describes this environment.

- **EndpointURL** *(string)* –
  For load-balanced, autoscaling environments, the URL to the LoadBalancer. For single-instance environments, the IP address of the instance.

- **CNAME** *(string)* –
  The URL to the CNAME for this environment.

- **DateCreated** *(datetime)* –
  The creation date for this environment.

- **DateUpdated** *(datetime)* –
  The last modified date for this environment.

- **Status** *(string)* –
  The current operational status of the environment:
  
  * Launching: Environment is in the process of initial deployment.
  * Updating: Environment is in the process of updating its configuration settings or application version.
  * Ready: Environment is available to have an action performed on it, such as update or terminate.
  * Terminating: Environment is in the shut-down process.
  * Terminated: Environment is not running.

- **AbortableOperationInProgress** *(boolean)* –
  Indicates if there is an in-progress environment configuration update or application version deployment that you can cancel.
  
  - true: There is an update in progress.
  - false: There are no updates currently in progress.

- **Health** *(string)* –
  Describes the health status of the environment. AWS Elastic Beanstalk indicates the failure levels for a running environment:
  
  - Red: Indicates the environment is not working.
  
  - Yellow: Indicates that something is wrong, the application might not be available, but the instances appear running.
  
  - Green: Indicates the environment is healthy and fully functional.
  
  - Red: Indicates the environment is not responsive. Occurs when three or more consecutive failures occur for an environment.
  
  - Yellow: Indicates that something is wrong. Occurs when two consecutive failures occur for an environment.
  
  - Green: Indicates the environment is healthy and fully functional.
  
  * Grey: Default health for a new environment. The environment is not fully launched and health checks have not started or health checks are suspended during an UpdateEnvironment or RestartEnvironment request.
  
  Default: Grey
- **HealthStatus** (*string*) –
  Returns the health status of the application running in your environment.
  For more information, see Health Colors and Statuses.

- **Resources** (*dict*) –
  The description of the AWS resources used by this environment.
  * **LoadBalancer** (*dict*) –
    Describes the LoadBalancer.
    - **LoadBalancerName** (*string*) –
      The name of the LoadBalancer.
    - **Domain** (*string*) –
      The domain name of the LoadBalancer.
    - **Listeners** (*list*) –
      A list of Listeners used by the LoadBalancer.
      - (**dict**) –
        Describes the properties of a Listener for the LoadBalancer.
        - **Protocol** (*string*) –
          The protocol that is used by the Listener.
        - **Port** (*integer*) –
          The port that is used by the Listener.

- **Tier** (*dict*) –
  Describes the current tier of this environment.
  * **Name** (*string*) –
    The name of this environment tier.
  * **Type** (*string*) –
    The type of this environment tier.
  * **Version** (*string*) –
    The version of this environment tier.

**create_storage_location()**

Creates the Amazon S3 storage location for the account.
This location is used to store user log files.

**Request Syntax**

```python
response = client.create_storage_location()
```

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'S3Bucket': 'string'
}
```

**Response Structure**

- (**dict**) –
  Results of a CreateStorageLocationResult call.
– **S3Bucket (string)** –

The name of the Amazon S3 bucket created.

delete_application(**kwargs)**

Deletes the specified application along with all associated versions and configurations. The application versions will not be deleted from your Amazon S3 bucket.

**Note:** You cannot delete an application that has a running environment.

**Request Syntax**

```python
response = client.delete_application(
    ApplicationName='string',
    TerminateEnvByForce=True|False
)
```

**Parameters**

- **ApplicationName (string)** – [REQUIRED]
  
The name of the application to delete.

- **TerminateEnvByForce (boolean)** – When set to true, running environments will be terminated before deleting the application.

**Returns** None

delete_application_version(**kwargs)**

Deletes the specified version from the specified application.

**Note:** You cannot delete an application version that is associated with a running environment.

**Request Syntax**

```python
response = client.delete_application_version(
    ApplicationName='string',
    VersionLabel='string',
    DeleteSourceBundle=True|False
)
```

**Parameters**

- **ApplicationName (string)** – [REQUIRED]
  
The name of the application to delete releases from.

- **VersionLabel (string)** – [REQUIRED]
  
The label of the version to delete.

- **DeleteSourceBundle (boolean)** – Indicates whether to delete the associated source bundle from Amazon S3:
  - true: An attempt is made to delete the associated Amazon S3 source bundle specified at time of creation.
  - false: No action is taken on the Amazon S3 source bundle specified at time of creation.

**Valid Values:** true | false

**Returns** None

delete_configuration_template(**kwargs)**

Deletes the specified configuration template.

**Note:** When you launch an environment using a configuration template, the environment gets a copy
of the template. You can delete or modify the environment’s copy of the template without affecting the running environment.

**Request Syntax**

```python
response = client.delete_configuration_template(
    ApplicationName='string',
    TemplateName='string'
)
```

**Parameters**

- **ApplicationName** (*string*) – [REQUIRED]
  The name of the application to delete the configuration template from.

- **TemplateName** (*string*) – [REQUIRED]
  The name of the configuration template to delete.

**Returns** None

`delete_environment_configuration(**kwargs)`

Deletes the draft configuration associated with the running environment.

Updating a running environment with any configuration changes creates a draft configuration set. You can get the draft configuration using DescribeConfigurationSettings while the update is in progress or if the update fails. The `DeploymentStatus` for the draft configuration indicates whether the deployment is in process or has failed. The draft configuration remains in existence until it is deleted with this action.

**Request Syntax**

```python
response = client.delete_environment_configuration(
    ApplicationName='string',
    EnvironmentName='string'
)
```

**Parameters**

- **ApplicationName** (*string*) – [REQUIRED]
  The name of the application the environment is associated with.

- **EnvironmentName** (*string*) – [REQUIRED]
  The name of the environment to delete the draft configuration from.

**Returns** None

`describe_application_versions(**kwargs)`

Returns descriptions for existing application versions.

**Request Syntax**

```python
response = client.describe_application_versions(
    ApplicationName='string',
    VersionLabels=[
        'string',
    ]
)
```

**Parameters**

- **ApplicationName** (*string*) – If specified, AWS Elastic Beanstalk restricts the returned descriptions to only include ones that are associated with the specified application.
• **VersionLabels (list)** – If specified, restricts the returned descriptions to only include ones that have the specified version labels.

   – *(string) –

**Return type** dict

**Returns**

**Response Syntax**

```
{
   'ApplicationVersions': [
      {
         'ApplicationName': 'string',
         'Description': 'string',
         'VersionLabel': 'string',
         'SourceBundle': {
            'S3Bucket': 'string',
            'S3Key': 'string'
         },
         'DateCreated': datetime(2015, 1, 1),
         'DateUpdated': datetime(2015, 1, 1)
      },
   ],
}
```

**Response Structure**

• *(dict) –

Result message wrapping a list of application version descriptions.

   – **ApplicationVersions (list)** –

A list of ApplicationVersionDescription .

   * *(dict) –

Describes the properties of an application version.

   • **ApplicationName (string) –**

   The name of the application associated with this release.

   • **Description (string) –**

   The description of this application version.

   • **VersionLabel (string) –**

   A label uniquely identifying the version for the associated application.

   • **SourceBundle (dict) –**

   The location where the source bundle is located for this version.

   • **S3Bucket (string) –**

   The Amazon S3 bucket where the data is located.

   • **S3Key (string) –**

   The Amazon S3 key where the data is located.

   • **DateCreated (datetime) –**

   The creation date of the application version.

   • **DateUpdated (datetime) –**

   The last modified date of the application version.
**describe_applications(**kwargs)**

Returns the descriptions of existing applications.

**Request Syntax**

```python
response = client.describe_applications(
    ApplicationNames=[
        'string',
    ]
)
```

**Parameters**

**ApplicationNames (list)** – If specified, AWS Elastic Beanstalk restricts the returned descriptions to only include those with the specified names.

**Return type**

`dict`

**Returns**

**Response Syntax**

```python
{
    'Applications': [
        {
            'ApplicationName': 'string',
            'Description': 'string',
            'DateCreated': datetime(2015, 1, 1),
            'DateUpdated': datetime(2015, 1, 1),
            'Versions': [
                'string',
            ],
            'ConfigurationTemplates': [
                'string',
            ],
        },
    ],
}
```

**Response Structure**

**(dict)** – Result message containing a list of application descriptions.

- **Applications (list)** –

  This parameter contains a list of ApplicationDescription.

**(dict)** – Describes the properties of an application.

- **ApplicationName (string)** – The name of the application.

- **Description (string)** – User-defined description of the application.

- **DateCreated (datetime)** – The date when the application was created.

- **DateUpdated (datetime)** – The date when the application was last modified.

- **Versions (list)** – The names of the versions for this application.
describe_configuration_options(**kwargs)

Describes the configuration options that are used in a particular configuration template or environment, or that a specified solution stack defines. The description includes the values the options, their default values, and an indication of the required action on a running environment if an option value is changed.

Request Syntax

```python
response = client.describe_configuration_options(
    ApplicationName='string',
    TemplateName='string',
    EnvironmentName='string',
    SolutionStackName='string',
    Options=[
        {'ResourceName': 'string',
         'Namespace': 'string',
         'OptionName': 'string'},
    ],
)
```

Parameters

- **ApplicationName (string)** – The name of the application associated with the configuration template or environment. Only needed if you want to describe the configuration options associated with either the configuration template or environment.
- **TemplateName (string)** – The name of the configuration template whose configuration options you want to describe.
- **EnvironmentName (string)** – The name of the environment whose configuration options you want to describe.
- **SolutionStackName (string)** – The name of the solution stack whose configuration options you want to describe.
- **Options (list)** – If specified, restricts the descriptions to only the specified options.
  - (dict) –
    - ResourceName (string) –
      A unique resource name for a time-based scaling configuration option.
    - Namespace (string) –
      A unique namespace identifying the option’s associated AWS resource.
    - OptionName (string) –
      The name of the configuration option.

Return type  dict

Returns

Response Syntax
{
    'SolutionStackName': 'string',
    'Options': [
        {
            'Namespace': 'string',
            'Name': 'string',
            'DefaultValue': 'string',
            'ChangeSeverity': 'string',
            'UserDefined': True|False,
            'ValueType': 'Scalar'|'List',
            'ValueOptions': [
                'string',
            ],
            'MinValue': 123,
            'MaxValue': 123,
            'MaxLength': 123,
            'Regex': {
                'Pattern': 'string',
                'Label': 'string'
            }
        },
    ],
}

Response Structure

* (dict) –

Describes the settings for a specified configuration set.

– **SolutionStackName (string)** –

    The name of the solution stack these configuration options belong to.

– **Options (list)** –

    A list of ConfigurationOptionDescription .

    * (dict) –

    Describes the possible values for a configuration option.

    · **Namespace (string)** –

        A unique namespace identifying the option’s associated AWS resource.

    · **Name (string)** –

        The name of the configuration option.

    · **DefaultValue (string)** –

        The default value for this configuration option.

    · **ChangeSeverity (string)** –

        An indication of which action is required if the value for this configuration option changes:

        NoInterruption - There is no interruption to the environment or application availability.

        RestartEnvironment - The environment is restarted, all AWS resources are deleted and recreated, and the environment is unavailable during the process.

        RestartApplicationServer - The environment is available the entire time. However, a short application outage occurs when
the application servers on the running Amazon EC2 instances are restarted.

- **No Interruption**: There is no interruption to the environment or application availability.
- **Restart Environment**: The environment is entirely restarted, all AWS resources are deleted and recreated, and the environment is unavailable during the process.
- **Restart Application Server**: The environment is available the entire time. However, a short application outage occurs when the application servers on the running Amazon EC2 instances are restarted.

- **User Defined** (boolean) –

  An indication of whether the user defined this configuration option:

  - `true`: This configuration option was defined by the user. It is a valid choice for specifying this as an Option to Remove when updating configuration settings.
  - `false`: This configuration was not defined by the user.

  - `true`: This configuration option was defined by the user. It is a valid choice for specifying if this as an Option to Remove when updating configuration settings.
  - `false`: This configuration was not defined by the user.

  **Constraint**: You can remove only User Defined options from a configuration.

  **Valid Values**: `true` | `false`

- **Value Type** (string) –

  An indication of which type of values this option has and whether it is allowable to select one or more than one of the possible values:

  - **Scalar**: Values for this option are a single selection from the possible values, or an unformatted string or numeric value governed by the MIN/MAX/Regex constraints:

    **List**: Values for this option are multiple selections of the possible values.

    **Boolean**: Values for this option are either `true` or `false`.

    **Json**: Values for this option are a JSON representation of a ConfigDocument.

  - **Scalar**: Values for this option are a single selection from the possible values, or an unformatted string, or numeric value governed by the MIN/MAX/Regex constraints.
  - **List**: Values for this option are multiple selections from the possible values.
  - **Boolean**: Values for this option are either `true` or `false`.
  - **Json**: Values for this option are a JSON representation of a ConfigDocument.
**ValueOptions (list)** –
If specified, values for the configuration option are selected from this list.

**MinValue (integer)** –
If specified, the configuration option must be a numeric value greater than this value.

**MaxValue (integer)** –
If specified, the configuration option must be a numeric value less than this value.

**MaxLength (integer)** –
If specified, the configuration option must be a string value no longer than this value.

**Regex (dict)** –
If specified, the configuration option must be a string value that satisfies this regular expression.

**Pattern (string)** –
The regular expression pattern that a string configuration option value with this restriction must match.

**Label (string)** –
A unique name representing this regular expression.

### describe_configuration_settings (**kwargs)**

Returns a description of the settings for the specified configuration set, that is, either a configuration template or the configuration set associated with a running environment.

When describing the settings for the configuration set associated with a running environment, it is possible to receive two sets of setting descriptions. One is the deployed configuration set, and the other is a draft configuration of an environment that is either in the process of deployment or that failed to deploy.

### Related Topics
- **DeleteEnvironmentConfiguration**

### Request Syntax

```python
response = client.describe_configuration_settings(
    ApplicationName='string',
    TemplateName='string',
    EnvironmentName='string'
)
```

### Parameters
- **ApplicationName (string)** – [REQUIRED]
  The application for the environment or configuration template.

- **TemplateName (string)** – The name of the configuration template to describe.
  Conditional: You must specify either this parameter or an EnvironmentName, but not both. If you specify both, AWS Elastic Beanstalk returns an InvalidParameterCombination error. If you do not specify either, AWS Elastic Beanstalk returns a MissingRequiredParameter error.

- **EnvironmentName (string)** – The name of the environment to describe.
  Condition: You must specify either this or a TemplateName, but not both. If you specify both, AWS Elastic Beanstalk returns an
InvalidParameterCombination error. If you do not specify either, AWS Elastic Beanstalk returns MissingRequiredParameter error.

Return type  dict

Returns

Response Syntax

```python

          'OptionName': 'string',
          'Value': 'string'
        }
      ]
    },
  ],
}
```

Response Structure

- (dict) –
  The results from a request to change the configuration settings of an environment.
  - ConfigurationSettings (list) –
    A list of ConfigurationSettingsDescription .
    * (dict) –
      Describes the settings for a configuration set.
      - SolutionStackName (string) –
        The name of the solution stack this configuration set uses.
      - ApplicationName (string) –
        The name of the application associated with this configuration set.
      - TemplateName (string) –
        If not null, the name of the configuration template for this configuration set.
      - Description (string) –
        Describes this configuration set.
      - EnvironmentName (string) –
        If not null, the name of the environment for this configuration set.
- **DeploymentStatus** *(string)*
  
  If this configuration set is associated with an environment, the `DeploymentStatus` parameter indicates the deployment status of this configuration set:
  
  * `null`: This configuration is not associated with a running environment.
  
  * `pending`: This is a draft configuration that is not deployed to the associated environment but is in the process of deploying.
  
  * `deployed`: This is the configuration that is currently deployed to the associated running environment.
  
  * `failed`: This is a draft configuration that failed to successfully deploy.

- **null**: This configuration is not associated with a running environment.
- **pending**: This is a draft configuration that is not deployed to the associated environment but is in the process of deploying.
- **deployed**: This is the configuration that is currently deployed to the associated running environment.
- **failed**: This is a draft configuration that failed to successfully deploy.

- **DateCreated** *(datetime)*
  
  The date (in UTC time) when this configuration set was created.

- **DateUpdated** *(datetime)*
  
  The date (in UTC time) when this configuration set was last modified.

- **OptionSettings** *(list)*
  
  A list of the configuration options and their values in this configuration set.
  
  *(dict)*

  A specification identifying an individual configuration option along with its current value. For a list of possible option values, go to Option Values in the [AWS Elastic Beanstalk Developer Guide](https://docs.aws.amazon.com/elasticbeanstalk/latest/dg/).

- **ResourceName** *(string)*
  
  A unique resource name for a time-based scaling configuration option.

- **Namespace** *(string)*
  
  A unique namespace identifying the option’s associated AWS resource.

- **OptionName** *(string)*
  
  The name of the configuration option.

- **Value** *(string)*
  
  The current value for the configuration option.
describe_environment_health(**kwargs)

Returns information about the overall health of the specified environment. The DescribeEnvironmentHealth operation is only available with AWS Elastic Beanstalk Enhanced Health.

Request Syntax

response = client.describe_environment_health(
    EnvironmentName='string',
    EnvironmentId='string',
    AttributeNames=['Status'|'Color'|'Causes'|'ApplicationMetrics'|'InstancesHealth'|'All'|'HealthStatus',
    ])

Parameters

- **EnvironmentName** (string) – Specifies the AWS Elastic Beanstalk environment name.
- **EnvironmentId** (string) – Specifies the AWS Elastic Beanstalk environment ID.
- **AttributeNames** (list) – Specifies the response elements you wish to receive. If no attribute names are specified, AWS Elastic Beanstalk returns all response elements.

Return type  dict

Returns

Response Syntax

```python
{
    'EnvironmentName': 'string',
    'HealthStatus': 'string',
    'Status': 'Green'|'Yellow'|'Red'|'Grey',
    'Color': 'string',
    'Causes': [  
        'string',
    ],
    'ApplicationMetrics': {
        'Duration': 123,
        'RequestCount': 123,
        'StatusCodes': {
            'Status2xx': 123,
            'Status3xx': 123,
            'Status4xx': 123,
            'Status5xx': 123
        },
        'Latency': {
            'P999': 123.0,
            'P99': 123.0,
            'P95': 123.0,
            'P90': 123.0,
            'P85': 123.0,
            'P75': 123.0,
            'P50': 123.0,
            'P10': 123.0
        }
    },
    'InstancesHealth': {
        'NoData': 123,
        'Unknown': 123,
    }
}
```
'Pending': 123,
'Ok': 123,
'Info': 123,
'Warning': 123,
'Degraded': 123,
'Severe': 123
},
'RefreshedAt': datetime(2015, 1, 1)
}

Response Structure
• (dict) –
  See the example below for a sample response.
  – **EnvironmentName**(string) –
    The AWS Elastic Beanstalk environment name.
  – **HealthStatus**(string) –
    Contains the response body with information about the health of the environment.
  – **Status**(string) –
    Returns the health status value of the environment. For more information, see Health Colors and Statuses.
  – **Color**(string) –
    Returns the color indicator that tells you information about the health of the environment. For more information, see Health Colors and Statuses.
  – **Causes**(list) –
    Returns potential causes for the reported status.
    * (string) –
  – **ApplicationMetrics**(dict) –
    Represents the application metrics for a specified environment.
    * **Duration**(integer) –
      The amount of time that the metrics cover (usually 10 seconds). For example, you might have 5 requests (request_count) within the most recent time slice of 10 seconds (duration).
    * **RequestCount**(integer) –
      Average number of requests handled by the web server per second over the last 10 seconds.
    * **StatusCodes**(dict) –
      Represents the percentage of requests over the last 10 seconds that resulted in each type of status code response.
      · **Status2xx**(integer) –
        The percentage of requests over the last 10 seconds that resulted in a 2xx (200, 201, etc.) status code.
      · **Status3xx**(integer) –
        The percentage of requests over the last 10 seconds that resulted in a 3xx (300, 301, etc.) status code.
      · **Status4xx**(integer) –
        The percentage of requests over the last 10 seconds that resulted in a 4xx (400, 401, etc.) status code.
- **Status5xx** *(integer)* –

  The percentage of requests over the last 10 seconds that resulted in a 5xx (500, 501, etc.) status code.

- **Latency** *(dict)* –

  Represents the average latency for the slowest X percent of requests over the last 10 seconds. Latencies are in seconds with one millisecond resolution.

  - **P999** *(float)* –

    The average latency for the slowest 0.1 percent of requests over the last 10 seconds.

  - **P99** *(float)* –

    The average latency for the slowest 1 percent of requests over the last 10 seconds.

  - **P95** *(float)* –

    The average latency for the slowest 5 percent of requests over the last 10 seconds.

  - **P90** *(float)* –

    The average latency for the slowest 10 percent of requests over the last 10 seconds.

  - **P85** *(float)* –

    The average latency for the slowest 15 percent of requests over the last 10 seconds.

  - **P75** *(float)* –

    The average latency for the slowest 25 percent of requests over the last 10 seconds.

  - **P50** *(float)* –

    The average latency for the slowest 50 percent of requests over the last 10 seconds.

  - **P10** *(float)* –

    The average latency for the slowest 90 percent of requests over the last 10 seconds.

- **InstancesHealth** *(dict)* –

  Represents summary information about the health of an instance. For more information, see Health Colors and Statuses.

  - **NoData** *(integer)* –

    Grey. AWS Elastic Beanstalk and the health agent are reporting no data on an instance.

  - **Unknown** *(integer)* –

    Grey. AWS Elastic Beanstalk and the health agent are reporting an insufficient amount of data on an instance.

  - **Pending** *(integer)* –

    Grey. An operation is in progress on an instance within the command timeout.

  - **Ok** *(integer)* –

    Green. An instance is passing health checks and the health agent is not reporting any problems.
* **Info** *(integer)* –
  
  **Green.** An operation is in progress on an instance.

* **Warning** *(integer)* –

  **Yellow.** The health agent is reporting a moderate number of request failures or other issues for an instance or environment.

* **Degraded** *(integer)* –

  **Red.** The health agent is reporting a high number of request failures or other issues for an instance or environment.

* **Severe** *(integer)* –

  **Red.** The health agent is reporting a very high number of request failures or other issues for an instance or environment.

  – **RefreshedAt** *(datetime)* –

    The date and time the information was last refreshed.

describe_environment_resources(**kwargs)

Returns AWS resources for this environment.

**Request Syntax**

```
response = client.describe_environment_resources(
    EnvironmentId='string',
    EnvironmentName='string'
)
```

**Parameters**

- **EnvironmentId** *(string)* – The ID of the environment to retrieve AWS resource usage data.

  Condition: You must specify either this or an EnvironmentName, or both. If you do not specify either, AWS Elastic Beanstalk returns MissingRequiredParameter error.

- **EnvironmentName** *(string)* – The name of the environment to retrieve AWS resource usage data.

  Condition: You must specify either this or an EnvironmentId, or both. If you do not specify either, AWS Elastic Beanstalk returns MissingRequiredParameter error.

**Return type** dict

**Returns**

**Response Syntax**

```
{
    'EnvironmentResources': {
        'EnvironmentName': 'string',
        'AutoScalingGroups': [{
            'Name': 'string'
        }],
        'Instances': [{
            'Id': 'string'
        }],
    }
}
```

3.1. Services 2067
'LaunchConfigurations': [  
  {  
    'Name': 'string'  
  },  
],  
'LoadBalancers': [  
  {  
    'Name': 'string'  
  },  
],  
'Triggers': [  
  {  
    'Name': 'string'  
  },  
],  
'Queues': [  
  {  
    'Name': 'string',  
    'URL': 'string'  
  },  
]  
}

Response Structure

* (dict) – Result message containing a list of environment resource descriptions.
  
  – EnvironmentResources (dict) – A list of EnvironmentResourceDescription.
    
      * EnvironmentName (string) – The name of the environment.
      
        * AutoScalingGroups (list) – The AutoScalingGroups used by this environment.
          
            * (dict) – Describes an Auto Scaling launch configuration.
              
                * Name (string) – The name of the AutoScalingGroup.
              
            * Instances (list) – The Amazon EC2 instances used by this environment.
              
                * (dict) – The description of an Amazon EC2 instance.
                  
                    * Id (string) – The ID of the Amazon EC2 instance.
                  
                * LaunchConfigurations (list) – The Auto Scaling launch configurations in use by this environment.
                  
                    * (dict) – Describes an Auto Scaling launch configuration.
                      
                        * Name (string) – The name of the launch configuration.
* **LoadBalancers** (*list*) –
  The LoadBalancers in use by this environment.
  
  · (**dict**) –
    Describes a LoadBalancer.
    · **Name** (*string*) –
      The name of the LoadBalancer.

* **Triggers** (*list*) –
  The AutoScaling triggers in use by this environment.
  · (**dict**) –
    Describes a trigger.
    · **Name** (*string*) –
      The name of the trigger.

* **Queues** (*list*) –
  The queues used by this environment.
  · (**dict**) –
    Describes a queue.
    · **Name** (*string*) –
      The name of the queue.
    · **URL** (*string*) –
      The URL of the queue.

describe_environments(**kwargs)

Returns descriptions for existing environments.

**Request Syntax**

```python
response = client.describe_environments(
    ApplicationName='string',
    VersionLabel='string',
    EnvironmentIds=[
        'string',
    ],
    EnvironmentNames=[
        'string',
    ],
    IncludeDeleted=True|False,
    IncludedDeletedBackTo=datetime(2015, 1, 1)
)
```

**Parameters**

- **ApplicationName** (*string*) – If specified, AWS Elastic Beanstalk restricts the returned descriptions to include only those that are associated with this application.
- **VersionLabel** (*string*) – If specified, AWS Elastic Beanstalk restricts the returned descriptions to include only those that are associated with this application version.
- **EnvironmentIds** (*list*) – If specified, AWS Elastic Beanstalk restricts the returned descriptions to include only those that have the specified IDs.
  - (**string**) –
- **EnvironmentNames** (*list*) – If specified, AWS Elastic Beanstalk restricts the returned descriptions to include only those that have the specified names.
- (string) –

- **IncludeDeleted** (boolean) – Indicates whether to include deleted environments:
  - `true` : Environments that have been deleted after `IncludedDeletedBackTo` are displayed.
  - `false` : Do not include deleted environments.

- **IncludedDeletedBackTo** (datetime) – If specified when `IncludeDeleted` is set to `true`, then environments deleted after this date are displayed.

**Return type** `dict`

**Response Syntax**

```python
{
    'Environments': [
        {
            'EnvironmentName': 'string',
            'EnvironmentId': 'string',
            'ApplicationName': 'string',
            'VersionLabel': 'string',
            'SolutionStackName': 'string',
            'TemplateName': 'string',
            'Description': 'string',
            'EndpointURL': 'string',
            'CNAME': 'string',
            'DateCreated': datetime(2015, 1, 1),
            'DateUpdated': datetime(2015, 1, 1),
            'Status': 'Launching'|'Updating'|'Ready'|'Terminating'|'Terminated',
            'AbortableOperationInProgress': True|False,
            'Health': 'Green'|'Yellow'|'Red'|'Grey',
            'HealthStatus': 'NoData'|'Unknown'|'Pending'|'Ok'|'Info'|'Warning'|'Degraded'|'Severe',
            'Resources': {
                'LoadBalancer': {
                    'LoadBalancerName': 'string',
                    'Domain': 'string',
                    'Listeners': [
                        {
                            'Protocol': 'string',
                            'Port': 123
                        }
                    ]
                },
                'Tier': {
                    'Name': 'string',
                    'Type': 'string',
                    'Version': 'string'
                }
            }
        }
    ]
}
```

**Response Structure**

- `(dict)` – Result message containing a list of environment descriptions.

- **Environments** (list) – Returns an EnvironmentDescription list.
* (dict) –

Describes the properties of an environment.

- **EnvironmentName** *(string)* –
  
The name of this environment.

- **EnvironmentId** *(string)* –
  
The ID of this environment.

- **ApplicationName** *(string)* –
  
The name of the application associated with this environment.

- **VersionLabel** *(string)* –
  
The application version deployed in this environment.

- **SolutionStackName** *(string)* –
  
The name of the SolutionStack deployed with this environment.

- **TemplateName** *(string)* –
  
The name of the configuration template used to originally launch this environment.

- **Description** *(string)* –
  
Describes this environment.

- **EndpointURL** *(string)* –
  
For load-balanced, autoscaling environments, the URL to the LoadBalancer. For single-instance environments, the IP address of the instance.

- **CNAME** *(string)* –
  
The URL to the CNAME for this environment.

- **DateCreated** *(datetime)* –
  
The creation date for this environment.

- **DateUpdated** *(datetime)* –
  
The last modified date for this environment.

- **Status** *(string)* –
  
The current operational status of the environment:
  
  - **Launching**: Environment is in the process of initial deployment.
  
  - **Updating**: Environment is in the process of updating its configuration settings or application version.
  
  - **Ready**: Environment is available to have an action performed on it, such as update or terminate.
  
  - **Terminating**: Environment is in the shut-down process.
  
  - **Terminated**: Environment is not running.

- **AbortableOperationInProgress** *(boolean)* –
  
Indicates if there is an in-progress environment configuration update or application version deployment that you can cancel.

  - **true**: There is an update in progress.
  
  - **false**: There are no updates currently in progress.

- **Health** *(string)* –
Describes the health status of the environment. AWS Elastic Beanstalk indicates the failure levels for a running environment:

- **Red**: Indicates the environment is not working.
- **Yellow**: Indicates that something is wrong, the application might not be available, but the instances appear running.
- **Green**: Indicates the environment is healthy and fully functional.
- **Red**: Indicates the environment is not responsive. Occurs when three or more consecutive failures occur for an environment.
- **Yellow**: Indicates that something is wrong. Occurs when two consecutive failures occur for an environment.
- **Green**: Indicates the environment is healthy and fully functional.
- **Grey**: Default health for a new environment. The environment is not fully launched and health checks have not started or health checks are suspended during an UpdateEnvironment or RestartEnvironment request.

Default: Grey

- **HealthStatus**: Returns the health status of the application running in your environment. For more information, see Health Colors and Statuses.

- **Resources**: The description of the AWS resources used by this environment.

  - **LoadBalancer**: Describes the LoadBalancer.
    - **LoadBalancerName**: The name of the LoadBalancer.
    - **Domain**: The domain name of the LoadBalancer.
    - **Listeners**: A list of Listeners used by the LoadBalancer.
      - **Protocol**: The protocol that is used by the Listener.
      - **Port**: The port that is used by the Listener.
    - **Tier**: Describes the current tier of this environment.

- **Name**: The name of this environment tier.
describe_events(**kwargs)

Returns list of event descriptions matching criteria up to the last 6 weeks.

Note: This action returns the most recent 1,000 events from the specified NextToken.

Request Syntax

```python
response = client.describe_events(
    ApplicationName='string',
    VersionLabel='string',
    TemplateName='string',
    EnvironmentId='string',
    EnvironmentName='string',
    RequestId='string',
    Severity='TRACE'|'DEBUG'|'INFO'|'WARN'|'ERROR'|'FATAL',
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    MaxRecords=123,
    NextToken='string'
)
```

Parameters

- **ApplicationName** *(string)* – If specified, AWS Elastic Beanstalk restricts the returned descriptions to include only those associated with this application.
- **VersionLabel** *(string)* – If specified, AWS Elastic Beanstalk restricts the returned descriptions to those associated with this application version.
- **TemplateName** *(string)* – If specified, AWS Elastic Beanstalk restricts the returned descriptions to those that are associated with this environment configuration.
- **EnvironmentId** *(string)* – If specified, AWS Elastic Beanstalk restricts the returned descriptions to those associated with this environment.
- **EnvironmentName** *(string)* – If specified, AWS Elastic Beanstalk restricts the returned descriptions to those associated with this environment.
- **RequestId** *(string)* – If specified, AWS Elastic Beanstalk restricts the described events to include only those associated with this request ID.
- **Severity** *(string)* – If specified, limits the events returned from this call to include only those with the specified severity or higher.
- **StartTime** *(datetime)* – If specified, AWS Elastic Beanstalk restricts the returned descriptions to those that occur on or after this time.
- **EndTime** *(datetime)* – If specified, AWS Elastic Beanstalk restricts the returned descriptions to those that occur up to, but not including, the EndTime.
- **MaxRecords** *(integer)* – Specifies the maximum number of events that can be returned, beginning with the most recent event.
- **NextToken** *(string)* – Pagination token. If specified, the events return the next batch of results.

Return type  **dict**

Returns

Response Syntax
```python
{
    'Events': [
        {
            'EventDate': datetime(2015, 1, 1),
            'Message': 'string',
            'ApplicationName': 'string',
            'VersionLabel': 'string',
            'TemplateName': 'string',
            'EnvironmentName': 'string',
            'RequestId': 'string',
            'Severity': 'TRACE'|'DEBUG'|'INFO'|'WARN'|'ERROR'|'FATAL'
        },
    ],
    'NextToken': 'string'
}
```

**Response Structure**

- *(dict)*
  - Result message wrapping a list of event descriptions.
    - **Events** *(list)*
      - A list of EventDescription.
        * *(dict)*
          - Describes an event.
            - **EventDate** *(datetime)*
              - The date when the event occurred.
            - **Message** *(string)*
              - The event message.
            - **ApplicationName** *(string)*
              - The application associated with the event.
            - **VersionLabel** *(string)*
              - The release label for the application version associated with this event.
            - **TemplateName** *(string)*
              - The name of the configuration associated with this event.
            - **EnvironmentName** *(string)*
              - The name of the environment associated with this event.
            - **RequestId** *(string)*
              - The web service request ID for the activity of this event.
            - **Severity** *(string)*
              - The severity level of this event.
        - **NextToken** *(string)*
          - If returned, this indicates that there are more results to obtain. Use this token in the next DescribeEvents call to get the next batch of events.

**describe_instances_health(**kwargs**)**

Returns more detailed information about the health of the specified instances (for example, CPU utilization, load average, and causes). The **DescribeInstancesHealth** operation is only available with AWS Elastic Beanstalk Enhanced Health.
Request Syntax

```python
response = client.describe_instances_health(
    EnvironmentName='string',
    EnvironmentId='string',
    AttributeNames=
        ['HealthStatus'|'Color'|'Causes'|'ApplicationMetrics'|'RefreshedAt'|'LaunchedAt'|'System'|'All'],
    NextToken='string'
)
```

Parameters

- **EnvironmentName** *(string)* – Specifies the AWS Elastic Beanstalk environment name.
- **EnvironmentId** *(string)* – Specifies the AWS Elastic Beanstalk environment ID.
- **AttributeNames** *(list)* – Specifies the response elements you wish to receive. If no attribute names are specified, AWS Elastic Beanstalk returns all response elements.
- **NextToken** *(string)* – Specifies the next token of the request.

Return type  *dict*

Returns

Response Syntax

```
{
    'InstanceHealthList': [
        {
            'InstanceId': 'string',
            'HealthStatus': 'string',
            'Color': 'string',
            'Causes': ['string'],
            'LaunchedAt': datetime(2015, 1, 1),
            'ApplicationMetrics': {
                'Duration': 123,
                'RequestCount': 123,
                'StatusCodes': {
                    'Status2xx': 123,
                    'Status3xx': 123,
                    'Status4xx': 123,
                    'Status5xx': 123
                },
                'Latency': {
                    'P999': 123.0,
                    'P99': 123.0,
                    'P95': 123.0,
                    'P90': 123.0,
                    'P85': 123.0,
                    'P75': 123.0,
                    'P50': 123.0,
                    'P10': 123.0
                }
            },
            'System': {
                'CPUUtilization': {
                    'User': 123.0,
                    'Nice': 123.0,
                    'System': 123.0,
                    'Idle': 123.0
                }
            }
        }
    ]
}
```
Response Structure

- *(dict)* –

  See the example below for a sample response.

  - **InstanceHealthList**(list) –

    Contains the response body with information about the health of the instance.

    - *(dict)* –

      Represents health information from the specified instance that belongs to the AWS Elastic Beanstalk environment. Use the InstanceId property to specify the application instance for which you’d like to return data.

      - **InstanceId**(string) –

        The ID of the Amazon EC2 instance.

      - **HealthStatus**(string) –

        Returns the health status of the specified instance. For more information, see http://docs.aws.amazon.com/elasticbeanstalk/latest/dg/health-enhanced-status.html.

      - **Color**(string) –

        Represents the color indicator that gives you information about the health of the EC2 instance. For more information, see Health Colors and Statuses.

      - **Causes**(list) –

        Represents the causes, which provide more information about the current health status.

      - *(string)* –

        - **LaunchedAt**(datetime) –

          The time at which the EC2 instance was launched.

      - **ApplicationMetrics**(dict) –

        Represents the application metrics for a specified environment.

      - **Duration**(integer) –

        The amount of time that the metrics cover (usually 10
seconds). For example, you might have 5 requests (request_count) within the most recent time slice of 10 seconds (duration).

- **RequestCount (integer)**

  Average number of requests handled by the web server per second over the last 10 seconds.

- **StatusCodes (dict)**

  Represents the percentage of requests over the last 10 seconds that resulted in each type of status code response.

  - **Status2xx (integer)**

    The percentage of requests over the last 10 seconds that resulted in a 2xx (200, 201, etc.) status code.

  - **Status3xx (integer)**

    The percentage of requests over the last 10 seconds that resulted in a 3xx (300, 301, etc.) status code.

  - **Status4xx (integer)**

    The percentage of requests over the last 10 seconds that resulted in a 4xx (400, 401, etc.) status code.

  - **Status5xx (integer)**

    The percentage of requests over the last 10 seconds that resulted in a 5xx (500, 501, etc.) status code.

- **Latency (dict)**

  Represents the average latency for the slowest X percent of requests over the last 10 seconds. Latencies are in seconds with one milisecond resolution.

  - **P999 (float)**

    The average latency for the slowest 0.1 percent of requests over the last 10 seconds.

  - **P99 (float)**

    The average latency for the slowest 1 percent of requests over the last 10 seconds.

  - **P95 (float)**

    The average latency for the slowest 5 percent of requests over the last 10 seconds.

  - **P90 (float)**

    The average latency for the slowest 10 percent of requests over the last 10 seconds.

  - **P85 (float)**

    The average latency for the slowest 15 percent of requests over the last 10 seconds.

  - **P75 (float)**

    The average latency for the slowest 25 percent of requests over the last 10 seconds.

  - **P50 (float)**

    The average latency for the slowest 50 percent of requests over the last 10 seconds.
- **P10** *(float)* – The average latency for the slowest 90 percent of requests over the last 10 seconds.
- **System** *(dict)* – Represents CPU utilization and load average information for applications running in the specified environment.
- **CPUUtilization** *(dict)* – Represents CPU utilization information from the specified instance that belongs to the AWS Elastic Beanstalk environment. Use the *instanceid* property to specify the application instance for which you’d like to return data.
- **User** *(float)* – Percentage of time that the CPU has spent in the *User* state over the last 10 seconds.
- **Nice** *(float)* – Percentage of time that the CPU has spent in the *Nice* state over the last 10 seconds.
- **System** *(float)* – Percentage of time that the CPU has spent in the *System* state over the last 10 seconds.
- **Idle** *(float)* – Percentage of time that the CPU has spent in the *Idle* state over the last 10 seconds.
- **IOWait** *(float)* – Percentage of time that the CPU has spent in the *I/O Wait* state over the last 10 seconds.
- **IRQ** *(float)* – Percentage of time that the CPU has spent in the *IRQ* state over the last 10 seconds.
- **SoftIRQ** *(float)* – Percentage of time that the CPU has spent in the *SoftIRQ* state over the last 10 seconds.
- **LoadAverage** *(list)* – Load average in the last 1-minute and 5-minute periods. For more information, see Operating System Metrics.
- **RefreshedAt** *(datetime)* – The date and time the information was last refreshed.
- **NextToken** *(string)* – The next token.

**generate_presigned_url** *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*
Generate a presigned url given a client, its method, and arguments

**Parameters**
- **ClientMethod** *(string)* – The client method to presign for
- **Params** *(dict)* – The parameters normally passed to *ClientMethod*.
- **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
• **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns** The presigned url

**get_paginator**(operation_name)
Create a paginator for an operation.

**Parameters** operation_name *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

**Raises** OperationNotPageableError Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

**Return type** L{botocore.paginate.Paginator}

**Returns** A paginator object.

**get_waiter**(waiter_name)

**list_available_solution_stacks**()
Returns a list of the available solution stack names.

**Request Syntax**

response = client.list_available_solution_stacks()

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'SolutionStacks': [ 'string',
    ],
    'SolutionStackDetails': [ {
        'SolutionStackName': 'string',
        'PermittedFileTypes': [ 'string',
        ]
    },
    ]
}
```

**Response Structure**

• *(dict)* –
  A list of available AWS Elastic Beanstalk solution stacks.
  – **SolutionStacks** *(list)* –
    A list of available solution stacks.
    * *(string)* –
  – **SolutionStackDetails** *(list)* –
    A list of available solution stacks and their SolutionStackDescription .
    * *(dict)* –
      Describes the solution stack.
SolutionStackName (string) –
The name of the solution stack.

PermittedFileTypes (list) –
The permitted file types allowed for a solution stack.

(rebuild_environment (**kwargs))
Deletes and recreates all of the AWS resources (for example: the Auto Scaling group, load balancer, etc.) for a specified environment and forces a restart.

Request Syntax

response = client.rebuild_environment(
    EnvironmentId='string',
    EnvironmentName='string'
)

Parameters

- EnvironmentId (string) – The ID of the environment to rebuild.
  
  Condition: You must specify either this or an EnvironmentName, or both. If you do not specify either, AWS Elastic Beanstalk returns MissingRequiredParameter error.

- EnvironmentName (string) – The name of the environment to rebuild.
  
  Condition: You must specify either this or an EnvironmentId, or both. If you do not specify either, AWS Elastic Beanstalk returns MissingRequiredParameter error.

Returns None

(request_environment_info (**kwargs))
Initiates a request to compile the specified type of information of the deployed environment.

Setting the InfoType to tail compiles the last lines from the application server log files of every Amazon EC2 instance in your environment.

Setting the InfoType to bundle compresses the application server log files for every Amazon EC2 instance into a .zip file. Legacy and .NET containers do not support bundle logs.

Use RetrieveEnvironmentInfo to obtain the set of logs.

Related Topics

RetrievesEnvironmentInfo

Request Syntax

response = client.request_environment_info(
    EnvironmentId='string',
    EnvironmentName='string',
    InfoType='tail' | 'bundle'
)

Parameters

- EnvironmentId (string) – The ID of the environment of the requested data.
  
  If no such environment is found, RequestEnvironmentInfo returns an InvalidParameterValue error.
Condition: You must specify either this or an EnvironmentName, or both. If you do not specify either, AWS Elastic Beanstalk returns MissingRequiredParameter error.

- **EnvironmentName (string)** – The name of the environment of the requested data.

  If no such environment is found, RequestEnvironmentInfo returns an InvalidParameterValue error.

Condition: You must specify either this or an EnvironmentId, or both. If you do not specify either, AWS Elastic Beanstalk returns MissingRequiredParameter error.

- **InfoType (string)** – [REQUIRED]

  The type of information to request.

Returns None

**restart_app_server(**kwargs\)**

Causes the environment to restart the application container server running on each Amazon EC2 instance.

Request Syntax

```python
response = client.restart_app_server(
    EnvironmentId='string',
    EnvironmentName='string'
)
```

Parameters

- **EnvironmentId (string)** – The ID of the environment to restart the server for.

  Condition: You must specify either this or an EnvironmentName, or both. If you do not specify either, AWS Elastic Beanstalk returns MissingRequiredParameter error.

- **EnvironmentName (string)** – The name of the environment to restart the server for.

  Condition: You must specify either this or an EnvironmentId, or both. If you do not specify either, AWS Elastic Beanstalk returns MissingRequiredParameter error.

Returns None

**retrieve_environment_info(**kwargs\)**

Retrieves the compiled information from a RequestEnvironmentInfo request.

Related Topics

- RequestEnvironmentInfo

Request Syntax

```python
response = client.retrieve_environment_info(
    EnvironmentId='string',
    EnvironmentName='string',
    InfoType='tail'|'bundle'
)
```

Parameters

- **EnvironmentId (string)** – The ID of the data’s environment.

  If no such environment is found, returns an InvalidParameterValue error.
Condition: You must specify either this or an EnvironmentName, or both. If you do not specify either, AWS Elastic Beanstalk returns MissingRequiredParameter error.

- **EnvironmentName** *(string)* – The name of the data’s environment.

If no such environment is found, returns an InvalidParameterValue error.

Condition: You must specify either this or an EnvironmentId, or both. If you do not specify either, AWS Elastic Beanstalk returns MissingRequiredParameter error.

- **InfoType** *(string)* – [REQUIRED]

The type of information to retrieve.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'EnvironmentInfo': [
        {
            'InfoType': 'tail'|'bundle',
            'Ec2InstanceId': 'string',
            'SampleTimestamp': datetime(2015, 1, 1),
            'Message': 'string'
        },
    ]
}
```

**Response Structure**

- *(dict)* –

Result message containing a description of the requested environment info.

  - **EnvironmentInfo** *(list)* –

    The EnvironmentInfoDescription of the environment.

    - *(dict)* –

      The information retrieved from the Amazon EC2 instances.

      - **InfoType** *(string)* –

        The type of information retrieved.

      - **Ec2InstanceId** *(string)* –

        The Amazon EC2 Instance ID for this information.

      - **SampleTimestamp** *(datetime)* –

        The time stamp when this information was retrieved.

      - **Message** *(string)* –

        The retrieved information.

**swap_environment_cnames(** **kwargs)**

Swaps the CNAMEs of two environments.

**Request Syntax**

```python
response = client.swap_environment_cnames(
    SourceEnvironmentId='string',
    SourceEnvironmentName='string',
    DestinationEnvironmentId='string',
```
Parameters

- **SourceEnvironmentId** *(string)* – The ID of the source environment.
  
  Condition: You must specify at least the **SourceEnvironmentId** or the **SourceEnvironmentName**. You may also specify both. If you specify the **SourceEnvironmentId**, you must specify the **DestinationEnvironmentId**.

- **SourceEnvironmentName** *(string)* – The name of the source environment.
  
  Condition: You must specify at least the **SourceEnvironmentId** or the **SourceEnvironmentName**. You may also specify both. If you specify the **SourceEnvironmentName**, you must specify the **DestinationEnvironmentName**.

- **DestinationEnvironmentId** *(string)* – The ID of the destination environment.
  
  Condition: You must specify at least the **DestinationEnvironmentId** or the **DestinationEnvironmentName**. You may also specify both. You must specify the **SourceEnvironmentId** with the **DestinationEnvironmentId**.

- **DestinationEnvironmentName** *(string)* – The name of the destination environment.
  
  Condition: You must specify at least the **DestinationEnvironmentId** or the **DestinationEnvironmentName**. You may also specify both. You must specify the **SourceEnvironmentName** with the **DestinationEnvironmentName**.

Returns

None

**terminate_environment** (**kwargs**)

Terminates the specified environment.

Request Syntax

```python
response = client.terminate_environment(
    EnvironmentId='string',
    EnvironmentName='string',
    TerminateResources=True|False
)
```

Parameters

- **EnvironmentId** *(string)* – The ID of the environment to terminate.
  
  Condition: You must specify either this or an EnvironmentName, or both. If you do not specify either, AWS Elastic Beanstalk returns **MissingRequiredParameter** error.

- **EnvironmentName** *(string)* – The name of the environment to terminate.
  
  Condition: You must specify either this or an EnvironmentId, or both. If you do not specify either, AWS Elastic Beanstalk returns **MissingRequiredParameter** error.

- **TerminateResources** *(boolean)* – Indicates whether the associated AWS resources should shut down when the environment is terminated:
  
  ```
  true: (default) The user AWS resources (for example, the Auto Scaling group, LoadBalancer, etc.) are terminated along with the environment.
  ```
false: The environment is removed from the AWS Elastic Beanstalk but the AWS resources continue to operate.

– true: The specified environment as well as the associated AWS resources, such as Auto Scaling group and LoadBalancer, are terminated.

– false: AWS Elastic Beanstalk resource management is removed from the environment, but the AWS resources continue to operate.

For more information, see the AWS Elastic Beanstalk User Guide.

Default: true

Valid Values: true|false

Return type dict

Returns

Response Syntax

```
{
'EnvironmentName': 'string',
'EnvironmentId': 'string',
'ApplicationName': 'string',
'VersionLabel': 'string',
'SolutionStackName': 'string',
'TemplateName': 'string',
'Description': 'string',
'EndpointURL': 'string',
'CNAME': 'string',
'DateCreated': datetime(2015, 1, 1),
'DateUpdated': datetime(2015, 1, 1),
'Status': 'Launching'|'Updating'|'Ready'|'Terminating'|'Terminated',
'AbortableOperationInProgress': True|False,
'Health': 'Green'|'Yellow'|'Red'|'Grey',
'HealthStatus': 'NoData'|'Unknown'|'Pending'|'Ok'|'Info'|'Warning'|'Degraded'|'Good',
'Resources': {
'LoadBalancer': {
'LoadBalancerName': 'string',
'Domain': 'string',
'Listeners': [
{
'Protocol': 'string',
'Port': 123
},
],
},
},
'Tier': {
'Name': 'string',
'Type': 'string',
'Version': 'string'
}
}
```

Response Structure

• (dict) –

Describes the properties of an environment.

– EnvironmentName (string) –

The name of this environment.
- **EnvironmentId** *(string)* –
  The ID of this environment.

- **ApplicationName** *(string)* –
  The name of the application associated with this environment.

- **VersionLabel** *(string)* –
  The application version deployed in this environment.

- **SolutionStackName** *(string)* –
  The name of the SolutionStack deployed with this environment.

- **TemplateName** *(string)* –
  The name of the configuration template used to originally launch this environment.

- **Description** *(string)* –
  Describes this environment.

- **EndpointURL** *(string)* –
  For load-balanced, autoscaling environments, the URL to the LoadBalancer. For single-instance environments, the IP address of the instance.

- **CNAME** *(string)* –
  The URL to the CNAME for this environment.

- **DateCreated** *(datetime)* –
  The creation date for this environment.

- **DateUpdated** *(datetime)* –
  The last modified date for this environment.

- **Status** *(string)* –
  The current operational status of the environment:
  * Launching: Environment is in the process of initial deployment.
  * Updating: Environment is in the process of updating its configuration settings or application version.
  * Ready: Environment is available to have an action performed on it, such as update or terminate.
  * Terminating: Environment is in the shut-down process.
  * Terminated: Environment is not running.

- **AbortableOperationInProgress** *(boolean)* –
  Indicates if there is an in-progress environment configuration update or application version deployment that you can cancel.
  - `true`: There is an update in progress.
  - `false`: There are no updates currently in progress.

- **Health** *(string)* –
  Describes the health status of the environment. AWS Elastic Beanstalk indicates the failure levels for a running environment:
  * Red: Indicates the environment is not working.
  * Yellow: Indicates that something is wrong, the application might not be available, but the instances appear running.
  * Green: Indicates the environment is healthy and fully functional.
* Red: Indicates the environment is not responsive. Occurs when three or more consecutive failures occur for an environment.
* Yellow: Indicates that something is wrong. Occurs when two consecutive failures occur for an environment.
* Green: Indicates the environment is healthy and fully functional.
* Grey: Default health for a new environment. The environment is not fully launched and health checks have not started or health checks are suspended during an UpdateEnvironment or RestartEnvironment request.

Default: Grey

- **HealthStatus** *(string)*

  Returns the health status of the application running in your environment. For more information, see Health Colors and Statuses.

- **Resources** *(dict)*

  The description of the AWS resources used by this environment.

  * **LoadBalancer** *(dict)*

    Describes the LoadBalancer.

    - **LoadBalancerName** *(string)*
      The name of the LoadBalancer.

    - **Domain** *(string)*
      The domain name of the LoadBalancer.

    - **Listeners** *(list)*
      A list of Listeners used by the LoadBalancer.

        - **Protocol** *(string)*
          The protocol that is used by the Listener.

        - **Port** *(integer)*
          The port that is used by the Listener.

  - **Tier** *(dict)*

    Describes the current tier of this environment.

    * **Name** *(string)*
      The name of this environment tier.

    * **Type** *(string)*
      The type of this environment tier.

    * **Version** *(string)*
      The version of this environment tier.

---

**update_application(** **kwargs** **)**

Updates the specified application to have the specified properties.

**Note:** If a property (for example, description) is not provided, the value remains unchanged. To clear these properties, specify an empty string.

---

**Request Syntax**
response = client.update_application(
    ApplicationName='string',
    Description='string'
)

Parameters

- **ApplicationName** (*string*) – [REQUIRED]
  The name of the application to update. If no such application is found, UpdateApplication returns an InvalidParameterValue error.

- **Description** (*string*) – A new description for the application.
  Default: If not specified, AWS Elastic Beanstalk does not update the description.

Return type  dict

Returns

Response Syntax

```python
{
    'Application': {
        'ApplicationName': 'string',
        'Description': 'string',
        'DateCreated': datetime(2015, 1, 1),
        'DateUpdated': datetime(2015, 1, 1),
        'Versions': [
            'string',
        ],
        'ConfigurationTemplates': [
            'string',
        ]
    }
}
```

Response Structure

- *(dict)* – Result message containing a single description of an application.
  - **Application** *(dict)* – The ApplicationDescription of the application.
    - **ApplicationName** (*string*) – The name of the application.
    - **Description** (*string*) – User-defined description of the application.
    - **DateCreated** (*datetime*) – The date when the application was created.
    - **DateUpdated** (*datetime*) – The date when the application was last modified.
    - **Versions** *(list)* – The names of the versions for this application.
      - *(string)* – 
    - **ConfigurationTemplates** *(list)* – The names of the configuration templates associated with this application.
**update_application_version**(**kwargs**)

Updates the specified application version to have the specified properties.

**Note:** If a property (for example, `description`) is not provided, the value remains unchanged. To clear properties, specify an empty string.

**Request Syntax**

```python
response = client.update_application_version(
    ApplicationName='string',
    VersionLabel='string',
    Description='string'
)
```

**Parameters**

- **ApplicationName** (*string*) – [REQUIRED]
  
  The name of the application associated with this version.
  
  If no application is found with this name, `UpdateApplication` returns an `InvalidParameterValue` error.

- **VersionLabel** (*string*) – [REQUIRED]
  
  The name of the version to update.
  
  If no application version is found with this label, `UpdateApplication` returns an `InvalidParameterValue` error.

- **Description** (*string*) – A new description for this release.

**Response Syntax**

```json
{}
```

**Response Structure**

- *(dict)* –
  
  Result message wrapping a single description of an application version.

  - **ApplicationVersion** *(dict)* –
    
    The ApplicationVersionDescription of the application version.

    - **ApplicationName** (*string*) –
      
      The name of the application associated with this release.
* **Description** *(string)* –
  The description of this application version.

* **VersionLabel** *(string)* –
  A label uniquely identifying the version for the associated application.

* **SourceBundle** *(dict)* –
  The location where the source bundle is located for this version.
  - **S3Bucket** *(string)* –
    The Amazon S3 bucket where the data is located.
  - **S3Key** *(string)* –
    The Amazon S3 key where the data is located.

* **DateCreated** *(datetime)* –
  The creation date of the application version.

* **DateUpdated** *(datetime)* –
  The last modified date of the application version.

### `update_configuration_template(**kwargs)`

Updates the specified configuration template to have the specified properties or configuration option values.

**Note:** If a property (for example, `ApplicationName`) is not provided, its value remains unchanged. To clear such properties, specify an empty string.

**Related Topics**
- [DescribeConfigurationOptions](#)

**Request Syntax**

```python
response = client.update_configuration_template(
    ApplicationName='string',
    TemplateName='string',
    Description='string',
    OptionSettings=[
        {
            'ResourceName': 'string',
            'Namespace': 'string',
            'OptionName': 'string',
            'Value': 'string'
        },
    ],
    OptionsToRemove=[
        {
            'ResourceName': 'string',
            'Namespace': 'string',
            'OptionName': 'string'
        },
    ]
)
```

**Parameters**

* **ApplicationName** *(string)* – [REQUIRED]
  The name of the application associated with the configuration template to update.
If no application is found with this name, UpdateConfigurationTemplate returns an InvalidParameterValue error.

• **TemplateName (string)** – [REQUIRED]

The name of the configuration template to update.

If no configuration template is found with this name, UpdateConfigurationTemplate returns an InvalidParameterValue error.

• **Description (string)** – A new description for the configuration.

• **OptionSettings (list)** – A list of configuration option settings to update with the new specified option value.

  – *(dict)* –

  A specification identifying an individual configuration option along with its current value. For a list of possible option values, go to Option Values in the AWS Elastic Beanstalk Developer Guide.

    * **ResourceName (string)** –
      A unique resource name for a time-based scaling configuration option.

    * **Namespace (string)** –
      A unique namespace identifying the option’s associated AWS resource.

    * **OptionName (string)** –
      The name of the configuration option.

    * **Value (string)** –
      The current value for the configuration option.

• **OptionsToRemove (list)** – A list of configuration options to remove from the configuration set.

  Constraint: You can remove only UserDefined configuration options.

  – *(dict)* –

  A specification identifying an individual configuration option.

    * **ResourceName (string)** –
      A unique resource name for a time-based scaling configuration option.

    * **Namespace (string)** –
      A unique namespace identifying the option’s associated AWS resource.

    * **OptionName (string)** –
      The name of the configuration option.

Return type  dict

**Returns**

**Response Syntax**

```python
{
    'SolutionStackName': 'string',
    'ApplicationName': 'string',
    'TemplateName': 'string',
    'Description': 'string',
    'EnvironmentName': 'string',
```
'DeploymentStatus': 'deployed'|'pending'|'failed',
'DateCreated': datetime(2015, 1, 1),
'DateUpdated': datetime(2015, 1, 1),
'OptionSettings': [
    
    
    
    
    
    ],
}

Response Structure

* (dict) –

Describes the settings for a configuration set.

  – SolutionStackName (string) –

    The name of the solution stack this configuration set uses.

  – ApplicationName (string) –

    The name of the application associated with this configuration set.

  – TemplateName (string) –

    If not null, the name of the configuration template for this configuration set.

  – Description (string) –

    Describes this configuration set.

  – EnvironmentName (string) –

    If not null, the name of the environment for this configuration set.

  – DeploymentStatus (string) –

    If this configuration set is associated with an environment, the DeploymentStatus parameter indicates the deployment status of this configuration set:

    null: This configuration is not associated with a running environment.

    pending: This is a draft configuration that is not deployed to the associated environment but is in the process of deploying.

    deployed: This is the configuration that is currently deployed to the associated running environment.

    failed: This is a draft configuration, that failed to successfully deploy.

    * null: This configuration is not associated with a running environment.

    * pending: This is a draft configuration that is not deployed to the associated environment but is in the process of deploying.

    * deployed: This is the configuration that is currently deployed to the associated running environment.

    * failed: This is a draft configuration that failed to successfully deploy.
– **DateCreated** *(datetime)* –
  The date (in UTC time) when this configuration set was created.

– **DateUpdated** *(datetime)* –
  The date (in UTC time) when this configuration set was last modified.

– **OptionSettings** *(list)* –
  A list of the configuration options and their values in this configuration set.

  # *(dict)* –
  A specification identifying an individual configuration option along with its current value. For a list of possible option values, go to Option Values in the AWS Elastic Beanstalk Developer Guide.

    * **ResourceName** *(string)* –
      A unique resource name for a time-based scaling configuration option.
    
    * **Namespace** *(string)* –
      A unique namespace identifying the option’s associated AWS resource.
    
    * **OptionName** *(string)* –
      The name of the configuration option.
    
    * **Value** *(string)* –
      The current value for the configuration option.

**update_environment** (**kwargs**)

Updates the environment description, deploys a new application version, updates the configuration settings to an entirely new configuration template, or updates select configuration option values in the running environment.

Attempting to update both the release and configuration is not allowed and AWS Elastic Beanstalk returns an InvalidParameterCombination error.

When updating the configuration settings to a new template or individual settings, a draft configuration is created and DescribeConfigurationSettings for this environment returns two setting descriptions with different DeploymentStatus values.

**Request Syntax**

```python
response = client.update_environment(
    EnvironmentId='string',
    EnvironmentName='string',
    Description='string',
    Tier={
        'Name': 'string',
        'Type': 'string',
        'Version': 'string'
    },
    VersionLabel='string',
    TemplateName='string',
    SolutionStackName='string',
    OptionSettings=[
        {
            'ResourceName': 'string',
            'Namespace': 'string',
            'OptionName': 'string',
            'Value': 'string'
        }
    ]
)
```
Parameters

- **EnvironmentId** *(string)* – The ID of the environment to update.

  If no environment with this ID exists, AWS Elastic Beanstalk returns an `InvalidParameterValue` error.

  Condition: You must specify either this or an `EnvironmentName`, or both. If you do not specify either, AWS Elastic Beanstalk returns `MissingRequiredParameter` error.

- **EnvironmentName** *(string)* – The name of the environment to update. If no environment with this name exists, AWS Elastic Beanstalk returns an `InvalidParameterValue` error.

  Condition: You must specify either this or an `EnvironmentId`, or both. If you do not specify either, AWS Elastic Beanstalk returns `MissingRequiredParameter` error.

- **Description** *(string)* – If this parameter is specified, AWS Elastic Beanstalk updates the description of this environment.

  Condition: At this time, if you change the tier version, name, or type, AWS Elastic Beanstalk returns `InvalidParameterValue` error.

  - **Name** *(string)* –

    The name of this environment tier.

  - **Type** *(string)* –

    The type of this environment tier.

  - **Version** *(string)* –

    The version of this environment tier.

- **VersionLabel** *(string)* – If this parameter is specified, AWS Elastic Beanstalk deploys the named application version to the environment. If no such application version is found, returns an `InvalidParameterValue` error.

- **TemplateName** *(string)* – If this parameter is specified, AWS Elastic Beanstalk deploys this configuration template to the environment. If no such configuration template is found, AWS Elastic Beanstalk returns an `InvalidParameterValue` error.

- **SolutionStackName** *(string)* – This specifies the platform version that the environment will run after the environment is updated.

- **OptionSettings** *(list)* – If specified, AWS Elastic Beanstalk updates the configuration set associated with the running environment and sets the specified configuration options to the requested value.

  - *(dict)* –

    A specification identifying an individual configuration option along with its current value. For a list of possible option values, go to **Option Values**.
in the *AWS Elastic Beanstalk Developer Guide*.  

- **ResourceName** *(string)*  
  A unique resource name for a time-based scaling configuration option.

- **Namespace** *(string)*  
  A unique namespace identifying the option’s associated AWS resource.

- **OptionName** *(string)*  
  The name of the configuration option.

- **Value** *(string)*  
  The current value for the configuration option.

- **OptionsToRemove** *(list)*  
  A list of custom user-defined configuration options to remove from the configuration set for this environment.

- **(dict)**  
  A specification identifying an individual configuration option.

- **ResourceName** *(string)*  
  A unique resource name for a time-based scaling configuration option.

- **Namespace** *(string)*  
  A unique namespace identifying the option’s associated AWS resource.

- **OptionName** *(string)*  
  The name of the configuration option.

**Return type** `dict`  
**Returns**

**Response Syntax**

```
{
    'EnvironmentName': 'string',
    'EnvironmentId': 'string',
    'ApplicationName': 'string',
    'VersionLabel': 'string',
    'SolutionStackName': 'string',
    'TemplateName': 'string',
    'Description': 'string',
    'EndpointURL': 'string',
    'CNAME': 'string',
    'DateCreated': datetime(2015, 1, 1),
    'DateUpdated': datetime(2015, 1, 1),
    'Status': 'Launching'|'Updating'|'Ready'|'Terminating'|'Terminated',
    'AbortableOperationInProgress': True|False,
    'Health': 'Green'|'Yellow'|'Red'|'Grey',
    'HealthStatus': 'NoData'|'Unknown'|'Pending'|'Ok'|'Info'|'Warning'|'Degraded'|...  
    'Resources': {
        'LoadBalancer': {
            'LoadBalancerName': 'string',
            'Domain': 'string',
            'Listeners': [
                {  
                    'Protocol': 'string',
                    'Port': 123
                }
            ]
        }
    }
}
```
Response Structure

- (dict) –

  Describes the properties of an environment.
  - EnvironmentName (string) –
    The name of this environment.
  - EnvironmentId (string) –
    The ID of this environment.
  - ApplicationName (string) –
    The name of the application associated with this environment.
  - VersionLabel (string) –
    The application version deployed in this environment.
  - SolutionStackName (string) –
    The name of the SolutionStack deployed with this environment.
  - TemplateName (string) –
    The name of the configuration template used to originally launch this environment.
  - Description (string) –
    Describes this environment.
  - EndpointURL (string) –
    For load-balanced, autoscaling environments, the URL to the LoadBalancer. For single-instance environments, the IP address of the instance.
  - CNAME (string) –
    The URL to the CNAME for this environment.
  - DateCreated (datetime) –
    The creation date for this environment.
  - DateUpdated (datetime) –
    The last modified date for this environment.
  - Status (string) –
    The current operational status of the environment:
    * Launching: Environment is in the process of initial deployment.
    * Updating: Environment is in the process of updating its configuration settings or application version.
    * Ready: Environment is available to have an action performed on it, such as update or terminate.
    * Terminating: Environment is in the shut-down process.
    * Terminated: Environment is not running.
– **AbortableOperationInProgress** *(boolean)* –

Indicates if there is an in-progress environment configuration update or application version deployment that you can cancel.

true: There is an update in progress.

false: There are no updates currently in progress.

– **Health** *(string)* –

Describes the health status of the environment. AWS Elastic Beanstalk indicates the failure levels for a running environment:

* Red: Indicates the environment is not working.

* Yellow: Indicates that something is wrong, the application might not be available, but the instances appear running.

* Green: Indicates the environment is healthy and fully functional.

* Red: Indicates the environment is not responsive. Occurs when three or more consecutive failures occur for an environment.

* Yellow: Indicates that something is wrong. Occurs when two consecutive failures occur for an environment.

* Green: Indicates the environment is healthy and fully functional.

* Grey: Default health for a new environment. The environment is not fully launched and health checks have not started or health checks are suspended during an UpdateEnvironment or RestartEnvironment request.

Default: Grey

– **HealthStatus** *(string)* –

Returns the health status of the application running in your environment. For more information, see Health Colors and Statuses.

– **Resources** *(dict)* –

The description of the AWS resources used by this environment.

* **LoadBalancer** *(dict)* –

  Describes the LoadBalancer.

  - **LoadBalancerName** *(string)* –

    The name of the LoadBalancer.

  - **Domain** *(string)* –

    The domain name of the LoadBalancer.

  - **Listeners** *(list)* –

    A list of Listeners used by the LoadBalancer.

  - **Protocol** *(string)* –

    The protocol that is used by the Listener.

  - **Port** *(integer)* –

    The port that is used by the Listener.

– **Tier** *(dict)* –

  Describes the current tier of this environment.
validate_configuration_settings(**kwargs)

Takes a set of configuration settings and either a configuration template or environment, and determines whether those values are valid.

This action returns a list of messages indicating any errors or warnings associated with the selection of option values.

**Request Syntax**

```python
response = client.validate_configuration_settings(
    ApplicationName='string',
    TemplateName='string',
    EnvironmentName='string',
    OptionSettings=[
        {'ResourceName': 'string',
        'Namespace': 'string',
        'OptionName': 'string',
        'Value': 'string'}
    ],
)
```

**Parameters**

- **ApplicationName (string)** – [REQUIRED]
  
  The name of the application that the configuration template or environment belongs to.

- **TemplateName (string)** – The name of the configuration template to validate the settings against.

  Condition: You cannot specify both this and an environment name.

- **EnvironmentName (string)** – The name of the environment to validate the settings against.

  Condition: You cannot specify both this and a configuration template name.

- **OptionSettings (list)** – [REQUIRED]
  
  A list of the options and desired values to evaluate.
  
  - (dict) –
    
    A specification identifying an individual configuration option along with its current value. For a list of possible option values, go to Option Values in the *AWS Elastic Beanstalk Developer Guide*.

    - **ResourceName (string)** –
      
      A unique resource name for a time-based scaling configuration option.

    - **Namespace (string)** –
      
      A unique namespace identifying the option’s associated AWS resource.
OptionName (string) –
The name of the configuration option.

Value (string) –
The current value for the configuration option.

Return type: dict

Response Syntax

```python
{}
'Messages': [
    
    'Message': 'string',
    'Severity': 'error'|'warning',
    'Namespace': 'string',
    'OptionName': 'string'
},
]
}
```

Response Structure

- (dict) – Provides a list of validation messages.
  - (list) – A list of ValidationMessage.
    - (dict) – An error or warning for a desired configuration option value.
      - Message (string) – A message describing the error or warning.
      - Severity (string) – An indication of the severity of this message:
        - error: This message indicates that this is not a valid setting for an option.
        - warning: This message is providing information you should take into account.
      - (dict) –

Paginators

The available paginators are:

- ElasticBeanstalk.Paginator.DescribeEvents class
paginator = client.get_paginator('describe_events')

paginate(**kwargs)

Creates an iterator that will paginate through responses from ElasticBeanstalk.Client.describe_events().

Request Syntax

response_iterator = paginator.paginate(
    ApplicationName='string',
    VersionLabel='string',
    TemplateName='string',
    EnvironmentId='string',
    EnvironmentName='string',
    RequestId='string',
    Severity='TRACE'|'DEBUG'|'INFO'|'WARN'|'ERROR'|'FATAL',
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **ApplicationName (string)** – If specified, AWS Elastic Beanstalk restricts the returned descriptions to include only those associated with this application.
- **VersionLabel (string)** – If specified, AWS Elastic Beanstalk restricts the returned descriptions to those associated with this application version.
- **TemplateName (string)** – If specified, AWS Elastic Beanstalk restricts the returned descriptions to those that are associated with this environment configuration.
- **EnvironmentId (string)** – If specified, AWS Elastic Beanstalk restricts the returned descriptions to those associated with this environment.
- **EnvironmentName (string)** – If specified, AWS Elastic Beanstalk restricts the returned descriptions to those associated with this environment.
- **RequestId (string)** – If specified, AWS Elastic Beanstalk restricts the described events to include only those associated with this request ID.
- **Severity (string)** – If specified, limits the events returned from this call to include only those with the specified severity or higher.
- **StartTime (datetime)** – If specified, AWS Elastic Beanstalk restricts the returned descriptions to those that occur on or after this time.
- **EndTime (datetime)** – If specified, AWS Elastic Beanstalk restricts the returned descriptions to those that occur up to, but not including, the EndTime.
- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** –
    
The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize (integer)** –
    
The size of each page.
  - **StartingToken (string)** –
A token to specify where to start paginating. This is the NextToken from a previous response.

Response Syntax

```python
{
    'Events': [  
        {'EventDate': datetime(2015, 1, 1),  
         'Message': 'string',  
         'ApplicationName': 'string',  
         'VersionLabel': 'string',  
         'TemplateName': 'string',  
         'EnvironmentName': 'string',  
         'RequestId': 'string',  
         'Severity': 'TRACE'|'DEBUG'|'INFO'|'WARN'|'ERROR'|'FATAL'  
    },
    ],
}
```

Response Structure

- (dict) –

  Result message wrapping a list of event descriptions.

  - Events (list) –

    A list of EventDescription.

    * (dict) –

      Describes an event.

      - EventDate (datetime) –

        The date when the event occurred.

      - Message (string) –

        The event message.

      - ApplicationName (string) –

        The application associated with the event.

      - VersionLabel (string) –

        The release label for the application version associated with this event.

      - TemplateName (string) –

        The name of the configuration associated with this event.

      - EnvironmentName (string) –

        The name of the environment associated with this event.

      - RequestId (string) –

        The web service request ID for the activity of this event.

      - Severity (string) –

        The severity level of this event.
ElasticTranscoder

Client

class ElasticTranscoder.Client
    A low-level client representing Amazon Elastic Transcoder:

    import boto3

    client = boto3.client('elastictranscoder')

    These are the available methods:
    • can_paginate()
    • cancel_job(**kwargs)
    • create_job()
    • create_pipeline()
    • create_preset()
    • delete_pipeline()
    • delete_preset()
    • generate_presigned_url()
    • get_paginators()
    • get_waiter()
    • list_jobs_by_pipeline()
    • list_jobs_by_status()
    • list_pipelines()
    • list_presets()
    • read_job()
    • read_pipeline()
    • read_preset()
    • test_role()
    • update_pipeline()
    • update_pipeline_notifications()
    • update_pipeline_status()

    can_paginate(operation_name)
    Check if an operation can be paginated.

    Parameters  operation_name  (string) – The operation name. This is the same name as
    the method name on the client. For example, if the method name is createFoo,
    and you'd normally invoke the operation as client.createFoo(**kwargs),
    if the createFoo operation can be paginated, you can use the call
    client.get_paginators("createFoo").

    Returns  True if the operation can be paginated, False otherwise.

    cancel_job(**kwargs)
    The CancelJob operation cancels an unfinished job.
Note: You can only cancel a job that has a status of Submitted. To prevent a pipeline from starting to process a job while you're getting the job identifier, use UpdatePipelineStatus to temporarily pause the pipeline.

Request Syntax

```python
response = client.cancel_job(
    Id='string'
)
```

Parameters  

Id (*string*) – [REQUIRED]

The identifier of the job that you want to cancel.

To get a list of the jobs (including their job Id) that have a status of Submitted, use the ListJobsByStatus API action.

Return type dict

Returns

Response Syntax

```plaintext
{}
```

Response Structure

* (dict) –

The response body contains a JSON object. If the job is successfully canceled, the value of Success is true.

create_job (**kwargs)

When you create a job, Elastic Transcoder returns JSON data that includes the values that you specified plus information about the job that is created.

If you have specified more than one output for your jobs (for example, one output for the Kindle Fire and another output for the Apple iPhone 4s), you currently must use the Elastic Transcoder API to list the jobs (as opposed to the AWS Console).

Request Syntax

```python
response = client.create_job(
    PipelineId='string',
    Input={
        'Key': 'string',
        'FrameRate': 'string',
        'Resolution': 'string',
        'AspectRatio': 'string',
        'Interlaced': 'string',
        'Container': 'string',
        'Encryption': {
            'Mode': 'string',
            'Key': 'string',
            'KeyMd5': 'string',
            'InitializationVector': 'string'
        },
        'DetectedProperties': {
            'Width': 123,
            'Height': 123,
            'FrameRate': 'string',
            'FileSize': 123,
        }
    }
)
```
'DurationMillis': 123
}
},
Output={

        'LicenseAcquisitionUrl': 'string'
    }
},
],
UserMetadata={
    'string': 'string'
}
)

Parameters

- **PipelineId** (string) – [REQUIRED]

  The Id of the pipeline that you want Elastic Transcoder to use for transcoding. The pipeline determines several settings, including the Amazon S3 bucket from which Elastic Transcoder gets the files to transcode and the bucket into which Elastic Transcoder puts the transcoded files.

- **Input** (dict) – [REQUIRED]

  A section of the request body that provides information about the file that is being transcoded.

    - **Key** (string)

      The name of the file to transcode. Elsewhere in the body of the JSON block is the the ID of the pipeline to use for processing the job. The InputBucket object in that pipeline tells Elastic Transcoder which Amazon S3 bucket to get the file from.

      If the file name includes a prefix, such as `cooking/lasagna.mpg`, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

    - **FrameRate** (string) –
The frame rate of the input file. If you want Elastic Transcoder to automatically detect the frame rate of the input file, specify auto. If you want to specify the frame rate for the input file, enter one of the following values:

10, 15, 23.97, 24, 25, 29.97, 30, 60

If you specify a value other than auto, Elastic Transcoder disables automatic detection of the frame rate.

- **Resolution (string)** –

  This value must be auto, which causes Elastic Transcoder to automatically detect the resolution of the input file.

- **AspectRatio (string)** –

  The aspect ratio of the input file. If you want Elastic Transcoder to automatically detect the aspect ratio of the input file, specify auto. If you want to specify the aspect ratio for the output file, enter one of the following values:

  1:1, 4:3, 3:2, 16:9

  If you specify a value other than auto, Elastic Transcoder disables automatic detection of the aspect ratio.

- **Interlaced (string)** –

  Whether the input file is interlaced. If you want Elastic Transcoder to automatically detect whether the input file is interlaced, specify auto. If you want to specify whether the input file is interlaced, enter one of the following values:

  true, false

  If you specify a value other than auto, Elastic Transcoder disables automatic detection of interlacing.

- **Container (string)** –

  The container type for the input file. If you want Elastic Transcoder to automatically detect the container type of the input file, specify auto. If you want to specify the container type for the input file, enter one of the following values:

  3gp, aac, asf, avi, divx, flv, m4a, mkv, mov, mp3, mp4, mpeg, mpeg-ps, mpeg-ts, mxf, ogg, vob, wav, webm

- **Encryption (dict)** –

  The encryption settings, if any, that are used for decrypting your input files. If your input file is encrypted, you must specify the mode that Elastic Transcoder will use to decrypt your file.

  - **Mode (string)** –

    The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

    - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
    - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
    - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
· **AES-CTR**: AES Counter Mode.
· **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

* **Key** *(string)* –
  
The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

* **KeyMd5** *(string)* –
  
The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

* **InitializationVector** *(string)* –
  
The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

– **DetectedProperties** *(dict)* –

  The detected properties of the input file.

  * **Width** *(integer)* –
    
The detected width of the input file, in pixels.

  * **Height** *(integer)* –
    
The detected height of the input file, in pixels.

  * **FrameRate** *(string)* –
    
The detected frame rate of the input file, in frames per second.

  * **FileSize** *(integer)* –
    
The detected file size of the input file, in bytes.

  * **DurationMillis** *(integer)* –
    
The detected duration of the input file, in milliseconds.
• **Output** *(dict)* – The CreateJobOutput structure.
  
  – **Key**(string) –

  The name to assign to the transcoded file. Elastic Transcoder saves the
  file in the Amazon S3 bucket specified by the **OutputBucket** object in
  the pipeline that is specified by the pipeline ID. If a file with the specified
  name already exists in the output bucket, the job fails.

  – **ThumbnailPattern**(string) –

    Whether you want Elastic Transcoder to create thumbnails for your videos
    and, if so, how you want Elastic Transcoder to name the files.

    If you don’t want Elastic Transcoder to create thumbnails, specify “”.

    If you do want Elastic Transcoder to create thumbnails, specify the
    information that you want to include in the file name for each thumbnail. You
    can specify the following values in any sequence:

    1. **“{count}”** *(Required)*: If you want to create thumbnails, you must
       include `{count}` in the **ThumbnailPattern** object. Wherever
       you specify `{count}`, Elastic Transcoder adds a five-digit se-
       quence number (beginning with **00001**) to thumbnail file names.
       The number indicates where a given thumbnail appears in the se-
       quence of thumbnails for a transcoded file. .. warning::If you spec-
       ify a literal value and/or `{resolution}` but you omit `{count}`,
       Elastic Transcoder returns a validation error and does not create the
       job.

    2. **Literal values** *(Optional)*: You can specify literal values any-
       where in the **ThumbnailPattern** object. For example, you
       can include them as a file name prefix or as a delimiter between
       `{resolution}` and `{count}`.

    3. **“{resolution}”** *(Optional)*: If you want Elastic Transcoder to in-
       clude the resolution in the file name, include `{resolution}` in
       the **ThumbnailPattern** object.

    When creating thumbnails, Elastic Transcoder automatically saves the
    files in the format (.jpg or .png) that appears in the preset that you specified
    in the **PresetID** value of CreateJobOutput. Elastic Transcoder
    also appends the applicable file name extension.

  – **ThumbnailEncryption** *(dict)* –

    The encryption settings, if any, that you want Elastic Transcoder to apply
    to your thumbnail.

    – **Mode**(string) –

      The specific server-side encryption mode that you want Elastic
      Transcoder to use when decrypting your input files or encrypting
      your output files. Elastic Transcoder supports the following options:

      1. **S3**: Amazon S3 creates and manages the keys used for en-
         crypted your files.

      2. **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Manage-
         ment Service, which creates and manages the keys that are
         used for encrypting your files. If you specify **S3-AWS-KMS**
         and you don’t want to use the default key, you must add the
         AWS-KMS key that you want to use to your pipeline.

      3. **AES-CBC-PKCS7**: A padded cipher-block mode of opera-
         tion originally used for HLS files.

      4. **AES-CTR**: AES Counter Mode.

      5. **AES-GCM**: AES Galois Counter Mode, a mode of operation
that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

* **Key** *(string)* –

The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

* **KeyMd5** *(string)* –

The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

* **Initialization Vector** *(string)* –

The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

* **Rotate** *(string)* –

The number of degrees clockwise by which you want Elastic Transcoder to rotate the output relative to the input. Enter one of the following values: auto, 0, 90, 180, 270. The value auto generally works only if the file that you’re transcoding contains rotation metadata.

* **PresetId** *(string)* –

The Id of the preset to use for this job. The preset determines the audio, video, and thumbnail settings that Elastic Transcoder uses for transcoding.

* **SegmentDuration** *(string)* –

**Warning:** (Outputs in Fragmented MP4 or MPEG-TS format only.

If you specify a preset in PresetId for which the value of Container is fmp4 (Fragmented MP4) or ts (MPEG-TS), SegmentDuration is the target maximum duration of each segment in seconds. For HLSv3 format playlists, each media segment is stored in a separate .ts file.
For HLSv4 and Smooth playlists, all media segments for an output are stored in a single file. Each segment is approximately the length of the \texttt{SegmentDuration}, though individual segments might be shorter or longer.

The range of valid values is 1 to 60 seconds. If the duration of the video is not evenly divisible by \texttt{SegmentDuration}, the duration of the last segment is the remainder of total length/\texttt{SegmentDuration}.

Elastic Transcoder creates an output-specific playlist for each output HLS output that you specify in \texttt{OutputKeys}. To add an output to the master playlist for this job, include it in the \texttt{OutputKeys} of the associated playlist.

- \textbf{Watermarks (list)} –

Information about the watermarks that you want Elastic Transcoder to add to the video during transcoding. You can specify up to four watermarks for each output. Settings for each watermark must be defined in the preset for the current output.

* \texttt{dict} –

Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

- \texttt{PresetWatermarkId (string)} –

The ID of the watermark settings that Elastic Transcoder uses to add watermarks to the video during transcoding. The settings are in the preset specified by \texttt{Preset} for the current output. In that preset, the value of Watermarks Id tells Elastic Transcoder which settings to use.

- \texttt{InputKey (string)} –

The name of the .png or .jpg file that you want to use for the watermark. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by \texttt{Pipeline}; the Input Bucket object in that pipeline identifies the bucket.

If the file name includes a prefix, for example, logos/128x64.png, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- \texttt{Encryption (dict)} –

The encryption settings, if any, that you want Elastic Transcoder to apply to your watermarks.

- \texttt{Mode (string)} –

The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

- \texttt{S3}: Amazon S3 creates and manages the keys used for encrypting your files.
- \texttt{S3-AWS-KMS}: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify \texttt{S3-AWS-KMS} and you don’t want to use the default key, you must add the
AWS-KMS key that you want to use to your pipeline.
- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:
- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AlbumArt (dict)** –

  Information about the album art that you want Elastic Transcoder to add to the file during transcoding. You can specify up to twenty album artworks for each output. Settings for each artwork must be defined in the job for the current output.

  - **MergePolicy (string)** –

    A policy that determines how Elastic Transcoder will handle the existence of multiple album artwork files.
- **Replace**: The specified album art will replace any existing album art.
- **Prepend**: The specified album art will be placed in front of any existing album art.
- **Append**: The specified album art will be placed after any existing album art.
- **Fallback**: If the original input file contains artwork, Elastic Transcoder will use that artwork for the output. If the original input does not contain artwork, Elastic Transcoder will use the specified album art file.

* **Artwork** *(list)* –

The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20. Valid formats are `.jpg` and `.png`

- *(dict)* –

  The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20.

  To remove artwork or leave the artwork empty, you can either set **Artwork** to null, or set the **Merge Policy** to “Replace” and use an empty **Artwork** array.

  To pass through existing artwork unchanged, set the **Merge Policy** to “Prepend”, “Append”, or “Fallback”, and use an empty **Artwork** array.

- **InputKey** *(string)* –

  The name of the file to be used as album art. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by **PipelineId**; the **InputBucket** object in that pipeline identifies the bucket.

  If the file name includes a prefix, for example, `cooking/pie.jpg`, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **MaxWidth** *(string)* –

  The maximum width of the output album art in pixels. If you specify **auto**, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 4096, inclusive.

- **MaxHeight** *(string)* –

  The maximum height of the output album art in pixels. If you specify **auto**, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 3072, inclusive.

- **SizingPolicy** *(string)* –

  Specify one of the following values to control scaling of the output album art:

  - **Fit**: Elastic Transcoder scales the output art so it matches the value that you specified in either **MaxWidth** or **MaxHeight** without exceeding the other value.
- **Fill**: Elastic Transcoder scales the output art so it matches the value that you specified in either `MaxWidth` or `MaxHeight` and matches or exceeds the other value. Elastic Transcoder centers the output art and then crops it in the dimension (if any) that exceeds the maximum value.

- **Stretch**: Elastic Transcoder stretches the output art to match the values that you specified for `MaxWidth` and `MaxHeight`. If the relative proportions of the input art and the output art are different, the output art will be distorted.

- **Keep**: Elastic Transcoder does not scale the output art. If either dimension of the input art exceeds the values that you specified for `MaxWidth` and `MaxHeight`, Elastic Transcoder crops the output art.

- **ShrinkToFit**: Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without exceeding either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **ShrinkToFit**: Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without dropping below either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **PaddingPolicy** *(string)* –

  When you set `PaddingPolicy` to `Pad`, Elastic Transcoder may add white bars to the top and bottom and/or left and right sides of the output album art to make the total size of the output art match the values that you specified for `MaxWidth` and `MaxHeight`.

- **AlbumArtFormat** *(string)* –

  The format of album art, if any. Valid formats are `.jpg` and `.png`.

- **Encryption** *(dict)* –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your artwork.

- **Mode** *(string)* –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file,
key, or initialization vector that has been tampered with will fail the decryption process.
For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –
  
The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –
  
The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit.
  The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –
  
The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Composition (list)** –
  
You can create an output file that contains an excerpt from the input file. This excerpt, called a clip, can come from the beginning, middle, or end of the file. The Composition object contains settings for the clips that make up an output file. For the current release, you can only specify settings for a single clip per output file. The Composition object cannot be null.

  * (dict) –
  
Settings for one clip in a composition. All jobs in a playlist must have the same clip settings.

  - **TimeSpan (dict)** –
    
Settings that determine when a clip begins and how long it lasts.

  - **StartTime (string)** –
The place in the input file where you want a clip to start. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder starts at the beginning of the input file.

- **Duration** *(string)*

  The duration of the clip. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder creates an output file from StartTime to the end of the file.

  If you specify a value longer than the duration of the input file, Elastic Transcoder transcodes the file and returns a warning message.

- **Captions** *(dict)*

  You can configure Elastic Transcoder to transcode captions, or subtitles, from one format to another. All captions must be in UTF-8. Elastic Transcoder supports two types of captions:

  * **Embedded**: Embedded captions are included in the same file as the audio and video. Elastic Transcoder supports only one embedded caption per language, to a maximum of 300 embedded captions per file. Valid input values include: CEA-608 (EIA-608, first non-empty channel only), CEA-708 (EIA-708, first non-empty channel only), and mov-text. Valid outputs include: mov-text. Elastic Transcoder supports a maximum of one embedded format per output.

  * **Sidecar**: Sidecar captions are kept in a separate metadata file from the audio and video data. Sidecar captions require a player that is capable of understanding the relationship between the video file and the sidecar file. Elastic Transcoder supports only one sidecar caption per language, to a maximum of 20 sidecar captions per file. Valid input values include: dfxp (first div element only), ebu-tt, scc, smpte, srt, ttml (first div element only), and webvtt. Valid outputs include: dfxp (first div element only), scc, srt, and webvtt.

  If you want ttml or smpte-tt compatible captions, specify dfxp as your output format.

  Elastic Transcoder does not support OCR (Optical Character Recognition), does not accept pictures as a valid input for captions, and is not available for audio-only transcoding. Elastic Transcoder does not preserve text formatting (for example, italics) during the transcoding process.

  To remove captions or leave the captions empty, set Captions to null. To pass through existing captions unchanged, set the MergePolicy to MergeRetain, and pass in a null CaptionSources array.

  For more information on embedded files, see the Subtitles Wikipedia page.

  For more information on sidecar files, see the Extensible Metadata Platform and Sidecar file Wikipedia pages.

  * **MergePolicy** *(string)*

    A policy that determines how Elastic Transcoder handles the existence of multiple captions.
- **MergeOverride**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the sidecar captions and ignores the embedded captions for that language.

- **MergeRetain**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the embedded captions and ignores the sidecar captions for that language. If `CaptionSources` is empty, Elastic Transcoder omits all sidecar captions from the output files.

- **Override**: Elastic Transcoder transcodes only the sidecar captions that you specify in `CaptionSources`. `MergePolicy` cannot be null.

* **CaptionSources** *(list)*

Source files for the input sidecar captions used during the transcoding process. To omit all sidecar captions, leave `CaptionSources` blank.

  - *(dict)*

    A source file for the input sidecar captions used during the transcoding process.

    - **Key** *(string)*

        The name of the sidecar caption file that you want Elastic Transcoder to include in the output file.

    - **Language** *(string)*

        A string that specifies the language of the caption. Specify this as one of:

        - 2-character ISO 639-1 code
        - 3-character ISO 639-2 code
        
        For more information on ISO language codes and language names, see the List of ISO 639-1 codes.

    - **TimeOffset** *(string)*

        For clip generation or captions that do not start at the same time as the associated video file, the `TimeOffset` tells Elastic Transcoder how much of the video to encode before including captions.

        Specify the `TimeOffset` in the form `[-+]SS.sss` or `[-+]HH:mm:SS.ss`.

    - **Label** *(string)*

        The label of the caption shown in the player when choosing a language. We recommend that you put the caption language name here, in the language of the captions.

    - **Encryption** *(dict)*

        The encryption settings, if any, that you want Elastic Transcoder to apply to your caption sources.

    - **Mode** *(string)*

        The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or en-
crypting your output files. Elastic Transcoder supports the following options:

- **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
- **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify **S3-AWS-KMS** and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **CaptionFormats** *(list)* –
The array of file formats for the output captions. If you leave this value blank, Elastic Transcoder returns an error.

- `(dict)` –

  The file format of the output captions. If you leave this value blank, Elastic Transcoder returns an error.

  - **Format (string)** –

    The format you specify determines whether Elastic Transcoder generates an embedded or sidecar caption for this output.

  - **Valid Embedded Caption Formats:**
    - *for FLAC*: None
    - *For MP3*: None
    - *For MP4*: mov-text
    - *For MPEG-TS*: None
    - *For ogg*: None
    - *For webm*: None

  - **Valid Sidecar Caption Formats:** Elastic Transcoder supports dfxp (first div element only), scc, srt, and webvtt. If you want ttml or smpte-tt compatible captions, specify dfxp as your output format. *For FMP4*: dfxp

  - **Non-FMP4 outputs**: All sidecar types

    fmp4 captions have an extension of `.ismt`

  - **Pattern (string)** –

    The prefix for caption filenames, in the form `description - {language}`, where:

    - **description** is a description of the video.
    - **{language}** is a literal value that Elastic Transcoder replaces with the two- or three-letter code for the language of the caption in the output file names.

    If you don’t include `{language}` in the file name pattern, Elastic Transcoder automatically appends “{language}” to the value that you specify for the description. In addition, Elastic Transcoder automatically appends the count to the end of the segment files.

    For example, suppose you’re transcoding into srt format. When you enter “Sydney-{language}-sunrise”, and the language of the captions is English (en), the name of the first caption file will be Sydney-en-sunrise00000.srt.

  - **Encryption (dict)** –

    The encryption settings, if any, that you want Elastic Transcoder to apply to your caption formats.

    - **Mode (string)** –

      The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

      - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
      - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the
AWS-KMS key that you want to use to your pipeline.

- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –

The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –

The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Encryption** *(dict)* –

You can specify encryption settings for any output files that you want to use for a transcoding job. This includes the output file and any watermarks, thumbnails, album art, or captions that you want to use. You must specify encryption settings for each file individually.

- **Mode** *(string)* –

The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting
your output files. Elastic Transcoder supports the following options:

- **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
- **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify **S3-AWS-KMS** and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* —
  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:
  
  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.
- **KeyMd5** *(string)* —
  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.
- **InitializationVector** *(string)* —
  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Outputs** *(list)* — A section of the request body that provides information about the transcoded (target) files. We recommend that you use the Outputs syntax instead of the Output syntax.
  
  - *(dict)* —
    
    The **CreateJobOutput** structure.
**Key (string)** –

The name to assign to the transcoded file. Elastic Transcoder saves the file in the Amazon S3 bucket specified by the `OutputBucket` object in the pipeline that is specified by the pipeline ID. If a file with the specified name already exists in the output bucket, the job fails.

**ThumbnailPattern (string)** –

Whether you want Elastic Transcoder to create thumbnails for your videos and, if so, how you want Elastic Transcoder to name the files.

If you don’t want Elastic Transcoder to create thumbnails, specify "".

If you do want Elastic Transcoder to create thumbnails, specify the information that you want to include in the file name for each thumbnail. You can specify the following values in any sequence:

- ""{count}"" (Required): If you want to create thumbnails, you must include `{count}` in the `ThumbnailPattern` object. Wherever you specify `{count}`, Elastic Transcoder adds a five-digit sequence number (beginning with 00001) to thumbnail file names. The number indicates where a given thumbnail appears in the sequence of thumbnails for a transcoded file. .. warning:: If you specify a literal value and/or `{resolution}` but you omit `{count}`, Elastic Transcoder returns a validation error and does not create the job.

- Literal values (Optional): You can specify literal values anywhere in the `ThumbnailPattern` object. For example, you can include them as a file name prefix or as a delimiter between `{resolution}` and `{count}`.

- ""{resolution}"" (Optional): If you want Elastic Transcoder to include the resolution in the file name, include `{resolution}` in the `ThumbnailPattern` object.

When creating thumbnails, Elastic Transcoder automatically saves the files in the format (.jpg or .png) that appears in the preset that you specified in the `PresetID` value of `CreateJobOutput`. Elastic Transcoder also appends the applicable file name extension.

**ThumbnailEncryption (dict)** –

The encryption settings, if any, that you want Elastic Transcoder to apply to your thumbnail.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
· AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
· AES-CTR: AES Counter Mode.
· AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

· **Key**
· **Key MD5**
· **Initialization Vector**

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won't be able to decrypt your data.

· **Key** *(string)* –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

· **KeyMd5** *(string)* –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

· **InitializationVector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

· **Rotate** *(string)* –

  The number of degrees clockwise by which you want Elastic Transcoder to rotate the output relative to the input. Enter one of the following values: auto, 0, 90, 180, 270. The value auto generally works only if the file that you're transcoding contains rotation metadata.

· **PresetId** *(string)* –

  The Id of the preset to use for this job. The preset determines the audio, video, and thumbnail settings that Elastic Transcoder uses for
transcoding.

- **SegmentDuration** *(string)*

<table>
<thead>
<tr>
<th>Warning:</th>
<th>(Outputs in Fragmented MP4 or MPEG-TS format only.)</th>
</tr>
</thead>
</table>

If you specify a preset in **PresetId** for which the value of **Container** is **fmp4** (Fragmented MP4) or **ts** (MPEG-TS), **SegmentDuration** is the target maximum duration of each segment in seconds. For HLSv3 format playlists, each media segment is stored in a separate .ts file. For HLSv4 and Smooth playlists, all media segments for an output are stored in a single file. Each segment is approximately the length of the **SegmentDuration**, though individual segments might be shorter or longer.

The range of valid values is 1 to 60 seconds. If the duration of the video is not evenly divisible by **SegmentDuration**, the duration of the last segment is the remainder of total length/SegmentDuration.

Elastic Transcoder creates an output-specific playlist for each output HLS output that you specify in **OutputKeys**. To add an output to the master playlist for this job, include it in the **OutputKeys** of the associated playlist.

- **Watermarks** *(list)*

Information about the watermarks that you want Elastic Transcoder to add to the video during transcoding. You can specify up to four watermarks for each output. Settings for each watermark must be defined in the preset for the current output.

  - *(dict)*

    Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

    - **PresetWatermarkId** *(string)*

      The ID of the watermark settings that Elastic Transcoder uses to add watermarks to the video during transcoding. The settings are in the preset specified by **Preset** for the current output. In that preset, the value of Watermarks Id tells Elastic Transcoder which settings to use.

    - **InputKey** *(string)*

      The name of the .png or .jpg file that you want to use for the watermark. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by **Pipeline**; the **Input Bucket** object in that pipeline identifies the bucket.

      If the file name includes a prefix, for example, logos/128x64.png, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

    - **Encryption** *(dict)*

      The encryption settings, if any, that you want Elastic Transcoder to apply to your watermarks.
Mode (string) –

The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

- **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
- **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

Key (string) –

The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

KeyMd5 (string) –

The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

InitializationVector (string) –

The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector
must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

* **AlbumArt** *(dict)*

Information about the album art that you want Elastic Transcoder to add to the file during transcoding. You can specify up to twenty album artworks for each output. Settings for each artwork must be defined in the job for the current output.

- **MergePolicy** *(string)* –
  A policy that determines how Elastic Transcoder will handle the existence of multiple album artwork files.
  - Replace: The specified album art will replace any existing album art.
  - Prepend: The specified album art will be placed in front of any existing album art.
  - Append: The specified album art will be placed after any existing album art.
  - Fallback: If the original input file contains artwork, Elastic Transcoder will use that artwork for the output. If the original input does not contain artwork, Elastic Transcoder will use the specified album art file.

- **Artwork** *(list)* –
  The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20. Valid formats are .jpg and .png

- **InputKey** *(string)* –
  The name of the file to be used as album art. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by PipelineId; the InputBucket object in that pipeline identifies the bucket.

  If the file name includes a prefix, for example, cooking/pie.jpg, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **MaxWidth** *(string)* –
  The maximum width of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 4096, inclusive.

- **MaxHeight** *(string)* –
The maximum height of the output album art in pixels. If you specify `auto`, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 3072, inclusive.

- **SizingPolicy** *(string)* –

  Specify one of the following values to control scaling of the output album art:
  - `Fit`: Elastic Transcoder scales the output art so it matches the value that you specified in either `MaxWidth` or `MaxHeight` without exceeding the other value.
  - `Fill`: Elastic Transcoder scales the output art so it matches the value that you specified in either `MaxWidth` or `MaxHeight` and matches or exceeds the other value. Elastic Transcoder centers the output art and then crops it in the dimension (if any) that exceeds the maximum value.
  - `Stretch`: Elastic Transcoder stretches the output art to match the values that you specified for `MaxWidth` and `MaxHeight`. If the relative proportions of the input art and the output art are different, the output art will be distorted.
  - `Keep`: Elastic Transcoder does not scale the output art. If either dimension of the input art exceeds the values that you specified for `MaxWidth` and `MaxHeight`, Elastic Transcoder crops the output art.
  - `ShrinkToFit`: Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without exceeding either value. If you specify this option, Elastic Transcoder does not scale the art up.
  - `ShrinkToFill`: Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without dropping below either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **PaddingPolicy** *(string)* –

  When you set `PaddingPolicy` to `Pad`, Elastic Transcoder may add white bars to the top and bottom and/or left and right sides of the output album art to make the total size of the output art match the values that you specified for `MaxWidth` and `MaxHeight`.

- **AlbumArtFormat** *(string)* –

  The format of album art, if any. Valid formats are `.jpg` and `.png`.

- **Encryption** *(dict)* –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your artwork.

- **Mode** *(string)* –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  - `S3`: Amazon S3 creates and manages the keys used for en-
cryp ting your files.

- **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.

- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.

- **AES-CTR**: AES Counter Mode.

- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –
  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  \[ 128, 192, \text{ or } 256 \]

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMD5 (string)** –
  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –
  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Composition (list)** –
  You can create an output file that contains an excerpt from the input file. This excerpt, called a clip, can come from the beginning, middle, or end of the file. The Composition object contains settings
for the clips that make up an output file. For the current release, you can only specify settings for a single clip per output file. The Composition object cannot be null.

- **(dict)** –
  
  Settings for one clip in a composition. All jobs in a playlist must have the same clip settings.

- **TimeSpan (dict)** –
  
  Settings that determine when a clip begins and how long it lasts.

- **StartTime (string)** –
  
  The place in the input file where you want a clip to start. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder starts at the beginning of the input file.

- **Duration (string)** –
  
  The duration of the clip. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder creates an output file from StartTime to the end of the file.

  If you specify a value longer than the duration of the input file, Elastic Transcoder transcodes the file and returns a warning message.

* **Captions (dict)** –

  You can configure Elastic Transcoder to transcode captions, or subtitles, from one format to another. All captions must be in UTF-8. Elastic Transcoder supports two types of captions:

  - **Embedded**: Embedded captions are included in the same file as the audio and video. Elastic Transcoder supports only one embedded caption per language, to a maximum of 300 embedded captions per file. Valid input values include: **CEA-608** (EIA-608, first non-empty channel only), **CEA-708** (EIA-708, first non-empty channel only), and **mov-text**. Valid outputs include: **mov-text**. Elastic Transcoder supports a maximum of one embedded format per output.

  - **Sidecar**: Sidecar captions are kept in a separate metadata file from the audio and video data. Sidecar captions require a player that is capable of understanding the relationship between the video file and the sidecar file. Elastic Transcoder supports only one sidecar caption per language, to a maximum of 20 sidecar captions per file. Valid input values include: **dfxp** (first div element only), **ebu-tt**, **scc**, **smpte**, **srt**, **ttml** (first div element only), and **webvtt**. Valid outputs include: **dfxp** (first div element only), **scc**, **srt**, and **webvtt**.

  If you want ttml or smpte-tt compatible captions, specify dfxp as your output format.

  Elastic Transcoder does not support OCR (Optical Character Recog-
Elastic Transcoder (et) does not accept pictures as a valid input for captions, and is not available for audio-only transcoding. Elastic Transcoder does not preserve text formatting (for example, italics) during the transcoding process.

To remove captions or leave the captions empty, set Captions to null. To pass through existing captions unchanged, set the MergePolicy to MergeRetain, and pass in a null CaptionSources array.

For more information on embedded files, see the Subtitles Wikipedia page.

For more information on sidecar files, see the Extensible Metadata Platform and Sidecar file Wikipedia pages.

- **MergePolicy**(string) –
  A policy that determines how Elastic Transcoder handles the existence of multiple captions.
- **MergeOverride**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the sidecar captions and ignores the embedded captions for that language.
- **MergeRetain**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the embedded captions and ignores the sidecar captions for that language. If CaptionSources is empty, Elastic Transcoder omits all sidecar captions from the output files.
- **Override**: Elastic Transcoder transcodes only the sidecar captions that you specify in CaptionSources. MergePolicy cannot be null.
- **CaptionSources**(list) –
  Source files for the input sidecar captions used during the transcoding process. To omit all sidecar captions, leave CaptionSources blank.
- **(dict)** –
  A source file for the input sidecar captions used during the transcoding process.
- **Key**(string) –
  The name of the sidecar caption file that you want Elastic Transcoder to include in the output file.
- **Language**(string) –
  A string that specifies the language of the caption. Specify this as one of:
  - 2-character ISO 639-1 code
  - 3-character ISO 639-2 code
  For more information on ISO language codes and language names, see the List of ISO 639-1 codes.
- **TimeOffset**(string) –
  For clip generation or captions that do not start at the same
time as the associated video file, the `TimeOffset` tells Elastic Transcoder how much of the video to encode before including captions.

Specify the `TimeOffset` in the form `+[+-]SS.sss` or `+[+-]HH:mm:SS.ss`.

- **Label (string)**

  The label of the caption shown in the player when choosing a language. We recommend that you put the caption language name here, in the language of the captions.

- **Encryption (dict)**

  The encryption settings, if any, that you want Elastic Transcoder to apply to your caption sources.

- **Mode (string)**

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to decrypt your data.

- **Key (string)**

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  
  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key
Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **CaptionFormats (list)** –

  The array of file formats for the output captions. If you leave this value blank, Elastic Transcoder returns an error.

  - *(dict)* –

    The file format of the output captions. If you leave this value blank, Elastic Transcoder returns an error.

- **Format (string)** –

  The format you specify determines whether Elastic Transcoder generates an embedded or sidecar caption for this output.

  - **Valid Embedded Caption Formats:** *for FLAC*: None
    - *For MP3*: None
    - *For MP4*: mov-text
    - *For MPEG-TS*: None
    - *For ogg*: None
    - *For webm*: None
  
  - **Valid Sidecar Caption Formats:** Elastic Transcoder supports dfxp (first div element only), scc, srt, and webvtt. If you want ttml or smpte-tt compatible captions, specify dfxp as your output format. *For FMP4*: dfxp
  
  - **Non-FMP4 outputs**: All sidecar types
    
  fmp4 captions have an extension of .ismt

- **Pattern (string)** –

  The prefix for caption filenames, in the form `{description} - {language}`, where:

  - `{description}` is a description of the video.
  - `{language}` is a literal value that Elastic Transcoder replaces with the two- or three-letter code for the language of the caption in the output file names.

  If you don’t include `{language}` in the file name pattern, Elastic Transcoder automatically appends “{language}” to the value that you specify for the description. In addition, Elastic Transcoder automatically appends the count to the end of the segment files.

  For example, suppose you’re transcoding into srt format.
When you enter “Sydney-{language}-sunrise”, and the language of the captions is English (en), the name of the first caption file will be Sydney-en-sunrise00000.srt.

- **Encryption** *(dict)* –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your caption formats.

- **Mode** *(string)* –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  
  - **AES-CTR**: AES Counter Mode.
  
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  
  - **Key MD5**
  
  - **Initialization Vector**

  **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  \[ 128, 192, \text{ or } 256 \] .

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly
16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

* **Encryption** *(dict)* –

You can specify encryption settings for any output files that you want to use for a transcoding job. This includes the output file and any watermarks, thumbnails, album art, or captions that you want to use. You must specify encryption settings for each file individually.

- **Mode** *(string)* –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify **S3-AWS-KMS** and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  \[128, 192, \text{or} 256\].

  The key must also be encrypted by using the Amazon Key
KeyMd5 (string)

The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

InitializationVector (string)

The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

OutputKeyPrefix (string)

The value, if any, that you want Elastic Transcoder to prepend to the names of all files that this job creates, including output files, thumbnails, and playlists.

Playlists (list)

If you specify a preset in PresetId for which the value of Container is fmp4 (Fragmented MP4) or ts (MPEG-TS), Playlists contains information about the master playlists that you want Elastic Transcoder to create.

The maximum number of master playlists in a job is 30.

- (dict)

Information about the master playlist.

  * Name (string)

    The name that you want Elastic Transcoder to assign to the master playlist, for example, nyc-vacation.m3u8. If the name includes a / character, the section of the name before the last / must be identical for all Name objects. If you create more than one master playlist, the values of all Name objects must be unique.

  * Format (string)

    The format of the output playlist. Valid formats include HLSv3, HLSv4, and Smooth.

  * OutputKeys (list)

    For each output in this job that you want to include in a master playlist, the value of the Outputs:Key object.

    - If your output is not HLS or does not have a segment duration set, the name of the output file is a concatenation of OutputKeyPrefix and Outputs:Key: OutputKeyPrefix``Outputs:Key``
    - If your output is HLSv3 and has a segment duration set, or is not included in a playlist, Elastic Transcoder creates an output playlist file with a file extension of .m3u8, and a series of .ts files that include a five-digit sequential counter beginning with 00000: OutputKeyPrefix``Outputs:Key`` .m3u8 OutputKeyPrefix``Outputs:Key`` 00000.ts
· If your output is HLSv4, has a segment duration set, and is included in an HLSv4 playlist, Elastic Transcoder creates an output playlist file with a file extension of _v4.m3u8. If the output is video, Elastic Transcoder also creates an output file with an extension of _iframe.m3u8: OutputKeyPrefix‘Outputs:Key’_v4.m3u8 OutputKeyPrefix‘Outputs:Key’_iframe.m3u8 OutputKeyPrefix‘Outputs:Key’.ts

Elastic Transcoder automatically appends the relevant file extension to the file name. If you include a file extension in Output Key, the file name will have two extensions.

If you include more than one output in a playlist, any segment duration settings, clip settings, or caption settings must be the same for all outputs in the playlist. For Smooth playlists, the Audio:Profile, Video:Profile, and Video:FrameRate to Video:KeyframesMaxDist ratio must be the same for all outputs.

· (string) –

* HlsContentProtection (dict) –

The HLS content protection settings, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

· Method (string) –

The content protection method for your output. The only valid value is: aes-128.

This value will be written into the method attribute of the EXT-X-KEY metadata tag in the output playlist.

· Key (string) –

If you want Elastic Transcoder to generate a key for you, leave this field blank.

If you choose to supply your own key, you must encrypt the key by using AWS KMS. The key must be base64-encoded, and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

· KeyMd5 (string) –

If Elastic Transcoder is generating your key for you, you must leave this field blank.

The MD5 digest of the key that you want Elastic Transcoder to use to encrypt your output file, and that you want Elastic Transcoder to use as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

· InitializationVector (string) –

If Elastic Transcoder is generating your key for you, you must leave this field blank.

The series of random bits created by a random bit generator, unique for every encryption operation, that you want Elastic
Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

- **LicenseAcquisitionUrl (string)** –

  The location of the license key required to decrypt your HLS playlist. The URL must be an absolute path, and is referenced in the URI attribute of the EXT-X-KEY metadata tag in the playlist file.

- **KeyStoragePolicy (string)** –

  Specify whether you want Elastic Transcoder to write your HLS license key to an Amazon S3 bucket. If you choose `WithVariantPlaylists`, `LicenseAcquisitionUrl` must be left blank and Elastic Transcoder writes your data key into the same bucket as the associated playlist.

- **PlayReadyDrm (dict)** –

  The DRM settings, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

  - **Format (string)** –

    The type of DRM, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

  - **Key (string)** –

    The DRM key for your file, provided by your DRM license provider. The key must be base64-encoded, and it must be one of the following bit lengths before being base64-encoded:

    $128, 192, \text{or} 256$.

    The key must also be encrypted by using AWS KMS.

  - **KeyMd5 (string)** –

    The MD5 digest of the key used for DRM on your file, and that you want Elastic Transcoder to use as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

  - **KeyId (string)** –

    The ID for your DRM key, so that your DRM license provider knows which key to provide.

    The key ID must be provided in big endian, and Elastic Transcoder will convert it to little endian before inserting it into the PlayReady DRM headers. If you are unsure whether your license server provides your key ID in big or little endian, check with your DRM provider.

  - **InitializationVector (string)** –

    The series of random bits created by a random bit generator, unique for every encryption operation, that you want Elastic Transcoder to use to encrypt your files. The initialization vector must be base64-encoded, and it must be exactly 8 bytes long before being base64-encoded. If no initialization vector is provided, Elastic Transcoder generates one for you.
· **LicenseAcquisitionUrl** *(string)*

The location of the license key required to play DRM content. The URL must be an absolute path, and is referenced by the PlayReady header. The PlayReady header is referenced in the protection header of the client manifest for Smooth Streaming outputs, and in the EXT-X-DXDRM and EXT-XDXDRMINFO metadata tags for HLS playlist outputs. An example URL looks like this:

https://www.example.com/exampleKey/

· **UserMetadata** *(dict)* – User-defined metadata that you want to associate with an Elastic Transcoder job. You specify metadata in key/value pairs, and you can add up to 10 key/value pairs per job. Elastic Transcoder does not guarantee that key/value pairs will be returned in the same order in which you specify them.

- *(string)*

Return type: *dict*

Returns

**Response Syntax**

```python
{
    'Job': {
        'Id': 'string',

Response Structure

- (dict) –

The CreateJobResponse structure.

- Job (dict) –

A section of the response body that provides information about the job that
is created.

* **Id (string)** –
  The identifier that Elastic Transcoder assigned to the job. You use this value to get settings for the job or to delete the job.

* **Arn (string)** –
  The Amazon Resource Name (ARN) for the job.

* **PipelineId (string)** –
  The Id of the pipeline that you want Elastic Transcoder to use for transcoding. The pipeline determines several settings, including the Amazon S3 bucket from which Elastic Transcoder gets the files to transcode and the bucket into which Elastic Transcoder puts the transcoded files.

* **Input (dict)** –
  A section of the request or response body that provides information about the file that is being transcoded.
  
  · **Key (string)** –
    The name of the file to transcode. Elsewhere in the body of the JSON block is the ID of the pipeline to use for processing the job. The *InputBucket* object in that pipeline tells Elastic Transcoder which Amazon S3 bucket to get the file from.
    
    If the file name includes a prefix, such as *cooking/lasagna.mpg*, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

  · **FrameRate (string)** –
    The frame rate of the input file. If you want Elastic Transcoder to automatically detect the frame rate of the input file, specify *auto*. If you want to specify the frame rate for the input file, enter one of the following values:
    
    10, 15, 23.97, 24, 25, 29.97, 30, 60
    
    If you specify a value other than *auto*, Elastic Transcoder disables automatic detection of the frame rate.

  · **Resolution (string)** –
    This value must be *auto*, which causes Elastic Transcoder to automatically detect the resolution of the input file.

  · **AspectRatio (string)** –
    The aspect ratio of the input file. If you want Elastic Transcoder to automatically detect the aspect ratio of the input file, specify *auto*. If you want to specify the aspect ratio for the output file, enter one of the following values:
    
    1:1, 4:3, 3:2, 16:9
    
    If you specify a value other than *auto*, Elastic Transcoder disables automatic detection of the aspect ratio.

  · **Interlaced (string)** –
    Whether the input file is interlaced. If you want Elastic Transcoder to automatically detect whether the input file is interlaced, specify *auto*. If you want to specify whether the input file is interlaced, enter one of the following values:
true, false

If you specify a value other than auto, Elastic Transcoder disables automatic detection of interlacing.

- **Container (string)** –

  The container type for the input file. If you want Elastic Transcoder to automatically detect the container type of the input file, specify auto. If you want to specify the container type for the input file, enter one of the following values:
  3gp, aac, asf, avi, divx, flv, m4a, mkv, mov, mp3, mp4, mpeg, mpeg-ps, mpeg-ts, mxf, ogg, vob, wav, webm

- **Encryption (dict)** –

  The encryption settings, if any, that are used for decrypting your input files. If your input file is encrypted, you must specify the mode that Elastic Transcoder will use to decrypt your file.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  **Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-
The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –
  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –
  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **DetectedProperties (dict)** –
  The detected properties of the input file.

  - **Width (integer)** –
    The detected width of the input file, in pixels.

  - **Height (integer)** –
    The detected height of the input file, in pixels.

  - **FrameRate (string)** –
    The detected frame rate of the input file, in frames per second.

  - **FileSize (integer)** –
    The detected file size of the input file, in bytes.

  - **DurationMillis (integer)** –
    The detected duration of the input file, in milliseconds.

- **Output (dict)** –
  If you specified one output for a job, information about that output. If you specified multiple outputs for a job, the Output object lists information about the first output. This duplicates the information that is listed for the first output in the Outputs object.

  - **Id (string)** –
    A sequential counter, starting with 1, that identifies an output among the outputs from the current job. In the Output syntax, this value is always 1.

  - **Key (string)** –
    The name to assign to the transcoded file. Elastic Transcoder saves the file in the Amazon S3 bucket specified by the
OutputBucket object in the pipeline that is specified by the pipeline ID.

- **ThumbnailPattern (string)** –

  Whether you want Elastic Transcoder to create thumbnails for your videos and, if so, how you want Elastic Transcoder to name the files.

  If you don’t want Elastic Transcoder to create thumbnails, specify "".

  If you do want Elastic Transcoder to create thumbnails, specify the information that you want to include in the file name for each thumbnail. You can specify the following values in any sequence:

  - `{{count}}` (Required): If you want to create thumbnails, you must include `{count}` in the ThumbnailPattern object. Wherever you specify `{count}`, Elastic Transcoder adds a five-digit sequence number (beginning with `00001`) to thumbnail file names. The number indicates where a given thumbnail appears in the sequence of thumbnails for a transcoded file. .. warning:: If you specify a literal value and/or `{resolution}` but you omit `{count}`, Elastic Transcoder returns a validation error and does not create the job.

  - **Literal values (Optional)**: You can specify literal values anywhere in the ThumbnailPattern object. For example, you can include them as a file name prefix or as a delimiter between `{resolution}` and `{count}`.

  - `{{resolution}}` (Optional): If you want Elastic Transcoder to include the resolution in the file name, include `{resolution}` in the ThumbnailPattern object. When creating thumbnails, Elastic Transcoder automatically saves the files in the format (.jpg or .png) that appears in the preset that you specified in the PresetID value of CreateJobOutput. Elastic Transcoder also appends the applicable file name extension.

- **ThumbnailEncryption (dict)** –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your thumbnail.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.

  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.

  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
AES-CTR: AES Counter Mode.
AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Rotate (string)** –

  The number of degrees clockwise by which you want Elastic Transcoder to rotate the output relative to the input. Enter one of the following values:

  auto, 0, 90, 180, 270

  The value auto generally works only if the file that you’re transcoding contains rotation metadata.

- **PresetId (string)** –

  The value of the Id object for the preset that you want to use for this job. The preset determines the audio, video, and
 thumbnail settings that Elastic Transcoder uses for transcoding. To use a preset that you created, specify the preset ID that Elastic Transcoder returned in the response when you created the preset. You can also use the Elastic Transcoder system presets, which you can get with ListPresets.

- **SegmentDuration (string)**

Warning: (Outputs in Fragmented MP4 or MPEG-TS format only.)

If you specify a preset in PresetId for which the value of Container is fmp4 (Fragmented MP4) or ts (MPEG-TS), SegmentDuration is the target maximum duration of each segment in seconds. For HLSv3 format playlists, each media segment is stored in a separate .ts file. For HLSv4 and Smooth playlists, all media segments for an output are stored in a single file. Each segment is approximately the length of the SegmentDuration, though individual segments might be shorter or longer.

The range of valid values is 1 to 60 seconds. If the duration of the video is not evenly divisible by SegmentDuration, the duration of the last segment is the remainder of total length/SegmentDuration.

Elastic Transcoder creates an output-specific playlist for each output HLS output that you specify in OutputKeys. To add an output to the master playlist for this job, include it in the OutputKeys of the associated playlist.

- **Status (string)**

The status of one output in a job. If you specified only one output for the job, Outputs:Status is always the same as Job:Status. If you specified more than one output:

  - Job:Status and Outputs:Status for all of the outputs is Submitted until Elastic Transcoder starts to process the first output.
  - When Elastic Transcoder starts to process the first output, Outputs:Status for that output and Job:Status both change to Progressing. For each output, the value of Outputs:Status remains Submitted until Elastic Transcoder starts to process the output.
  - Job:Status remains Progressing until all of the outputs reach a terminal status, either Complete or Error.
  - When all of the outputs reach a terminal status, Job:Status changes to Complete only if Outputs:Status for all of the outputs is Complete. If Outputs:Status for one or more outputs is Error, the terminal status for Job:Status is also Error.

  The value of Status is one of the following: Submitted, Progressing, Complete, Canceled, or Error.

- **StatusDetail (string)**

Information that further explains Status.

- **Duration (integer)**
Duration of the output file, in seconds.

- **Width (integer)** –
  Specifies the width of the output file in pixels.

- **Height (integer)** –
  Height of the output file, in pixels.

- **FrameRate (string)** –
  Frame rate of the output file, in frames per second.

- **FileSize (integer)** –
  File size of the output file, in bytes.

- **DurationMillis (integer)** –
  Duration of the output file, in milliseconds.

- **Watermarks (list)** –
  Information about the watermarks that you want Elastic Transcoder to add to the video during transcoding. You can specify up to four watermarks for each output. Settings for each watermark must be defined in the preset that you specify in **Preset** for the current output.

  Watermarks are added to the output video in the sequence in which you list them in the job output. The first watermark in the list is added to the output video first, the second watermark in the list is added next, and so on. As a result, if the settings in a preset cause Elastic Transcoder to place all watermarks in the same location, the second watermark that you add will cover the first one, the third one will cover the second, and the fourth one will cover the third.

- **Encryption (dict)** –
  The encryption settings, if any, that you want Elastic Transcoder to apply to your watermarks.

  Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

- **PresetWatermarkId (string)** –
  The ID of the watermark settings that Elastic Transcoder uses to add watermarks to the video during transcoding. The settings are in the preset specified by **Preset** for the current output. In that preset, the value of Watermarks Id tells Elastic Transcoder which settings to use.

- **InputKey (string)** –
  The name of the .png or .jpg file that you want to use for the watermark. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by **Pipeline**; the **Input Bucket** object in that pipeline identifies the bucket.

  If the file name includes a prefix, for example, logos/128x64.png, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **Encryption (dict)** –
  The encryption settings, if any, that you want Elastic Transcoder to apply to your watermarks.
· **Mode** *(string)* –

   The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
   - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
   - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify **S3-AWS-KMS** and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
   - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
   - **AES-CTR**: AES Counter Mode.
   - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

   For all three AES options, you must provide the following settings, which must be base64-encoded:

   - **Key**
   - **Key MD5**
   - **Initialization Vector**

   **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

   - **Key** *(string)* –

     The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

     128, 192, or 256.

     The key must also be encrypted by using the Amazon Key Management Service.

   - **KeyMd5** *(string)* –

     The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

   - **InitializationVector** *(string)* –

     The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector
must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AlbumArt (dict)** –

  The album art to be associated with the output file, if any.

- **MergePolicy (string)** –

  A policy that determines how Elastic Transcoder will handle the existence of multiple album artwork files.
  - Replace: The specified album art will replace any existing album art.
  - Prepend: The specified album art will be placed in front of any existing album art.
  - Append: The specified album art will be placed after any existing album art.
  - Fallback: If the original input file contains artwork, Elastic Transcoder will use that artwork for the output. If the original input does not contain artwork, Elastic Transcoder will use the specified album art file.

- **Artwork (list)** –

  The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20. Valid formats are .jpg and .png.

- **InputKey (string)** –

  The name of the file to be used as album art. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by PipelineId; the InputBucket object in that pipeline identifies the bucket.

  If the file name includes a prefix, for example, cooking/pie.jpg, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **MaxWidth (string)** –

  The maximum width of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 4096, inclusive.

- **MaxHeight (string)** –

  The maximum height of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value.
value. If you specify a numeric value, enter an even integer between 32 and 3072, inclusive.

- **SizingPolicy (string)** –

  Specify one of the following values to control scaling of the output album art:
  - **Fit:** Elastic Transcoder scales the output art so it matches the value that you specified in either `MaxWidth` or `MaxHeight` without exceeding the other value.
  - **Fill:** Elastic Transcoder scales the output art so it matches the value that you specified in either `MaxWidth` or `MaxHeight` and matches or exceeds the other value. Elastic Transcoder centers the output art and then crops it in the dimension (if any) that exceeds the maximum value.
  - **Stretch:** Elastic Transcoder stretches the output art to match the values that you specified for `MaxWidth` and `MaxHeight`. If the relative proportions of the input art and the output art are different, the output art will be distorted.
  - **Keep:** Elastic Transcoder does not scale the output art. If either dimension of the input art exceeds the values that you specified for `MaxWidth` and `MaxHeight`, Elastic Transcoder crops the output art.
  - **ShrinkToFit:** Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without exceeding either value. If you specify this option, Elastic Transcoder does not scale the art up.
  - **ShrinkToFill:** Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without dropping below either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **PaddingPolicy (string)** –

  When you set PaddingPolicy to `Pad`, Elastic Transcoder may add white bars to the top and bottom and/or left and right sides of the output album art to make the total size of the output art match the values that you specified for `MaxWidth` and `MaxHeight`.

- **AlbumArtFormat (string)** –

  The format of album art, if any. Valid formats are `.jpg` and `.png`.

- **Encryption (dict)** –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your artwork.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  - **S3:** Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS:** Amazon S3 calls the Amazon Key Manage-
ment Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.

- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

| Warning: | For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to un-encrypt your data. |

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  \[128, 192, \text{ or } 256\].

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Composition (list)** –

  You can create an output file that contains an excerpt from the input file. This excerpt, called a clip, can come from the beginning, middle, or end of the file. The Composition object contains settings for the clips that make up an output file. For the current release, you can only specify settings for a single
clip per output file. The Composition object cannot be null.

- *(dict)* –
  Settings for one clip in a composition. All jobs in a playlist must have the same clip settings.

- **TimeSpan** *(dict)* –
  Settings that determine when a clip begins and how long it lasts.

  - **StartTime** *(string)* –
    The place in the input file where you want a clip to start. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder starts at the beginning of the input file.

  - **Duration** *(string)* –
    The duration of the clip. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder creates an output file from StartTime to the end of the file.

    If you specify a value longer than the duration of the input file, Elastic Transcoder transcodes the file and returns a warning message.

- **Captions** *(dict)* –
  You can configure Elastic Transcoder to transcode captions, or subtitles, from one format to another. All captions must be in UTF-8. Elastic Transcoder supports two types of captions:

  - **Embedded**: Embedded captions are included in the same file as the audio and video. Elastic Transcoder supports only one embedded caption per language, to a maximum of 300 embedded captions per file. Valid input values include: CEA-608 (EIA-608, first non-empty channel only), CEA-708 (EIA-708, first non-empty channel only), and mov-text. Valid outputs include: mov-text

  - **Sidecar**: Sidecar captions are kept in a separate metadata file from the audio and video data. Sidecar captions require a player that is capable of understanding the relationship between the video file and the sidecar file. Elastic Transcoder supports only one sidecar caption per language, to a maximum of 20 sidecar captions per file. Valid input values include: dfxp (first div element only), ebu-tt, scc, smpte-srt, ttml (first div element only), and webvtt. Valid outputs include: dfxp (first div element only), scc, srt, and webvtt.

    If you want ttml or smpte-tt compatible captions, specify dfxp as your output format.

    Elastic Transcoder does not support OCR (Optical Character Recognition), does not accept pictures as a valid input for captions, and is not available for audio-only transcoding. Elastic
Transcoder does not preserve text formatting (for example, italics) during the transcoding process.

To remove captions or leave the captions empty, set Captions to null. To pass through existing captions unchanged, set the MergePolicy to MergeRetain, and pass in a null CaptionSources array.

For more information on embedded files, see the Subtitles Wikipedia page.

For more information on sidecar files, see the Extensible Metadata Platform and Sidecar file Wikipedia pages.

**MergePolicy** *(string)*

A policy that determines how Elastic Transcoder handles the existence of multiple captions.

- **MergeOverride**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the embedded captions and ignores the sidecar captions for that language.

- **MergeRetain**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the embedded captions and ignores the sidecar captions for that language. If CaptionSources is empty, Elastic Transcoder omits all sidecar captions from the output files.

- **Override**: Elastic Transcoder transcodes only the sidecar captions that you specify in CaptionSources. MergePolicy cannot be null.

**CaptionSources** *(list)*

Source files for the input sidecar captions used during the transcoding process. To omit all sidecar captions, leave CaptionSources blank.

- *(dict)*

  A source file for the input sidecar captions used during the transcoding process.

- **Key** *(string)*

  The name of the sidecar caption file that you want Elastic Transcoder to include in the output file.

- **Language** *(string)*

  A string that specifies the language of the caption. Specify this as one of:

  - 2-character ISO 639-1 code
  - 3-character ISO 639-2 code

  For more information on ISO language codes and language names, see the List of ISO 639-1 codes.

- **TimeOffset** *(string)*

  For clip generation or captions that do not start at the same time as the associated video file, the TimeOffset tells Elastic Transcoder how much of the video to encode before in-
Including captions.

Specify the TimeOffset in the form [±]SS.sss or [±]HH:mm:SS.sss.

- **Label** *(string)* —
  The label of the caption shown in the player when choosing a language. We recommend that you put the caption language name here, in the language of the captions.

- **Encryption** *(dict)* —
  The encryption settings, if any, that you want Elastic Transcoder to apply to your caption sources.

- **Mode** *(string)* —
  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

  **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* —
  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* —
The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Initialization Vector** *(string)*

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Caption Formats** *(list)*

  The array of file formats for the output captions. If you leave this value blank, Elastic Transcoder returns an error.

- **Format** *(string)*

  The file format of the output captions. If you leave this value blank, Elastic Transcoder returns an error.

- **Valid Embedded Caption Formats**: *for FLAC : None
  - For MP3 : None
  - For MP4 : mov-text
  - For MPEG-TS : None
  - For ogg : None
  - For webm : None
  - **Valid Sidecar Caption Formats**: Elastic Transcoder supports dfxp (first div element only), scc, srt, and webvtt. If you want html or smpte-tt compatible captions, specify dfxp as your output format. *For FMP4 : dfxp

- **Non-FMP4 outputs** : All sidecar types
  - Fmp4 captions have an extension of .ismt

- **Pattern** *(string)*

  The prefix for caption filenames, in the form description-\{language\}, where:
  
  - *description* is a description of the video.
  - *\{language\}* is a literal value that Elastic Transcoder replaces with the two- or three-letter code for the language of the caption in the output file names.

  If you don’t include *\{language\}* in the file name pattern, Elastic Transcoder automatically appends “*\{language\} “ to the value that you specify for the description. In addition, Elastic Transcoder automatically appends the count to the end of the segment files.

  For example, suppose you’re transcoding into srt format. When you enter “Sydney-{language}-sunrise”, and the language of the captions is English (en), the name of the first caption file will be Sydney-en-sunrise00000.srt.
- **Encryption** *(dict)* –
  The encryption settings, if any, that you want Elastic Transcoder to apply to your caption formats.

- **Mode** *(string)* –
  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.
  
  For all three AES options, you must provide the following settings, which must be base64-encoded:
  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –
  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –
  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –
The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Encryption (dict)** –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your output files. If you choose to use encryption, you must specify a mode to use. If you choose not to use encryption, Elastic Transcoder will write an unencrypted file to your Amazon S3 bucket.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  - S3: Amazon S3 creates and manages the keys used for encrypting your files.
  - S3-AWS-KMS: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
  - AES-CTR: AES Counter Mode.
  - AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  **Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  \[128, 192, \text{or} 256\].

  The key must also be encrypted by using the Amazon Key Management Service.
- **KeyMd5** *(string)* –
  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –
  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AppliedColorSpaceConversion** *(string)* –
  If Elastic Transcoder used a preset with a ColorSpaceConversionMode to transcode the output file, the AppliedColorSpaceConversion parameter shows the conversion used. If no ColorSpaceConversionMode was defined in the preset, this parameter will not be included in the job response.

* **Outputs** *(list)* –
Information about the output files. We recommend that you use the Outputs syntax for all jobs, even when you want Elastic Transcoder to transcode a file into only one format. Do not use both the Outputs and Output syntaxes in the same request. You can create a maximum of 30 outputs per job.

If you specify more than one output for a job, Elastic Transcoder creates the files for each output in the order in which you specify them in the job.

- *(dict)* –

  **Warning:** Outputs recommended instead.

If you specified one output for a job, information about that output. If you specified multiple outputs for a job, the Output object lists information about the first output. This duplicates the information that is listed for the first output in the Outputs object.

- **Id** *(string)* –
  A sequential counter, starting with 1, that identifies an output among the outputs from the current job. In the Output syntax, this value is always 1.

- **Key** *(string)* –
  The name to assign to the transcoded file. Elastic Transcoder saves the file in the Amazon S3 bucket specified by the OutputBucket object in the pipeline that is specified by the pipeline ID.

- **ThumbnailPattern** *(string)* –
Whether you want Elastic Transcoder to create thumbnails for your videos and, if so, how you want Elastic Transcoder to name the files.

If you don’t want Elastic Transcoder to create thumbnails, specify “”.

If you do want Elastic Transcoder to create thumbnails, specify the information that you want to include in the file name for each thumbnail. You can specify the following values in any sequence:

- “{count}” (Required): If you want to create thumbnails, you must include {count} in the ThumbnailPattern object. Wherever you specify {count}, Elastic Transcoder adds a five-digit sequence number (beginning with 00001) to thumbnail file names. The number indicates where a given thumbnail appears in the sequence of thumbnails for a transcoded file. .. warning:: If you specify a literal value and/or {resolution} but you omit {count}, Elastic Transcoder returns a validation error and does not create the job.

- Literal values (Optional): You can specify literal values anywhere in the ThumbnailPattern object. For example, you can include them as a file name prefix or as a delimiter between {resolution} and {count}.

- “{resolution}” (Optional): If you want Elastic Transcoder to include the resolution in the file name, include {resolution} in the ThumbnailPattern object.

When creating thumbnails, Elastic Transcoder automatically saves the files in the format (.jpg or .png) that appears in the preset that you specified in the PresetID value of CreateJobOutput. Elastic Transcoder also appends the applicable file name extension.

- ThumbnailEncryption (dict) –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your thumbnail.

- Mode (string) –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - S3: Amazon S3 creates and manages the keys used for encrypting your files.
  - S3-AWS-KMS: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
  - AES-CTR: AES Counter Mode.
  - AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will...
fail the decryption process.
For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)*

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)*

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)*

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Rotate** *(string)*

  The number of degrees clockwise by which you want Elastic Transcoder to rotate the output relative to the input. Enter one of the following values:

  auto, 0, 90, 180, 270

  The value **auto** generally works only if the file that you’re transcoding contains rotation metadata.

- **PresetId** *(string)*

  The value of the *Id* object for the preset that you want to use for this job. The preset determines the audio, video, and thumbnail settings that Elastic Transcoder uses for transcoding. To use a preset that you created, specify the preset ID that Elastic Transcoder returned in the response when you created the preset. You can also use the Elastic Transcoder system
presets, which you can get with `ListPresets`.

- **SegmentDuration (string)** –

  **Warning:** (Outputs in Fragmented MP4 or MPEG-TS format only)

  If you specify a preset in `PresetId` for which the value of `Container` is `fmp4` (Fragmented MP4) or `ts` (MPEG-TS), `SegmentDuration` is the target maximum duration of each segment in seconds. For HLSv3 format playlists, each media segment is stored in a separate `.ts` file. For HLSv4 and Smooth playlists, all media segments for an output are stored in a single file. Each segment is approximately the length of the `SegmentDuration`, though individual segments might be shorter or longer.

  The range of valid values is 1 to 60 seconds. If the duration of the video is not evenly divisible by `SegmentDuration`, the duration of the last segment is the remainder of total length/`SegmentDuration`.

  Elastic Transcoder creates an output-specific playlist for each output HLS output that you specify in `OutputKeys`. To add an output to the master playlist for this job, include it in the `OutputKeys` of the associated playlist.

- **Status (string)** –

  The status of one output in a job. If you specified only one output for the job, `Outputs:Status` is always the same as `Job:Status`. If you specified more than one output:

  - `Job:Status` and `Outputs:Status` for all of the outputs is Submitted until Elastic Transcoder starts to process the first output.
  - When Elastic Transcoder starts to process the first output, `Outputs:Status` for that output and `Job:Status` both change to Progressing. For each output, the value of `Outputs:Status` remains Submitted until Elastic Transcoder starts to process the output.
  - `Job:Status` remains Progressing until all of the outputs reach a terminal status, either Complete or Error.
  - When all of the outputs reach a terminal status, `Job:Status` changes to Complete only if `Outputs:Status` for all of the outputs is Complete. If `Outputs:Status` for one or more outputs is Error, the terminal status for `Job:Status` is also Error.

  The value of `Status` is one of the following: Submitted, Progressing, Complete, Canceled, or Error.

- **StatusDetail (string)** –

  Information that further explains `Status`.

- **Duration (integer)** –

  Duration of the output file, in seconds.

- **Width (integer)** –

  Specifies the width of the output file in pixels.

- **Height (integer)** –
Height of the output file, in pixels.

- **FrameRate (string)** –

  Frame rate of the output file, in frames per second.

- **FileSize (integer)** –

  File size of the output file, in bytes.

- **DurationMillis (integer)** –

  Duration of the output file, in milliseconds.

- **Watermarks (list)** –

  Information about the watermarks that you want Elastic Transcoder to add to the video during transcoding. You can specify up to four watermarks for each output. Settings for each watermark must be defined in the preset that you specify in `Preset` for the current output.

  Watermarks are added to the output video in the sequence in which you list them in the job output. The first watermark in the list is added to the output video first, the second watermark in the list is added next, and so on. As a result, if the settings in a preset cause Elastic Transcoder to place all watermarks in the same location, the second watermark that you add will cover the first one, the third one will cover the second, and the fourth one will cover the third.

- **(dict)** –

  Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

- **PresetWatermarkId (string)** –

  The ID of the watermark settings that Elastic Transcoder uses to add watermarks to the video during transcoding. The settings are in the preset specified by `Preset` for the current output. In that preset, the value of Watermarks Id tells Elastic Transcoder which settings to use.

- **InputKey (string)** –

  The name of the .png or .jpg file that you want to use for the watermark. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by `Pipeline`; the `Input Bucket` object in that pipeline identifies the bucket.

  If the file name includes a prefix, for example, logos/128x64.png, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **Encryption (dict)** –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your watermarks.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
- S3: Amazon S3 creates and manages the keys used for encrypting your files.
- S3-AWS-KMS: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
- AES-CTR: AES Counter Mode.
- AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –
  
The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –
  
The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –
  
The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AlbumArt** *(dict)* –
  
The album art to be associated with the output file, if any.

- **MergePolicy** *(string)* –
A policy that determines how Elastic Transcoder will handle the existence of multiple album artwork files.

- **Replace**: The specified album art will replace any existing album art.
- **Prepend**: The specified album art will be placed in front of any existing album art.
- **Append**: The specified album art will be placed after any existing album art.
- **Fallback**: If the original input file contains artwork, Elastic Transcoder will use that artwork for the output. If the original input does not contain artwork, Elastic Transcoder will use the specified album art file.

**Artwork (list)** –

The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20. Valid formats are `.jpg` and `.png`

**Artwork (dict)** –

The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20.

To remove artwork or leave the artwork empty, you can either set `Artwork` to null, or set the `Merge Policy` to “Replace” and use an empty `Artwork` array.

To pass through existing artwork unchanged, set the `Merge Policy` to “Prepend”, “Append”, or “Fallback”, and use an empty `Artwork` array.

**InputKey (string)** –

The name of the file to be used as album art. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by `PipelineId`; the `InputBucket` object in that pipeline identifies the bucket.

If the file name includes a prefix, for example, `cooking/pie.jpg`, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

**MaxWidth (string)** –

The maximum width of the output album art in pixels. If you specify `auto`, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 4096, inclusive.

**MaxHeight (string)** –

The maximum height of the output album art in pixels. If you specify `auto`, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 3072, inclusive.

**SizingPolicy (string)** –

Specify one of the following values to control scaling of the output album art:
• **Fit:** Elastic Transcoder scales the output art so it matches the value that you specified in either `MaxWidth` or `MaxHeight` without exceeding the other value.

• **Fill:** Elastic Transcoder scales the output art so it matches the value that you specified in either `MaxWidth` or `MaxHeight` and matches or exceeds the other value. Elastic Transcoder centers the output art and then crops it in the dimension (if any) that exceeds the maximum value.

• **Stretch:** Elastic Transcoder stretches the output art to match the values that you specified for `MaxWidth` and `MaxHeight`. If the relative proportions of the input art and the output art are different, the output art will be distorted.

• **Keep:** Elastic Transcoder does not scale the output art. If either dimension of the input art exceeds the values that you specified for `MaxWidth` and `MaxHeight`, Elastic Transcoder crops the output art.

• **ShrinkToFit:** Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without exceeding either value. If you specify this option, Elastic Transcoder does not scale the art up.

• **ShrinkToFill** Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without dropping below either value. If you specify this option, Elastic Transcoder does not scale the art up.

• **PaddingPolicy** *(string)* –

  When you set `PaddingPolicy` to `Pad`, Elastic Transcoder may add white bars to the top and bottom and/or left and right sides of the output album art to make the total size of the output art match the values that you specified for `MaxWidth` and `MaxHeight`.

• **AlbumArtFormat** *(string)* –

  The format of album art, if any. Valid formats are `.jpg` and `.png`.

• **Encryption** *(dict)* –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your artwork.

• **Mode** *(string)* –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  • **S3:** Amazon S3 creates and manages the keys used for encrypting your files.

  • **S3-AWS-KMS:** Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.

  • **AES-CBC-PKCS7:** A padded cipher-block mode of operation originally used for HLS files.
· AES-CTR: AES Counter Mode.
· AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:
· Key
· Key MD5
· Initialization Vector

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

**Key (string)**

The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

**KeyMd5 (string)**

The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

**InitializationVector (string)**

The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

**Composition (list)**

You can create an output file that contains an excerpt from the input file. This excerpt, called a clip, can come from the beginning, middle, or end of the file. The Composition object contains settings for the clips that make up an output file. For the current release, you can only specify settings for a single clip per output file. The Composition object cannot be null.

**TimeSpan (dict)**

Settings for one clip in a composition. All jobs in a playlist must have the same clip settings.
Settings that determine when a clip begins and how long it lasts.

- **StartTime** *(string)* — The place in the input file where you want a clip to start. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder starts at the beginning of the input file.

- **Duration** *(string)* — The duration of the clip. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder creates an output file from StartTime to the end of the file.

If you specify a value longer than the duration of the input file, Elastic Transcoder transcodes the file and returns a warning message.

- **Captions** *(dict)* — You can configure Elastic Transcoder to transcode captions, or subtitles, from one format to another. All captions must be in UTF-8. Elastic Transcoder supports two types of captions:
  - **Embedded**: Embedded captions are included in the same file as the audio and video. Elastic Transcoder supports only one embedded caption per language, to a maximum of 300 embedded captions per file. Valid input values include: CEA-608 (EIA-608, first non-empty channel only), CEA-708 (EIA-708, first non-empty channel only), and mov-text. Valid outputs include: mov-text. Elastic Transcoder supports a maximum of one embedded format per output.
  - **Sidecar**: Sidecar captions are kept in a separate metadata file from the audio and video data. Sidecar captions require a player that is capable of understanding the relationship between the video file and the sidecar file. Elastic Transcoder supports only one sidecar caption per language, to a maximum of 20 sidecar captions per file. Valid input values include: dfxp (first div element only), ebu-tt, scc, smpte, srt, ttml (first div element only), and webvtt. Valid outputs include: dfxp (first div element only), scc, srt, and webvtt.

If you want ttml or smpte-tt compatible captions, specify dfxp as your output format.

Elastic Transcoder does not support OCR (Optical Character Recognition), does not accept pictures as a valid input for captions, and is not available for audio-only transcoding. Elastic Transcoder does not preserve text formatting (for example, italics) during the transcoding process.

To remove captions or leave the captions empty, set **Captions** to null. To pass through existing captions unchanged, set the **MergePolicy** to **MergeRetain**, and pass in a null **CaptionSources** array.
For more information on embedded files, see the Subtitles Wikipedia page.

For more information on sidecar files, see the Extensible Metadata Platform and Sidecar file Wikipedia pages.

- **MergePolicy** *(string)*
  A policy that determines how Elastic Transcoder handles the existence of multiple captions.

- **MergeOverride**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the sidecar captions and ignores the embedded captions for that language.

- **MergeRetain**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the embedded captions and ignores the sidecar captions for that language. If CaptionSources is empty, Elastic Transcoder omits all sidecar captions from the output files.

- **Override**: Elastic Transcoder transcodes only the sidecar captions that you specify in CaptionSources. MergePolicy cannot be null.

- **CaptionSources** *(list)*
  Source files for the input sidecar captions used during the transcoding process. To omit all sidecar captions, leave CaptionSources blank.

- **(dict)**
  A source file for the input sidecar captions used during the transcoding process.

  - **Key** *(string)*
    The name of the sidecar caption file that you want Elastic Transcoder to include in the output file.

  - **Language** *(string)*
    A string that specifies the language of the caption. Specify this as one of:
    - 2-character ISO 639-1 code
    - 3-character ISO 639-2 code
    For more information on ISO language codes and language names, see the List of ISO 639-1 codes.

  - **TimeOffset** *(string)*
    For clip generation or captions that do not start at the same time as the associated video file, the TimeOffset tells Elastic Transcoder how much of the video to encode before including captions.
    Specify the TimeOffset in the form [+/-]SS.sss or [+/-]HH:mm:SS.ss.

  - **Label** *(string)*
    The label of the caption shown in the player when choosing a language. We recommend that you put the caption language
Encryption (dict) –

The encryption settings, if any, that you want Elastic Transcoder to apply to your caption sources.

Mode (string) –

The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

- **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
- **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify **S3-AWS-KMS** and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

Key (string) –

The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

KeyMD5 (string) –

The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

InitializationVector (string) –
The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **CaptionFormats (list)** –

  The array of file formats for the output captions. If you leave this value blank, Elastic Transcoder returns an error.

  - *(dict)* –

    The file format of the output captions. If you leave this value blank, Elastic Transcoder returns an error.

- **Format (string)** –

  The format you specify determines whether Elastic Transcoder generates an embedded or sidecar caption for this output.

- **Valid Embedded Caption Formats:** *for FLAC*: None
  *for MP3*: None
  *for MP4*: mov-text
  *for MPEG-TS*: None
  *for ogg*: None
  *for webm*: None

- **Valid Sidecar Caption Formats**: Elastic Transcoder supports dfxp (first div element only), scc, srt, and webvtt. If you want ttml or smpte-tt compatible captions, specify dfxp as your output format. *For FMP4*: dfxp

- **Non-F MP4 outputs**: All sidecar types

  F MP4 captions have an extension of .ismt

- **Pattern (string)** –

  The prefix for caption filenames, in the form description - {language}, where:
  
  - **description** is a description of the video.
  - **{language}** is a literal value that Elastic Transcoder replaces with the two- or three-letter code for the language of the caption in the output file names.

  If you don’t include **{language}** in the file name pattern, Elastic Transcoder automatically appends “{language}” to the value that you specify for the description. In addition, Elastic Transcoder automatically appends the count to the end of the segment files.

  For example, suppose you’re transcoding into srt format. When you enter “Sydney-{language}-sunrise”, and the language of the captions is English (en), the name of the first caption file will be Sydney-en-sunrise00000.srt.

- **Encryption (dict)** –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your caption formats.

  - **Mode (string)** –

    The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or en-
crypting your output files. Elastic Transcoder supports the following options:

- **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
- **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

| Warning: | For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data. |

| Key (string) — |

The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

| KeyMd5 (string) — |

The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

| InitializationVector (string) — |

The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

| Encryption (dict) — |
The encryption settings, if any, that you want Elastic Transcoder to apply to your output files. If you choose to use encryption, you must specify a mode to use. If you choose not to use encryption, Elastic Transcoder will write an unencrypted file to your Amazon S3 bucket.

- **Mode** *(string)* –
  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:
  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –
  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –
  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.
· **InitializationVector (string)** –

The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

· **AppliedColorSpaceConversion (string)** –

If Elastic Transcoder used a preset with a ColorSpaceConversionMode to transcode the output file, the AppliedColorSpaceConversion parameter shows the conversion used. If no ColorSpaceConversionMode was defined in the preset, this parameter will not be included in the job response.

* **OutputKeyPrefix (string)** –

The value, if any, that you want Elastic Transcoder to prepend to the names of all files that this job creates, including output files, thumbnails, and playlists. We recommend that you add a / or some other delimiter to the end of the OutputKeyPrefix.

* **Playlists (list)** –

<table>
<thead>
<tr>
<th>Warning: Outputs in Fragmented MP4 or MPEG-TS format only.</th>
</tr>
</thead>
</table>

If you specify a preset in PresetId for which the value of Container is fmp4 (Fragmented MP4) or ts (MPEG-TS), Playlists contains information about the master playlists that you want Elastic Transcoder to create.

The maximum number of master playlists in a job is 30.

· **(dict)** –

Use Only for Fragmented MP4 or MPEG-TS Outputs. If you specify a preset for which the value of Container is fmp4 (Fragmented MP4) or ts (MPEG-TS), Playlists contains information about the master playlists that you want Elastic Transcoder to create. We recommend that you create only one master playlist per output format. The maximum number of master playlists in a job is 30.

· **Name (string)** –

The name that you want Elastic Transcoder to assign to the master playlist, for example, nyc-vacation.m3u8. If the name includes a / character, the section of the name before the last / must be identical for all Name objects. If you create more than one master playlist, the values of all Name objects must be unique.

**Note**: Elastic Transcoder automatically appends the relevant file extension to the file name (.m3u8 for HLSv3 and HLSv4 playlists, and .ism and .ismc for Smooth playlists). If you include a file extension in Name, the file name will have two extensions.
· **Format (string)** –

The format of the output playlist. Valid formats include HLSv3, HLSv4, and Smooth.

· **OutputKeys (list)** –

For each output in this job that you want to include in a master playlist, the value of the Outputs:Key object.

- If your output is not HLS or does not have a segment duration set, the name of the output file is a concatenation of OutputKeyPrefix and Outputs:Key: OutputKeyPrefix: Outputs:Key

- If your output is HLSv3 and has a segment duration set, or is not included in a playlist, Elastic Transcoder creates an output playlist file with a file extension of .m3u8, and a series of .ts files that include a five-digit sequential counter beginning with 00000: OutputKeyPrefix: Outputs:Key: Outputs:Key: Outputs:Key: Outputs:Key: 00000.ts

- If your output is HLSv4, has a segment duration set, and is included in an HLSv4 playlist, Elastic Transcoder creates an output playlist file with a file extension of _v4.m3u8. If the output is video, Elastic Transcoder also creates an output file with an extension of _iframe.m3u8: OutputKeyPrefix: Outputs:Key: _v4.m3u8: OutputKeyPrefix: Outputs:Key: _iframe.m3u8: OutputKeyPrefix: Outputs:Key: _iframe.m3u8: OutputKeyPrefix: Outputs:Key: .ts

Elastic Transcoder automatically appends the relevant file extension to the file name. If you include a file extension in Output Key, the file name will have two extensions.

If you include more than one output in a playlist, any segment duration settings, clip settings, or caption settings must be the same for all outputs in the playlist. For Smooth playlists, the Audio:Profile, Video:Profile, and Video:FrameRate to Video:KeyframesMaxDist ratio must be the same for all outputs.

· **HlsContentProtection (dict)** –

The HLS content protection settings, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

· **Method (string)** –

The content protection method for your output. The only valid value is: aes-128.

This value will be written into the method attribute of the EXT-X-KEY metadata tag in the output playlist.

· **Key (string)** –

If you want Elastic Transcoder to generate a key for you, leave this field blank.

If you choose to supply your own key, you must encrypt the key by using AWS KMS. The key must be base64-encoded, and it must be one of the following bit lengths before being base64-encoded:
· **KeyMd5 (string)** –

If Elastic Transcoder is generating your key for you, you must leave this field blank.

The MD5 digest of the key that you want Elastic Transcoder to use to encrypt your output file, and that you want Elastic Transcoder to use as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

· **InitializationVector (string)** –

If Elastic Transcoder is generating your key for you, you must leave this field blank.

The series of random bits created by a random bit generator, unique for every encryption operation, that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

· **LicenseAcquisitionUrl (string)** –

The location of the license key required to decrypt your HLS playlist. The URL must be an absolute path, and is referenced in the URI attribute of the EXT-X-KEY metadata tag in the playlist file.

· **KeyStoragePolicy (string)** –

Specify whether you want Elastic Transcoder to write your HLS license key to an Amazon S3 bucket. If you choose **WithVariantPlaylists**, **LicenseAcquisitionUrl** must be left blank and Elastic Transcoder writes your data key into the same bucket as the associated playlist.

· **PlayReadyDrm (dict)** –

The DRM settings, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

· **Format (string)** –

The type of DRM, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

· **Key (string)** –

The DRM key for your file, provided by your DRM license provider. The key must be base64-encoded, and it must be one of the following bit lengths before being base64-encoded:

```plaintext
128, 192, or 256.
```

The key must also be encrypted by using AWS KMS.

· **KeyMd5 (string)** –

The MD5 digest of the key used for DRM on your file, and that you want Elastic Transcoder to use as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.
- **KeyId** *(string)* –
  
The ID for your DRM key, so that your DRM license provider knows which key to provide.

  The key ID must be provided in big endian, and Elastic Transcoder will convert it to little endian before inserting it into the PlayReady DRM headers. If you are unsure whether your license server provides your key ID in big or little endian, check with your DRM provider.

- **InitializationVector** *(string)* –
  
The series of random bits created by a random bit generator, unique for every encryption operation, that you want Elastic Transcoder to use to encrypt your files. The initialization vector must be base64-encoded, and it must be exactly 8 bytes long before being base64-encoded. If no initialization vector is provided, Elastic Transcoder generates one for you.

- **LicenseAcquisitionUrl** *(string)* –
  
The location of the license key required to play DRM content. The URL must be an absolute path, and is referenced by the PlayReady header. The PlayReady header is referenced in the protection header of the client manifest for Smooth Streaming outputs, and in the EXT-X-DXDRM and EXT-X-DXDRMINFO metadata tags for HLS playlist outputs. An example URL looks like this: https://www.example.com/exampleKey/

- **Status** *(string)* –
  
The status of the job with which the playlist is associated.

- **StatusDetail** *(string)* –
  
  Information that further explains the status.

  * **Status** *(string)* –
    
    The status of the job: Submitted, Progressing, Complete, Canceled, or Error.

  * **UserMetadata** *(dict)* –
    
    User-defined metadata that you want to associate with an Elastic Transcoder job. You specify metadata in key/value pairs, and you can add up to 10 key/value pairs per job. Elastic Transcoder does not guarantee that key/value pairs will be returned in the same order in which you specify them.

    Metadata keys and values must use characters from the following list:
    
    - \(0-9\)
    - \(A-Z\) and \(a-z\)
    - Space
    - The following symbols: _ . : / = + % @

    * **Timing** *(dict)* –
      
      Details about the timing of a job.

      * **SubmitTimeMillis** *(integer)* –
The time the job was submitted to Elastic Transcoder, in epoch milliseconds.

- **StartTimeMillis** (integer) –

  The time the job began transcoding, in epoch milliseconds.

- **FinishTimeMillis** (integer) –

  The time the job finished transcoding, in epoch milliseconds.

---

**create_pipeline(** **kwargs**)**

The CreatePipeline operation creates a pipeline with settings that you specify.

**Request Syntax**

```python
response = client.create_pipeline(
    Name='string',
    InputBucket='string',
    OutputBucket='string',
    Role='string',
    AwsKmsKeyArn='string',
    Notifications={
        'Progressing': 'string',
        'Completed': 'string',
        'Warning': 'string',
        'Error': 'string'
    },
    ContentConfig={
        'Bucket': 'string',
        'StorageClass': 'string',
        'Permissions': [
            {'GranteeType': 'string',
            'Grantee': 'string',
            'Access': ['string',
            ]
        },
    ],
    ),
    ThumbnailConfig={
        'Bucket': 'string',
        'StorageClass': 'string',
        'Permissions': [
            {'GranteeType': 'string',
            'Grantee': 'string',
            'Access': ['string',
            ]
        },
    ]
)
```

**Parameters**

- **Name (string)** – [REQUIRED]

  The name of the pipeline. We recommend that the name be unique within the AWS account, but uniqueness is not enforced.
Constraints: Maximum 40 characters.

- **InputBucket** *(string)* – [REQUIRED]

  The Amazon S3 bucket in which you saved the media files that you want to transcode.

- **OutputBucket** *(string)* – The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. (Use this, or use ContentConfig:Bucket plus ThumbnailConfig:Bucket.)

Specify this value when all of the following are true:

- You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.
- You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.
- You do not want to specify the permissions that Elastic Transcoder grants to the files. .. warning::When Elastic Transcoder saves files in OutputBucket, it grants full control over the files only to the AWS account that owns the role that is specified by Role.
- You want to associate the transcoded files and thumbnails with the Amazon S3 Standard storage class.

If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit OutputBucket and specify values for ContentConfig and ThumbnailConfig instead.

- **Role** *(string)* – [REQUIRED]

  The IAM Amazon Resource Name (ARN) for the role that you want Elastic Transcoder to use to create the pipeline.

- **AwsKmsKeyArn** *(string)* – The AWS Key Management Service (AWS KMS) key that you want to use with this pipeline.

  If you use either S3 or S3-AWS-KMS as your Encryption:Mode, you don’t need to provide a key with your job because a default key, known as an AWS-KMS key, is created for you automatically. You need to provide an AWS-KMS key only if you want to use a non-default AWS-KMS key, or if you are using an Encryption:Mode of AES-PKCS7, AES-CTR, or AES-GCM.

- **Notifications** *(dict)* – The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify to report job status.

  **Warning**: To receive notifications, you must also subscribe to the new topic in the Amazon SNS console.

  - **Progressing** : The topic ARN for the Amazon Simple Notification Service (Amazon SNS) topic that you want to notify when Elastic Transcoder has started to process a job in this pipeline. This is the ARN that Amazon SNS returned when you created the topic. For more information, see Create a Topic in the Amazon Simple Notification Service Developer Guide.

  - **Completed** : The topic ARN for the Amazon SNS topic that you want to notify when Elastic Transcoder has finished processing a job in this pipeline. This is the ARN that Amazon SNS returned when you created the topic.

  - **Warning** : The topic ARN for the Amazon SNS topic that you want to notify when Elastic Transcoder encounters a warning condition while processing a job in this pipeline. This is the ARN that Amazon SNS returned when you created the topic.

  - **Error** : The topic ARN for the Amazon SNS topic that you want to notify
when Elastic Transcoder encounters an error condition while processing a job in this pipeline. This is the ARN that Amazon SNS returned when you created the topic.

- **Progressing** *(string)* –
  The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify when Elastic Transcoder has started to process the job.

- **Completed** *(string)* –
  The Amazon SNS topic that you want to notify when Elastic Transcoder has finished processing the job.

- **Warning** *(string)* –
  The Amazon SNS topic that you want to notify when Elastic Transcoder encounters a warning condition.

- **Error** *(string)* –
  The Amazon SNS topic that you want to notify when Elastic Transcoder encounters an error condition.

- **ContentConfig** *(dict)* – The optional `ContentConfig` object specifies information about the Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists: which bucket to use, which users you want to have access to the files, the type of access you want users to have, and the storage class that you want to assign to the files.

  If you specify values for `ContentConfig`, you must also specify values for `ThumbnailConfig`.

  If you specify values for `ContentConfig` and `ThumbnailConfig`, omit the `OutputBucket` object.

  - **Bucket** : The Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists.

  - **Permissions** *(Optional)*: The Permissions object specifies which users you want to have access to transcoded files and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.

  - **Grantee Type** : Specify the type of value that appears in the `Grantee` object: * **Canonical** : The value in the `Grantee` object is either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. For more information about canonical user IDs, see Access Control List (ACL) Overview in the Amazon Simple Storage Service Developer Guide. For more information about using CloudFront origin access identities to require that users use CloudFront URLs instead of Amazon S3 URLs, see Using an Origin Access Identity to Restrict Access to Your Amazon S3 Content. .. warning:: A canonical user ID is not the same as an AWS account number.

  - **Email** : The value in the `Grantee` object is the registered email address of an AWS account.

  - **Group** : The value in the `Grantee` object is one of the following predefined Amazon S3 groups: AllUsers, AuthenticatedUsers, or LogDelivery.

  - **Grantee** : The AWS user or group that you want to have access to transcoded files and playlists. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.
– **Access**: The permission that you want to give to the AWS user that you specified in `Grantee`. Permissions are granted on the files that Elastic Transcoder adds to the bucket, including playlists and video files. Valid values include: * **READ**: The grantee can read the objects and metadata for objects that Elastic Transcoder adds to the Amazon S3 bucket.
  - **READ_ACP**: The grantee can read the object ACL for objects that Elastic Transcoder adds to the Amazon S3 bucket.
  - **WRITE_ACP**: The grantee can write the ACL for the objects that Elastic Transcoder adds to the Amazon S3 bucket.
  - **FULL_CONTROL**: The grantee has **READ**, **READ_ACP**, and **WRITE_ACP** permissions for the objects that Elastic Transcoder adds to the Amazon S3 bucket.

– **StorageClass**: The Amazon S3 storage class, **Standard** or **ReducedRedundancy**, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

– **Bucket** *(string)* –

  The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the following are true:
  - You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.
  - You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.
  - You do not want to specify the permissions that Elastic Transcoder grants to the files.
  - You want to associate the transcoded files and thumbnails with the Amazon S3 Standard storage class.

  If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit `OutputBucket` and specify values for `ContentConfig` and `ThumbnailConfig` instead.

– **StorageClass** *(string)* –

  The Amazon S3 storage class, **Standard** or **ReducedRedundancy**, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

– **Permissions** *(list)* –

  Optional. The **Permissions** object specifies which users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.

  If you include `Permissions`, Elastic Transcoder grants only the permissions that you specify. It does not grant full permissions to the owner of the role specified by `Role`. If you want that user to have full control, you must explicitly grant full control to the user.

  If you omit `Permissions`, Elastic Transcoder grants full control over the transcoded files and playlists to the owner of the role specified by `Role`, and grants no other permissions to any other user or group.

  * *(dict)* –

    The **Permission** structure.

    - **GranteeType** *(string)* –
The type of value that appears in the Grantee object:

- **Canonical:** Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. **Warning:** A canonical user ID is not the same as an AWS account number.
- **Email:** The registered email address of an AWS account.
- **Group:** One of the following predefined Amazon S3 groups: AllUsers, AuthenticatedUsers, or LogDelivery.
- **Grantee (string)**

  The AWS user or group that you want to have access to transcoded files and playlists. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.

- **Access (list)**

  The permission that you want to give to the AWS user that is listed in Grantee. Valid values include:

  - **READ:** The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **READ_ACP:** The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **WRITE_ACP:** The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **FULL_CONTROL:** The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

- **(string)**

  - **ThumbnailConfig (dict)** — The ThumbnailConfig object specifies several values, including the Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files, which users you want to have access to the files, the type of access you want users to have, and the storage class that you want to assign to the files.

    If you specify values for ContentConfig, you must also specify values for ThumbnailConfig even if you don’t want to create thumbnails.

    If you specify values for ContentConfig and ThumbnailConfig, omit the OutputBucket object.

    - **Bucket:** The Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files.
    - **Permissions** (Optional): The Permissions object specifies which users and/or predefined Amazon S3 groups you want to have access to thumbnail files, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.
    - **GranteeType:** Specify the type of value that appears in the Grantee object: * **Canonical:** The value in the Grantee object is either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. **Warning:** A canonical user ID is not the same as an AWS account number.
    - **Email:** The value in the Grantee object is the registered email address
of an AWS account.

- Group: The value in the Grantee object is one of the following pre-defined Amazon S3 groups: AllUsers, AuthenticatedUsers, or LogDelivery.

- Grantee: The AWS user or group that you want to have access to thumbnail files. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.

- Access: The permission that you want to give to the AWS user that you specified in Grantee. Permissions are granted on the thumbnail files that Elastic Transcoder adds to the bucket. Valid values include: * READ: The grantee can read the thumbnails and metadata for objects that Elastic Transcoder adds to the Amazon S3 bucket.

- READ_ACP: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

- WRITE_ACP: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

- FULL_CONTROL: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

- StorageClass: The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the thumbnails that it stores in your Amazon S3 bucket.

- Bucket (string) –

  The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the following are true:
  * You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.
  * You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.
  * You do not want to specify the permissions that Elastic Transcoder grants to the files.
  * You want to associate the transcoded files and thumbnails with the Amazon S3 Standard storage class.

  If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit OutputBucket and specify values for ContentConfig and ThumbnailConfig instead.

- StorageClass (string) –

  The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

- Permissions (list) –

  Optional. The Permissions object specifies which users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.

  If you include Permissions, Elastic Transcoder grants only the permissions that you specify. It does not grant full permissions to the owner
of the role specified by `Role`. If you want that user to have full control, you must explicitly grant full control to the user.

If you omit `Permissions`, Elastic Transcoder grants full control over the transcoded files and playlists to the owner of the role specified by `Role`, and grants no other permissions to any other user or group.

```python
* (dict) –

The `Permission` structure.

- **GranteeType (string) –**

  The type of value that appears in the `Grantee` object:
  - **Canonical**: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. **warning**: A canonical user ID is not the same as an AWS account number.
  - **Email**: The registered email address of an AWS account.
  - **Group**: One of the following predefined Amazon S3 groups: `AllUsers`, `AuthenticatedUsers`, or `LogDelivery`.

- **Grantee (string) –**

  The AWS user or group that you want to have access to transcoded files and playlists. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.

- **Access (list) –**

  The permission that you want to give to the AWS user that is listed in `Grantee`. Valid values include:
  - **READ**: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **READ_ACP**: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **WRITE_ACP**: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **FULL_CONTROL**: The grantee has **READ**, **READ_ACP**, and **WRITE_ACP** permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Pipeline': {
        'Id': 'string',
        'Arn': 'string',
        'Name': 'string',
        'Status': 'string',
        'InputBucket': 'string',
        'OutputBucket': 'string',
        'Role': 'string',
    }
}
```
Response Structure

* (dict) –

When you create a pipeline, Elastic Transcoder returns the values that you specified in the request.

– **Pipeline** (dict) –

A section of the response body that provides information about the pipeline that is created.

* **Id** (string) –

The identifier for the pipeline. You use this value to identify the pipeline in which you want to perform a variety of operations, such as creating a job or a preset.

* **Arn** (string) –

The Amazon Resource Name (ARN) for the pipeline.
* **Name (string)** –
  The name of the pipeline. We recommend that the name be unique within the AWS account, but uniqueness is not enforced.
  Constraints: Maximum 40 characters
* **Status (string)** –
  The current status of the pipeline:
  · **Active**: The pipeline is processing jobs.
  · **Paused**: The pipeline is not currently processing jobs.
* **InputBucket (string)** –
  The Amazon S3 bucket from which Elastic Transcoder gets media files for transcoding and the graphics files, if any, that you want to use for watermarks.
* **OutputBucket (string)** –
  The Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files, thumbnails, and playlists. Either you specify this value, or you specify both `ContentConfig` and `ThumbnailConfig`.
* **Role (string)** –
  The IAM Amazon Resource Name (ARN) for the role that Elastic Transcoder uses to transcode jobs for this pipeline.
* **AwsKmsKeyArn (string)** –
  The AWS Key Management Service (AWS KMS) key that you want to use with this pipeline.
  If you use either S3 or S3-AWS-KMS as your `Encryption:Mode`, you don’t need to provide a key with your job because a default key, known as an AWS-KMS key, is created for you automatically. You need to provide an AWS-KMS key only if you want to use a non-default AWS-KMS key, or if you are using an `Encryption:Mode` of AES-PKCS7, AES-CTR, or AES-GCM.
* **Notifications (dict)** –
  The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify to report job status.

<table>
<thead>
<tr>
<th><strong>Warning:</strong></th>
<th>To receive notifications, you must also subscribe to the new topic in the Amazon SNS console.</th>
</tr>
</thead>
<tbody>
<tr>
<td>· <strong>Progressing</strong> (optional): The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify when Elastic Transcoder has started to process the job.</td>
<td></td>
</tr>
<tr>
<td>· <strong>Completed</strong> (optional): The Amazon SNS topic that you want to notify when Elastic Transcoder has finished processing the job.</td>
<td></td>
</tr>
<tr>
<td>· <strong>Warning</strong> (optional): The Amazon SNS topic that you want to notify when Elastic Transcoder encounters a warning condition.</td>
<td></td>
</tr>
<tr>
<td>· <strong>Error</strong> (optional): The Amazon SNS topic that you want to notify when Elastic Transcoder encounters an error condition.</td>
<td></td>
</tr>
<tr>
<td>· <strong>Progressing</strong> (string) –</td>
<td></td>
</tr>
</tbody>
</table>
The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify when Elastic Transcoder has started to process the job.

- **Completed (string)** –
  The Amazon SNS topic that you want to notify when Elastic Transcoder has finished processing the job.

- **Warning (string)** –
  The Amazon SNS topic that you want to notify when Elastic Transcoder encounters a warning condition.

- **Error (string)** –
  The Amazon SNS topic that you want to notify when Elastic Transcoder encounters an error condition.

*ContentConfig (dict)* –
Information about the Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists. Either you specify both `ContentConfig` and `ThumbnailConfig`, or you specify `OutputBucket`.

- **Bucket** : The Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists.
- **Permissions** : A list of the users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access that you want them to have. *GranteeType*: The type of value that appears in the `Grantee` object: *Canonical*: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution.
- **Email** : The registered email address of an AWS account.
- **Group** : One of the following predefined Amazon S3 groups: AllUsers, AuthenticatedUsers, or LogDelivery.
- **Grantee** : The AWS user or group that you want to have access to transcoded files and playlists.
- **Access** : The permission that you want to give to the AWS user that is listed in `Grantee`. Valid values include: *READ*: The grantee can read the objects and metadata for objects that Elastic Transcoder adds to the Amazon S3 bucket.
- **READ_ACP**: The grantee can read the object ACL for objects that Elastic Transcoder adds to the Amazon S3 bucket.
- **WRITE_ACP**: The grantee can write the ACL for the objects that Elastic Transcoder adds to the Amazon S3 bucket.
- **FULL_CONTROL**: The grantee has `READ`, `READ_ACP`, and `WRITE_ACP` permissions for the objects that Elastic Transcoder adds to the Amazon S3 bucket.
- **StorageClass**: The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

- **Bucket (string)** –
  The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the following are true:
You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.

You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.

You do not want to specify the permissions that Elastic Transcoder grants to the files.

You want to associate the transcoded files and thumbnails with the Amazon S3 Standard storage class.

If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit OutputBucket and specify values for ContentConfig and ThumbnailConfig instead.

**StorageClass** *(string)* —

The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

**Permissions** *(list)* —

Optional. The Permissions object specifies which users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.

If you include Permissions, Elastic Transcoder grants only the permissions that you specify. It does not grant full permissions to the owner of the role specified by Role. If you want that user to have full control, you must explicitly grant full control to the user.

If you omit Permissions, Elastic Transcoder grants full control over the transcoded files and playlists to the owner of the role specified by Role, and grants no other permissions to any other user or group.

**(dict)** —

The Permission structure.

**GranteeType** *(string)* —

The type of value that appears in the Grantee object:

- **Canonical**: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. **Warning**: A canonical user ID is not the same as an AWS account number.
- **Email**: The registered email address of an AWS account.
- **Group**: One of the following predefined Amazon S3 groups: AllUsers, AuthenticatedUsers, or LogDelivery.

**Grantee** *(string)* —

The AWS user or group that you want to have access to transcoded files and playlists. To identify the user or group, you can specify the canonical user ID for an AWS account, an
origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.

- **Access** (list) –

   The permission that you want to give to the AWS user that is listed in Grantee. Valid values include:
   - **READ**: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
   - **READ_ACP**: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
   - **WRITE_ACP**: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
   - **FULL_CONTROL**: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

- **(string)** –

- **ThumbnailConfig** (dict) –

   Information about the Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files. Either you specify both `ContentConfig` and `ThumbnailConfig`, or you specify `OutputBucket`.

   - **Bucket**: The Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files.
   - **Permissions**: A list of the users and/or predefined Amazon S3 groups you want to have access to thumbnail files, and the type of access that you want them to have.
   - **GranteeType**: The type of value that appears in the Grantee object:
     - **Canonical**: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. **Warning**: A canonical user ID is not the same as an AWS account number.
   - **Email**: The registered email address of an AWS account.
   - **Group**: One of the following predefined Amazon S3 groups: `AllUsers`, `AuthenticatedUsers`, or `LogDelivery`.
   - **Grantee**: The AWS user or group that you want to have access to thumbnail files.
   - **Access**: The permission that you want to give to the AWS user that is listed in Grantee. Valid values include:
     - **READ**: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
     - **READ_ACP**: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
     - **WRITE_ACP**: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
     - **FULL_CONTROL**: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
   - **StorageClass**: The Amazon S3 storage class, `Standard` or `ReducedRedundancy`, that you want Elastic Transcoder to assign to the thumbnails that it stores in your Amazon S3 bucket.
- **Bucket** *(string)* –
  The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the following are true:
  - You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.
  - You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.
  - You do not want to specify the permissions that Elastic Transcoder grants to the files.
  - You want to associate the transcoded files and thumbnails with the Amazon S3 Standard storage class.
  
  If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit OutputBucket and specify values for ContentConfig and ThumbnailConfig instead.

- **StorageClass** *(string)* –
  The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

- **Permissions** *(list)* –
  Optional. The Permissions object specifies which users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.
  
  If you include Permissions, Elastic Transcoder grants only the permissions that you specify. It does not grant full permissions to the owner of the role specified by Role. If you want that user to have full control, you must explicitly grant full control to the user.
  
  If you omit Permissions, Elastic Transcoder grants full control over the transcoded files and playlists to the owner of the role specified by Role, and grants no other permissions to any other user or group.

- *(dict)* –
  The Permission structure.

- **GranteeType** *(string)* –
  The type of value that appears in the Grantee object:
  - **Canonical**: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning:: A canonical user ID is not the same as an AWS account number.
  - **Email**: The registered email address of an AWS account.
  - **Group**: One of the following predefined Amazon S3 groups: **AllUsers**, **AuthenticatedUsers**, or **LogDelivery**.
**Grantee** *(string)* –

The AWS user or group that you want to have access to transcoded files and playlists. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.

**Access** *(list)* –

The permission that you want to give to the AWS user that is listed in Grantee. Valid values include:

- **READ**: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
- **READ_ACP**: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
- **WRITE_ACP**: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
- **FULL_CONTROL**: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

**Warnings** *(list)* –

Elastic Transcoder returns a warning if the resources used by your pipeline are not in the same region as the pipeline.

Using resources in the same region, such as your Amazon S3 buckets, Amazon SNS notification topics, and AWS KMS key, reduces processing time and prevents cross-regional charges.

- *(dict)* –

  Elastic Transcoder returns a warning if the resources used by your pipeline are not in the same region as the pipeline.

Using resources in the same region, such as your Amazon S3 buckets, Amazon SNS notification topics, and AWS KMS key, reduces processing time and prevents cross-regional charges.

- **Code** *(string)* –

  The code of the cross-regional warning.

- **Message** *(string)* –

  The message explaining what resources are in a different region from the pipeline.

  **Note**: AWS KMS keys must be in the same region as the pipeline.

**create_preset** (**kwargs**)

The CreatePreset operation creates a preset with settings that you specify.
Elastic Transcoder checks the CreatePreset settings to ensure that they meet Elastic Transcoder requirements and to determine whether they comply with H.264 standards. If your settings are not valid for Elastic Transcoder, Elastic Transcoder returns an HTTP 400 response (ValidationException) and does not create the preset. If the settings are valid for Elastic Transcoder but aren’t strictly compliant with the H.264 standard, Elastic Transcoder creates the preset and returns a warning message in the response. This helps you determine whether your settings comply with the H.264 standard while giving you greater flexibility with respect to the video that Elastic Transcoder produces.

Elastic Transcoder uses the H.264 video-compression format. For more information, see the International Telecommunication Union publication Recommendation ITU-T H.264: Advanced video coding for generic audiovisual services.

**Request Syntax**

```python
response = client.create_preset(
    Name='string',
    Description='string',
    Container='string',
    Video={
        'Codec': 'string',
        'CodecOptions': {
            'string': 'string'
        },
        'KeyframesMaxDist': 'string',
        'FixedGOP': 'string',
        'BitRate': 'string',
        'FrameRate': 'string',
        'MaxFrameRate': 'string',
        'Resolution': 'string',
        'AspectRatio': 'string',
        'MaxWidth': 'string',
        'MaxHeight': 'string',
        'DisplayAspectRatio': 'string',
        'SizingPolicy': 'string',
        'PaddingPolicy': 'string',
        'Watermarks': [
            {
                'Id': 'string',
                'MaxWidth': 'string',
                'MaxHeight': 'string',
                'SizingPolicy': 'string',
                'HorizontalAlign': 'string',
                'HorizontalOffset': 'string',
                'VerticalAlign': 'string',
                'VerticalOffset': 'string',
                'Opacity': 'string',
                'Target': 'string'
            }
        ],
    },
    Audio={
        'Codec': 'string',
        'SampleRate': 'string',
        'BitRate': 'string',
        'Channels': 'string',
        'AudioPackingMode': 'string',
    })
```
Parameters

- **Name (string)** – [REQUIRED]
  The name of the preset. We recommend that the name be unique within the AWS account, but uniqueness is not enforced.
- **Description (string)** – A description of the preset.
- **Container (string)** – [REQUIRED]
  The container type for the output file. Valid values include flac, flv, fmp4, gif, mp3, mp4, mpeg, mxf, oga, ogg, ts, and webm.
- **Video (dict)** – A section of the request body that specifies the video parameters.
  - **Codec (string)** –
    The video codec for the output file. Valid values include gif, H.264, mpeg2, and vp8. You can only specify vp8 when the container type is webm, gif when the container type is gif, and mpeg2 when the container type is mpeg.
  - **CodecOptions (dict)** –
    **Profile (H.264/VP8 Only)**
    The H.264 profile that you want to use for the output file. Elastic Transcoder supports the following profiles:
    * baseline: The profile most commonly used for videoconferencing and for mobile applications.
    * main: The profile used for standard-definition digital TV broadcasts.
    * high: The profile used for high-definition digital TV broadcasts and for Blu-ray discs.
    **Level (H.264 Only)**
    The H.264 level that you want to use for the output file. Elastic Transcoder supports the following levels:
    1, 1b, 1.1, 1.2, 1.3, 2, 2.1, 2.2, 3, 3.1, 3.2, 4, 4.1
  - **MaxReferenceFrames (H.264 Only)**
    Applicable only when the value of Video:Codec is H.264. The maximum number of previously decoded frames to use as a reference for decoding future frames. Valid values are integers 0 through 16, but we recommend that you not use a value greater than the following:

```json
'CodecOptions': {
    'Profile': 'string',
    'BitDepth': 'string',
    'BitOrder': 'string',
    'Signed': 'string'
}

Thumbnails={
    'Format': 'string',
    'Interval': 'string',
    'Resolution': 'string',
    'AspectRatio': 'string',
    'MaxWidth': 'string',
    'MaxHeight': 'string',
    'SizingPolicy': 'string',
    'PaddingPolicy': 'string'
}
```
Min(Floor(Maximum decoded picture buffer in macroblocks * 256 / (Width in pixels * Height in pixels)), 16)

where Width in pixels and Height in pixels represent either MaxWidth and MaxHeight, or Resolution. Maximum decoded picture buffer in macroblocks depends on the value of the Level object. See the list below. (A macroblock is a block of pixels measuring 16x16.)

* 1 - 396
* 1b - 396
* 1.1 - 900
* 1.2 - 2376
* 1.3 - 2376
* 2 - 2376
* 2.1 - 4752
* 2.2 - 8100
* 3 - 8100
* 3.1 - 18000
* 3.2 - 20480
* 4 - 32768
* 4.1 - 32768

MaxBitRate (Optional, H.264/MPEG2/VP8 only)

The maximum number of bits per second in a video buffer; the size of the buffer is specified by BufferSize. Specify a value between 16 and 62,500. You can reduce the bandwidth required to stream a video by reducing the maximum bit rate, but this also reduces the quality of the video.

BufferSize (Optional, H.264/MPEG2/VP8 only)

The maximum number of bits in any x seconds of the output video. This window is commonly 10 seconds, the standard segment duration when you're using FMP4 or MPEG-TS for the container type of the output video. Specify an integer greater than 0. If you specify MaxBitRate and omit BufferSize, Elastic Transcoder sets BufferSize to 10 times the value of MaxBitRate.

InterlacedMode (Optional, H.264/MPEG2 Only)

The interlace mode for the output video.

Interlaced video is used to double the perceived frame rate for a video by interlacing two fields (one field on every other line, the other field on the other lines) so that the human eye registers multiple pictures per frame. Interlacing reduces the bandwidth required for transmitting a video, but can result in blurred images and flickering.

Valid values include Progressive (no interlacing, top to bottom), TopFirst (top field first), BottomFirst (bottom field first), and Auto.

If InterlaceMode is not specified, Elastic Transcoder uses Progressive for the output. If Auto is specified, Elastic Transcoder interlaces the output.

ColorSpaceConversionMode (Optional, H.264/MPEG2 Only)

The color space conversion Elastic Transcoder applies to the output video. Color spaces are the algorithms used by the computer to store information about how to render color. Bt.601 is the standard for standard definition
video, while Bt.709 is the standard for high definition video.

Valid values include None, Bt709toBt601, Bt601toBt709, and Auto.

If you chose Auto for ColorSpaceConversionMode and your output is interlaced, your frame rate is one of 23.97, 24, 25, 29.97, 50, or 60, your SegmentDuration is null, and you are using one of the resolution changes from the list below, Elastic Transcoder applies the following color space conversions:

- **Standard to HD, 720x480 to 1920x1080** - Elastic Transcoder applies Bt601ToBt709.
- **Standard to HD, 720x576 to 1920x1080** - Elastic Transcoder applies Bt601ToBt709.
- **HD to Standard, 1920x1080 to 720x480** - Elastic Transcoder applies Bt709ToBt601.
- **HD to Standard, 1920x1080 to 720x576** - Elastic Transcoder applies Bt709ToBt601.

**Note:** Elastic Transcoder may change the behavior of the ColorSpaceConversionMode Auto mode in the future. All outputs in a playlist must use the same ColorSpaceConversionMode.

If you do not specify a ColorSpaceConversionMode, Elastic Transcoder does not change the color space of a file. If you are unsure what ColorSpaceConversionMode was applied to your output file, you can check the AppliedColorSpaceConversion parameter included in your job response. If your job does not have an AppliedColorSpaceConversion in its response, no ColorSpaceConversionMode was applied.

**ChromaSubsampling**

The sampling pattern for the chroma (color) channels of the output video. Valid values include yuv420p and yuv422p.

yuv420p samples the chroma information of every other horizontal and every other vertical line, yuv422p samples the color information of every horizontal line and every other vertical line.

**LoopCount (Gif Only)**

The number of times you want the output gif to loop. Valid values include Infinite and integers between 0 and 100, inclusive.

- (string) – (string) –

- **KeyframesMaxDist (string) –**

Applicable only when the value of Video:Codec is one of H.264, MPEG2, or VP8.

The maximum number of frames between key frames. Key frames are fully encoded frames; the frames between key frames are encoded based, in part, on the content of the key frames. The value is an integer formatted as a string; valid values are between 1 (every frame is a key frame) and 100000, inclusive. A higher value results in higher compression but may also discernibly decrease video quality.

For Smooth outputs, the FrameRate must have a constant ratio to the KeyframesMaxDist. This allows Smooth playlists to switch be-
between different quality levels while the file is being played.

For example, an input file can have a FrameRate of 30 with a KeyframesMaxDist of 90. The output file then needs to have a ratio of 1:3. Valid outputs would have FrameRate of 30, 25, and 10, and KeyframesMaxDist of 90, 75, and 30, respectively.

Alternately, this can be achieved by setting FrameRate to auto and having the same values for MaxFrameRate and KeyframesMaxDist.

- FixedGOP (string) –

Applicable only when the value of Video:Codec is one of H.264, MPEG2, or VP8.

Whether to use a fixed value for FixedGOP. Valid values are true and false:
- true: Elastic Transcoder uses the value of KeyframesMaxDist for the distance between key frames (the number of frames in a group of pictures, or GOP).
- false: The distance between key frames can vary.

**Warning:** FixedGOP must be set to true for fmp4 containers.

- BitRate (string) –

The bit rate of the video stream in the output file, in kilobits/second. Valid values depend on the values of Level and Profile. If you specify auto, Elastic Transcoder uses the detected bit rate of the input source. If you specify a value other than auto, we recommend that you specify a value less than or equal to the maximum H.264-compliant value listed for your level and profile:

<table>
<thead>
<tr>
<th>Level - Maximum video bit rate in kilobits/second (baseline and main Profile)</th>
<th>maximum video bit rate in kilobits/second (high Profile)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 - 64</td>
<td>80</td>
</tr>
<tr>
<td>1b - 128</td>
<td>160</td>
</tr>
<tr>
<td>1.1 - 192</td>
<td>240</td>
</tr>
<tr>
<td>1.2 - 384</td>
<td>480</td>
</tr>
<tr>
<td>1.3 - 768</td>
<td>960</td>
</tr>
<tr>
<td>2 - 2000</td>
<td>2500</td>
</tr>
<tr>
<td>3 - 10000</td>
<td>12500</td>
</tr>
<tr>
<td>3.1 - 14000</td>
<td>17500</td>
</tr>
<tr>
<td>3.2 - 20000</td>
<td>25000</td>
</tr>
<tr>
<td>4 - 20000</td>
<td>25000</td>
</tr>
<tr>
<td>4.1 - 50000</td>
<td>62500</td>
</tr>
</tbody>
</table>

- FrameRate (string) –

The frames per second for the video stream in the output file. Valid values include:

auto, 10, 15, 23.97, 24, 25, 29.97, 30, 60

If you specify auto, Elastic Transcoder uses the detected frame rate of the input source. If you specify a frame rate, we recommend that you perform the following calculation:

\[
\text{Frame rate} = \frac{\text{maximum recommended decoding speed in luma samples/second}}{(\text{width in pixels} \times \text{height in pixels})}
\]
where:

- *width in pixels* and *height in pixels* represent the Resolution of the output video.
- *maximum recommended decoding speed in Luma samples/second* is less than or equal to the maximum value listed in the following table, based on the value that you specified for Level.

The maximum recommended decoding speed in Luma samples/second for each level is described in the following list (*Level* - *Decoding speed*):

- 1 - 380160
- 1b - 380160
- 1.1 - 76800
- 1.2 - 1536000
- 1.3 - 3041280
- 2 - 3041280
- 2.1 - 5068800
- 2.2 - 5184000
- 3 - 10368000
- 3.1 - 27648000
- 3.2 - 55296000
- 4 - 62914560
- 4.1 - 62914560

- **MaxFrameRate** *(string)* –

  If you specify *auto* for FrameRate, Elastic Transcoder uses the frame rate of the input video for the frame rate of the output video. Specify the maximum frame rate that you want Elastic Transcoder to use when the frame rate of the input video is greater than the desired maximum frame rate of the output video. Valid values include: 10, 15, 23.97, 24, 25, 29.97, 30, 60.

- **Resolution** *(string)* –

  **Warning:** To better control resolution and aspect ratio of output videos, we recommend that you use the values MaxWidth, MaxHeight, SizingPolicy, PaddingPolicy, and DisplayAspectRatio instead of Resolution and AspectRatio. The two groups of settings are mutually exclusive. Do not use them together.

The width and height of the video in the output file, in pixels. Valid values are *auto* and *width x height*:

- *auto*: Elastic Transcoder attempts to preserve the width and height of the input file, subject to the following rules.
- *width* x *height*: The width and height of the output video in pixels.

Note the following about specifying the width and height:

- The width must be an even integer between 128 and 4096, inclusive.
- The height must be an even integer between 96 and 3072, inclusive.
- If you specify a resolution that is less than the resolution of the input file, Elastic Transcoder rescales the output file to the lower resolution.
- If you specify a resolution that is greater than the resolution of the input file, Elastic Transcoder rescales the output to the higher resolution.
- We recommend that you specify a resolution for which the product
of width and height is less than or equal to the applicable value in the following list (List - Max width x height value):

- 1  - 25344
- 1b - 25344
- 1.1 - 101376
- 1.2 - 101376
- 1.3 - 101376
- 2  - 101376
- 2.1 - 202752
- 2.2 - 404720
- 3  - 404720
- 3.1 - 921600
- 3.2 - 1310720
- 4  - 2097152
- 4.1 - 2097152

- **AspectRatio** *(string)* –

**Warning:** To better control resolution and aspect ratio of output videos, we recommend that you use the values `MaxWidth`, `MaxHeight`, `SizingPolicy`, `PaddingPolicy`, and `DisplayAspectRatio` instead of `Resolution` and `AspectRatio`. The two groups of settings are mutually exclusive. Do not use them together.

The display aspect ratio of the video in the output file. Valid values include:

- `auto`
- `1:1`
- `4:3`
- `3:2`
- `16:9`

If you specify `auto`, Elastic Transcoder tries to preserve the aspect ratio of the input file.

If you specify an aspect ratio for the output file that differs from aspect ratio of the input file, Elastic Transcoder adds pillarboxing (black bars on the sides) or letterboxing (black bars on the top and bottom) to maintain the aspect ratio of the active region of the video.

- **MaxWidth** *(string)* –

The maximum width of the output video in pixels. If you specify `auto`, Elastic Transcoder uses 1920 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 128 and 4096.

- **MaxHeight** *(string)* –

The maximum height of the output video in pixels. If you specify `auto`, Elastic Transcoder uses 1080 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 96 and 3072.

- **DisplayAspectRatio** *(string)* –

The value that Elastic Transcoder adds to the metadata in the output file.

- **SizingPolicy** *(string)* –

Specify one of the following values to control scaling of the output video:

- **Fit**: Elastic Transcoder scales the output video so it matches the value that you specified in either `MaxWidth` or `MaxHeight` without exceeding the other value.
- **Fill**: Elastic Transcoder scales the output video so it matches the value that you specified in either `MaxWidth` or `MaxHeight` and
matches or exceeds the other value. Elastic Transcoder centers the output video and then crops it in the dimension (if any) that exceeds the maximum value.

* **Stretch**: Elastic Transcoder stretches the output video to match the values that you specified for `MaxWidth` and `MaxHeight`. If the relative proportions of the input video and the output video are different, the output video will be distorted.

* **Keep**: Elastic Transcoder does not scale the output video. If either dimension of the input video exceeds the values that you specified for `MaxWidth` and `MaxHeight`, Elastic Transcoder crops the output video.

* **ShrinkToFit**: Elastic Transcoder scales the output video down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without exceeding either value. If you specify this option, Elastic Transcoder does not scale the video up.

* **ShrinkToFit**: Elastic Transcoder scales the output video down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without dropping below either value. If you specify this option, Elastic Transcoder does not scale the video up.

  - **PaddingPolicy** *(string)* —

    When you set `PaddingPolicy` to `Pad`, Elastic Transcoder may add black bars to the top and bottom and/or left and right sides of the output video to make the total size of the output video match the values that you specified for `MaxWidth` and `MaxHeight`.

  - **Watermarks** *(list)* —

    Settings for the size, location, and opacity of graphics that you want Elastic Transcoder to overlay over videos that are transcoded using this preset. You can specify settings for up to four watermarks. Watermarks appear in the specified size and location, and with the specified opacity for the duration of the transcoded video.

    Watermarks can be in `.png` or `.jpg` format. If you want to display a watermark that is not rectangular, use the `.png` format, which supports transparency.

    When you create a job that uses this preset, you specify the `.png` or `.jpg` graphics that you want Elastic Transcoder to include in the transcoded videos. You can specify fewer graphics in the job than you specify watermark settings in the preset, which allows you to use the same preset for up to four watermarks that have different dimensions.

    * *(dict)* —

      Settings for the size, location, and opacity of graphics that you want Elastic Transcoder to overlay over videos that are transcoded using this preset. You can specify settings for up to four watermarks. Watermarks appear in the specified size and location, and with the specified opacity for the duration of the transcoded video.

      Watermarks can be in `.png` or `.jpg` format. If you want to display a watermark that is not rectangular, use the `.png` format, which supports transparency.

      When you create a job that uses this preset, you specify the `.png`
or .jpg graphics that you want Elastic Transcoder to include in the transcoded videos. You can specify fewer graphics in the job than you specify watermark settings in the preset, which allows you to use the same preset for up to four watermarks that have different dimensions.

- **Id (string)** – A unique identifier for the settings for one watermark. The value of `Id` can be up to 40 characters long.

- **MaxWidth (string)** –
  
  The maximum width of the watermark in one of the following formats:
  
  - number of pixels (px): The minimum value is 16 pixels, and the maximum value is the value of `MaxWidth`.
  - integer percentage (%): The range of valid values is 0 to 100. Use the value of `Target` to specify whether you want Elastic Transcoder to include the black bars that are added by Elastic Transcoder, if any, in the calculation.
  
  If you specify the value in pixels, it must be less than or equal to the value of `MaxWidth`.

- **MaxHeight (string)** –
  
  The maximum height of the watermark in one of the following formats:
  
  - number of pixels (px): The minimum value is 16 pixels, and the maximum value is the value of `MaxHeight`.
  - integer percentage (%): The range of valid values is 0 to 100. Use the value of `Target` to specify whether you want Elastic Transcoder to include the black bars that are added by Elastic Transcoder, if any, in the calculation.
  
  If you specify the value in pixels, it must be less than or equal to the value of `MaxHeight`.

- **SizingPolicy (string)** –
  
  A value that controls scaling of the watermark:
  
  - **Fit**: Elastic Transcoder scales the watermark so it matches the value that you specified in either `MaxWidth` or `MaxHeight` without exceeding the other value.
  
  - **Stretch**: Elastic Transcoder stretches the watermark to match the values that you specified for `MaxWidth` and `MaxHeight`. If the relative proportions of the watermark and the values of `MaxWidth` and `MaxHeight` are different, the watermark will be distorted.
  
  - **ShrinkToFit**: Elastic Transcoder scales the watermark down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without exceeding either value. If you specify this option, Elastic Transcoder does not scale the watermark up.

- **HorizontalAlign (string)** –
  
  The horizontal position of the watermark unless you specify a non-zero value for `HorizontalOffset`:
  
  - **Left**: The left edge of the watermark is aligned with the left border of the video.
  
  - **Right**: The right edge of the watermark is aligned with the right border of the video.
  
  - **Center**: The watermark is centered between the left and right edges of the video.
borders.

- **HorizontalOffset (string)** –

  The amount by which you want the horizontal position of the watermark to be offset from the position specified by HorizontalAlign:

  - number of pixels (px): The minimum value is 0 pixels, and the maximum value is the value of MaxWidth.
  - integer percentage (%): The range of valid values is 0 to 100.

  For example, if you specify Left for HorizontalAlign and 5px for HorizontalOffset, the left side of the watermark appears 5 pixels from the left border of the output video.

  HorizontalOffset is only valid when the value of HorizontalAlign is Left or Right. If you specify an offset that causes the watermark to extend beyond the left or right border and Elastic Transcoder has not added black bars, the watermark is cropped. If Elastic Transcoder has added black bars, the watermark extends into the black bars. If the watermark extends beyond the black bars, it is cropped.

  Use the value of Target to specify whether you want to include the black bars that are added by Elastic Transcoder, if any, in the offset calculation.

- **VerticalAlign (string)** –

  The vertical position of the watermark unless you specify a non-zero value for VerticalOffset:

  - **Top**: The top edge of the watermark is aligned with the top border of the video.
  - **Bottom**: The bottom edge of the watermark is aligned with the bottom border of the video.
  - **Center**: The watermark is centered between the top and bottom borders.

- **VerticalOffset (string)** – VerticalOffset

  The amount by which you want the vertical position of the watermark to be offset from the position specified by VerticalAlign:

  - number of pixels (px): The minimum value is 0 pixels, and the maximum value is the value of MaxHeight.
  - integer percentage (%): The range of valid values is 0 to 100.

  For example, if you specify Top for VerticalAlign and 5px for VerticalOffset, the top of the watermark appears 5 pixels from the top border of the output video.

  VerticalOffset is only valid when the value of VerticalAlign is Top or Bottom.

  If you specify an offset that causes the watermark to extend beyond the top or bottom border and Elastic Transcoder has not added black bars, the watermark is cropped. If Elastic Transcoder has added black bars, the watermark extends into the black bars. If the watermark extends beyond the black bars, it is cropped.

  Use the value of Target to specify whether you want Elastic Transcoder to add black bars.
Transcoder to include the black bars that are added by Elastic Transcoder, if any, in the offset calculation.

- **Opacity (string)** –
  
  A percentage that indicates how much you want a watermark to obscure the video in the location where it appears. Valid values are 0 (the watermark is invisible) to 100 (the watermark completely obscures the video in the specified location). The datatype of Opacity is float.

  Elastic Transcoder supports transparent .png graphics. If you use a transparent .png, the transparent portion of the video appears as if you had specified a value of 0 for Opacity. The .jpg file format doesn’t support transparency.

- **Target (string)** –
  
  A value that determines how Elastic Transcoder interprets values that you specified for HorizontalOffset, VerticalOffset, MaxWidth, and MaxHeight:

  - **Content**: HorizontalOffset and VerticalOffset values are calculated based on the borders of the video excluding black bars added by Elastic Transcoder, if any. In addition, MaxWidth and MaxHeight, if specified as a percentage, are calculated based on the borders of the video excluding black bars added by Elastic Transcoder, if any.
  - **Frame**: HorizontalOffset and VerticalOffset values are calculated based on the borders of the video including black bars added by Elastic Transcoder, if any. In addition, MaxWidth and MaxHeight, if specified as a percentage, are calculated based on the borders of the video including black bars added by Elastic Transcoder, if any.

- **Audio (dict)** – A section of the request body that specifies the audio parameters.

  - **Codec (string)** –
    
    The audio codec for the output file. Valid values include aac, flac, mp2, mp3, pcm, and vorbis.

  - **SampleRate (string)** –
    
    The sample rate of the audio stream in the output file, in Hertz. Valid values include:
    
    auto, 22050, 32000, 44100, 48000, 96000

    If you specify auto, Elastic Transcoder automatically detects the sample rate.

  - **BitRate (string)** –
    
    The bit rate of the audio stream in the output file, in kilobits/second. Enter an integer between 64 and 320, inclusive.

  - **Channels (string)** –
    
    The number of audio channels in the output file. The following values are valid:
    
    auto, 0, 1, 2

    One channel carries the information played by a single speaker. For example, a stereo track with two channels sends one channel to the left speaker,
and the other channel to the right speaker. The output channels are organized into tracks. If you want Elastic Transcoder to automatically detect the number of audio channels in the input file and use that value for the output file, select auto.

The output of a specific channel value and inputs are as follows:

- **auto channel specified, with any input**: Pass through up to eight input channels.
- **0 channels specified, with any input**: Audio omitted from the output.
- **1 channel specified, with at least one input channel**: Mono sound.
- **2 channels specified, with any input**: Two identical mono channels or stereo. For more information about tracks, see :func:`~boto3.typeconverter.AudioPackingMode`.

For more information about how Elastic Transcoder organizes channels and tracks, see :func:`~boto3.typeconverter.AudioPackingMode`.

- **AudioPackingMode** *(string)* –

  The following values are valid:

  SingleTrack, OneChannelPerTrack, and OneChannelPerTrackWithMosTo8Tracks

  When you specify SingleTrack, Elastic Transcoder creates a single track for your output. The track can have up to eight channels. Use SingleTrack for all non-mxf containers.

  The outputs of SingleTrack for a specific channel value and inputs are as follows:

  - **0 channels with any input**: Audio omitted from the output
  - **1, 2, or auto channels with no audio input**: Audio omitted from the output
  - **1 channel with any input with audio**: One track with one channel, downmixed if necessary
  - **2 channels with one track with one channel**: One track with two identical channels
  - **2 or auto channels with two tracks with one channel each**: One track with two channels
  - **2 or auto channels with one track with two channels**: One track with two channels
  - **2 channels with one track with multiple channels**: One track with multiple channels
  - **auto channels with one track with one channel**: One track with one channel
  - **auto channels with one track with multiple channels**: One track with multiple channels

  When you specify OneChannelPerTrack, Elastic Transcoder creates a new track for every channel in your output. Your output can have up to eight single-channel tracks.
The outputs of `OneChannelPerTrack` for a specific channel value and inputs are as follows:

- **0 channels with any input**: Audio omitted from the output
- **1, 2, or auto channels with no audio input**: Audio omitted from the output
- **1 channel with any input with audio**: One track with one channel, downmixed if necessary
- **2 channels with one track with one channel**: Two tracks with one identical channel each
- **2 or auto channels with two tracks with one channel each**: Two tracks with one channel each
- **2 or auto channels with one track with two channels**: Two tracks with one channel each
- **2 or auto channels with one track with multiple channels**: Two tracks with one channel each
- **auto channels with one track with one channel**: One track with one channel
- **auto channels with one track with multiple channels**: Up to eight tracks with one channel each

When you specify `OneChannelPerTrackWithMosTo8Tracks`, Elastic Transcoder creates eight single-channel tracks for your output. All tracks that do not contain audio data from an input channel are MOS, or Mit Out Sound, tracks.

The outputs of `OneChannelPerTrackWithMosTo8Tracks` for a specific channel value and inputs are as follows:

- **0 channels with any input**: Audio omitted from the output
- **1, 2, or auto channels with no audio input**: Audio omitted from the output
- **1 channel with any input with audio**: One track with one channel, downmixed if necessary, plus six MOS tracks
- **2 channels with one track with one channel**: Two tracks with one identical channel each, plus six MOS tracks
- **2 or auto channels with two tracks with one channel each**: Two tracks with one channel each, plus six MOS tracks
- **2 or auto channels with one track with two channels**: Two tracks with one channel each, plus six MOS tracks
- **2 channels with one track with multiple channels**: Two tracks with one channel each, plus six MOS tracks
- **auto channels with one track with one channel**: One track with one channel, plus seven MOS tracks
- **auto channels with one track with multiple channels**: Up to eight tracks with one channel each, plus MOS tracks until there are eight tracks in all

### CodecOptions (dict)

If you specified AAC for `Audio:Codec`, this is the AAC compression profile to use. Valid values include:

- `auto`
- `AAC-LC`, `HE-AAC`, `HE-AACv2`

If you specify `auto`, Elastic Transcoder chooses a profile based on the bit rate of the output file.

- **Profile (string)**
  
  You can only choose an audio profile when you specify AAC for the
value of Audio:Codec.

Specify the AAC profile for the output file. Elastic Transcoder supports the following profiles:
- **auto**: If you specify *auto*, Elastic Transcoder will select the profile based on the bit rate selected for the output file.
- **AAC-LC**: The most common AAC profile. Use for bit rates larger than 64 kbps.
- **HE-AAC**: Not supported on some older players and devices. Use for bit rates between 40 and 80 kbps.
- **HE-AACv2**: Not supported on some players and devices. Use for bit rates less than 48 kbps.

All outputs in a *Smooth* playlist must have the same value for Profile.

**Note:** If you created any presets before AAC profiles were added, Elastic Transcoder automatically updated your presets to use AAC-LC. You can change the value as required.

* **BitDepth** (*string*) –
  You can only choose an audio bit depth when you specify *flac* or *pcm* for the value of Audio:Codec.

  The bit depth of a sample is how many bits of information are included in the audio samples. The higher the bit depth, the better the audio, but the larger the file.

  Valid values are 16 and 24.

  The most common bit depth is 24.

* **BitOrder** (*string*) –
  You can only choose an audio bit order when you specify *pcm* for the value of Audio:Codec.

  The order the bits of a PCM sample are stored in.

  The supported value is *LittleEndian*.

* **Signed** (*string*) –
  You can only choose whether an audio sample is signed when you specify *pcm* for the value of Audio:Codec.

  Whether audio samples are represented with negative and positive numbers (signed) or only positive numbers (unsigned).

  The supported value is *Signed*.

* **Thumbnails** (*dict*) – A section of the request body that specifies the thumbnail parameters, if any.
  - **Format** (*string*) –
    The format of thumbnails, if any. Valid values are *jpg* and *png*.

    You specify whether you want Elastic Transcoder to create thumbnails when you create a job.
  - **Interval** (*string*) –
    The approximate number of seconds between thumbnails. Specify an integer value.
- **Resolution** *(string)*

  **Warning:** To better control resolution and aspect ratio of thumbnails, we recommend that you use the values MaxWidth, MaxHeight, SizingPolicy, and PaddingPolicy instead of Resolution and AspectRatio. The two groups of settings are mutually exclusive. Do not use them together.

  The width and height of thumbnail files in pixels. Specify a value in the format `*width* x *height*` where both values are even integers. The values cannot exceed the width and height that you specified in the Video:Resolution object.

- **AspectRatio** *(string)*

  **Warning:** To better control resolution and aspect ratio of thumbnails, we recommend that you use the values MaxWidth, MaxHeight, SizingPolicy, and PaddingPolicy instead of Resolution and AspectRatio. The two groups of settings are mutually exclusive. Do not use them together.

  The aspect ratio of thumbnails. Valid values include:
  
  `auto`, `1:1`, `4:3`, `3:2`, `16:9`

  If you specify `auto`, Elastic Transcoder tries to preserve the aspect ratio of the video in the output file.

- **MaxWidth** *(string)*

  The maximum width of thumbnails in pixels. If you specify `auto`, Elastic Transcoder uses 1920 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 32 and 4096.

- **MaxHeight** *(string)*

  The maximum height of thumbnails in pixels. If you specify `auto`, Elastic Transcoder uses 1080 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 32 and 3072.

- **SizingPolicy** *(string)*

  Specify one of the following values to control scaling of thumbnails:
  
  * **Fit**: Elastic Transcoder scales thumbnails so they match the value that you specified in thumbnail MaxWidth or MaxHeight settings without exceeding the other value.
  * **Fill**: Elastic Transcoder scales thumbnails so they match the value that you specified in thumbnail MaxWidth or MaxHeight settings and matches or exceeds the other value. Elastic Transcoder centers the image in thumbnails and then crops in the dimension (if any) that exceeds the maximum value.
  * **Stretch**: Elastic Transcoder stretches thumbnails to match the values that you specified for thumbnail MaxWidth and MaxHeight settings. If the relative proportions of the input video and thumbnails are different, the thumbnails will be distorted.
  * **Keep**: Elastic Transcoder does not scale thumbnails. If either dimension of the input video exceeds the values that you specified for thumbnail MaxWidth and MaxHeight settings, Elastic Transcoder crops the thumbnails.
* **ShrinkToFit**: Elastic Transcoder scales thumbnails down so that their dimensions match the values that you specified for at least one of thumbnail `MaxWidth` and `MaxHeight` without exceeding either value. If you specify this option, Elastic Transcoder does not scale thumbnails up.

* **ShrinkToFill**: Elastic Transcoder scales thumbnails down so that their dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without dropping below either value. If you specify this option, Elastic Transcoder does not scale thumbnails up.

– **PaddingPolicy** *(string)* –

When you set `PaddingPolicy` to `Pad`, Elastic Transcoder may add black bars to the top and bottom and/or left and right sides of thumbnails to make the total size of the thumbnails match the values that you specified for thumbnail `MaxWidth` and `MaxHeight` settings.

**Return type** `dict`

**Returns**

Response Structure

• (dict) –

The CreatePresetResponse structure.

– Preset (dict) –

A section of the response body that provides information about the preset that is created.

• **Id** (string) –

  Identifier for the new preset. You use this value to get settings for the preset or to delete it.

• **Arn** (string) –

  The Amazon Resource Name (ARN) for the preset.

• **Name** (string) –

  The name of the preset.

• **Description** (string) –

  A description of the preset.

• **Container** (string) –

  The container type for the output file. Valid values include flac, flv, fmp4, gif, mp3, mp4, mpg, mxf, oga, ogg, ts, and webm.

• **Audio** (dict) –

  A section of the response body that provides information about the audio preset values.
- **Codec (string)** –
  The audio codec for the output file. Valid values include `aac`, `flac`, `mp2`, `mp3`, `pcm`, and `vorbis`.

- **SampleRate (string)** –
  The sample rate of the audio stream in the output file, in Hertz. Valid values include:
  
  `auto`, `22050`, `32000`, `44100`, `48000`, `96000`
  
  If you specify `auto`, Elastic Transcoder automatically detects the sample rate.

- **BitRate (string)** –
  The bit rate of the audio stream in the output file, in kilo-bits/second. Enter an integer between 64 and 320, inclusive.

- **Channels (string)** –
  The number of audio channels in the output file. The following values are valid:
  
  `auto`, `0`, `1`, `2`
  
  One channel carries the information played by a single speaker. For example, a stereo track with two channels sends one channel to the left speaker, and the other channel to the right speaker. The output channels are organized into tracks. If you want Elastic Transcoder to automatically detect the number of audio channels in the input file and use that value for the output file, select `auto`.

  The output of a specific channel value and inputs are as follows:
  
  - **auto channel specified, with any input**: Pass through up to eight input channels.
  - **0 channels specified, with any input**: Audio omitted from the output.
  - **1 channel specified, with at least one input channel**: Mono sound.
  - **2 channels specified, with any input**: Two identical mono channels or stereo. For more information about tracks, see `Audio:AudioPackingMode`.

- **AudioPackingMode (string)** –
  The method of organizing audio channels and tracks. Use `Audio:Channels` to specify the number of channels in your output, and `Audio:AudioPackingMode` to specify the number of tracks and their relation to the channels. If you do not specify an `Audio:AudioPackingMode`, Elastic Transcoder uses `SingleTrack`.

  The following values are valid:
  
  `SingleTrack`, `OneChannelPerTrack`, and `OneChannelPerTrackWithMosTo8Tracks`
When you specify `SingleTrack`, Elastic Transcoder creates a single track for your output. The track can have up to eight channels. Use `SingleTrack` for all non-mxf containers.

The outputs of `SingleTrack` for a specific channel value and inputs are as follows:

- **0 channels with any input**: Audio omitted from the output
- **1, 2, or auto channels with no audio input**: Audio omitted from the output
- **1 channel with any input with audio**: One track with one channel, downmixed if necessary
- **2 channels with one track with one channel**: One track with two identical channels
- **2 or auto channels with two tracks with one channel each**: One track with two channels
- **2 or auto channels with one track with two channels**: One track with two channels
- **2 channels with one track with multiple channels**: One track with two channels
- **auto channels with one track with one channel**: One track with one channel
- **auto channels with one track with multiple channels**: One track with multiple channels

When you specify `OneChannelPerTrack`, Elastic Transcoder creates a new track for every channel in your output. Your output can have up to eight single-channel tracks.

The outputs of `OneChannelPerTrack` for a specific channel value and inputs are as follows:

- **0 channels with any input**: Audio omitted from the output
- **1, 2, or auto channels with no audio input**: Audio omitted from the output
- **1 channel with any input with audio**: One track with one channel, downmixed if necessary
- **2 channels with one track with one channel**: Two tracks with one identical channel each
- **2 or auto channels with two tracks with one channel each**: Two tracks with one channel each
- **2 or auto channels with one track with two channels**: Two tracks with one channel each
- **2 channels with one track with multiple channels**: Two tracks with one channel each
- **auto channels with one track with one channel**: One track with one channel
- **auto channels with one track with multiple channels**: Up to eight tracks with one channel each

When you specify `OneChannelPerTrackWithMosTo8Tracks`, Elastic Transcoder creates eight single-channel tracks for your output. All tracks that do not contain audio data from an input channel are MOS, or Mit Out Sound, tracks.

The outputs of `OneChannelPerTrackWithMosTo8Tracks` for a specific channel value and inputs are as follows:

- **0 channels with any input**: Audio omitted from the output
· **1, 2, or auto channels with no audio input**: Audio omitted from the output
· **1 channel with any input with audio**: One track with one channel, downmixed if necessary, plus six MOS tracks
· **2 channels with one track with one channel**: Two tracks with one identical channel each, plus six MOS tracks
· **2 or auto channels with two tracks with one channel each**: Two tracks with one channel each, plus six MOS tracks
· **2 or auto channels with one track with two channels**: Two tracks with one channel each, plus six MOS tracks
· **2 channels with one track with multiple channels**: Two tracks with one channel each, plus six MOS tracks
· **auto channels with one track with one channel**: One track with one channel, plus seven MOS tracks
· **auto channels with one track with multiple channels**: Up to eight tracks with one channel each, plus MOS tracks until there are eight tracks in all

**CodecOptions (dict)** –

If you specified AAC for Audio:Codec, this is the AAC compression profile to use. Valid values include:
- **auto**, **AAC-LC**, **HE-AAC**, **HE-AACv2**

If you specify **auto**, Elastic Transcoder chooses a profile based on the bit rate of the output file.

**Profile (string)** –

You can only choose an audio profile when you specify AAC for the value of Audio:Codec.

Specify the AAC profile for the output file. Elastic Transcoder supports the following profiles:
- **auto**: If you specify **auto**, Elastic Transcoder will select the profile based on the bit rate selected for the output file.
- **AAC-LC**: The most common AAC profile. Use for bit rates larger than 64 kbps.
- **HE-AAC**: Not supported on some older players and devices. Use for bit rates between 40 and 80 kbps.
- **HE-AACv2**: Not supported on some players and devices. Use for bit rates less than 48 kbps.

All outputs in a Smooth playlist must have the same value for **Profile**.

**Note**: If you created any presets before AAC profiles were added, Elastic Transcoder automatically updated your presets to use AAC-LC. You can change the value as required.

**BitDepth (string)** –

You can only choose an audio bit depth when you specify **flac** or **pcm** for the value of Audio:Codec.

The bit depth of a sample is how many bits of information are included in the audio samples. The higher the bit depth, the better the audio, but the larger the file.

Valid values are **16** and **24**.
The most common bit depth is 24.

- **BitOrder (string)** –
  You can only choose an audio bit order when you specify pcm for the value of Audio:Codec.
  The order the bits of a PCM sample are stored in.
  The supported value is LittleEndian.

- **Signed (string)** –
  You can only choose whether an audio sample is signed when you specify pcm for the value of Audio:Codec.
  Whether audio samples are represented with negative and positive numbers (signed) or only positive numbers (unsigned).
  The supported value is Signed.

* **Video (dict)** –
  A section of the response body that provides information about the video preset values.
  - **Codec (string)** –
    The video codec for the output file. Valid values include gif, H.264, mpeg2, and vp8. You can only specify vp8 when the container type is webm, gif when the container type is gif, and mpeg2 when the container type is mpg.
  - **CodecOptions (dict)** –
    - **Profile (H.264/VP8 Only)**
      The H.264 profile that you want to use for the output file. Elastic Transcoder supports the following profiles:
      - **baseline**: The profile most commonly used for videoconferencing and for mobile applications.
      - **main**: The profile used for standard-definition digital TV broadcasts.
      - **high**: The profile used for high-definition digital TV broadcasts and for Blu-ray discs.
    - **Level (H.264 Only)**
      The H.264 level that you want to use for the output file. Elastic Transcoder supports the following levels:
      1, 1b, 1.1, 1.2, 1.3, 2, 2.1, 2.2, 3, 3.1, 3.2, 4, 4.1

  - **MaxReferenceFrames (H.264 Only)**
    Applicable only when the value of Video:Codec is H.264.
    The maximum number of previously decoded frames to use as a reference for decoding future frames. Valid values are integers 0 through 16, but we recommend that you not use a value greater than the following:
    \[
    \text{Min}(\text{Floor}(\text{Maximum decoded picture buffer in macroblocks} \times 256 / (\text{Width in pixels} \times \text{Height in pixels})), 16)
    \]
    where \text{Width in pixels} and \text{Height in pixels} represent either MaxWidth and MaxHeight, or Resolution.
coded picture buffer in macroblocks depends on the value of the Level object. See the list below. (A macroblock is a block of pixels measuring 16x16.)

- 1 - 396
- 1b - 396
- 1.1 - 900
- 1.2 - 2376
- 1.3 - 2376
- 2 - 2376
- 2.1 - 4752
- 2.2 - 8100
- 3 - 8100
- 3.1 - 18000
- 3.2 - 20480
- 4 - 32768
- 4.1 - 32768

MaxBitRate (Optional, H.264/MPEG2/VP8 only)
The maximum number of bits per second in a video buffer; the size of the buffer is specified by BufferSize. Specify a value between 16 and 62,500. You can reduce the bandwidth required to stream a video by reducing the maximum bit rate, but this also reduces the quality of the video.

BufferSize (Optional, H.264/MPEG2/VP8 only)
The maximum number of bits in any x seconds of the output video. This window is commonly 10 seconds, the standard segment duration when you’re using FMP4 or MPEG-TS for the container type of the output video. Specify an integer greater than 0. If you specify MaxBitRate and omit BufferSize, Elastic Transcoder sets BufferSize to 10 times the value of MaxBitRate.

InterlacedMode (Optional, H.264/MPEG2 Only)
The interlace mode for the output video.

Interlaced video is used to double the perceived frame rate for a video by interlacing two fields (one field on every other line, the other field on the other lines) so that the human eye registers multiple pictures per frame. Interlacing reduces the bandwidth required for transmitting a video, but can result in blurred images and flickering.

Valid values include Progressive (no interlacing, top to bottom), TopFirst (top field first), BottomFirst (bottom field first), and Auto.

If InterlaceMode is not specified, Elastic Transcoder uses Progressive for the output. If Auto is specified, Elastic Transcoder interlaces the output.

ColorSpaceConversionMode (Optional, H.264/MPEG2 Only)
The color space conversion Elastic Transcoder applies to the output video. Color spaces are the algorithms used by the
computer to store information about how to render color. Bt.601 is the standard for standard definition video, while Bt.709 is the standard for high definition video.

Valid values include None, Bt709toBt601, Bt601toBt709, and Auto.

If you chose Auto for ColorSpaceConversionMode and your output is interlaced, your frame rate is one of 23.97, 24, 25, 29.97, 50, or 60, your SegmentDuration is null, and you are using one of the resolution changes from the list below, Elastic Transcoder applies the following color space conversions:

- Standard to HD, 720x480 to 1920x1080 - Elastic Transcoder applies Bt601ToBt709
- Standard to HD, 720x576 to 1920x1080 - Elastic Transcoder applies Bt601ToBt709
- HD to Standard, 1920x1080 to 720x480 - Elastic Transcoder applies Bt709ToBt601
- HD to Standard, 1920x1080 to 720x576 - Elastic Transcoder applies Bt709ToBt601

Note: Elastic Transcoder may change the behavior of the ColorSpaceConversionMode Auto mode in the future. All outputs in a playlist must use the same ColorSpaceConversionMode.

If you do not specify a ColorSpaceConversionMode, Elastic Transcoder does not change the color space of a file. If you are unsure what ColorSpaceConversionMode was applied to your output file, you can check the AppliedColorSpaceConversion parameter included in your job response. If your job does not have an AppliedColorSpaceConversion in its response, no ColorSpaceConversionMode was applied.

ChromaSubsampling
The sampling pattern for the chroma (color) channels of the output video. Valid values include yuv420p and yuv422p.

- yuv420p samples the chroma information of every other horizontal and every other vertical line, yuv422p samples the color information of every horizontal line and every other vertical line.

LoopCount (Gif Only)
The number of times you want the output gif to loop. Valid values include Infinite and integers between 0 and 100, inclusive.

- (string) –
- (string) –

- KeyframesMaxDist (string) –

Applicable only when the value of Video:Codec is one of H.264, MPEG2, or VP8.

The maximum number of frames between key frames. Key frames are fully encoded frames; the frames between key
frames are encoded based, in part, on the content of the key frames. The value is an integer formatted as a string; valid values are between 1 (every frame is a key frame) and 100000, inclusive. A higher value results in higher compression but may also discernibly decrease video quality.

For Smooth outputs, the FrameRate must have a constant ratio to the KeyframesMaxDist. This allows Smooth playlists to switch between different quality levels while the file is being played.

For example, an input file can have a FrameRate of 30 with a KeyframesMaxDist of 90. The output file then needs to have a ratio of 1:3. Valid outputs would have FrameRate of 30, 25, and 10, and KeyframesMaxDist of 90, 75, and 30, respectively.

Alternately, this can be achieved by setting FrameRate to auto and having the same values for MaxFrameRate and KeyframesMaxDist.

- **FixedGOP (string)** –

  Applicable only when the value of Video:Codec is one of H.264, MPEG2, or VP8.

  Whether to use a fixed value for FixedGOP. Valid values are true and false:
  - true: Elastic Transcoder uses the value of KeyframesMaxDist for the distance between key frames (the number of frames in a group of pictures, or GOP).
  - false: The distance between key frames can vary.

  **Warning:** FixedGOP must be set to true for fmp4 containers.

- **BitRate (string)** –

  The bit rate of the video stream in the output file, in kilo-bits/second. Valid values depend on the values of Level and Profile. If you specify auto, Elastic Transcoder uses the detected bit rate of the input source. If you specify a value other than auto, we recommend that you specify a value less than or equal to the maximum H.264-compliant value listed for your level and profile:

  - Level - Maximum video bit rate in kilobits/second
  - (baseline and main Profile): maximum video bit rate in kilobits/second (high Profile)

  - 1 - 64 : 80
  - 1b - 128 : 160
  - 1.1 - 192 : 240
  - 1.2 - 384 : 480
  - 1.3 - 768 : 960
  - 2 - 2000 : 2500
  - 3 - 10000 : 12500
  - 3.1 - 14000 : 17500
  - 3.2 - 20000 : 25000
  - 4 - 20000 : 25000
4.1 - 50000 : 62500

FrameRate (string) –

The frames per second for the video stream in the output file. Valid values include:

auto, 10, 15, 23.97, 24, 25, 29.97, 30, 60

If you specify auto, Elastic Transcoder uses the detected frame rate of the input source. If you specify a frame rate, we recommend that you perform the following calculation:

\[
\text{Frame rate} = \frac{\text{maximum recommended decoding speed in luma samples/second}}{\text{width in pixels} \times \text{height in pixels}}
\]

where:

- width in pixels and height in pixels represent the Resolution of the output video.
- maximum recommended decoding speed in Luma samples/second is less than or equal to the maximum value listed in the following table, based on the value that you specified for Level.

The maximum recommended decoding speed in Luma samples/second for each level is described in the following list (Level - Decoding speed):

<table>
<thead>
<tr>
<th>Level</th>
<th>Decoding speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>380160</td>
</tr>
<tr>
<td>1b</td>
<td>380160</td>
</tr>
<tr>

<tr>
<td>4</td>
<td>62914560</td>
</tr>
<tr>
<td>4.1</td>
<td>62914560</td>
</tr>
</tbody>
</table>

MaxFrameRate (string) –

If you specify auto for FrameRate, Elastic Transcoder uses the frame rate of the input video for the frame rate of the output video. Specify the maximum frame rate that you want Elastic Transcoder to use when the frame rate of the input video is greater than the desired maximum frame rate of the output video. Valid values include: 10, 15, 23.97, 24, 25, 29.97, 30, 60.

Resolution (string) –

Warning: To better control resolution and aspect ratio of output videos, we recommend that you use the values MaxWidth, MaxHeight, SizingPolicy, PaddingPolicy, and DisplayAspectRatio instead of Resolution and AspectRatio. The two groups of settings are mutually exclusive. Do not use them together.
The width and height of the video in the output file, in pixels. Valid values are `auto` and `width x height`:
- `auto`: Elastic Transcoder attempts to preserve the width and height of the input file, subject to the following rules.
- `width x height`: The width and height of the output video in pixels.

Note the following about specifying the width and height:
- The width must be an even integer between 128 and 4096, inclusive.
- The height must be an even integer between 96 and 3072, inclusive.
- If you specify a resolution that is less than the resolution of the input file, Elastic Transcoder rescales the output file to the lower resolution.
- If you specify a resolution that is greater than the resolution of the input file, Elastic Transcoder rescales the output to the higher resolution.
- We recommend that you specify a resolution for which the product of width and height is less than or equal to the applicable value in the following list (List - Max width x height value):
  - 1 - 25344
  - 1b - 25344
  - 1.1 - 101376
  - 1.2 - 101376
  - 1.3 - 101376
  - 2 - 101376
  - 2.1 - 202752
  - 2.2 - 404720
  - 3 - 404720
  - 3.1 - 921600
  - 3.2 - 1310720
  - 4 - 2097152
  - 4.1 - 2097152

- `AspectRatio (string)` —

**Warning**: To better control resolution and aspect ratio of output videos, we recommend that you use the values `MaxWidth`, `MaxHeight`, `SizingPolicy`, `PaddingPolicy`, and `DisplayAspectRatio` instead of `Resolution` and `AspectRatio`. The two groups of settings are mutually exclusive. Do not use them together.

The display aspect ratio of the video in the output file. Valid values include:

- `auto`, `1:1`, `4:3`, `3:2`, `16:9`

If you specify `auto`, Elastic Transcoder tries to preserve the aspect ratio of the input file.

If you specify an aspect ratio for the output file that differs from aspect ratio of the input file, Elastic Transcoder adds
pillarboxing (black bars on the sides) or letterboxing (black bars on the top and bottom) to maintain the aspect ratio of the active region of the video.

- **MaxWidth (string)** –
  
The maximum width of the output video in pixels. If you specify `auto`, Elastic Transcoder uses 1920 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 128 and 4096.

- **MaxHeight (string)** –
  
The maximum height of the output video in pixels. If you specify `auto`, Elastic Transcoder uses 1080 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 96 and 3072.

- **DisplayAspectRatio (string)** –
  
The value that Elastic Transcoder adds to the metadata in the output file.

- **SizingPolicy (string)** –
  
Specify one of the following values to control scaling of the output video:

  - **Fit**: Elastic Transcoder scales the output video so it matches the value that you specified in either `MaxWidth` or `MaxHeight` without exceeding the other value.
  
  - **Fill**: Elastic Transcoder scales the output video so it matches the value that you specified in either `MaxWidth` or `MaxHeight` and matches or exceeds the other value. Elastic Transcoder centers the output video and then crops it in the dimension (if any) that exceeds the maximum value.
  
  - **Stretch**: Elastic Transcoder stretches the output video to match the values that you specified for `MaxWidth` and `MaxHeight`. If the relative proportions of the input video and the output video are different, the output video will be distorted.
  
  - **Keep**: Elastic Transcoder does not scale the output video. If either dimension of the input video exceeds the values that you specified for `MaxWidth` and `MaxHeight`, Elastic Transcoder crops the output video.
  
  - **ShrinkToFit**: Elastic Transcoder scales the output video down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without exceeding either value. If you specify this option, Elastic Transcoder does not scale the video up.
  
  - **ShrinkToFill**: Elastic Transcoder scales the output video down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without dropping below either value. If you specify this option, Elastic Transcoder does not scale the video up.

- **PaddingPolicy (string)** –
  
When you set **PaddingPolicy** to **Pad**, Elastic Transcoder may add black bars to the top and bottom and/or left and right sides of the output video to make the total size of the output video match the values that you specified for `MaxWidth` and `MaxHeight`.
· **Watermarks** *(list)* –

Settings for the size, location, and opacity of graphics that you want Elastic Transcoder to overlay over videos that are transcoded using this preset. You can specify settings for up to four watermarks. Watermarks appear in the specified size and location, and with the specified opacity for the duration of the transcoded video.

Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

When you create a job that uses this preset, you specify the .png or .jpg graphics that you want Elastic Transcoder to include in the transcoded videos. You can specify fewer graphics in the job than you specify watermark settings in the preset, which allows you to use the same preset for up to four watermarks that have different dimensions.

· *(dict)* –

Settings for the size, location, and opacity of graphics that you want Elastic Transcoder to overlay over videos that are transcoded using this preset. You can specify settings for up to four watermarks. Watermarks appear in the specified size and location, and with the specified opacity for the duration of the transcoded video.

Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

When you create a job that uses this preset, you specify the .png or .jpg graphics that you want Elastic Transcoder to include in the transcoded videos. You can specify fewer graphics in the job than you specify watermark settings in the preset, which allows you to use the same preset for up to four watermarks that have different dimensions.

· **Id** *(string)* – A unique identifier for the settings for one watermark. The value of Id can be up to 40 characters long.

· **MaxWidth** *(string)* –

The maximum width of the watermark in one of the following formats:

- number of pixels (px): The minimum value is 16 pixels, and the maximum value is the value of MaxWidth.
- integer percentage (%): The range of valid values is 0 to 100. Use the value of Target to specify whether you want Elastic Transcoder to include the black bars that are added by Elastic Transcoder, if any, in the calculation. If you specify the value in pixels, it must be less than or equal to the value of MaxWidth.

· **MaxHeight** *(string)* –

The maximum height of the watermark in one of the following formats:
- number of pixels (px): The minimum value is 16 pixels, and the maximum value is the value of MaxHeight.
- integer percentage (%): The range of valid values is 0 to 100. Use the value of Target to specify whether you want Elastic Transcoder to include the black bars that are added by Elastic Transcoder, if any, in the calculation.
  If you specify the value in pixels, it must be less than or equal to the value of MaxHeight.
- **SizingPolicy** (string) –
  A value that controls scaling of the watermark:
  - **Fit**: Elastic Transcoder scales the watermark so it matches the value that you specified in either MaxWidth or MaxHeight without exceeding the other value.
  - **Stretch**: Elastic Transcoder stretches the watermark to match the values that you specified for MaxWidth and MaxHeight. If the relative proportions of the watermark and the values of MaxWidth and MaxHeight are different, the watermark will be distorted.
  - **ShrinkToFit**: Elastic Transcoder scales the watermark down so that its dimensions match the values that you specified for at least one of MaxWidth and MaxHeight without exceeding either value. If you specify this option, Elastic Transcoder does not scale the watermark up.
  - **HorizontalAlign** (string) –
    The horizontal position of the watermark unless you specify a non-zero value for HorizontalOffset:
    - **Left**: The left edge of the watermark is aligned with the left border of the video.
    - **Right**: The right edge of the watermark is aligned with the right border of the video.
    - **Center**: The watermark is centered between the left and right borders.
  - **HorizontalOffset** (string) –
    The amount by which you want the horizontal position of the watermark to be offset from the position specified by HorizontalAlign:
    - number of pixels (px): The minimum value is 0 pixels, and the maximum value is the value of MaxWidth.
    - integer percentage (%): The range of valid values is 0 to 100. For example, if you specify Left for HorizontalAlign and 5px for HorizontalOffset, the left side of the watermark appears 5 pixels from the left border of the output video.

HorizontalOffset is only valid when the value of HorizontalAlign is Left or Right. If you specify an offset that causes the watermark to extend beyond the left or right border and Elastic Transcoder has not added black bars, the watermark is cropped. If Elastic Transcoder has added black bars, the watermark extends into the black bars. If the watermark extends beyond the black bars, it is cropped.

Use the value of Target to specify whether you want to in-
 include the black bars that are added by Elastic Transcoder, if any, in the offset calculation.

- **VerticalAlign (string)**

  The vertical position of the watermark unless you specify a non-zero value for VerticalOffset:
  - **Top**: The top edge of the watermark is aligned with the top border of the video.
  - **Bottom**: The bottom edge of the watermark is aligned with the bottom border of the video.
  - **Center**: The watermark is centered between the top and bottom borders.
  - **VerticalOffset (string)** – VerticalOffset

  The amount by which you want the vertical position of the watermark to be offset from the position specified by VerticalAlign:
  - number of pixels (px): The minimum value is 0 pixels, and the maximum value is the value of MaxHeight.
  - integer percentage (%): The range of valid values is 0 to 100. For example, if you specify Top for VerticalAlign and 5px for VerticalOffset, the top of the watermark appears 5 pixels from the top border of the output video.

  VerticalOffset is only valid when the value of VerticalAlign is Top or Bottom.

  If you specify an offset that causes the watermark to extend beyond the top or bottom border and Elastic Transcoder has not added black bars, the watermark is cropped. If Elastic Transcoder has added black bars, the watermark extends into the black bars. If the watermark extends beyond the black bars, it is cropped.

  Use the value of Target to specify whether you want Elastic Transcoder to include the black bars that are added by Elastic Transcoder, if any, in the offset calculation.

- **Opacity (string)**

  A percentage that indicates how much you want a watermark to obscure the video in the location where it appears. Valid values are 0 (the watermark is invisible) to 100 (the watermark completely obscures the video in the specified location). The datatype of Opacity is float.

  Elastic Transcoder supports transparent .png graphics. If you use a transparent .png, the transparent portion of the video appears as if you had specified a value of 0 for Opacity. The .jpg file format doesn’t support transparency.

- **Target (string)**

  A value that determines how Elastic Transcoder interprets values that you specified for HorizontalOffset, VerticalOffset, MaxWidth, and MaxHeight:
  - **Content**: HorizontalOffset and VerticalOffset values are calculated based on the borders of the video excluding black bars added by Elastic Transcoder, if any. In addition, MaxWidth and MaxHeight, if specified as a per-
percentage, are calculated based on the borders of the video excluding black bars added by Elastic Transcoder, if any.

- **Frame**: HorizontalOffset and VerticalOffset values are calculated based on the borders of the video including black bars added by Elastic Transcoder, if any. In addition, MaxWidth and MaxHeight, if specified as a percentage, are calculated based on the borders of the video including black bars added by Elastic Transcoder, if any.

* **Thumbnails** *(dict)* –

A section of the response body that provides information about the thumbnail preset values, if any.

- **Format** *(string)* –

The format of thumbnails, if any. Valid values are jpg and png.

You specify whether you want Elastic Transcoder to create thumbnails when you create a job.

- **Interval** *(string)* –

The approximate number of seconds between thumbnails. Specify an integer value.

- **Resolution** *(string)* –

  **Warning**: To better control resolution and aspect ratio of thumbnails, we recommend that you use the values MaxWidth, MaxHeight, SizingPolicy, and PaddingPolicy instead of Resolution and AspectRatio. The two groups of settings are mutually exclusive. Do not use them together.

The width and height of thumbnail files in pixels. Specify a value in the format \*width\* x \*height\* where both values are even integers. The values cannot exceed the width and height that you specified in the Video:Resolution object.

- **AspectRatio** *(string)* –

  **Warning**: To better control resolution and aspect ratio of thumbnails, we recommend that you use the values MaxWidth, MaxHeight, SizingPolicy, and PaddingPolicy instead of Resolution and AspectRatio. The two groups of settings are mutually exclusive. Do not use them together.

The aspect ratio of thumbnails. Valid values include:

auto, 1:1, 4:3, 3:2, 16:9

If you specify auto, Elastic Transcoder tries to preserve the aspect ratio of the video in the output file.

- **MaxWidth** *(string)* –

The maximum width of thumbnails in pixels. If you specify auto, Elastic Transcoder uses 1920 (Full HD) as the default
value. If you specify a numeric value, enter an even integer between 32 and 4096.

- **MaxHeight (string)** –
  
  The maximum height of thumbnails in pixels. If you specify auto, Elastic Transcoder uses 1080 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 32 and 3072.

- **SizingPolicy (string)** –
  
  Specify one of the following values to control scaling of thumbnails:
  - **Fit**: Elastic Transcoder scales thumbnails so they match the value that you specified in thumbnail MaxWidth or MaxHeight settings without exceeding the other value.
  - **Fill**: Elastic Transcoder scales thumbnails so they match the value that you specified in thumbnail MaxWidth or MaxHeight settings and matches or exceeds the other value. Elastic Transcoder centers the image in thumbnails and then crops in the dimension (if any) that exceeds the maximum value.
  - **Stretch**: Elastic Transcoder stretches thumbnails to match the values that you specified for thumbnail MaxWidth and MaxHeight settings. If the relative proportions of the input video and thumbnails are different, the thumbnails will be distorted.
  - **Keep**: Elastic Transcoder does not scale thumbnails. If either dimension of the input video exceeds the values that you specified for thumbnail MaxWidth and MaxHeight settings, Elastic Transcoder crops the thumbnails.
  - **ShrinkToFit**: Elastic Transcoder scales thumbnails down so that their dimensions match the values that you specified for at least one of thumbnail MaxWidth and MaxHeight without exceeding either value. If you specify this option, Elastic Transcoder does not scale thumbnails up.
  - **ShrinkToFill**: Elastic Transcoder scales thumbnails down so that their dimensions match the values that you specified for at least one of MaxWidth and MaxHeight without dropping below either value. If you specify this option, Elastic Transcoder does not scale thumbnails up.

- **PaddingPolicy (string)** –
  
  When you set PaddingPolicy to Pad, Elastic Transcoder may add black bars to the top and bottom and/or left and right sides of thumbnails to make the total size of the thumbnails match the values that you specified for thumbnail MaxWidth and MaxHeight settings.

- **Type (string)** –
  
  Whether the preset is a default preset provided by Elastic Transcoder (System) or a preset that you have defined (Custom).

- **Warning (string)** –
  
  If the preset settings don’t comply with the standards for the video codec but Elastic Transcoder created the preset, this message explains the reason the preset settings don’t meet the standard. Elastic Transcoder created the
preset because the settings might produce acceptable output.

```python
def delete_pipeline(**kwargs):
    """The DeletePipeline operation removes a pipeline."
    You can only delete a pipeline that has never been used or that is not currently in use (doesn’t contain any active jobs). If the pipeline is currently in use, DeletePipeline returns an error.

    Request Syntax

    response = client.delete_pipeline(
        Id='string'
    )

    Parameters  Id (string) – [REQUIRED]
    The identifier of the pipeline that you want to delete.
    Return type  dict
    Returns

    Response Syntax

    {}

    Response Structure
    • (dict) –
        The DeletePipelineResponse structure.
```

```python
def delete_preset(**kwargs):
    """The DeletePreset operation removes a preset that you’ve added in an AWS region.
    Note: You can’t delete the default presets that are included with Elastic Transcoder.

    Request Syntax

    response = client.delete_preset(
        Id='string'
    )

    Parameters  Id (string) – [REQUIRED]
    The identifier of the preset for which you want to get detailed information.
    Return type  dict
    Returns

    Response Syntax

    {}

    Response Structure
    • (dict) –
        The DeletePresetResponse structure.
```

```python
def generate_presigned_url(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None):
    """Generate a presigned url given a client, its method, and arguments

    Parameters
    • ClientMethod (string) – The client method to presign for
    • Params (dict) – The parameters normally passed to ClientMethod.
```

3.1. Services
ExpiresIn (int) – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)

HttpMethod (string) – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns The presigned url

get_paginator (operation_name)
Create a paginator for an operation.

Parameters operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

Raises OperationNotPageableError Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

Return type L{botocore.paginate.Paginator}

Returns A paginator object.

get_waiter (waiter_name)

list_jobs_by_pipeline (**kwargs)
The ListJobsByPipeline operation gets a list of the jobs currently in a pipeline.

Elastic Transcoder returns all of the jobs currently in the specified pipeline. The response body contains one element for each job that satisfies the search criteria.

Request Syntax

response = client.list_jobs_by_pipeline(
    PipelineId='string',
    Ascending='string',
    PageToken='string'
)

Parameters

- PipelineId (string) – [REQUIRED]
  The ID of the pipeline for which you want to get job information.
- Ascending (string) – To list jobs in chronological order by the date and time that they were submitted, enter true. To list jobs in reverse chronological order, enter false.
- PageToken (string) – When Elastic Transcoder returns more than one page of results, use pageToken in subsequent GET requests to get each successive page of results.

Return type dict

Returns

Response Structure

- (dict) –

The `ListJobsByPipelineResponse` structure.

- Jobs (list) –

  An array of Job objects that are in the specified pipeline.

  - (dict) –

    A section of the response body that provides information about the job that is created.

    - Id (string) –

      The identifier that Elastic Transcoder assigned to the job. You use this value to get settings for the job or to delete the job.

    - Arn (string) –

      The Amazon Resource Name (ARN) for the job.

    - PipelineId (string) –

      The Id of the pipeline that you want Elastic Transcoder to use for transcoding. The pipeline determines several settings, including the Amazon S3 bucket from which Elastic Transcoder gets the files to transcode and the bucket into which Elastic Transcoder puts the transcoded files.

    - Input (dict) –

      A section of the request or response body that provides information about the file that is being transcoded.

      - Key (string) –

        The name of the file to transcode. Elsewhere in the body of the JSON block is the ID of the pipeline to use for processing the job. The InputBucket object in that pipeline tells Elastic Transcoder which Amazon S3 bucket to get the file from.
If the file name includes a prefix, such as `cooking/lasagna.mpg`, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **FrameRate** *(string)* –
  The frame rate of the input file. If you want Elastic Transcoder to automatically detect the frame rate of the input file, specify `auto`. If you want to specify the frame rate for the input file, enter one of the following values:
  
  - 10, 15, 23.97, 24, 25, 29.97, 30, 60
  
  If you specify a value other than `auto`, Elastic Transcoder disables automatic detection of the frame rate.

- **Resolution** *(string)* –
  This value must be `auto`, which causes Elastic Transcoder to automatically detect the resolution of the input file.

- **AspectRatio** *(string)* –
  The aspect ratio of the input file. If you want Elastic Transcoder to automatically detect the aspect ratio of the input file, specify `auto`. If you want to specify the aspect ratio for the output file, enter one of the following values:
  
  - 1:1, 4:3, 3:2, 16:9
  
  If you specify a value other than `auto`, Elastic Transcoder disables automatic detection of the aspect ratio.

- **Interlaced** *(string)* –
  Whether the input file is interlaced. If you want Elastic Transcoder to automatically detect whether the input file is interlaced, specify `auto`. If you want to specify whether the input file is interlaced, enter one of the following values:
  
  - true, false
  
  If you specify a value other than `auto`, Elastic Transcoder disables automatic detection of interlacing.

- **Container** *(string)* –
  The container type for the input file. If you want Elastic Transcoder to automatically detect the container type of the input file, specify `auto`. If you want to specify the container type for the input file, enter one of the following values:
  
  - 3gp, aac, asf, avi, divx, flv, m4a, mkv, mov, mp3, mp4, mpeg, mpeg-ps, mpeg-ts, mxf, ogg, vob, wav, webm

- **Encryption** *(dict)* –
  The encryption settings, if any, that are used for decrypting your input files. If your input file is encrypted, you must specify the mode that Elastic Transcoder will use to decrypt your file.

- **Mode** *(string)* –
  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
- **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
- **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –
  
The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –
  
The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –
  
The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **DetectedProperties** *(dict)* –
  
The detected properties of the input file.

- **Width** *(integer)* –
The detected width of the input file, in pixels.

- **Height (integer)** –
  The detected height of the input file, in pixels.

- **FrameRate (string)** –
  The detected frame rate of the input file, in frames per second.

- **FileSize (integer)** –
  The detected file size of the input file, in bytes.

- **DurationMillis (integer)** –
  The detected duration of the input file, in milliseconds.

- **Output (dict)** –
  If you specified one output for a job, information about that output. If you specified multiple outputs for a job, the Output object lists information about the first output. This duplicates the information that is listed for the first output in the Outputs object.

  **Warning:** Outputs recommended instead.

A section of the request or response body that provides information about the transcoded (target) file.

- **Id (string)** –
  A sequential counter, starting with 1, that identifies an output among the outputs from the current job. In the Output syntax, this value is always 1.

- **Key (string)** –
  The name to assign to the transcoded file. Elastic Transcoder saves the file in the Amazon S3 bucket specified by the `OutputBucket` object in the pipeline that is specified by the pipeline ID.

- **ThumbnailPattern (string)** –
  Whether you want Elastic Transcoder to create thumbnails for your videos and, if so, how you want Elastic Transcoder to name the files.

  If you don’t want Elastic Transcoder to create thumbnails, specify "".

  If you do want Elastic Transcoder to create thumbnails, specify the information that you want to include in the file name for each thumbnail. You can specify the following values in any sequence:

  - **"{count}" (Required)**: If you want to create thumbnails, you must include `{count}` in the ThumbnailPattern object. Wherever you specify `{count}`, Elastic Transcoder adds a five-digit sequence number (beginning with 00001) to thumbnail file names. The number indicates where a given thumbnail appears in the sequence of thumbnails for a transcoded file. .. warning::If you specify a literal value and/or `{resolution}` but you omit `{count}`, Elastic
Transcoder returns a validation error and does not create the job.

- **Literal values (Optional)**: You can specify literal values anywhere in the ThumbnailPattern object. For example, you can include them as a file name prefix or as a delimiter between \{resolution\} and \{count\}.
- \"\{resolution\}\" (Optional): If you want Elastic Transcoder to include the resolution in the file name, include \{resolution\} in the ThumbnailPattern object.

When creating thumbnails, Elastic Transcoder automatically saves the files in the format (.jpg or .png) that appears in the preset that you specified in the PresetID value of CreateJobOutput. Elastic Transcoder also appends the applicable file name extension.

- **ThumbnailEncryption (dict)** –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your thumbnail.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-
encoded: 128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Rotate (string)** –

  The number of degrees clockwise by which you want Elastic Transcoder to rotate the output relative to the input. Enter one of the following values:

  auto, 0, 90, 180, 270

  The value auto generally works only if the file that you’re transcoding contains rotation metadata.

- **PresetId (string)** –

  The value of the Id object for the preset that you want to use for this job. The preset determines the audio, video, and thumbnail settings that Elastic Transcoder uses for transcoding. To use a preset that you created, specify the preset ID that Elastic Transcoder returned in the response when you created the preset. You can also use the Elastic Transcoder system presets, which you can get with ListPresets.

- **SegmentDuration (string)** –

  Warning: (Outputs in Fragmented MP4 or MPEG-TS format only.)

  If you specify a preset in PresetId for which the value of Container is fmp4 (Fragmented MP4) or ts (MPEG-TS), SegmentDuration is the target maximum duration of each segment in seconds. For HLSv3 format playlists, each media segment is stored in a separate .ts file. For HLSv4 and Smooth playlists, all media segments for an output are stored in a single file. Each segment is approximately the length of the SegmentDuration, though individual segments might be shorter or longer.

  The range of valid values is 1 to 60 seconds. If the duration of the video is not evenly divisible by SegmentDuration.
the duration of the last segment is the remainder of total
length/SegmentDuration.

Elastic Transcoder creates an output-specific playlist for each
output HLS output that you specify in OutputKeys. To add
an output to the master playlist for this job, include it in the
OutputKeys of the associated playlist.

- **Status (string)** –
  The status of one output in a job. If you specified only one
  output for the job, Outputs:Status is always the same as
  Job:Status. If you specified more than one output:
  - **Job:Status** and Outputs:Status for all of the outputs
    is Submitted until Elastic Transcoder starts to process the first
    output.
  - When Elastic Transcoder starts to process the first out-
    put, Outputs:Status for that output and Job:Status
    both change to Progressing. For each output, the value
    of Outputs:Status remains Submitted until Elastic
    Transcoder starts to process the output.
  - Job:Status remains Progressing until all of the outputs reach a
    terminal status, either Complete or Error.
  - When all of the outputs reach a terminal sta-
    tus, Job:Status changes to Complete only if
    Outputs:Status for all of the outputs is Complete. If
    Outputs:Status for one or more outputs is Error, the
    terminal status for Job:Status is also Error.
  - The value of Status is one of the following: Submitted,
    Progressing, Complete, Canceled, or Error.

- **StatusDetail (string)** –
  Information that further explains Status.

- **Duration (integer)** –
  Duration of the output file, in seconds.

- **Width (integer)** –
  Specifies the width of the output file in pixels.

- **Height (integer)** –
  Height of the output file, in pixels.

- **FrameRate (string)** –
  Frame rate of the output file, in frames per second.

- **FileSize (integer)** –
  File size of the output file, in bytes.

- **DurationMillis (integer)** –
  Duration of the output file, in milliseconds.

- **Watermarks (list)** –
  Information about the watermarks that you want Elastic
  Transcoder to add to the video during transcoding. You can
  specify up to four watermarks for each output. Settings for
each watermark must be defined in the preset that you specify
in Preset for the current output.

Watermarks are added to the output video in the sequence in
which you list them in the job output. The first watermark in the list is added to the output video first, the second watermark in the list is added next, and so on. As a result, if the settings in a preset cause Elastic Transcoder to place all watermarks in the same location, the second watermark that you add will cover the first one, the third one will cover the second, and the fourth one will cover the third.

- (dict) –

   Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

- PresetWatermarkId (string) –

   The ID of the watermark settings that Elastic Transcoder uses to add watermarks to the video during transcoding. The settings are in the preset specified by Preset for the current output. In that preset, the value of Watermarks Id tells Elastic Transcoder which settings to use.

- InputKey (string) –

   The name of the .png or .jpg file that you want to use for the watermark. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by Pipeline; the Input Bucket object in that pipeline identifies the bucket.

   If the file name includes a prefix, for example, logos/128x64.png, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- Encryption (dict) –

   The encryption settings, if any, that you want Elastic Transcoder to apply to your watermarks.

- Mode (string) –

   The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

   - S3: Amazon S3 creates and manages the keys used for encrypting your files.
   - S3-AWS-KMS: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
   - AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
   - AES-CTR: AES Counter Mode.
   - AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

   For all three AES options, you must provide the following settings, which must be base64-encoded:

   - Key
· **Key MD5**
· **Initialization Vector**

| Warning | For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data. |

· **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

· **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

· **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

· **AlbumArt (dict)** –

  The album art to be associated with the output file, if any.

· **MergePolicy (string)** –

  A policy that determines how Elastic Transcoder will handle the existence of multiple album artwork files.

  · **Replace**: The specified album art will replace any existing album art.
  · **Prepend**: The specified album art will be placed in front of any existing album art.
  · **Append**: The specified album art will be placed after any existing album art.
  · **Fallback**: If the original input file contains artwork, Elastic Transcoder will use that artwork for the output. If the original input does not contain artwork, Elastic Transcoder will use the specified album art file.

· **Artwork (list)** –

  The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20. Valid formats are .jpg and .png
· (dict) –

The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20.

To remove artwork or leave the artwork empty, you can either set Artwork to null, or set the Merge Policy to “Replace” and use an empty Artwork array.

To pass through existing artwork unchanged, set the Merge Policy to “Prepend”, “Append”, or “Fallback”, and use an empty Artwork array.

· InputKey (string) –

The name of the file to be used as album art. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by PipelineId; the InputBucket object in that pipeline identifies the bucket.

If the file name includes a prefix, for example, cooking/pie.jpg, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

· MaxWidth (string) –

The maximum width of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 4096, inclusive.

· MaxHeight (string) –

The maximum height of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 3072, inclusive.

· SizingPolicy (string) –

Specify one of the following values to control scaling of the output album art:

· Fit: Elastic Transcoder scales the output art so it matches the value that you specified in either MaxWidth or MaxHeight without exceeding the other value.

· Fill: Elastic Transcoder scales the output art so it matches the value that you specified in either MaxWidth or MaxHeight and matches or exceeds the other value. Elastic Transcoder centers the output art and then crops it in the dimension (if any) that exceeds the maximum value.

· Stretch: Elastic Transcoder stretches the output art to match the values that you specified for MaxWidth and MaxHeight. If the relative proportions of the input art and the output art are different, the output art will be distorted.

· Keep: Elastic Transcoder does not scale the output art. If either dimension of the input art exceeds the values that you specified for MaxWidth and MaxHeight, Elastic Transcoder crops the output art.

· ShrinkToFit: Elastic Transcoder scales the output art down so that its dimensions match the values that you spec-
ified for at least one of `MaxWidth` and `MaxHeight` without exceeding either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **ShrinkToFill** Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without dropping below either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **PaddingPolicy (string)** –

  When you set `PaddingPolicy` to `Pad`, Elastic Transcoder may add white bars to the top and bottom and/or left and right sides of the output album art to make the total size of the output art match the values that you specified for `MaxWidth` and `MaxHeight`.

- **AlbumArtFormat (string)** –

  The format of album art, if any. Valid formats are `.jpg` and `.png`.

- **Encryption (dict)** –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your artwork.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won't be able to unencrypt your data.

  - **Key (string)** –
The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Composition (list)** –

  You can create an output file that contains an excerpt from the input file. This excerpt, called a clip, can come from the beginning, middle, or end of the file. The Composition object contains settings for the clips that make up an output file. For the current release, you can only specify settings for a single clip per output file. The Composition object cannot be null.

  - **Settings (dict)** –

    Settings for one clip in a composition. All jobs in a playlist must have the same clip settings.

  - **TimeSpan (dict)** –

    Settings that determine when a clip begins and how long it lasts.

  - **StartTime (string)** –

    The place in the input file where you want a clip to start. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder starts at the beginning of the input file.

  - **Duration (string)** –

    The duration of the clip. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder creates an output file from StartTime to the end of the file.

    If you specify a value longer than the duration of the input file, Elastic Transcoder transcodes the file and returns a warning
Captions (dict) –

You can configure Elastic Transcoder to transcode captions, or subtitles, from one format to another. All captions must be in UTF-8. Elastic Transcoder supports two types of captions:

- **Embedded**: Embedded captions are included in the same file as the audio and video. Elastic Transcoder supports only one embedded caption per language, to a maximum of 300 embedded captions per file. Valid input values include: CEA-608 (EIA-608, first non-empty channel only), CEA-708 (EIA-708, first non-empty channel only), and mov-text. Valid outputs include: mov-text. Elastic Transcoder supports a maximum of one embedded format per output.

- **Sidecar**: Sidecar captions are kept in a separate metadata file from the audio and video data. Sidecar captions require a player that is capable of understanding the relationship between the video file and the sidecar file. Elastic Transcoder supports only one sidecar caption per language, to a maximum of 20 sidecar captions per file. Valid input values include: dfxp (first div element only), ebu-tt, scc, smpt, srt, ttml (first div element only), and webvtt. Valid outputs include: dfxp (first div element only), scc, srt, and webvtt.

If you want ttml or smpte-tt compatible captions, specify dfxp as your output format.

Elastic Transcoder does not support OCR (Optical Character Recognition), does not accept pictures as a valid input for captions, and is not available for audio-only transcoding. Elastic Transcoder does not preserve text formatting (for example, italics) during the transcoding process.

To remove captions or leave the captions empty, set Captions to null. To pass through existing captions unchanged, set the MergePolicy to MergeRetain, and pass in a null CaptionSources array.

For more information on embedded files, see the Subtitles Wikipedia page.

For more information on sidecar files, see the Extensible Metadata Platform and Sidecar file Wikipedia pages.

- **MergePolicy** (string) –

A policy that determines how Elastic Transcoder handles the existence of multiple captions.

- **MergeOverride**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the sidecar captions and ignores the embedded captions for that language.

- **MergeRetain**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the embedded captions and ignores
the sidecar captions for that language. If `CaptionSources` is empty, Elastic Transcoder omits all sidecar captions from the output files.

- **Override**: Elastic Transcoder transcodes only the sidecar captions that you specify in `CaptionSources`. `MergePolicy` cannot be null.

- **CaptionSources** *(list)*
  
  Source files for the input sidecar captions used during the transcoding process. To omit all sidecar captions, leave `CaptionSources` blank.

- **(dict)**
  
  A source file for the input sidecar captions used during the transcoding process.

- **Key** *(string)*
  
  The name of the sidecar caption file that you want Elastic Transcoder to include in the output file.

- **Language** *(string)*
  
  A string that specifies the language of the caption. Specify this as one of:
  
  - 2-character ISO 639-1 code
  - 3-character ISO 639-2 code
  
  For more information on ISO language codes and language names, see the List of ISO 639-1 codes.

- **TimeOffset** *(string)*
  
  For clip generation or captions that do not start at the same time as the associated video file, the `TimeOffset` tells Elastic Transcoder how much of the video to encode before including captions.

  Specify the `TimeOffset` in the form `[-+]SS.sss` or `[-+]HH:mm:SS.ss`.

- **Label** *(string)*
  
  The label of the caption shown in the player when choosing a language. We recommend that you put the caption language name here, in the language of the captions.

- **Encryption** *(dict)*
  
  The encryption settings, if any, that you want Elastic Transcoder to apply to your caption sources.

- **Mode** *(string)*
  
  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won't be able to unencrypt your data.

- **Key** *(string)* –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **CaptionFormats** *(list)* –

  The array of file formats for the output captions. If you leave this value blank, Elastic Transcoder returns an error.

- **Format** *(string)* –

  The format you specify determines whether Elastic Transcoder generates an embedded or sidecar caption.
Valid Embedded Caption Formats: * for FLAC : None
· For MP3 : None
· For MP4 : mov-text
· For MPEG-TS : None
· For ogg : None
· For webm : None
Valid Sidecar Caption Formats: Elastic Transcoder supports dfxp (first div element only), scc, srt, and webvtt. If you want ttml or smpte-tt compatible captions, specify dfxp as your output format. * For FMP4 : dfxp
· Non-FMP4 outputs : All sidecar types
  fmp4 captions have an extension of .ismt
Pattern (string) –
The prefix for caption filenames, in the form description - {language}, where:
· description is a description of the video.
· {language} is a literal value that Elastic Transcoder replaces with the two- or three-letter code for the language of the caption in the output file names.
If you don’t include {language} in the file name pattern, Elastic Transcoder automatically appends “{language}” to the value that you specify for the description. In addition, Elastic Transcoder automatically appends the count to the end of the segment files.
For example, suppose you’re transcoding into srt format. When you enter “Sydney-{language}-sunrise”, and the language of the captions is English (en), the name of the first caption file will be Sydney-en-sunrise00000.srt.
Encryption (dict) –
The encryption settings, if any, that you want Elastic Transcoder to apply to your caption formats.
· Mode (string) –
The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  · S3: Amazon S3 creates and manages the keys used for encrypting your files.
  · S3-AWS-KMS: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  · AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
  · AES-CTR: AES Counter Mode.
  · AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.
For all three AES options, you must provide the following
settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Encryption (dict)** –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your output files. If you choose to use encryption, you must specify a mode to use. If you choose not to use encryption, Elastic Transcoder will write an unencrypted file to your Amazon S3 bucket.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3:** Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS:** Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the
AWS-KMS key that you want to use to your pipeline.

- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to decrypt your data.

- **Key** *(string)* –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  \[ 128, 192, \text{or} \, 256 \].

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AppliedColorSpaceConversion** *(string)* –

  If Elastic Transcoder used a preset with a ColorSpaceConversionMode to transcode the output file, the AppliedColorSpaceConversion parameter shows the conversion used. If no ColorSpaceConversionMode was defined in the preset, this parameter will not be included in the job response.

- **Outputs** *(list)* –

---

**2248 Chapter 3. API Reference**
Information about the output files. We recommend that you use the `Outputs` syntax for all jobs, even when you want Elastic Transcoder to transcode a file into only one format. Do not use both the `Outputs` and `Output` syntaxes in the same request. You can create a maximum of 30 outputs per job.

If you specify more than one output for a job, Elastic Transcoder creates the files for each output in the order in which you specify them in the job.

- `(dict)` –
  
  **Warning:** Outputs recommended instead.

If you specified one output for a job, information about that output. If you specified multiple outputs for a job, the `Output` object lists information about the first output. This duplicates the information that is listed for the first output in the `Outputs` object.

- `Id` *(string)* –
  
  A sequential counter, starting with 1, that identifies an output among the outputs from the current job. In the Output syntax, this value is always 1.

- `Key` *(string)* –
  
  The name to assign to the transcoded file. Elastic Transcoder saves the file in the Amazon S3 bucket specified by the `OutputBucket` object in the pipeline that is specified by the pipeline ID.

- `ThumbnailPattern` *(string)* –
  
  Whether you want Elastic Transcoder to create thumbnails for your videos and, if so, how you want Elastic Transcoder to name the files.

  If you don’t want Elastic Transcoder to create thumbnails, specify `""`.

  If you do want Elastic Transcoder to create thumbnails, specify the information that you want to include in the file name for each thumbnail. You can specify the following values in any sequence:

  - `{count}` *(Required)*: If you want to create thumbnails, you must include `{count}` in the `ThumbnailPattern` object. Wherever you specify `{count}`, Elastic Transcoder adds a five-digit sequence number (beginning with `00001`) to thumbnail file names. The number indicates where a given thumbnail appears in the sequence of thumbnails for a transcoded file. .. warning::If you specify a literal value and/or `{resolution}` but you omit `{count}`, Elastic Transcoder returns a validation error and does not create the job.

  - `Literal values` *(Optional)*: You can specify literal values anywhere in the `ThumbnailPattern` object. For example, you can include them as a file name prefix or as a delimiter.
between `{resolution}` and `{count}`.

- `{resolution}` (Optional): If you want Elastic Transcoder to include the resolution in the file name, include `{resolution}` in the ThumbnailPattern object. When creating thumbnails, Elastic Transcoder automatically saves the files in the format (.jpg or .png) that appears in the preset that you specified in the PresetID value of CreateJobOutput. Elastic Transcoder also appends the applicable file name extension.

- **ThumbnailEncryption (dict)** –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your thumbnail.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  **Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to encrypt your data.

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.
· **KeyMd5** *(string)* –

The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

· **InitializationVector** *(string)* –

The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

· **Rotate** *(string)* –

The number of degrees clockwise by which you want Elastic Transcoder to rotate the output relative to the input. Enter one of the following values:

*auto*, 0, 90, 180, 270

The value *auto* generally works only if the file that you’re transcoding contains rotation metadata.

· **PresetId** *(string)* –

The value of the *Id* object for the preset that you want to use for this job. The preset determines the audio, video, and thumbnail settings that Elastic Transcoder uses for transcoding. To use a preset that you created, specify the preset ID that Elastic Transcoder returned in the response when you created the preset. You can also use the Elastic Transcoder system presets, which you can get with `ListPresets`.

· **SegmentDuration** *(string)* –

If you specify a preset in `PresetId` for which the value of `Container` is *fmp4* (Fragmented MP4) or *ts* (MPEG-TS), `SegmentDuration` is the target maximum duration of each segment in seconds. For HLSv3 format playlists, each media segment is stored in a separate `.ts` file. For HLSv4 and Smooth playlists, all media segments for an output are stored in a single file. Each segment is approximately the length of the `SegmentDuration`, though individual segments might be shorter or longer.

The range of valid values is 1 to 60 seconds. If the duration of the video is not evenly divisible by `SegmentDuration`, the duration of the last segment is the remainder of total length/`SegmentDuration`.

Elastic Transcoder creates an output-specific playlist for each output HLS output that you specify in `OutputKeys`. To add...
an output to the master playlist for this job, include it in the OutputKeys of the associated playlist.

- **Status (string)**

  The status of one output in a job. If you specified only one output for the job, Outputs:Status is always the same as Job:Status. If you specified more than one output:

  - Job:Status and Outputs:Status for all of the outputs is Submitted until Elastic Transcoder starts to process the first output.
  - When Elastic Transcoder starts to process the first output, Outputs:Status for that output and Job:Status both change to Progressing. For each output, the value of Outputs:Status remains Submitted until Elastic Transcoder starts to process the output.
  - Job:Status remains Progressing until all of the outputs reach a terminal status, either Complete or Error.
  - When all of the outputs reach a terminal status, Job:Status changes to Complete only if Outputs:Status for all of the outputs is Complete. If Outputs:Status for one or more outputs is Error, the terminal status for Job:Status is also Error.

  The value of Status is one of the following: Submitted, Progressing, Complete, Canceled, or Error.

- **StatusDetail (string)**

  Information that further explains Status.

- **Duration (integer)**

  Duration of the output file, in seconds.

- **Width (integer)**

  Specifies the width of the output file in pixels.

- **Height (integer)**

  Height of the output file, in pixels.

- **FrameRate (string)**

  Frame rate of the output file, in frames per second.

- **FileSize (integer)**

  File size of the output file, in bytes.

- **DurationMillis (integer)**

  Duration of the output file, in milliseconds.

- **Watermarks (list)**

  Information about the watermarks that you want Elastic Transcoder to add to the video during transcoding. You can specify up to four watermarks for each output. Settings for each watermark must be defined in the preset that you specify in Preset for the current output.

  Watermarks are added to the output video in the sequence in which you list them in the job output. The first watermark in the list is added to the output video first, the second watermark in the list is added next, and so on. As a result, if the settings in a preset cause Elastic Transcoder to place all watermarks in the same location, the second watermark that you add will
cover the first one, the third one will cover the second, and the fourth one will cover the third.

- *(dict)* –

Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

- **PresetWatermarkId** *(string)* –

  The ID of the watermark settings that Elastic Transcoder uses to add watermarks to the video during transcoding. The settings are in the preset specified by Preset for the current output. In that preset, the value of Watermarks Id tells Elastic Transcoder which settings to use.

- **InputKey** *(string)* –

  The name of the .png or .jpg file that you want to use for the watermark. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by Pipeline; the Input Bucket object in that pipeline identifies the bucket.

  If the file name includes a prefix, for example, logos/128x64.png, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **Encryption** *(dict)* –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your watermarks.

- **Mode** *(string)* –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  - **Key MD5**
  - **Initialization Vector**
Warning: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –
  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –
  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –
  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AlbumArt (dict)** –
  The album art to be associated with the output file, if any.

- **MergePolicy (string)** –
  A policy that determines how Elastic Transcoder will handle the existence of multiple album artwork files.

  - **Replace**: The specified album art will replace any existing album art.
  - **Prepend**: The specified album art will be placed in front of any existing album art.
  - **Append**: The specified album art will be placed after any existing album art.
  - **Fallback**: If the original input file contains artwork, Elastic Transcoder will use that artwork for the output. If the original input does not contain artwork, Elastic Transcoder will use the specified album art file.

- **Artwork (list)** –
  The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20. Valid formats are .jpg and .png
The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20.

To remove artwork or leave the artwork empty, you can either set Artwork to null, or set the Merge Policy to “Replace” and use an empty Artwork array.

To pass through existing artwork unchanged, set the Merge Policy to “Prepend”, “Append”, or “Fallback”, and use an empty Artwork array.

- **InputKey (string)** –

  The name of the file to be used as album art. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by PipelineId; the InputBucket object in that pipeline identifies the bucket.

  If the file name includes a prefix, for example, cooking/pie.jpg, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **MaxWidth (string)** –

  The maximum width of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 4096, inclusive.

- **MaxHeight (string)** –

  The maximum height of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 3072, inclusive.

- **SizingPolicy (string)** –

  Specify one of the following values to control scaling of the output album art:

  - **Fit**: Elastic Transcoder scales the output art so it matches the value that you specified in either MaxWidth or MaxHeight without exceeding the other value.
  - **Fill**: Elastic Transcoder scales the output art so it matches the value that you specified in either MaxWidth or MaxHeight and matches or exceeds the other value. Elastic Transcoder centers the output art and then crops it in the dimension (if any) that exceeds the maximum value.
  - **Stretch**: Elastic Transcoder stretches the output art to match the values that you specified for MaxWidth and MaxHeight. If the relative proportions of the input art and the output art are different, the output art will be distorted.
  - **Keep**: Elastic Transcoder does not scale the output art. If either dimension of the input art exceeds the values that you specified for MaxWidth and MaxHeight, Elastic Transcoder crops the output art.
  - **ShrinkToFit**: Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of MaxWidth and MaxHeight with-
out exceeding either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **ShrinkToFill** Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of MaxWidth and MaxHeight without dropping below either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **PaddingPolicy** *(string)*
  
  When you set PaddingPolicy to Pad, Elastic Transcoder may add white bars to the top and bottom and/or left and right sides of the output album art to make the total size of the output art match the values that you specified for MaxWidth and MaxHeight.

- **AlbumArtFormat** *(string)*
  
  The format of album art, if any. Valid formats are .jpg and .png.

- **Encryption** *(dict)*
  
  The encryption settings, if any, that you want Elastic Transcoder to apply to your artwork.

- **Mode** *(string)*
  
  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  *Warning:* For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

  - **Key** *(string)*
    
    The data encryption key that you want Elastic Transcoder
to use to encrypt your output file, or that was used to en-
rypt your input file. The key must be base64-encoded and it
must be one of the following bit lengths before being base64-
encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key
Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your in-
put file, or that you want Elastic Transcoder to use to encrypt
your output file. Elastic Transcoder uses the key digest as a
checksum to make sure your key was not corrupted in transit.
The key MD5 must be base64-encoded, and it must be exactly
16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit genera-
tor, unique for every encryption operation, that you used to
encrypt your input files or that you want Elastic Transcoder
to use to encrypt your output files. The initialization vector
must be base64-encoded, and it must be exactly 16 bytes long
before being base64-encoded.

- **Composition (list)** –

  You can create an output file that contains an excerpt from
the input file. This excerpt, called a clip, can come from the
beginning, middle, or end of the file. The Composition object
contains settings for the clips that make up an output file. For
the current release, you can only specify settings for a single
clip per output file. The Composition object cannot be null.

  - **(dict)** –

    Settings for one clip in a composition. All jobs in a playlist
must have the same clip settings.

  - **TimeSpan (dict)** –

    Settings that determine when a clip begins and how long it
lasts.

  - **StartTime (string)** –

    The place in the input file where you want a clip to start.
The format can be either HH:mm:ss.SSS (maximum value:
23:59:59.999; SSS is thousandths of a second) or sssss.SSS
(maximum value: 86399.999). If you don’t specify a value,
Elastic Transcoder starts at the beginning of the input file.

  - **Duration (string)** –

    The duration of the clip. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder creates an output file from StartTime to the end of the file.

If you specify a value longer than the duration of the input file,
Elastic Transcoder transcodes the file and returns a warning
message.
· **Captions** (dict) –

You can configure Elastic Transcoder to transcode captions, or subtitles, from one format to another. All captions must be in UTF-8. Elastic Transcoder supports two types of captions:

- **Embedded:** Embedded captions are included in the same file as the audio and video. Elastic Transcoder supports only one embedded caption per language, to a maximum of 300 embedded captions per file. Valid input values include: CEA-608 (EIA-608, first non-empty channel only), CEA-708 (EIA-708, first non-empty channel only), and mov-text Valid outputs include: mov-text Elastic Transcoder supports a maximum of one embedded format per output.

- **Sidecar:** Sidecar captions are kept in a separate metadata file from the audio and video data. Sidecar captions require a player that is capable of understanding the relationship between the video file and the sidecar file. Elastic Transcoder supports only one sidecar caption per language, to a maximum of 20 sidecar captions per file. Valid input values include: dfxp (first div element only), ebu-tt, scc, smpte, srt, ttml (first div element only), and webvtt Valid outputs include: dfxp (first div element only), scc, srt, and webvtt.

If you want ttml or smpte-tt compatible captions, specify dfxp as your output format.

Elastic Transcoder does not support OCR (Optical Character Recognition), does not accept pictures as a valid input for captions, and is not available for audio-only transcoding. Elastic Transcoder does not preserve text formatting (for example, italics) during the transcoding process.

To remove captions or leave the captions empty, set Captions to null. To pass through existing captions unchanged, set the MergePolicy to MergeRetain, and pass in a null CaptionSources array.

For more information on embedded files, see the Subtitles Wikipedia page.

For more information on sidecar files, see the Extensible Metadata Platform and Sidecar file Wikipedia pages.

· **MergePolicy** (string) –

A policy that determines how Elastic Transcoder handles the existence of multiple captions.

- **MergeOverride:** Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the sidecar captions and ignores the embedded captions for that language.

- **MergeRetain:** Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the embedded captions and ignores the sidecar captions for that language.
is empty, Elastic Transcoder omits all sidecar captions from the output files.

- **Override**: Elastic Transcoder transcodes only the sidecar captions that you specify in `CaptionSources`. `MergePolicy` cannot be null.

- **CaptionSources (list)** –

  Source files for the input sidecar captions used during the transcoding process. To omit all sidecar captions, leave `CaptionSources` blank.

  - **Key (string)** –

    A source file for the input sidecar captions used during the transcoding process.

  - **Language (string)** –

    A string that specifies the language of the caption. Specify this as one of:

    - 2-character ISO 639-1 code
    - 3-character ISO 639-2 code

    For more information on ISO language codes and language names, see the List of ISO 639-1 codes.

  - **TimeOffset (string)** –

    For clip generation or captions that do not start at the same time as the associated video file, the `TimeOffset` tells Elastic Transcoder how much of the video to encode before including captions.

    Specify the `TimeOffset` in the form `[+|-]SS.sss` or `[+-]HH:mm:SS.sss`.

  - **Label (string)** –

    The label of the caption shown in the player when choosing a language. We recommend that you put the caption language name here, in the language of the captions.

  - **Encryption (dict)** –

    The encryption settings, if any, that you want Elastic Transcoder to apply to your caption sources.

    - **Mode (string)** –

      The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

      - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
      - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
· **AES-CBC-PKCS7:** A padded cipher-block mode of operation originally used for HLS files.

· **AES-CTR:** AES Counter Mode.

· **AES-GCM:** AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

· **Key**

· **Key MD5**

· **Initialization Vector**

<table>
<thead>
<tr>
<th>Warning: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to un-encrypt your data.</th>
</tr>
</thead>
</table>

· **Key (string)**

The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

· **KeyMd5 (string)**

The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

· **InitializationVector (string)**

The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

· **CaptionFormats (list)**

The array of file formats for the output captions. If you leave this value blank, Elastic Transcoder returns an error.

· **(dict)**

The file format of the output captions. If you leave this value blank, Elastic Transcoder returns an error.

· **Format (string)**

The format you specify determines whether Elastic Transcoder generates an embedded or sidecar caption
Valid Embedded Caption Formats: * for FLAC: None
  · For MP3: None
  · For MP4: mov-text
  · For MPEG-TS: None
  · For ogg: None
  · For webm: None

Valid Sidecar Caption Formats: Elastic Transcoder supports txvp (first div element only), scc, srt, and webvtt. If you want ttml or smpte-tt compatible captions, specify dfxp as your output format. * For FMP4: dfxp
  · Non-FMP4 outputs: All sidecar types
    fmp4 captions have an extension of .ismt

Pattern (string) –

The prefix for caption filenames, in the form description -
{language}, where:
  · description is a description of the video.
  · {language} is a literal value that Elastic Transcoder replaces with the two- or three-letter code for the language of the caption in the output file names.

For non-FMP4 outputs, Elastic Transcoder automatically appends the language to the value that you specify for the description. In addition, Elastic Transcoder automatically appends the count to the end of the segment files.

For example, suppose you’re transcoding into srt format. When you enter “Sydney-{language}-sunrise”, and the language of the captions is English (en), the name of the first caption file will be Sydney-en-sunrise00000.srt.

Encryption (dict) –

The encryption settings, if any, that you want Elastic Transcoder to apply to your caption formats.

Mode (string) –

The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  · S3: Amazon S3 creates and manages the keys used for encrypting your files.
  · S3-AWS-KMS: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  · AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
  · AES-CTR: AES Counter Mode.
  · AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following
settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

  **Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Encryption** *(dict)* –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your output files. If you choose to use encryption, you must specify a mode to use. If you choose not to use encryption, Elastic Transcoder will write an unencrypted file to your Amazon S3 bucket.

- **Mode** *(string)* –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the
AWS-KMS key that you want to use to your pipeline.

- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AppliedColorSpaceConversion** *(string)* –

  If Elastic Transcoder used a preset with a ColorSpaceConversionMode to transcode the output file, the AppliedColorSpaceConversion parameter shows the conversion used. If no ColorSpaceConversionMode was defined in the preset, this parameter will not be included in the job response.

- **OutputKeyPrefix** *(string)* –
The value, if any, that you want Elastic Transcoder to prepend to the names of all files that this job creates, including output files, thumbnails, and playlists. We recommend that you add a / or some other delimiter to the end of the `OutputKeyPrefix`.

- **Playlists** *(list)*

  | Warning: Outputs in Fragmented MP4 or MPEG-TS format only. |

If you specify a preset in `PresetId` for which the value of `Container` is `fmp4` (Fragmented MP4) or `ts` (MPEG-TS), `Playlists` contains information about the master playlists that you want Elastic Transcoder to create.

The maximum number of master playlists in a job is 30.

- **(dict)**

  Use Only for Fragmented MP4 or MPEG-TS Outputs. If you specify a preset for which the value of `Container` is `fmp4` (Fragmented MP4) or `ts` (MPEG-TS), `Playlists` contains information about the master playlists that you want Elastic Transcoder to create. We recommend that you create only one master playlist per output format. The maximum number of master playlists in a job is 30.

- **Name** *(string)*

  The name that you want Elastic Transcoder to assign to the master playlist, for example, `nyc-vacation.m3u8`. If the name includes a / character, the section of the name before the last / must be identical for all `Name` objects. If you create more than one master playlist, the values of all `Name` objects must be unique.

  **Note**: Elastic Transcoder automatically appends the relevant file extension to the file name (.m3u8 for HLSv3 and HLSv4 playlists, and .ism and .ismc for Smooth playlists). If you include a file extension in `Name`, the file name will have two extensions.

- **Format** *(string)*

  The format of the output playlist. Valid formats include HLSv3, HLSv4, and Smooth.

- **OutputKeys** *(list)*

  For each output in this job that you want to include in a master playlist, the value of the Outputs:Key object.

  - If your output is not HLS or does not have a segment duration set, the name of the output file is a concatenation of `OutputKeyPrefix` and `Outputs:Key`: `OutputKeyPrefix``Outputs:Key``.ts`

  - If your output is HLSv3 and has a segment duration set, or is not included in a playlist, Elastic Transcoder creates an output playlist file with a file extension of .m3u8, and a series of .ts files that include a five-digit sequential counter beginning with 00000: `OutputKeyPrefix``Outputs:Key``.m3u8 OutputKeyPrefix``Outputs:Key`` 00000.ts
· If your output is HLSv4, has a segment duration set, and is included in an HLSv4 playlist, Elastic Transcoder creates an output playlist file with a file extension of _v4.m3u8. If the output is video, Elastic Transcoder also creates an output file with an extension of _iframe.m3u8. Elastic Transcoder automatically appends the relevant file extension to the file name. If you include a file extension in Output Key, the file name will have two extensions.

If you include more than one output in a playlist, any segment duration settings, clip settings, or caption settings must be the same for all outputs in the playlist. For Smooth playlists, the Audio:Profile, Video:Profile, and Video:FrameRate to Video:KeyframesMaxDist ratio must be the same for all outputs.

· **OutputKeyPrefix**

`OutputKeyPrefix``Outputs:Key``v4.m3u8` `OutputKeyPrefix``Outputs:Key``_iframe.m3u8` `OutputKeyPrefix``Outputs:Key``.ts`

If you want Elastic Transcoder to generate a key for you, leave this field blank.

If you choose to supply your own key, you must encrypt the key by using AWS KMS. The key must be base64-encoded, and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

· **KeyMd5**

If Elastic Transcoder is generating your key for you, you must leave this field blank.

The MD5 digest of the key that you want Elastic Transcoder to use to encrypt your output file, and that you want Elastic Transcoder to use as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

· **InitializationVector**

If Elastic Transcoder is generating your key for you, you must leave this field blank.

The series of random bits created by a random bit generator,
unique for every encryption operation, that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

- **LicenseAcquisitionUrl** (*string*)
  
  The location of the license key required to decrypt your HLS playlist. The URL must be an absolute path, and is referenced in the URI attribute of the EXT-X-KEY metadata tag in the playlist file.

- **KeyStoragePolicy** (*string*)
  
  Specify whether you want Elastic Transcoder to write your HLS license key to an Amazon S3 bucket. If you choose WithVariantPlaylists, LicenseAcquisitionUrl must be left blank and Elastic Transcoder writes your data key into the same bucket as the associated playlist.

- **PlayReadyDrm** (*dict*)
  
  The DRM settings, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

  - **Format** (*string*)
    
    The type of DRM, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

  - **Key** (*string*)
    
    The DRM key for your file, provided by your DRM license provider. The key must be base64-encoded, and it must be one of the following bit lengths before being base64-encoded:

    128, 192, or 256.

    The key must also be encrypted by using AWS KMS.

  - **KeyId** (*string*)
    
    The ID for your DRM key, so that your DRM license provider knows which key to provide.

    The key ID must be provided in big endian, and Elastic Transcoder will convert it to little endian before inserting it into the PlayReady DRM headers. If you are unsure whether your license server provides your key ID in big or little endian, check with your DRM provider.

  - **InitializationVector** (*string*)
    
    The series of random bits created by a random bit generator, unique for every encryption operation, that you want Elastic Transcoder to use to encrypt your files. The initialization vector must be base64-encoded, and it must be exactly 8 bytes before being base64-encoded.
long before being base64-encoded. If no initialization vector is provided, Elastic Transcoder generates one for you.

- LicenseAcquisitionUrl (string)

  The location of the license key required to play DRM content. The URL must be an absolute path, and is referenced by the PlayReady header. The PlayReady header is referenced in the protection header of the client manifest for Smooth Streaming outputs, and in the EXT-X-DXDRM and EXT-XDXDRMINFO metadata tags for HLS playlist outputs. An example URL looks like this: https://www.example.com/exampleKey/

- Status (string)

  The status of the job with which the playlist is associated.

- StatusDetail (string)

  Information that further explains the status.

- UserMetadata (dict)

  User-defined metadata that you want to associate with an Elastic Transcoder job. You specify metadata in key/value pairs, and you can add up to 10 key/value pairs per job. Elastic Transcoder does not guarantee that key/value pairs will be returned in the same order in which you specify them.

Metadata keys and values must use characters from the following list:

- 0-9
- A-Z and a-z
- Space
- The following symbols: ___.:/=+-%@

- Timing (dict)

  Details about the timing of a job.

- SubmitTimeMillis (integer)

  The time the job was submitted to Elastic Transcoder, in epoch milliseconds.

- StartTimeMillis (integer)

  The time the job began transcoding, in epoch milliseconds.

- FinishTimeMillis (integer)

  The time the job finished transcoding, in epoch milliseconds.

- NextPageToken (string)

  A value that you use to access the second and subsequent pages of results, if any. When the jobs in the specified pipeline fit on one page or when you’ve reached the last page of results, the value of NextPageToken is null.

list_jobs_by_status (**kwargs)

The ListJobsByStatus operation gets a list of jobs that have a specified status. The response body contains
one element for each job that satisfies the search criteria.

**Request Syntax**

```python
response = client.list_jobs_by_status(
    Status='string',
    Ascending='string',
    PageToken='string'
)
```

**Parameters**

- **Status (string)** – [REQUIRED]
  
  To get information about all of the jobs associated with the current AWS account that have a given status, specify the following status: Submitted, Progressing, Complete, Canceled, or Error.

- **Ascending (string)** – To list jobs in chronological order by the date and time that they were submitted, enter true. To list jobs in reverse chronological order, enter false.

- **PageToken (string)** – When Elastic Transcoder returns more than one page of results, use pageToken in subsequent GET requests to get each successive page of results.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Jobs': [
        {
            'Id': 'string',
            'Arn': 'string',
            'PipelineId': 'string',
            'Input': {
                'Key': 'string',
                'FrameRate': 'string',
                'Resolution': 'string',
                'AspectRatio': 'string',
                'Interlaced': 'string',
                'Container': 'string',
                'Encryption': {
                    'Mode': 'string',
                    'Key': 'string',
                    'KeyMd5': 'string',
                    'InitializationVector': 'string'
                },

Response Structure

- (dict) –
  The ListJobsByStatusResponse structure.
  - Jobs (list) –
    An array of Job objects that have the specified status.
    * (dict) –
      A section of the response body that provides information about the job that is created.
      - Id (string) –
        The identifier that Elastic Transcoder assigned to the job. You use this value to get settings for the job or to delete the job.
      - Arn (string) –
        The Amazon Resource Name (ARN) for the job.
      - PipelineId (string) –
        The Id of the pipeline that you want Elastic Transcoder to use for transcoding. The pipeline determines several settings, including the Amazon S3 bucket from which Elastic Transcoder gets the files to transcode and the bucket into which Elastic Transcoder puts the transcoded files.
      - Input (dict) –
        A section of the request or response body that provides information about the file that is being transcoded.
        - Key (string) –
          The name of the file to transcode. Elsewhere in the body of the JSON block is the the ID of the pipeline to use for processing the job. The InputBucket object in that pipeline tells Elastic Transcoder which Amazon S3 bucket to get the file from.
          If the file name includes a prefix, such as cooking/lasagna.mpg, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.
        - FrameRate (string) –
          The frame rate of the input file. If you want Elastic Transcoder to automatically detect the frame rate of the input file, specify auto. If you want to specify the frame rate for the input file, enter one of the following values:
            10, 15, 23.97, 24, 25, 29.97, 30, 60
          If you specify a value other than auto, Elastic Transcoder disables automatic detection of the frame rate.
        - Resolution (string) –
          This value must be auto, which causes Elastic Transcoder to automatically detect the resolution of the input file.
        -AspectRatio (string) –
          The aspect ratio of the input file. If you want Elastic Transcoder to automatically detect the aspect ratio of the in-
put file, specify auto. If you want to specify the aspect ratio for the output file, enter one of the following values:

1:1, 4:3, 3:2, 16:9

If you specify a value other than auto, Elastic Transcoder disables automatic detection of the aspect ratio.

- **Interlaced (string)** –

Whether the input file is interlaced. If you want Elastic Transcoder to automatically detect whether the input file is interlaced, specify auto. If you want to specify whether the input file is interlaced, enter one of the following values:

true, false

If you specify a value other than auto, Elastic Transcoder disables automatic detection of interlacing.

- **Container (string)** –

The container type for the input file. If you want Elastic Transcoder to automatically detect the container type of the input file, specify auto. If you want to specify the container type for the input file, enter one of the following values:

3gp, aac, asf, avi, divx, flv, m4a, mkv, mov, mp3, mp4, mpeg, mpeg-ps, mpeg-ts, mxf, ogg, vob, wav, webm

- **Encryption (dict)** –

The encryption settings, if any, that are used for decrypting your input files. If your input file is encrypted, you must specify the mode that Elastic Transcoder will use to decrypt your file.

- **Mode (string)** –

The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

- S3: Amazon S3 creates and manages the keys used for encrypting your files.
- S3-AWS-KMS: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
- AES-CTR: AES Counter Mode.
- AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**
Warning: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **DetectedProperties (dict)** –

  The detected properties of the input file.

  - **Width (integer)** –

    The detected width of the input file, in pixels.

  - **Height (integer)** –

    The detected height of the input file, in pixels.

  - **FrameRate (string)** –

    The detected frame rate of the input file, in frames per second.

  - **FileSize (integer)** –

    The detected file size of the input file, in bytes.

  - **DurationMillis (integer)** –

    The detected duration of the input file, in milliseconds.

- **Output (dict)** –

  If you specified one output for a job, information about that output. If you specified multiple outputs for a job, the Output object lists information about the first output. This duplicates the information that is listed for the first output in the Outputs object.
Warning: Outputs recommended instead.

A section of the request or response body that provides information about the transcoded (target) file.

- **Id (string)** –
  
  A sequential counter, starting with 1, that identifies an output among the outputs from the current job. In the Output syntax, this value is always 1.

- **Key (string)** –
  
  The name to assign to the transcoded file. Elastic Transcoder saves the file in the Amazon S3 bucket specified by the `OutputBucket` object in the pipeline that is specified by the pipeline ID.

- **ThumbnailPattern (string)** –
  
  Whether you want Elastic Transcoder to create thumbnails for your videos and, if so, how you want Elastic Transcoder to name the files.

  If you don’t want Elastic Transcoder to create thumbnails, specify ““.

  If you do want Elastic Transcoder to create thumbnails, specify the information that you want to include in the file name for each thumbnail. You can specify the following values in any sequence:

  - **“{count}“ (Required)**: If you want to create thumbnails, you must include `{count}` in the `ThumbnailPattern` object. Wherever you specify `{count}`, Elastic Transcoder adds a five-digit sequence number (beginning with `00001`) to thumbnail file names. The number indicates where a given thumbnail appears in the sequence of thumbnails for a transcoded file. .. warning::If you specify a literal value and/or `{resolution}` but you omit `{count}`, Elastic Transcoder returns a validation error and does not create the job.

  - **Literal values (Optional)**: You can specify literal values anywhere in the `ThumbnailPattern` object. For example, you can include them as a file name prefix or as a delimiter between `{resolution}` and `{count}`.

  - **“{resolution}“ (Optional)**: If you want Elastic Transcoder to include the resolution in the file name, include `{resolution}` in the `ThumbnailPattern` object. When creating thumbnails, Elastic Transcoder automatically saves the files in the format (.jpg or .png) that appears in the preset that you specified in the `PresetID` value of `CreateJobOutput`. Elastic Transcoder also appends the applicable file name extension.

- **ThumbnailEncryption (dict)** –
  
  The encryption settings, if any, that you want Elastic Transcoder to apply to your thumbnail.

- **Mode (string)** –
The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

- **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
- **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify **S3-AWS-KMS** and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

**Key** *(string)* –

The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

**KeyMd5** *(string)* –

The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

**InitializationVector** *(string)* –

The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long.
before being base64-encoded.

- **Rotate (string)** –

  The number of degrees clockwise by which you want Elastic Transcoder to rotate the output relative to the input. Enter one of the following values:

  auto, 0, 90, 180, 270

  The value auto generally works only if the file that you’re transcoding contains rotation metadata.

- **PresetId (string)** –

  The value of the Id object for the preset that you want to use for this job. The preset determines the audio, video, and thumbnail settings that Elastic Transcoder uses for transcoding. To use a preset that you created, specify the preset ID that Elastic Transcoder returned in the response when you created the preset. You can also use the Elastic Transcoder system presets, which you can get with `ListPresets`.

- **SegmentDuration (string)** –

  Warning: (Outputs in Fragmented MP4 or MPEG-TS format only.)

  If you specify a preset in `PresetId` for which the value of `Container` is fmp4 (Fragmented MP4) or ts (MPEG-TS), `SegmentDuration` is the target maximum duration of each segment in seconds. For HLSv3 format playlists, each media segment is stored in a separate .ts file. For HLSv4 and Smooth playlists, all media segments for an output are stored in a single file. Each segment is approximately the length of the `SegmentDuration`, though individual segments might be shorter or longer.

  The range of valid values is 1 to 60 seconds. If the duration of the video is not evenly divisible by `SegmentDuration`, the duration of the last segment is the remainder of total length/`SegmentDuration`.

  Elastic Transcoder creates an output-specific playlist for each output HLS output that you specify in `OutputKeys`. To add an output to the master playlist for this job, include it in the `OutputKeys` of the associated playlist.

- **Status (string)** –

  The status of one output in a job. If you specified only one output for the job, `Outputs:Status` is always the same as `Job:Status`. If you specified more than one output:

  - Job:Status and Outputs:Status for all of the outputs is Submitted until Elastic Transcoder starts to process the first output.
  - When Elastic Transcoder starts to process the first output, `Outputs:Status` for that output and `Job:Status` both change to Progressing. For each output, the value of `Outputs:Status` remains Submitted until Elastic Transcoder starts to process the output.
- Job:Status remains Progressing until all of the outputs reach a terminal status, either Complete or Error.
- When all of the outputs reach a terminal status, Job:Status changes to Complete only if Outputs:Status for all of the outputs is Complete. If Outputs:Status for one or more outputs is Error, the terminal status for Job:Status is also Error.

The value of Status is one of the following: Submitted, Progressing, Complete, Canceled, or Error.

- **StatusDetail (string)** –
  Information that further explains Status.

- **Duration (integer)** –
  Duration of the output file, in seconds.

- **Width (integer)** –
  Specifies the width of the output file in pixels.

- **Height (integer)** –
  Height of the output file, in pixels.

- **FrameRate (string)** –
  Frame rate of the output file, in frames per second.

- **FileSize (integer)** –
  File size of the output file, in bytes.

- **DurationMillis (integer)** –
  Duration of the output file, in milliseconds.

- **Watermarks (list)** –
  Information about the watermarks that you want Elastic Transcoder to add to the video during transcoding. You can specify up to four watermarks for each output. Settings for each watermark must be defined in the preset that you specify in Preset for the current output.

  Watermarks are added to the output video in the sequence in which you list them in the job output. The first watermark in the list is added to the output video first, the second watermark in the list is added next, and so on. As a result, if the settings in a preset cause Elastic Transcoder to place all watermarks in the same location, the second watermark that you add will cover the first one, the third one will cover the second, and the fourth one will cover the third.

- **(dict)** –
  Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

- **PresetWatermarkId (string)** –
  The ID of the watermark settings that Elastic Transcoder uses to add watermarks to the video during transcoding. The settings are in the preset specified by Preset for the current output. In that preset, the value of Watermarks Id tells Elastic Transcoder which settings to use.

- **InputKey (string)** –
The name of the .png or .jpg file that you want to use for the watermark. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by `Pipeline`; the `Input Bucket` object in that pipeline identifies the bucket.

If the file name includes a prefix, for example, `logos/128x64.png`, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **Encryption (dict)** –
  The encryption settings, if any, that you want Elastic Transcoder to apply to your watermarks.

- **Mode (string)** –
  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.
  
  For all three AES options, you must provide the following settings, which must be base64-encoded:
  - **Key**
  - **Key MD5**
  - **Initialization Vector**

<table>
<thead>
<tr>
<th>Warning: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.</th>
</tr>
</thead>
</table>

- **Key (string)** –
  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –
The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** (string) –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AlbumArt** (dict) –

  The album art to be associated with the output file, if any.

- **MergePolicy** (string) –

  A policy that determines how Elastic Transcoder will handle the existence of multiple album artwork files.

  - Replace: The specified album art will replace any existing album art.
  - Prepend: The specified album art will be placed in front of any existing album art.
  - Append: The specified album art will be placed after any existing album art.
  - Fallback: If the original input file contains artwork, Elastic Transcoder will use that artwork for the output. If the original input does not contain artwork, Elastic Transcoder will use the specified album art file.

- **Artwork** (list) –

  The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20. Valid formats are .jpg and .png

  (dict) –

  The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20.

  To remove artwork or leave the artwork empty, you can either set Artwork to null, or set the Merge Policy to “Replace” and use an empty Artwork array.

  To pass through existing artwork unchanged, set the Merge Policy to “Prepend”, “Append”, or “Fallback”, and use an empty Artwork array.

- **InputKey** (string) –

  The name of the file to be used as album art. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by PipelineId; the InputBucket object in that pipeline identifies the bucket.

  If the file name includes a prefix, for example, cooking/pie.jpg, include the prefix in the key. If
the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **MaxWidth** *(string)*

  The maximum width of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 4096, inclusive.

- **MaxHeight** *(string)*

  The maximum height of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 3072, inclusive.

- **SizingPolicy** *(string)*

  Specify one of the following values to control scaling of the output album art:
  
  - **Fit**: Elastic Transcoder scales the output art so it matches the value that you specified in either MaxWidth or MaxHeight without exceeding the other value.
  
  - **Fill**: Elastic Transcoder scales the output art so it matches the value that you specified in either MaxWidth or MaxHeight and matches or exceeds the other value. Elastic Transcoder centers the output art and then crops it in the dimension (if any) that exceeds the maximum value.
  
  - **Stretch**: Elastic Transcoder stretches the output art to match the values that you specified for MaxWidth and MaxHeight. If the relative proportions of the input art and the output art are different, the output art will be distorted.
  
  - **Keep**: Elastic Transcoder does not scale the output art. If either dimension of the input art exceeds the values that you specified for MaxWidth and MaxHeight, Elastic Transcoder crops the output art.
  
  - **ShrinkToFit**: Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of MaxWidth and MaxHeight without exceeding either value. If you specify this option, Elastic Transcoder does not scale the art up.
  
  - **ShrinkToFill**: Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of MaxWidth and MaxHeight without dropping below either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **PaddingPolicy** *(string)*

  When you set PaddingPolicy to **Pad**, Elastic Transcoder may add white bars to the top and bottom and/or left and right sides of the output album art to make the total size of the output art match the values that you specified for MaxWidth and MaxHeight.

- **AlbumArtFormat** *(string)*

  The format of album art, if any. Valid formats are .jpg and .png.

- **Encryption** *(dict)*
The encryption settings, if any, that you want Elastic Transcoder to apply to your artwork.

- **Mode** (string) –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key Md5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to encrypt your data.

- **Key** (string) –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** (string) –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** (string) –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to
encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Composition** *(list)* –

  You can create an output file that contains an excerpt from the input file. This excerpt, called a clip, can come from the beginning, middle, or end of the file. The Composition object contains settings for the clips that make up an output file. For the current release, you can only specify settings for a single clip per output file. The Composition object cannot be null.

  - **(dict)** –

    Settings for one clip in a composition. All jobs in a playlist must have the same clip settings.

    - **TimeSpan** *(dict)* –

      Settings that determine when a clip begins and how long it lasts.

    - **StartTime** *(string)* –

      The place in the input file where you want a clip to start. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder starts at the beginning of the input file.

    - **Duration** *(string)* –

      The duration of the clip. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder creates an output file from StartTime to the end of the file.

      If you specify a value longer than the duration of the input file, Elastic Transcoder transcodes the file and returns a warning message.

    - **Captions** *(dict)* –

      You can configure Elastic Transcoder to transcode captions, or subtitles, from one format to another. All captions must be in UTF-8. Elastic Transcoder supports two types of captions:

    - **Embedded**: Embedded captions are included in the same file as the audio and video. Elastic Transcoder supports only one embedded caption per language, to a maximum of 300 embedded captions per file. Valid input values include: CEA-608 (EIA-608, first non-empty channel only), CEA-708 (EIA-708, first non-empty channel only), and mov-text. Valid outputs include: mov-text. Elastic Transcoder supports a maximum of one embedded format per output.

    - **Sidecar**: Sidecar captions are kept in a separate metadata file from the audio and video data. Sidecar captions require a player that is capable of understanding the relationship between the video file and the sidecar file. Elastic Transcoder supports only one sidecar caption per language, to a maxi-
mum of 20 sidecar captions per file. Valid input values include: dfxp (first div element only), ebu-tt, scc, smpte, srt, ttml (first div element only), and webvtt. Valid outputs include: dfxp (first div element only), scc, srt, and webvtt.

If you want ttml or smpte-tt compatible captions, specify dfxp as your output format.

Elastic Transcoder does not support OCR (Optical Character Recognition), does not accept pictures as a valid input for captions, and is not available for audio-only transcoding. Elastic Transcoder does not preserve text formatting (for example, italics) during the transcoding process.

To remove captions or leave the captions empty, set Captions to null. To pass through existing captions unchanged, set the MergePolicy to MergeRetain, and pass in a null CaptionSources array.

For more information on embedded files, see the Subtitles Wikipedia page.

For more information on sidecar files, see the Extensible Metadata Platform and Sidecar file Wikipedia pages.

- **MergePolicy** *(string)* –

  A policy that determines how Elastic Transcoder handles the existence of multiple captions.

- **MergeOverride**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the sidecar captions and ignores the embedded captions for that language.

- **MergeRetain**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the embedded captions and ignores the sidecar captions for that language. If CaptionSources is empty, Elastic Transcoder omits all sidecar captions from the output files.

- **Override**: Elastic Transcoder transcodes only the sidecar captions that you specify in CaptionSources.

  MergePolicy cannot be null.

- **CaptionSources** *(list)* –

  Source files for the input sidecar captions used during the transcoding process. To omit all sidecar captions, leave CaptionSources blank.

  *(dict)* –

  A source file for the input sidecar captions used during the transcoding process.

  - **Key** *(string)* –

    The name of the sidecar caption file that you want Elastic Transcoder to include in the output file.

  - **Language** *(string)* –
A string that specifies the language of the caption. Specify this as one of:
- 2-character ISO 639-1 code
- 3-character ISO 639-2 code
For more information on ISO language codes and language names, see the List of ISO 639-1 codes.

**TimeOffset** *(string)* –
For clip generation or captions that do not start at the same time as the associated video file, the *TimeOffset* tells Elastic Transcoder how much of the video to encode before including captions.

Specify the *TimeOffset* in the form 

\[ \text{[+-]}SS.sss \text{ or } \text{[+-]}HH:mm:SS.sss. \]

**Label** *(string)* –
The label of the caption shown in the player when choosing a language. We recommend that you put the caption language name here, in the language of the captions.

**Encryption** *(dict)* –
The encryption settings, if any, that you want Elastic Transcoder to apply to your caption sources.

**Mode** *(string)* –
The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
- **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
- **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify **S3-AWS-KMS** and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:
- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

**Key** *(string)* –
The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **CaptionFormats** *(list)* –

  The array of file formats for the output captions. If you leave this value blank, Elastic Transcoder returns an error.

  *(dict)* –

  The file format of the output captions. If you leave this value blank, Elastic Transcoder returns an error.

- **Format** *(string)* –

  The format you specify determines whether Elastic Transcoder generates an embedded or sidecar caption for this output.

- **Valid Embedded Caption Formats:** *for FLAC*: None
  *for MP3*: None
  *for MP4*: mov-text
  *for MPEG-TS*: None
  *for ogg*: None
  *for webm*: None

- **Valid Sidecar Caption Formats:** Elastic Transcoder supports dfxp (first div element only), scc, srt, and webvtt. If you want ttml or smpte-tt compatible captions, specify dfxp as your output format. *For FMP4*: dfxp

- **Non-FMP4 outputs**: All sidecar types

  fmp4 captions have an extension of .ismt

- **Pattern** *(string)* –

  The prefix for caption filenames, in the form *description-* *(language)*, where:

  - **description** is a description of the video.
  - *(language)* is a literal value that Elastic Transcoder replaces with the two- or three-letter code for the language of
the caption in the output file names.
If you don’t include {language} in the file name pattern, Elastic Transcoder automatically appends “{language}” to the value that you specify for the description. In addition, Elastic Transcoder automatically appends the count to the end of the segment files.

For example, suppose you’re transcoding into srt format. When you enter “Sydney-{language}-sunrise”, and the language of the captions is English (en), the name of the first caption file will be Sydney-en-sunrise00000.srt.

- **Encryption (dict)**
  
The encryption settings, if any, that you want Elastic Transcoder to apply to your caption formats.

- **Mode (string)**
  
The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that if a file, key, or initialization vector has been tampered with it will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:
  
  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)**

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  \[128, 192, \text{or} 256\]

  The key must also be encrypted by using the Amazon Key
Management Service.

- **KeyMd5 (string)** –
  
The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –
  
The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Encryption (dict)** –
  
The encryption settings, if any, that you want Elastic Transcoder to apply to your output files. If you choose to use encryption, you must specify a mode to use. If you choose not to use encryption, Elastic Transcoder will write an unencrypted file to your Amazon S3 bucket.

- **Mode (string)** –
  
The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

*Warning:* For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to decrypt your data.
The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AppliedColorSpaceConversion (string)** –

  If Elastic Transcoder used a preset with a ColorSpaceConversionMode to transcode the output file, the AppliedColorSpaceConversion parameter shows the conversion used. If no ColorSpaceConversionMode was defined in the preset, this parameter will not be included in the job response.

- **Outputs (list)** –

  Information about the output files. We recommend that you use the Outputs syntax for all jobs, even when you want Elastic Transcoder to transcode a file into only one format. Do not use both the Outputs and Output syntaxes in the same request. You can create a maximum of 30 outputs per job.

  If you specify more than one output for a job, Elastic Transcoder creates the files for each output in the order in which you specify them in the job.

- **(dict)** –

  **Warning:** Outputs recommended instead.

  If you specified one output for a job, information about that output. If you specified multiple outputs for a job, the Output object lists information about the first output. This duplicates the information that is listed for the first output in the Outputs object.

- **Id (string)** –
A sequential counter, starting with 1, that identifies an output among the outputs from the current job. In the Output syntax, this value is always 1.

- **Key (string)** –

  The name to assign to the transcoded file. Elastic Transcoder saves the file in the Amazon S3 bucket specified by the `OutputBucket` object in the pipeline that is specified by the pipeline ID.

- **ThumbnailPattern (string)** –

  Whether you want Elastic Transcoder to create thumbnails for your videos and, if so, how you want Elastic Transcoder to name the files.

  If you don’t want Elastic Transcoder to create thumbnails, specify `""`.

  If you do want Elastic Transcoder to create thumbnails, specify the information that you want to include in the file name for each thumbnail. You can specify the following values in any sequence:

  - **{{count}}** (Required): If you want to create thumbnails, you must include `{{count}}` in the `ThumbnailPattern` object. Wherever you specify `{{count}}`, Elastic Transcoder adds a five-digit sequence number (beginning with `00001`) to thumbnail file names. The number indicates where a given thumbnail appears in the sequence of thumbnails for a transcoded file. .. warning::If you specify a literal value and/or `{{resolution}}` but you omit `{{count}}`, Elastic Transcoder returns a validation error and does not create the job.

  - **Literal values (Optional)**: You can specify literal values anywhere in the `ThumbnailPattern` object. For example, you can include them as a file name prefix or as a delimiter between `{{resolution}}` and `{{count}}`.

  - **{{resolution}}** (Optional): If you want Elastic Transcoder to include the resolution in the file name, include `{{resolution}}` in the `ThumbnailPattern` object. When creating thumbnails, Elastic Transcoder automatically saves the files in the format `.jpg` or `.png` that appears in the preset that you specified in the `PresetID` value of `CreateJobOutput`. Elastic Transcoder also appends the applicable file name extension.

- **ThumbnailEncryption (dict)** –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your thumbnail.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
- **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.

- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.

- **AES-CTR**: AES Counter Mode.

- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

| **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data. |

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  \[ 128, 192, \text{ or } 256 \] .

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Rotate (string)** –

  The number of degrees clockwise by which you want Elastic Transcoder to rotate the output relative to the input. Enter one of the following values:
The value `auto` generally works only if the file that you’re transcoding contains rotation metadata.

- **PresetId** *(string)* –

  The value of the `Id` object for the preset that you want to use for this job. The preset determines the audio, video, and thumbnail settings that Elastic Transcoder uses for transcoding. To use a preset that you created, specify the preset ID that Elastic Transcoder returned in the response when you created the preset. You can also use the Elastic Transcoder system presets, which you can get with `ListPresets`.

- **SegmentDuration** *(string)* –

  **Warning:** (Outputs in Fragmented MP4 or MPEG-TS format only.)

  If you specify a preset in `PresetId` for which the value of `Container` is `fmp4` (Fragmented MP4) or `ts` (MPEG-TS), `SegmentDuration` is the target maximum duration of each segment in seconds. For HLSv3 format playlists, each media segment is stored in a separate `.ts` file. For HLSv4 and Smooth playlists, all media segments for an output are stored in a single file. Each segment is approximately the length of the `SegmentDuration`, though individual segments might be shorter or longer.

  The range of valid values is 1 to 60 seconds. If the duration of the video is not evenly divisible by `SegmentDuration`, the duration of the last segment is the remainder of total length/`SegmentDuration`.

  Elastic Transcoder creates an output-specific playlist for each output HLS output that you specify in `OutputKeys`. To add an output to the master playlist for this job, include it in the `OutputKeys` of the associated playlist.

- **Status** *(string)* –

  The status of one output in a job. If you specified only one output for the job, `Outputs:Status` is always the same as `Job:Status`. If you specified more than one output:
  - `Job:Status` and `Outputs:Status` for all of the outputs is Submitted until Elastic Transcoder starts to process the first output.
  - When Elastic Transcoder starts to process the first output, `Outputs:Status` for that output and `Job:Status` both change to Progressing. For each output, the value of `Outputs:Status` remains Submitted until Elastic Transcoder starts to process the output.
  - `Job:Status` remains Progressing until all of the outputs reach a terminal status, either Complete or Error.
  - When all of the outputs reach a terminal status, `Job:Status` changes to Complete only if `Outputs:Status` for all of the outputs is Complete. If `Outputs:Status` for one or more outputs is Error, the
The value of `Status` is one of the following: `Submitted`, `Progressing`, `Complete`, `Canceled`, or `Error`.

- **StatusDetail (string)** –
  Information that further explains `Status`.

- **Duration (integer)** –
  Duration of the output file, in seconds.

- **Width (integer)** –
  Specifies the width of the output file in pixels.

- **Height (integer)** –
  Height of the output file, in pixels.

- **FrameRate (string)** –
  Frame rate of the output file, in frames per second.

- **FileSize (integer)** –
  File size of the output file, in bytes.

- **DurationMillis (integer)** –
  Duration of the output file, in milliseconds.

- **Watermarks (list)** –
  Information about the watermarks that you want Elastic Transcoder to add to the video during transcoding. You can specify up to four watermarks for each output. Settings for each watermark must be defined in the preset that you specify in `Preset` for the current output.

  Watermarks are added to the output video in the sequence in which you list them in the job output—the first watermark in the list is added to the output video first, the second watermark in the list is added next, and so on. As a result, if the settings in a preset cause Elastic Transcoder to place all watermarks in the same location, the second watermark that you add will cover the first one, the third one will cover the second, and the fourth one will cover the third.

  Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

- **PresetWatermarkId (string)** –
  The ID of the watermark settings that Elastic Transcoder uses to add watermarks to the video during transcoding. The settings are in the preset specified by `Preset` for the current output. In that preset, the value of Watermarks Id tells Elastic Transcoder which settings to use.

- **InputKey (string)** –
  The name of the .png or .jpg file that you want to use for the watermark. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by `Pipeline`; the `InputBucket` object in that pipeline identifies the bucket.
If the file name includes a prefix, for example, logos/128x64.png, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **Encryption** *(dict)* –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your watermarks.

- **Mode** *(string)* –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key** *(string)* – The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

    128, 192, or 256.

    The key must also be encrypted by using the Amazon Key Management Service.

  - **KeyMd5** *(string)* –

    The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly
16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AlbumArt** *(dict)* –

  The album art to be associated with the output file, if any.

- **MergePolicy** *(string)* –

  A policy that determines how Elastic Transcoder will handle the existence of multiple album artwork files.

  - **Replace**: The specified album art will replace any existing album art.
  - **Prepend**: The specified album art will be placed in front of any existing album art.
  - **Append**: The specified album art will be placed after any existing album art.
  - **Fallback**: If the original input file contains artwork, Elastic Transcoder will use that artwork for the output. If the original input does not contain artwork, Elastic Transcoder will use the specified album art file.

- **Artwork** *(list)* –

  The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20. Valid formats are `.jpg` and `.png`

- **InputKey** *(string)* –

  The name of the file to be used as album art. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by `PipelineId`; the `InputBucket` object in that pipeline identifies the bucket.

  If the file name includes a prefix, for example, `cooking/pie.jpg`, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **MaxWidth** *(string)* –

  The maximum width of the output album art in pixels. If you specify `auto`, Elastic Transcoder uses 600 as the default.
value. If you specify a numeric value, enter an even integer between 32 and 4096, inclusive.

- **MaxHeight (string)** –

  The maximum height of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 3072, inclusive.

- **SizingPolicy (string)** –

  Specify one of the following values to control scaling of the output album art:

  - **Fit**: Elastic Transcoder scales the output art so it matches the value that you specified in either MaxWidth or MaxHeight without exceeding the other value.
  
  - **Fill**: Elastic Transcoder scales the output art so it matches the value that you specified in either MaxWidth or MaxHeight and matches or exceeds the other value. Elastic Transcoder centers the output art and then crops it in the dimension (if any) that exceeds the maximum value.
  
  - **Stretch**: Elastic Transcoder stretches the output art to match the values that you specified for MaxWidth and MaxHeight. If the relative proportions of the input art and the output art are different, the output art will be distorted.
  
  - **Keep**: Elastic Transcoder does not scale the output art. If either dimension of the input art exceeds the values that you specified for MaxWidth and MaxHeight, Elastic Transcoder crops the output art.
  
  - **ShrinkToFit**: Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of MaxWidth and MaxHeight without exceeding either value. If you specify this option, Elastic Transcoder does not scale the art up.
  
  - **ShrinkToFill** Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of MaxWidth and MaxHeight without dropping below either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **PaddingPolicy (string)** –

  When you set PaddingPolicy to Pad, Elastic Transcoder may add white bars to the top and bottom and/or left and right sides of the output album art to make the total size of the output art match the values that you specified for MaxWidth and MaxHeight.

- **AlbumArtFormat (string)** –

  The format of album art, if any. Valid formats are .jpg and .png.

- **Encryption (dict)** –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your artwork.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or en-
Boto3 supports the following options:

- **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
- **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to un-encrypt your data.

- **Key (string)** –
  
The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  \[128, 192, \text{ or } 256\].

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –
  
The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –
  
The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Composition (list)** –
You can create an output file that contains an excerpt from the input file. This excerpt, called a clip, can come from the beginning, middle, or end of the file. The Composition object contains settings for the clips that make up an output file. For the current release, you can only specify settings for a single clip per output file. The Composition object cannot be null.

- **(dict)** –
  Settings for one clip in a composition. All jobs in a playlist must have the same clip settings.

- **TimeSpan (dict)** –
  Settings that determine when a clip begins and how long it lasts.

- **StartTime (string)** –
  The place in the input file where you want a clip to start. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder starts at the beginning of the input file.

- **Duration (string)** –
  The duration of the clip. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder creates an output file from StartTime to the end of the file.

If you specify a value longer than the duration of the input file, Elastic Transcoder transcodes the file and returns a warning message.

- **Captions (dict)** –
  You can configure Elastic Transcoder to transcode captions, or subtitles, from one format to another. All captions must be in UTF-8. Elastic Transcoder supports two types of captions:

  - **Embedded**: Embedded captions are included in the same file as the audio and video. Elastic Transcoder supports only one embedded caption per language, to a maximum of 300 embedded captions per file. Valid input values include: CEA-608 (EIA-608, first non-empty channel only), CEA-708 (EIA-708, first non-empty channel only), and mov-text. Valid outputs include: mov-text. Elastic Transcoder supports a maximum of one embedded format per output.

  - **Sidecar**: Sidecar captions are kept in a separate metadata file from the audio and video data. Sidecar captions require a player that is capable of understanding the relationship between the video file and the sidecar file. Elastic Transcoder supports only one sidecar caption per language, to a maximum of 20 sidecar captions per file. Valid input values include: dfxp (first div element only), ebu-tt, scc, smpt, srt, ttml (first div element only), and webvtt. Valid outputs include: dfxp (first div element only), scc, srt, and webvtt.
If you want ttml or smpte-tt compatible captions, specify dfxp as your output format.

Elastic Transcoder does not support OCR (Optical Character Recognition), does not accept pictures as a valid input for captions, and is not available for audio-only transcoding. Elastic Transcoder does not preserve text formatting (for example, italics) during the transcoding process.

To remove captions or leave the captions empty, set Captions to null. To pass through existing captions unchanged, set the MergePolicy to MergeRetain, and pass in a null CaptionSources array.

For more information on embedded files, see the Subtitles Wikipedia page.

For more information on sidecar files, see the Extensible Metadata Platform and Sidecar file Wikipedia pages.

- **MergePolicy** *(string)* –
  A policy that determines how Elastic Transcoder handles the existence of multiple captions.

  - **MergeOverride**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the sidecar captions and ignores the embedded captions for that language.

  - **MergeRetain**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the embedded captions and ignores the sidecar captions for that language. If CaptionSources is empty, Elastic Transcoder omits all sidecar captions from the output files.

  - **Override**: Elastic Transcoder transcodes only the sidecar captions that you specify in CaptionSources. MergePolicy cannot be null.

- **CaptionSources** *(list)* –
  Source files for the input sidecar captions used during the transcoding process. To omit all sidecar captions, leave CaptionSources blank.

  - *(dict)* –
    A source file for the input sidecar captions used during the transcoding process.

    - **Key** *(string)* –
      The name of the sidecar caption file that you want Elastic Transcoder to include in the output file.

    - **Language** *(string)* –
      A string that specifies the language of the caption. Specify this as one of:
      - 2-character ISO 639-1 code
      - 3-character ISO 639-2 code
For more information on ISO language codes and language names, see the List of ISO 639-1 codes.

- **TimeOffset** *(string)* –

  For clip generation or captions that do not start at the same time as the associated video file, the `TimeOffset` tells Elastic Transcoder how much of the video to encode before including captions.

  Specify the `TimeOffset` in the form `[+-]SS.sss` or `[+-]HH:mm:SS.ss`.

- **Label** *(string)* –

  The label of the caption shown in the player when choosing a language. We recommend that you put the caption language name here, in the language of the captions.

- **Encryption** *(dict)* –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your caption sources.

- **Mode** *(string)* –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to encrypt your data.

- **Key** *(string)* –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it
must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **CaptionFormats (list)** –

  The array of file formats for the output captions. If you leave this value blank, Elastic Transcoder returns an error.

  - **(dict)** –

    The file format of the output captions. If you leave this value blank, Elastic Transcoder returns an error.

  - **Format (string)** –

    The format you specify determines whether Elastic Transcoder generates an embedded or sidecar caption for this output.

    - **Valid Embedded Caption Formats:** * for FLAC : None
      - For MP3 : None
      - For MP4 : mov-text
      - For MPEG-TS : None
      - For ogg : None
      - For webm : None
    - **Valid Sidecar Caption Formats:** Elastic Transcoder supports dfxp (first div element only), scc, srt, and webvtt. If you want ttml or smpte-tt compatible captions, specify dfxp as your output format. * For FMP4 : dfxp
      - **Non-FMP4 outputs:** All sidecar types
        - FMP4 captions have an extension of .ismt
      - **Pattern (string)** –

    The prefix for caption filenames, in the form description - {language}, where:

    - **description** is a description of the video.
    - **{language}** is a literal value that Elastic Transcoder replaces with the two- or three-letter code for the language of the caption in the output file names.

    If you don’t include **{language}** in the file name pattern, Elastic Transcoder automatically appends “{language}”
to the value that you specify for the description. In addition, Elastic Transcoder automatically appends the count to the end of the segment files.

For example, suppose you’re transcoding into srt format. When you enter “Sydney-(language)-sunrise”, and the language of the captions is English (en), the name of the first caption file will be Sydney-en-sunrise00000.srt.

- **Encryption** *(dict)* –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your caption formats.

- **Mode** *(string)* –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key** *(string)* –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  $$128, 192, 256.$$  

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –

Warning: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.
The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)*

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Encryption** *(dict)*

  The encryption settings, if any, that you want Elastic Transcoder to apply to your output files. If you choose to use encryption, you must specify a mode to use. If you choose not to use encryption, Elastic Transcoder will write an unencrypted file to your Amazon S3 bucket.

- **Mode** *(string)*

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify **S3-AWS-KMS** and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

  - **Key** *(string)*

    The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to en-
decrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –
  
The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –
  
The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AppliedColorSpaceConversion (string)** –
  
If Elastic Transcoder used a preset with a ColorSpaceConversionMode to transcode the output file, the AppliedColorSpaceConversion parameter shows the conversion used. If no ColorSpaceConversionMode was defined in the preset, this parameter will not be included in the job response.

- **OutputKeyPrefix (string)** –
  
The value, if any, that you want Elastic Transcoder to prepend to the names of all files that this job creates, including output files, thumbnails, and playlists. We recommend that you add a / or some other delimiter to the end of the OutputKeyPrefix.

- **Playlists (list)** –

  **Warning**: Outputs in Fragmented MP4 or MPEG-TS format only.

If you specify a preset in PresetId for which the value of Container is fmp4 (Fragmented MP4) or ts (MPEG-TS), Playlists contains information about the master playlists that you want Elastic Transcoder to create.

The maximum number of master playlists in a job is 30.

- **(dict)** –

  Use Only for Fragmented MP4 or MPEG-TS Outputs. If you specify a preset for which the value of Container is fmp4 (Fragmented MP4) or ts (MPEG-TS), Playlists contains information about the master playlists that you want Elastic Transcoder to create. We recommend that you create only
one master playlist per output format. The maximum number of master playlists in a job is 30.

- **Name (string)** –

  The name that you want Elastic Transcoder to assign to the master playlist, for example, nyc-vacation.m3u8. If the name includes a `/` character, the section of the name before the last `/` must be identical for all Name objects. If you create more than one master playlist, the values of all Name objects must be unique.

  **Note:** Elastic Transcoder automatically appends the relevant file extension to the file name (.m3u8 for HLSv3 and HLSv4 playlists, and .ism and .ismc for Smooth playlists). If you include a file extension in Name, the file name will have two extensions.

- **Format (string)** –

  The format of the output playlist. Valid formats include HLSv3, HLSv4, and Smooth.

- **OutputKeys (list)** –

  For each output in this job that you want to include in a master playlist, the value of the Outputs:Key object.

  If your output is not HLS or does not have a segment duration set, the name of the output file is a concatenation of OutputKeyPrefix and Outputs:Key: OutputKeyPrefix"Outputs:Key".

  If your output is HLSv3 and has a segment duration set, or is not included in a playlist, Elastic Transcoder creates an output playlist file with a file extension of .m3u8, and a series of .ts files that include a five-digit sequential counter beginning with 00000: OutputKeyPrefix"Outputs:Key".m3u8.

  If your output is HLSv4, has a segment duration set, and is included in an HLSv4 playlist, Elastic Transcoder creates an output playlist file with a file extension of_v4.m3u8. If the output is video, Elastic Transcoder also creates an output file with an extension of _iframe.m3u8: OutputKeyPrefix"Outputs:Key"_v4.m3u8. OutputKeyPrefix"Outputs:Key"_iframe.m3u8.

  Elastic Transcoder automatically appends the relevant file extension to the file name. If you include a file extension in Output Key, the file name will have two extensions.

  If you include more than one output in a playlist, any segment duration settings, clip settings, or caption settings must be the same for all outputs in the playlist. For Smooth playlists, the Audio:Profile, Video:Profile, and Video:FrameRate to Video:KeyframesMaxDist ratio must be the same for all outputs.

- **(string)** –

- **HlsContentProtection (dict)** –

  The HLS content protection settings, if any, that you want Elastic Transcoder to apply to the output files associated with
this playlist.

- **Method (string)** –
  
  The content protection method for your output. The only valid value is: `aes-128`.
  
  This value will be written into the method attribute of the `EXT-X-KEY` metadata tag in the output playlist.

- **Key (string)** –
  
  If you want Elastic Transcoder to generate a key for you, leave this field blank.
  
  If you choose to supply your own key, you must encrypt the key by using AWS KMS. The key must be base64-encoded, and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

- **KeyMd5 (string)** –
  
  If Elastic Transcoder is generating your key for you, you must leave this field blank.
  
  The MD5 digest of the key that you want Elastic Transcoder to use to encrypt your output file, and that you want Elastic Transcoder to use as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

- **InitializationVector (string)** –
  
  If Elastic Transcoder is generating your key for you, you must leave this field blank.
  
  The series of random bits created by a random bit generator, unique for every encryption operation, that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

- **LicenseAcquisitionUrl (string)** –
  
  The location of the license key required to decrypt your HLS playlist. The URL must be an absolute path, and is referenced in the URI attribute of the `EXT-X-KEY` metadata tag in the playlist file.

- **KeyStoragePolicy (string)** –
  
  Specify whether you want Elastic Transcoder to write your HLS license key to an Amazon S3 bucket. If you choose `WithVariantPlaylists`, `LicenseAcquisitionUrl` must be left blank and Elastic Transcoder writes your data key into the same bucket as the associated playlist.

- **PlayReadyDrm (dict)** –
  
  The DRM settings, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

- **Format (string)** –
The type of DRM, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

- **Key (string)** –

  The DRM key for your file, provided by your DRM license provider. The key must be base64-encoded, and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using AWS KMS.

- **KeyMd5 (string)** –

  The MD5 digest of the key used for DRM on your file, and that you want Elastic Transcoder to use as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

- **KeyId (string)** –

  The ID for your DRM key, so that your DRM license provider knows which key to provide.

  The key ID must be provided in big endian, and Elastic Transcoder will convert it to little endian before inserting it into the PlayReady DRM headers. If you are unsure whether your license server provides your key ID in big or little endian, check with your DRM provider.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you want Elastic Transcoder to use to encrypt your files. The initialization vector must be base64-encoded, and it must be exactly 8 bytes long before being base64-encoded. If no initialization vector is provided, Elastic Transcoder generates one for you.

- **LicenseAcquisitionUrl (string)** –

  The location of the license key required to play DRM content. The URL must be an absolute path, and is referenced by the PlayReady header. The PlayReady header is referenced in the protection header of the client manifest for Smooth Streaming outputs, and in the EXT-X-DXDRM and EXT-XDXDRMINFO metadata tags for HLS playlist outputs. An example URL looks like this: https://www.example.com/exampleKey/

- **Status (string)** –

  The status of the job with which the playlist is associated.

  - **StatusDetail (string)** –

    Information that further explains the status.

  - **Status (string)** –

    The status of the job: Submitted, Progressing, Complete, Cancelled, or Error.

- **UserMetadata (dict)** –

  User-defined metadata that you want to associate with an Elastic Transcoder job. You specify metadata in key/value pairs.
pairs, and you can add up to 10 key/value pairs per job. Elastic Transcoder does not guarantee that key/value pairs will be returned in the same order in which you specify them.

Metadata keys and values must use characters from the following list:

- 0-9
- A-Z and a-z
- Space
- The following symbols: _, : /=+-%@
- (string)
- (string)
- Timing (dict)

Details about the timing of a job.

- SubmitTimeMillis (integer)
  The time the job was submitted to Elastic Transcoder, in epoch milliseconds.
- StartTimeMillis (integer)
  The time the job began transcoding, in epoch milliseconds.
- FinishTimeMillis (integer)
  The time the job finished transcoding, in epoch milliseconds.

- NextPageToken (string)
  A value that you use to access the second and subsequent pages of results, if any. When the jobs in the specified pipeline fit on one page or when you've reached the last page of results, the value of NextPageToken must be null.

`list_pipelines(**kwargs)`

The ListPipelines operation gets a list of the pipelines associated with the current AWS account.

Request Syntax

```python
response = client.list_pipelines(
    Ascending='string',
    PageToken='string'
)
```

Parameters

- **Ascending (string)** – To list pipelines in chronological order by the date and time that they were created, enter `true`. To list pipelines in reverse chronological order, enter `false`.
- **PageToken (string)** – When Elastic Transcoder returns more than one page of results, use `pageToken` in subsequent GET requests to get each successive page of results.

Return type: dict

Returns

Response Syntax

```json
{
    'Pipelines': [
        {
            'Id': 'string',
            'Arn': 'string',
```
Response Structure

- (dict) –

A list of the pipelines associated with the current AWS account.

- Pipelines (list) –

An array of Pipeline objects.

- (dict) –

The pipeline (queue) that is used to manage jobs.

- Id (string) –

The identifier for the pipeline. You use this value to identify the pipeline in which you want to perform a variety of operations, such as creating a job or a preset.

- Arn (string) –
The Amazon Resource Name (ARN) for the pipeline.

- **Name** (*string*) –
  
  The name of the pipeline. We recommend that the name be unique within the AWS account, but uniqueness is not enforced.

  Constraints: Maximum 40 characters

- **Status** (*string*) –
  
  The current status of the pipeline:
  
  - **Active**: The pipeline is processing jobs.
  
  - **Paused**: The pipeline is not currently processing jobs.

- **InputBucket** (*string*) –
  
  The Amazon S3 bucket from which Elastic Transcoder gets media files for transcoding and the graphics files, if any, that you want to use for watermarks.

- **OutputBucket** (*string*) –
  
  The Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files, thumbnails, and playlists. Either you specify this value, or you specify both `ContentConfig` and `ThumbnailConfig`.

- **Role** (*string*) –
  
  The IAM Amazon Resource Name (ARN) for the role that Elastic Transcoder uses to transcode jobs for this pipeline.

- **AwsKmsKeyArn** (*string*) –
  
  The AWS Key Management Service (AWS KMS) key that you want to use with this pipeline.

  If you use either S3 or S3-AWS-KMS as your Encryption:Mode, you don’t need to provide a key with your job because a default key, known as an AWS-KMS key, is created for you automatically. You need to provide an AWS-KMS key only if you want to use a non-default AWS-KMS key, or if you are using an Encryption:Mode of AES-PKCS7, AES-CTR, or AES-GCM.

- **Notifications** (*dict*) –
  
  The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify to report job status.

  - **Warning** *(optional)*: The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify when Elastic Transcoder encounters a warning condition.
  
  - **Error** *(optional)*: The Amazon SNS topic that you want to notify when Elastic Transcoder encounters an error condition.
- **Progressing** *(string)* –
  The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify when Elastic Transcoder has started to process the job.

- **Completed** *(string)* –
  The Amazon SNS topic that you want to notify when Elastic Transcoder has finished processing the job.

- **Warning** *(string)* –
  The Amazon SNS topic that you want to notify when Elastic Transcoder encounters a warning condition.

- **Error** *(string)* –
  The Amazon SNS topic that you want to notify when Elastic Transcoder encounters an error condition.

- **ContentConfig** *(dict)* –
  Information about the Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists. Either you specify both `ContentConfig` and `ThumbnailConfig`, or you specify `OutputBucket`.

  - **Bucket** : The Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists.
  - **Permissions** : A list of the users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access that you want them to have. **GranteeType**: The type of value that appears in the Grantee object: **Canonical** : Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution.
    - **Grantee** : The AWS user or group that you want to have access to transcoded files and playlists.
    - **Access** : The permission that you want to give to the AWS user that is listed in Grantee. Valid values include: **READ** : The grantee can read the objects and metadata for objects that Elastic Transcoder adds to the Amazon S3 bucket.
      - **READ_ACP** : The grantee can read the object ACL for objects that Elastic Transcoder adds to the Amazon S3 bucket.
      - **WRITE_ACP** : The grantee can write the ACL for the objects that Elastic Transcoder adds to the Amazon S3 bucket.
      - **FULL_CONTROL** : The grantee has READ, READ_ACP, and WRITE_ACP permissions for the objects that Elastic Transcoder adds to the Amazon S3 bucket.
    - **StorageClass** : The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

  - **Bucket** *(string)* –
    The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the
following are true:

- You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.
- You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.
- You do not want to specify the permissions that Elastic Transcoder grants to the files.
- You want to associate the transcoded files and thumbnails with the Amazon S3 Standard storage class.

If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit OutputBucket and specify values for ContentConfig and ThumbnailConfig instead.

- **StorageClass** *(string)* –

  The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

- **Permissions** *(list)* –

  Optional. The Permissions object specifies which users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.

  If you include Permissions, Elastic Transcoder grants only the permissions that you specify. It does not grant full permissions to the owner of the role specified by Role. If you want that user to have full control, you must explicitly grant full control to the user.

  If you omit Permissions, Elastic Transcoder grants full control over the transcoded files and playlists to the owner of the role specified by Role, and grants no other permissions to any other user or group.

- **(dict)** –

  The Permission structure.

- **GranteeType** *(string)* –

  The type of value that appears in the Grantee object:

  - **Canonical** : Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning:: A canonical user ID is not the same as an AWS account number.
  - **Email** : The registered email address of an AWS account.
  - **Group** : One of the following predefined Amazon S3 groups: AllUsers, AuthenticatedUsers, or LogDelivery.
  - **Grantee** *(string)* –

    The AWS user or group that you want to have access to transcoded files and playlists. To identify the user or group,
you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.

- **Access** *(list)*

  The permission that you want to give to the AWS user that is listed in Grantee. Valid values include:
  - **READ**: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **READ_ACP**: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **WRITE_ACP**: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **FULL_CONTROL**: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

- **(string)**

- **ThumbnailConfig** *(dict)*

  Information about the Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files. Either you specify both **ContentConfig** and **ThumbnailConfig**, or you specify **OutputBucket**.
  - **Bucket**: The Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files.
  - **Permissions**: A list of the users and/or predefined Amazon S3 groups you want to have access to thumbnail files, and the type of access that you want them to have. *GranteeType*: The type of value that appears in the Grantee object: *
    - **Canonical**: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning:: A canonical user ID is not the same as an AWS account number.
  - **Email**: The registered email address of an AWS account.
  - **Group**: One of the following predefined Amazon S3 groups: **AllUsers**, **AuthenticatedUsers**, or **LogDelivery**.
  - **Grantee**: The AWS user or group that you want to have access to thumbnail files.
  - **Access**: The permission that you want to give to the AWS user that is listed in Grantee. Valid values include: *
    - **READ**: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
    - **READ_ACP**: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
    - **WRITE_ACP**: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
    - **FULL_CONTROL**: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **StorageClass**: The Amazon S3 storage class, **Standard** or **ReducedRedundancy**, that you want Elastic Transcoder to assign to the thumbnails that it stores in your
Bucket *(string)* –

The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the following are true:

- You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.
- You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.
- You do not want to specify the permissions that Elastic Transcoder grants to the files.
- You want to associate the transcoded files and thumbnails with the Amazon S3 Standard storage class.

If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit OutputBucket and specify values for ContentConfig and ThumbnailConfig instead.

StorageClass *(string)* –

The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

Permissions *(list)* –

Optional. The Permissions object specifies which users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.

If you include Permissions, Elastic Transcoder grants only the permissions that you specify. It does not grant full permissions to the owner of the role specified by Role. If you want that user to have full control, you must explicitly grant full control to the user.

If you omit Permissions, Elastic Transcoder grants full control over the transcoded files and playlists to the owner of the role specified by Role, and grants no other permissions to any other user or group.

GranteeType *(string)* –

The type of value that appears in the Grantee object:

- Canonical: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning::A canonical user ID is not the same as an AWS account number.
- Email: The registered email address of an AWS account.
- Group: One of the following predefined Amazon S3 groups: AllUsers, AuthenticatedUsers, or
LogDelivery.

- **Grantee (string)** –
  The AWS user or group that you want to have access to transcoded files and playlists. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.

- **Access (list)** –
  The permission that you want to give to the AWS user that is listed in Grantee. Valid values include:
  - **READ**: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **READ_ACP**: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **WRITE_ACP**: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **FULL_CONTROL**: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

- **NextPageToken (string)** –
  A value that you use to access the second and subsequent pages of results, if any. When the pipelines fit on one page or when you’ve reached the last page of results, the value of **NextPageToken** is **null**.

---

**list_presets(****kwargs***)

The ListPresets operation gets a list of the default presets included with Elastic Transcoder and the presets that you’ve added in an AWS region.

**Request Syntax**

```python
response = client.list_presets(
    Ascending='string',
    PageToken='string'
)
```

**Parameters**

- **Ascending (string)** – To list presets in chronological order by the date and time that they were created, enter **true**. To list presets in reverse chronological order, enter **false**.
- **PageToken (string)** – When Elastic Transcoder returns more than one page of results, use **pageToken** in subsequent GET requests to get each successive page of results.

**Return type** dict

**Returns**

**Response Syntax**

```json

'3.1. Services 2317
Response Structure

- (dict) –

  The ListPresetsResponse structure.

  - Presets (list) –

    An array of Preset objects.

    * (dict) –

      Presets are templates that contain most of the settings for transcoding media files from one format to another. Elastic Transcoder includes some default presets for common formats, for example, several iPod and iPhone versions. You can also create your own presets for formats that aren’t included among the default presets. You specify which preset you want to use when you create a job.

      - Id (string) –

        Identifier for the new preset. You use this value to get settings for the preset or to delete it.

      - Arn (string) –

        The Amazon Resource Name (ARN) for the preset.

      - Name (string) –

        The name of the preset.

      - Description (string) –

        A description of the preset.

      - Container (string) –

        The container type for the output file. Valid values include flac, flv, fmp4, gif, mp3, mp4, mpg, mxf, oga, ogg, ts, and webm.

      - Audio (dict) –

        A section of the response body that provides information about the audio preset values.

      - Codec (string) –

        The audio codec for the output file. Valid values include aac, flac, mp2, mp3, pcm, and vorbis.

      - SampleRate (string) –

        The sample rate of the audio stream in the output file, in Hertz. Valid values include:

        auto, 22050, 32000, 44100, 48000, 96000

        If you specify auto, Elastic Transcoder automatically detects the sample rate.

      - BitRate (string) –

        The bit rate of the audio stream in the output file, in kilobits/second. Enter an integer between 64 and 320, inclusive.
Channels (string) –

The number of audio channels in the output file. The following values are valid:

auto, 0, 1, 2

One channel carries the information played by a single speaker. For example, a stereo track with two channels sends one channel to the left speaker, and the other channel to the right speaker. The output channels are organized into tracks. If you want Elastic Transcoder to automatically detect the number of audio channels in the input file and use that value for the output file, select auto.

The output of a specific channel value and inputs are as follows:

- auto channel specified, with any input: Pass through up to eight input channels.
- 0 channels specified, with any input: Audio omitted from the output.
- 1 channel specified, with at least one input channel: Mono sound.
- 2 channels specified, with any input: Two identical mono channels or stereo. For more information about tracks, see Audio:AudioPackingMode.

For more information about how Elastic Transcoder organizes channels and tracks, see Audio:AudioPackingMode.

AudioPackingMode (string) –

The method of organizing audio channels and tracks. Use Audio:Channels to specify the number of channels in your output, and Audio:AudioPackingMode to specify the number of tracks and their relation to the channels. If you do not specify an Audio:AudioPackingMode, Elastic Transcoder uses SingleTrack.

The following values are valid:

SingleTrack, OneChannelPerTrack, and OneChannelPerTrackWithMosTo8Tracks

When you specify SingleTrack, Elastic Transcoder creates a single track for your output. The track can have up to eight channels. Use SingleTrack for all non-mxf containers.

The outputs of SingleTrack for a specific channel value and inputs are as follows:

- 0 channels with any input: Audio omitted from the output
- 1, 2, or auto channels with no audio input: Audio omitted from the output
- 1 channel with any input with audio: One track with one channel, downmixed if necessary
- 2 channels with one track with one channel: One track with two identical channels
- 2 or auto channels with two tracks with one channel each: One track with two channels
- **2 or auto** channels with one track with two channels:
  One track with two channels
- **2** channels with one track with multiple channels:
  One track with two channels
- **auto** channels with one track with one channel:
  One track with one channel
- **auto** channels with one track with multiple channels:
  One track with multiple channels
  When you specify `OneChannelPerTrack`, Elastic Transcoder creates a new track for every channel in your output. Your output can have up to eight single-channel tracks.

The outputs of `OneChannelPerTrack` for a specific channel value and inputs are as follows:
- **0 channels with any input**: Audio omitted from the output
- **1, 2, or auto** channels with no audio input:
  Audio omitted from the output
- **1 channel with any input with audio**: One track with one channel, downmixed if necessary
- **2 channels with one track with one channel**: Two tracks with one identical channel each
- **2 or auto** channels with two tracks with one channel each:
  Two tracks with one channel each
- **2 or auto** channels with one track with two channels:
  Two tracks with one channel each
- **2 channels with one track with multiple channels**: Two tracks with one channel each
- **auto** channels with one track with one channel:
  One track with one channel
- **auto** channels with one track with multiple channels:
  Up to eight tracks with one channel each
  When you specify `OneChannelPerTrackWithMosTo8Tracks`, Elastic Transcoder creates eight single-channel tracks for your output. All tracks that do not contain audio data from an input channel are MOS, or Mit Out Sound, tracks.

The outputs of `OneChannelPerTrackWithMosTo8Tracks` for a specific channel value and inputs are as follows:
- **0 channels with any input**: Audio omitted from the output
- **1, 2, or auto** channels with no audio input:
  Audio omitted from the output
- **1 channel with any input with audio**: One track with one channel, downmixed if necessary, plus six MOS tracks
- **2 channels with one track with one channel**: Two tracks with one identical channel each, plus six MOS tracks
- **2 or auto** channels with two tracks with one channel each:
  Two tracks with one channel each, plus six MOS tracks
- **2 or auto** channels with one track with two channels:
  Two tracks with one channel each, plus six MOS tracks
- **2 channels with one track with multiple channels**: Two tracks with one channel each, plus six MOS tracks
- **auto** channels with one track with one channel:
  One track with one channel, plus seven MOS tracks
- **auto** channels with one track with multiple channels:
  Up to eight tracks with one channel each, plus MOS tracks until
there are eight tracks in all

- CodecOptions (dict) –

  If you specified AAC for Audio:Codec, this is the AAC compression profile to use. Valid values include:

  auto, AAC-LC, HE-AAC, HE-AACv2

  If you specify auto, Elastic Transcoder chooses a profile based on the bit rate of the output file.

- Profile (string) –

  You can only choose an audio profile when you specify AAC for the value of Audio:Codec.

  Specify the AAC profile for the output file. Elastic Transcoder supports the following profiles:

  - auto: If you specify auto, Elastic Transcoder will select the profile based on the bit rate selected for the output file.
  - AAC-LC: The most common AAC profile. Use for bit rates larger than 64 kbps.
  - HE-AAC: Not supported on some older players and devices. Use for bit rates between 40 and 80 kbps.
  - HE-AACv2: Not supported on some players and devices. Use for bit rates less than 48 kbps.

  All outputs in a Smooth playlist must have the same value for Profile.

Note: If you created any presets before AAC profiles were added, Elastic Transcoder automatically updated your presets to use AAC-LC. You can change the value as required.

- BitDepth (string) –

  You can only choose an audio bit depth when you specify flac or pcm for the value of Audio:Codec.

  The bit depth of a sample is how many bits of information are included in the audio samples. The higher the bit depth, the better the audio, but the larger the file.

  Valid values are 16 and 24.

  The most common bit depth is 24.

- BitOrder (string) –

  You can only choose an audio bit order when you specify pcm for the value of Audio:Codec.

  The order the bits of a PCM sample are stored in.

  The supported value is LittleEndian.

- Signed (string) –

  You can only choose whether an audio sample is signed when you specify pcm for the value of Audio:Codec.

  Whether audio samples are represented with negative and positive numbers (signed) or only positive numbers (unsigned).

  The supported value is Signed.
· **Video** *(dict)* –
  
  A section of the response body that provides information about the video preset values.

· **Codec** *(string)* –
  
  The video codec for the output file. Valid values include *gif*, *H.264*, *mpeg2*, and *vp8*. You can only specify *vp8* when the container type is *webm*, *gif* when the container type is *gif*, and *mpeg2* when the container type is *mpg*.

· **CodecOptions** *(dict)* –

  **Profile (H.264/VP8 Only)**
  
  The H.264 profile that you want to use for the output file. Elastic Transcoder supports the following profiles:

  · **baseline**: The profile most commonly used for videoconferencing and for mobile applications.
  
  · **main**: The profile used for standard-definition digital TV broadcasts.
  
  · **high**: The profile used for high-definition digital TV broadcasts and for Blu-ray discs.

  **Level (H.264 Only)**
  
  The H.264 level that you want to use for the output file. Elastic Transcoder supports the following levels:
  
  1, 1.1, 1.2, 1.3, 2, 2.1, 2.2, 3, 3.1, 3.2, 4
  
  · **MaxReferenceFrames (H.264 Only)**

  Applicable only when the value of Video:Codec is H.264. The maximum number of previously decoded frames to use as a reference for decoding future frames. Valid values are integers 0 through 16, but we recommend that you not use a value greater than the following:

  \[
  \text{Min}(\text{Floor}(\text{Maximum decoded picture buffer in macroblocks} \times 256 / (\text{Width in pixels} \times \text{Height in pixels})), 16)
  \]

  where *Width in pixels* and *Height in pixels* represent either MaxWidth and MaxHeight, or Resolution. *Maximum decoded picture buffer in macroblocks* depends on the value of the Level object. See the list below. (A macroblock is a block of pixels measuring 16x16.)

  · 1 - 396
  
  · 1b - 396
  
  · 1.1 - 900
  
  · 1.2 - 2376
  
  · 1.3 - 2376
  
  · 2 - 2376
  
  · 2.1 - 4752
  
  · 2.2 - 8100
  
  · 3 - 8100
  
  · 3.1 - 18000
  
  · 3.2 - 20480
  
  · 4 - 32768
  
  · 4.1 - 32768
MaxBitRate (Optional, H.264/MPEG2/VP8 only)
The maximum number of bits per second in a video buffer; the size of the buffer is specified by BufferSize. Specify a value between 16 and 62,500. You can reduce the bandwidth required to stream a video by reducing the maximum bit rate, but this also reduces the quality of the video.

BufferSize (Optional, H.264/MPEG2/VP8 only)
The maximum number of bits in any x seconds of the output video. This window is commonly 10 seconds, the standard segment duration when you’re using FMP4 or MPEG-TS for the container type of the output video. Specify an integer greater than 0. If you specify MaxBitRate and omit BufferSize, Elastic Transcoder sets BufferSize to 10 times the value of MaxBitRate.

InterlacedMode (Optional, H.264/MPEG2 Only)
The interlace mode for the output video.
Interlaced video is used to double the perceived frame rate for a video by interlacing two fields (one field on every other line, the other field on the other lines) so that the human eye registers multiple pictures per frame. Interlacing reduces the bandwidth required for transmitting a video, but can result in blurred images and flickering.
Valid values include Progressive (no interlacing, top to bottom), TopFirst (top field first), BottomFirst (bottom field first), and Auto.
If InterlaceMode is not specified, Elastic Transcoder uses Progressive for the output. If Auto is specified, Elastic Transcoder interlaces the output.

ColorSpaceConversionMode (Optional, H.264/MPEG2 Only)
The color space conversion Elastic Transcoder applies to the output video. Color spaces are the algorithms used by the computer to store information about how to render color. Bt.601 is the standard for standard definition video, while Bt.709 is the standard for high definition video.
Valid values include None, Bt709toBt601, Bt601toBt709, and Auto.
If you chose Auto for ColorSpaceConversionMode and your output is interlaced, your frame rate is one of 23.97, 24, 25, 29.97, 50, or 60, your SegmentDuration is null, and you are using one of the resolution changes from the list below, Elastic Transcoder applies the following color space conversions:
- Standard to HD, 720x480 to 1920x1080 - Elastic Transcoder applies Bt601ToBt709
- Standard to HD, 720x576 to 1920x1080 - Elastic Transcoder applies Bt601ToBt709
· **HD to Standard, 1920x1080 to 720x480** - Elastic Transcoder applies Bt709ToBt601
· **HD to Standard, 1920x1080 to 720x576** - Elastic Transcoder applies Bt709ToBt601

**Note:** Elastic Transcoder may change the behavior of the ColorSpaceConversionMode Auto mode in the future. All outputs in a playlist must use the same ColorSpaceConversionMode.

If you do not specify a ColorSpaceConversionMode, Elastic Transcoder does not change the color space of a file. If you are unsure what ColorSpaceConversionMode was applied to your output file, you can check the AppliedColorSpaceConversion parameter included in your job response. If your job does not have an AppliedColorSpaceConversion in its response, no ColorSpaceConversionMode was applied.

**ChromaSubsampling**

The sampling pattern for the chroma (color) channels of the output video. Valid values include yuv420p and yuv422p.

- **yuv420p** samples the chroma information of every other horizontal and every other vertical line, yuv422p samples the color information of every horizontal line and every other vertical line.

**LoopCount (Gif Only)**

The number of times you want the output gif to loop. Valid values include Infinite and integers between 0 and 100, inclusive.

- *(string)* –
- *(string)* –

**KeyframesMaxDist (string)** –

Applicable only when the value of Video:Codec is one of H.264, MPEG2, or VP8.

The maximum number of frames between key frames. Key frames are fully encoded frames; the frames between key frames are encoded based, in part, on the content of the key frames. The value is an integer formatted as a string; valid values are between 1 (every frame is a key frame) and 100000, inclusive. A higher value results in higher compression but may also discernibly decrease video quality.

For Smooth outputs, the FrameRate must have a constant ratio to the KeyframesMaxDist. This allows Smooth playlists to switch between different quality levels while the file is being played.

For example, an input file can have a FrameRate of 30 with a KeyframesMaxDist of 90. The output file then needs to have a ratio of 1:3. Valid outputs would have FrameRate of 30, 25, and 10, and KeyframesMaxDist of 90, 75, and 30, respectively.
Alternately, this can be achieved by setting FrameRate to auto and having the same values for MaxFrameRate and KeyframesMaxDist.

- **FixedGOP (string)** –
  
  Applicable only when the value of Video:Codec is one of H.264, MPEG2, or VP8.
  
  Whether to use a fixed value for FixedGOP. Valid values are true and false:
  - true: Elastic Transcoder uses the value of KeyframesMaxDist for the distance between key frames (the number of frames in a group of pictures, or GOP).
  - false: The distance between key frames can vary.

  **Warning:** FixedGOP must be set to true for fmp4 containers.

- **BitRate (string)** –
  
  The bit rate of the video stream in the output file, in kilo-bits/second. Valid values depend on the values of Level and Profile. If you specify auto, Elastic Transcoder uses the detected bit rate of the input source. If you specify a value other than auto, we recommend that you specify a value less than or equal to the maximum H.264-compliant value listed for your level and profile:

  * Level - Maximum video bit rate in kilobits/second (baseline and main Profile) : maximum video bit rate in kilobits/second (high Profile)
  
  - 1 - 64 : 80
  - 1b - 128 : 160
  - 1.1 - 192 : 240
  - 1.2 - 384 : 480
  - 1.3 - 768 : 960
  - 2 - 2000 : 2500
  - 3 - 10000 : 12500
  - 3.1 - 14000 : 17500
  - 3.2 - 20000 : 25000
  - 4 - 20000 : 25000
  - 4.1 - 50000 : 62500

- **FrameRate (string)** –
  
  The frames per second for the video stream in the output file. Valid values include:

  auto, 10, 15, 23.97, 24, 25, 29.97, 30, 60

  If you specify auto, Elastic Transcoder uses the detected frame rate of the input source. If you specify a frame rate, we recommend that you perform the following calculation:

  \[
  \text{Frame rate} = \text{maximum recommended decoding speed in luma samples/second / (width in pixels} \times \text{height in pixels)}
  \]

  where:
width in pixels and height in pixels represent the Resolution of the output video.

maximum recommended decoding speed in Luma samples/second is less than or equal to the maximum value listed in the following table, based on the value that you specified for Level.

The maximum recommended decoding speed in Luma samples/second for each level is described in the following list (Level - Decoding speed):

- 1 - 380160
- 1b - 380160
- 1.1 - 76800
- 1.2 - 153600
- 1.3 - 3041280
- 2 - 3041280
- 2.1 - 5068800
- 2.2 - 5184000
- 3 - 10368000
- 3.1 - 27648000
- 3.2 - 55296000
- 4 - 62914560
- 4.1 - 62914560

MaxFrameRate (string) –

If you specify auto for FrameRate, Elastic Transcoder uses the frame rate of the input video for the frame rate of the output video. Specify the maximum frame rate that you want Elastic Transcoder to use when the frame rate of the input video is greater than the desired maximum frame rate of the output video. Valid values include: 10, 15, 23.97, 24, 25, 29.97, 30, 60.

Resolution (string) –

Warning: To better control resolution and aspect ratio of output videos, we recommend that you use the values MaxWidth, MaxHeight, SizingPolicy, PaddingPolicy, and DisplayAspectRatio instead of Resolution andAspectRatio. The two groups of settings are mutually exclusive. Do not use them together.

The width and height of the video in the output file, in pixels. Valid values are auto and width x height:

- auto: Elastic Transcoder attempts to preserve the width and height of the input file, subject to the following rules.
- *width* x *height*: The width and height of the output video in pixels.

Note the following about specifying the width and height:

- The width must be an even integer between 128 and 4096, inclusive.
- The height must be an even integer between 96 and 3072, inclusive.
- If you specify a resolution that is less than the resolution of the input file, Elastic Transcoder rescales the output file to the
lower resolution.

- If you specify a resolution that is greater than the resolution of the input file, Elastic Transcoder rescales the output to the higher resolution.
- We recommend that you specify a resolution for which the product of width and height is less than or equal to the applicable value in the following list (\textit{List - Max width \times height value}):
  - 1 - 25344
  - 1b - 25344
  - 1.1 - 101376
  - 1.2 - 101376
  - 1.3 - 101376
  - 2 - 101376
  - 2.1 - 202752
  - 2.2 - 404720
  - 3 - 404720
  - 3.1 - 921600
  - 3.2 - 1310720
  - 4 - 2097152
  - 4.1 - 2097152

- \texttt{AspectRatio (string)} –

\begin{center}
\begin{tabular}{|l|}
\hline
\textbf{Warning:} To better control resolution and aspect ratio of output videos, we recommend that you use the values \texttt{MaxWidth, MaxHeight, SizingPolicy, PaddingPolicy}, and \texttt{DisplayAspectRatio} instead of \texttt{Resolution} and \texttt{AspectRatio}. The two groups of settings are mutually exclusive. Do not use them together. \\
\hline
\end{tabular}
\end{center}

The display aspect ratio of the video in the output file. Valid values include:

\texttt{auto, 1:1, 4:3, 3:2, 16:9}

If you specify \texttt{auto}, Elastic Transcoder tries to preserve the aspect ratio of the input file.

If you specify an aspect ratio for the output file that differs from aspect ratio of the input file, Elastic Transcoder adds pillarboxing (black bars on the sides) or letterboxing (black bars on the top and bottom) to maintain the aspect ratio of the active region of the video.

- \texttt{MaxWidth (string)} –

The maximum width of the output video in pixels. If you specify \texttt{auto}, Elastic Transcoder uses 1920 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 128 and 4096.

- \texttt{MaxHeight (string)} –

The maximum height of the output video in pixels. If you specify \texttt{auto}, Elastic Transcoder uses 1080 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 96 and 3072.
- **DisplayAspectRatio** *(string)* –
  The value that Elastic Transcoder adds to the metadata in the output file.

- **SizingPolicy** *(string)* –
  Specify one of the following values to control scaling of the output video:
  - **Fit**: Elastic Transcoder scales the output video so it matches the value that you specified in either `MaxWidth` or `MaxHeight` without exceeding the other value.
  - **Fill**: Elastic Transcoder scales the output video so it matches the value that you specified in either `MaxWidth` or `MaxHeight` and matches or exceeds the other value. Elastic Transcoder centers the output video and then crops it in the dimension (if any) that exceeds the maximum value.
  - **Stretch**: Elastic Transcoder stretches the output video to match the values that you specified for `MaxWidth` and `MaxHeight`. If the relative proportions of the input video and the output video are different, the output video will be distorted.
  - **Keep**: Elastic Transcoder does not scale the output video. If either dimension of the input video exceeds the values that you specified for `MaxWidth` and `MaxHeight`, Elastic Transcoder crops the output video.
  - **ShrinkToFit**: Elastic Transcoder scales the output video down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without exceeding either value. If you specify this option, Elastic Transcoder does not scale the video up.
  - **ShrinkToFill**: Elastic Transcoder scales the output video down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without dropping below either value. If you specify this option, Elastic Transcoder does not scale the video up.

- **PaddingPolicy** *(string)* –
  When you set `PaddingPolicy` to `Pad`, Elastic Transcoder may add black bars to the top and bottom and/or left and right sides of the output video to make the total size of the output video match the values that you specified for `MaxWidth` and `MaxHeight`.

- **Watermarks** *(list)* –
  Settings for the size, location, and opacity of graphics that you want Elastic Transcoder to overlay over videos that are transcoded using this preset. You can specify settings for up to four watermarks. Watermarks appear in the specified size and location, and with the specified opacity for the duration of the transcoded video.

  Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

  When you create a job that uses this preset, you specify the .png or .jpg graphics that you want Elastic Transcoder to in-
clude in the transcoded videos. You can specify fewer graphics in the job than you specify watermark settings in the preset, which allows you to use the same preset for up to four watermarks that have different dimensions.

- **(dict)** –

  Settings for the size, location, and opacity of graphics that you want Elastic Transcoder to overlay over videos that are transcoded using this preset. You can specify settings for up to four watermarks. Watermarks appear in the specified size and location, and with the specified opacity for the duration of the transcoded video.

  Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

  When you create a job that uses this preset, you specify the .png or .jpg graphics that you want Elastic Transcoder to include in the transcoded videos. You can specify fewer graphics in the job than you specify watermark settings in the preset, which allows you to use the same preset for up to four watermarks that have different dimensions.

- **Id** (**string**) – A unique identifier for the settings for one watermark. The value of Id can be up to 40 characters long.

- **MaxWidth** (**string**) –

  The maximum width of the watermark in one of the following formats:
  - number of pixels (px): The minimum value is 16 pixels, and the maximum value is the value of MaxWidth.
  - integer percentage (%): The range of valid values is 0 to 100. Use the value of Target to specify whether you want Elastic Transcoder to include the black bars that are added by Elastic Transcoder, if any, in the calculation.
  If you specify the value in pixels, it must be less than or equal to the value of MaxWidth.

- **MaxHeight** (**string**) –

  The maximum height of the watermark in one of the following formats:
  - number of pixels (px): The minimum value is 16 pixels, and the maximum value is the value of MaxHeight.
  - integer percentage (%): The range of valid values is 0 to 100. Use the value of Target to specify whether you want Elastic Transcoder to include the black bars that are added by Elastic Transcoder, if any, in the calculation.
  If you specify the value in pixels, it must be less than or equal to the value of MaxHeight.

- **SizingPolicy** (**string**) –

  A value that controls scaling of the watermark:
  - **Fit**: Elastic Transcoder scales the watermark so it matches the value that you specified in either MaxWidth or MaxHeight without exceeding the other value.
  - **Stretch**: Elastic Transcoder stretches the watermark to match the values that you specified for MaxWidth and
MaxHeight. If the relative proportions of the watermark and the values of MaxWidth and MaxHeight are different, the watermark will be distorted.

- **ShrinkToFit**: Elastic Transcoder scales the watermark down so that its dimensions match the values that you specified for at least one of MaxWidth and MaxHeight without exceeding either value. If you specify this option, Elastic Transcoder does not scale the watermark up.

- **HorizontalAlign (string)** –

  The horizontal position of the watermark unless you specify a non-zero value for HorizontalOffset:
  - **Left**: The left edge of the watermark is aligned with the left border of the video.
  - **Right**: The right edge of the watermark is aligned with the right border of the video.
  - **Center**: The watermark is centered between the left and right borders.

- **HorizontalOffset (string)** –

  The amount by which you want the horizontal position of the watermark to be offset from the position specified by HorizontalAlign:
  - number of pixels (px): The minimum value is 0 pixels, and the maximum value is the value of MaxWidth.
  - integer percentage (%): The range of valid values is 0 to 100.

  For example, if you specify **Left** for HorizontalAlign and 5px for HorizontalOffset, the left side of the watermark appears 5 pixels from the left border of the output video.

  HorizontalOffset is only valid when the value of HorizontalAlign is **Left** or **Right**. If you specify an offset that causes the watermark to extend beyond the left or right border and Elastic Transcoder has not added black bars, the watermark is cropped. If Elastic Transcoder has added black bars, the watermark extends into the black bars. If the watermark extends beyond the black bars, it is cropped.

  Use the value of Target to specify whether you want to include the black bars that are added by Elastic Transcoder, if any, in the offset calculation.

- **VerticalAlign (string)** –

  The vertical position of the watermark unless you specify a non-zero value for VerticalOffset:
  - **Top**: The top edge of the watermark is aligned with the top border of the video.
  - **Bottom**: The bottom edge of the watermark is aligned with the bottom border of the video.
  - **Center**: The watermark is centered between the top and bottom borders.

- **VerticalOffset (string)** – VerticalOffset

  The amount by which you want the vertical position of the watermark to be offset from the position specified by VerticalAlign:
· number of pixels (px): The minimum value is 0 pixels, and the maximum value is the value of MaxHeight.
· integer percentage (%): The range of valid values is 0 to 100. For example, if you specify Top for VerticalAlign and 5px for VerticalOffset, the top of the watermark appears 5 pixels from the top border of the output video.

VerticalOffset is only valid when the value of VerticalAlign is Top or Bottom.

If you specify an offset that causes the watermark to extend beyond the top or bottom border and Elastic Transcoder has not added black bars, the watermark is cropped. If Elastic Transcoder has added black bars, the watermark extends into the black bars. If the watermark extends beyond the black bars, it is cropped.

Use the value of Target to specify whether you want Elastic Transcoder to include the black bars that are added by Elastic Transcoder, if any, in the offset calculation.

· Opacity (string) –
  
  A percentage that indicates how much you want a watermark to obscure the video in the location where it appears. Valid values are 0 (the watermark is invisible) to 100 (the watermark completely obscures the video in the specified location). The datatype of Opacity is float.

  Elastic Transcoder supports transparent .png graphics. If you use a transparent .png, the transparent portion of the video appears as if you had specified a value of 0 for Opacity. The .jpg file format doesn’t support transparency.

· Target (string) –
  
  A value that determines how Elastic Transcoder interprets values that you specified for HorizontalOffset, VerticalOffset, MaxWidth, and MaxHeight:

  · Content: HorizontalOffset and VerticalOffset values are calculated based on the borders of the video excluding black bars added by Elastic Transcoder, if any. In addition, MaxWidth and MaxHeight, if specified as a percentage, are calculated based on the borders of the video excluding black bars added by Elastic Transcoder, if any.

  · Frame: HorizontalOffset and VerticalOffset values are calculated based on the borders of the video including black bars added by Elastic Transcoder, if any. In addition, MaxWidth and MaxHeight, if specified as a percentage, are calculated based on the borders of the video including black bars added by Elastic Transcoder, if any.

· Thumbnails (dict) –
  
  A section of the response body that provides information about the thumbnail preset values, if any.

· Format (string) –
  
  The format of thumbnails, if any. Valid values are jpg and png.
You specify whether you want Elastic Transcoder to create thumbnails when you create a job.

- **Interval** *(string)* –

  The approximate number of seconds between thumbnails. Specify an integer value.

- **Resolution** *(string)* –

  Warning: To better control resolution and aspect ratio of thumbnails, we recommend that you use the values MaxWidth, MaxHeight, SizingPolicy, and PaddingPolicy instead of Resolution andAspectRatio. The two groups of settings are mutually exclusive. Do not use them together.

  The width and height of thumbnail files in pixels. Specify a value in the format *width* x *height* where both values are even integers. The values cannot exceed the width and height that you specified in the Video:Resolution object.

- **AspectRatio** *(string)* –

  Warning: To better control resolution and aspect ratio of thumbnails, we recommend that you use the values MaxWidth, MaxHeight, SizingPolicy, and PaddingPolicy instead of Resolution andAspectRatio. The two groups of settings are mutually exclusive. Do not use them together.

  The aspect ratio of thumbnails. Valid values include:

  auto, 1:1, 4:3, 3:2, 16:9

  If you specify auto, Elastic Transcoder tries to preserve the aspect ratio of the video in the output file.

- **MaxWidth** *(string)* –

  The maximum width of thumbnails in pixels. If you specify auto, Elastic Transcoder uses 1920 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 32 and 4096.

- **MaxHeight** *(string)* –

  The maximum height of thumbnails in pixels. If you specify auto, Elastic Transcoder uses 1080 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 32 and 3072.

- **SizingPolicy** *(string)* –

  Specify one of the following values to control scaling of thumbnails:

  - **Fit**: Elastic Transcoder scales thumbnails so they match the value that you specified in thumbnail MaxWidth or MaxHeight settings without exceeding the other value.
  - **Fill**: Elastic Transcoder scales thumbnails so they match the value that you specified in thumbnail MaxWidth or
MaxHeight settings and matches or exceeds the other value. Elastic Transcoder centers the image in thumbnails and then crops in the dimension (if any) that exceeds the maximum value.

- **Stretch**: Elastic Transcoder stretches thumbnails to match the values that you specified for thumbnail MaxWidth and MaxHeight settings. If the relative proportions of the input video and thumbnails are different, the thumbnails will be distorted.

- **Keep**: Elastic Transcoder does not scale thumbnails. If either dimension of the input video exceeds the values that you specified for thumbnail MaxWidth and MaxHeight settings, Elastic Transcoder crops the thumbnails.

- **ShrinkToFit**: Elastic Transcoder scales thumbnails down so that their dimensions match the values that you specified for at least one of thumbnail MaxWidth and MaxHeight without exceeding either value. If you specify this option, Elastic Transcoder does not scale thumbnails up.

- **ShrinkToFill**: Elastic Transcoder scales thumbnails down so that their dimensions match the values that you specified for at least one of MaxWidth and MaxHeight without dropping below either value. If you specify this option, Elastic Transcoder does not scale thumbnails up.

- **PaddingPolicy (string)** –

  When you set PaddingPolicy to **Pad**, Elastic Transcoder may add black bars to the top and bottom and/or left and right sides of thumbnails to make the total size of the thumbnails match the values that you specified for thumbnail MaxWidth and MaxHeight settings.

- **Type (string)** –

  Whether the preset is a default preset provided by Elastic Transcoder (**System**) or a preset that you have defined (**Custom**).

- **NextPageToken (string)** –

  A value that you use to access the second and subsequent pages of results, if any. When the presets fit on one page or when you’ve reached the last page of results, the value of NextPageToken is **null**.

**read_job(**kwargs)**

The ReadJob operation returns detailed information about a job.

**Request Syntax**

```python
response = client.read_job( Id='string'
)
```

**Parameters**

- **Id (string)** – [REQUIRED]

  The identifier of the job for which you want to get detailed information.

**Return type**

dict

**Returns**

Response Structure

- (dict) –

The ReadJobResponse structure.

- Job (dict) –

A section of the response body that provides information about the job.

  - Id (string) –
    
    The identifier that Elastic Transcoder assigned to the job. You use this value to get settings for the job or to delete the job.

  - Arn (string) –
    
    The Amazon Resource Name (ARN) for the job.

  - PipelineId (string) –
    
    The Id of the pipeline that you want Elastic Transcoder to use for transcoding. The pipeline determines several settings, including the Amazon S3 bucket from which Elastic Transcoder gets the files to transcode and the bucket into which Elastic Transcoder puts the transcoded files.

  - Input (dict) –
    
    A section of the request or response body that provides information about the file that is being transcoded.

    1. Key (string) –
        
        The name of the file to transcode. Elsewhere in the body of the JSON block is the the ID of the pipeline to use for processing the job. The InputBucket object in that pipeline
tells Elastic Transcoder which Amazon S3 bucket to get the file from.

If the file name includes a prefix, such as `cooking/lasagna.mpg`, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **FrameRate (string)**

  The frame rate of the input file. If you want Elastic Transcoder to automatically detect the frame rate of the input file, specify `auto`. If you want to specify the frame rate for the input file, enter one of the following values:
  
  10, 15, 23.97, 24, 25, 29.97, 30, 60

  If you specify a value other than `auto`, Elastic Transcoder disables automatic detection of the frame rate.

- **Resolution (string)**

  This value must be `auto`, which causes Elastic Transcoder to automatically detect the resolution of the input file.

- **AspectRatio (string)**

  The aspect ratio of the input file. If you want Elastic Transcoder to automatically detect the aspect ratio of the input file, specify `auto`. If you want to specify the aspect ratio for the output file, enter one of the following values:
  
  1:1, 4:3, 3:2, 16:9

  If you specify a value other than `auto`, Elastic Transcoder disables automatic detection of the aspect ratio.

- **Interlaced (string)**

  Whether the input file is interlaced. If you want Elastic Transcoder to automatically detect whether the input file is interlaced, specify `auto`. If you want to specify whether the input file is interlaced, enter one of the following values:
  
  true, false

  If you specify a value other than `auto`, Elastic Transcoder disables automatic detection of interlacing.

- **Container (string)**

  The container type for the input file. If you want Elastic Transcoder to automatically detect the container type of the input file, specify `auto`. If you want to specify the container type for the input file, enter one of the following values:
  
  3gp, aac, asf, avi, divx, flv, m4a, mkv, mov, mp3, mp4, mpeg, mpeg-ps, mpeg-ts, mxf, ogg, vob, wav, webm

- **Encryption (dict)**

  The encryption settings, if any, that are used for decrypting your input files. If your input file is encrypted, you must specify the mode that Elastic Transcoder will use to decrypt your file.

  - **Mode (string)**

    The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or en-
crypting your output files. Elastic Transcoder supports the following options:

- **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
- **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify **S3-AWS-KMS** and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key (string)** –
  
  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –
  
  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –
  
  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.
The detected properties of the input file.

- **Width** *(integer)* —
  The detected width of the input file, in pixels.

- **Height** *(integer)* —
  The detected height of the input file, in pixels.

- **FrameRate** *(string)* —
  The detected frame rate of the input file, in frames per second.

- **FileSize** *(integer)* —
  The detected file size of the input file, in bytes.

- **DurationMillis** *(integer)* —
  The detected duration of the input file, in milliseconds.

* **Output** *(dict)* —

If you specified one output for a job, information about that output. If you specified multiple outputs for a job, the `Output` object lists information about the first output. This duplicates the information that is listed for the first output in the `Outputs` object.

**Warning:** Outputs recommended instead.

A section of the request or response body that provides information about the transcoded (target) file.

- **Id** *(string)* —
  A sequential counter, starting with 1, that identifies an output among the outputs from the current job. In the `Output` syntax, this value is always 1.

- **Key** *(string)* —
  The name to assign to the transcoded file. Elastic Transcoder saves the file in the Amazon S3 bucket specified by the `OutputBucket` object in the pipeline that is specified by the pipeline ID.

- **ThumbnailPattern** *(string)* —
  Whether you want Elastic Transcoder to create thumbnails for your videos and, if so, how you want Elastic Transcoder to name the files.

  If you don’t want Elastic Transcoder to create thumbnails, specify "".

  If you do want Elastic Transcoder to create thumbnails, specify the information that you want to include in the file name for each thumbnail. You can specify the following values in any sequence:

  - **"{count}"** *(Required)*: If you want to create thumbnails, you must include `{count}` in the `ThumbnailPattern` object. Wherever you specify `{count}`, Elastic Transcoder adds a five-digit sequence number (beginning with 00001) to thumbnail file names. The number indicates where a given thumbnail appears in the sequence of thumbnails for a transcoded file.

  **Warning:** If you specify a literal value and/or `{resolution}` but you omit `{count}`, Elastic
Transcoder returns a validation error and does not create the job.

- **Literal values (Optional)**: You can specify literal values anywhere in the `ThumbnailPattern` object. For example, you can include them as a file name prefix or as a delimiter between `{resolution}` and `{count}`.
- `{resolution}` (Optional): If you want Elastic Transcoder to include the resolution in the file name, include `{resolution}` in the `ThumbnailPattern` object. When creating thumbnails, Elastic Transcoder automatically saves the files in the format (.jpg or .png) that appears in the preset that you specified in the `PresetID` value of `CreateJobOutput`. Elastic Transcoder also appends the applicable file name extension.

**ThumbnailEncryption (dict)** –

The encryption settings, if any, that you want Elastic Transcoder to apply to your thumbnail.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.
  
  For all three AES options, you must provide the following settings, which must be base64-encoded:
  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-
encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Rotate (string)** –

  The number of degrees clockwise by which you want Elastic Transcoder to rotate the output relative to the input. Enter one of the following values:

  auto, 0, 90, 180, 270

  The value auto generally works only if the file that you’re transcoding contains rotation metadata.

- **PresetId (string)** –

  The value of the Id object for the preset that you want to use for this job. The preset determines the audio, video, and thumbnail settings that Elastic Transcoder uses for transcoding. To use a preset that you created, specify the preset ID that Elastic Transcoder returned in the response when you created the preset. You can also use the Elastic Transcoder system presets, which you can get with ListPresets.

- **SegmentDuration (string)** –

  **Warning:** (Outputs in Fragmented MP4 or MPEG-TS format only.)

  If you specify a preset in PresetId for which the value of Container is fmp4 (Fragmented MP4) or ts (MPEG-TS), SegmentDuration is the target maximum duration of each segment in seconds. For HLSv3 format playlists, each media segment is stored in a separate .ts file. For HLSv4 and Smooth playlists, all media segments for an output are stored in a single file. Each segment is approximately the length of the SegmentDuration, though individual segments might be shorter or longer.

  The range of valid values is 1 to 60 seconds. If the duration of the video is not evenly divisible by SegmentDuration
the duration of the last segment is the remainder of total length/SegmentDuration.

Elastic Transcoder creates an output-specific playlist for each output HLS output that you specify in OutputKeys. To add an output to the master playlist for this job, include it in the OutputKeys of the associated playlist.

- **Status (string)** –

  The status of one output in a job. If you specified only one output for the job, Outputs:Status is always the same as Job:Status. If you specified more than one output:
  - Job:Status and Outputs:Status for all of the outputs is Submitted until Elastic Transcoder starts to process the first output.
  - When Elastic Transcoder starts to process the first output, Outputs:Status for that output and Job:Status both change to Progressing. For each output, the value of Outputs:Status remains Submitted until Elastic Transcoder starts to process the output.
  - Job:Status remains Progressing until all of the outputs reach a terminal status, either Complete or Error.
  - When all of the outputs reach a terminal status, Job:Status changes to Complete only if Outputs:Status for all of the outputs is Complete. If Outputs:Status for one or more outputs is Error, the terminal status for Job:Status is also Error.

  The value of Status is one of the following: Submitted, Progressing, Complete, Cancelled, or Error.

- **StatusDetail (string)** –

  Information that further explains Status.

- **Duration (integer)** –

  Duration of the output file, in seconds.

- **Width (integer)** –

  Specifies the width of the output file in pixels.

- **Height (integer)** –

  Height of the output file, in pixels.

- **FrameRate (string)** –

  Frame rate of the output file, in frames per second.

- **FileSize (integer)** –

  File size of the output file, in bytes.

- **DurationMillis (integer)** –

  Duration of the output file, in milliseconds.

- **Watermarks (list)** –

  Information about the watermarks that you want Elastic Transcoder to add to the video during transcoding. You can specify up to four watermarks for each output. Settings for each watermark must be defined in the preset that you specify in Preset for the current output.

  Watermarks are added to the output video in the sequence in
which you list them in the job output. The first watermark in the
list is added to the output video first, the second watermark in
the list is added next, and so on. As a result, if the settings
in a preset cause Elastic Transcoder to place all watermarks
in the same location, the second watermark that you add will
cover the first one, the third one will cover the second, and the
fourth one will cover the third.

- (dict) –

  Watermarks can be in .png or .jpg format. If you want to dis-
  play a watermark that is not rectangular, use the .png format,
  which supports transparency.

- PresetWatermarkId (string) –

  The ID of the watermark settings that Elastic Transcoder uses
to add watermarks to the video during transcoding. The set-
tings are in the preset specified by Preset for the current out-
put. In that preset, the value of Watermarks Id tells Elastic
Transcoder which settings to use.

- InputKey (string) –

  The name of the .png or .jpg file that you want to use for
  the watermark. To determine which Amazon S3 bucket con-
tains the specified file, Elastic Transcoder checks the pipeline
  specified by Pipeline; the Input Bucket object in that
pipeline identifies the bucket.

  If the file name includes a prefix, for example, logos/128x64.png,
  include the prefix in the key. If the file isn't
  in the specified bucket, Elastic Transcoder returns an error.

- Encryption (dict) –

  The encryption settings, if any, that you want Elastic
  Transcoder to apply to your watermarks.

- Mode (string) –

  The specific server-side encryption mode that you want Elas-
  tic Transcoder to use when decrypting your input files or en-
crypting your output files. Elastic Transcoder supports the
  following options:

  - S3: Amazon S3 creates and manages the keys used for en-
crypting your files.

  - S3-AWS-KMS: Amazon S3 calls the Amazon Key Manage-
  ment Service, which creates and manages the keys that are
  used for encrypting your files. If you specify S3-AWS-KMS
  and you don't want to use the default key, you must add the
  AWS-KMS key that you want to use to your pipeline.

  - AES-CBC-PKCS7: A padded cipher-block mode of opera-
tion originally used for HLS files.

  - AES-CTR: AES Counter Mode.

  - AES-GCM: AES Galois Counter Mode, a mode of operation
  that is an authenticated encryption format, meaning that a file,
  key, or initialization vector that has been tampered with will
  fail the decryption process.

  For all three AES options, you must provide the following
settings, which must be base64-encoded:

- Key
· Key MD5
· Initialization Vector

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

· **Key** *(string)* –

The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256

The key must also be encrypted by using the Amazon Key Management Service.

· **KeyMd5** *(string)* –

The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

· **InitializationVector** *(string)* –

The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

· **AlbumArt** *(dict)* –

The album art to be associated with the output file, if any.

· **MergePolicy** *(string)* –

A policy that determines how Elastic Transcoder will handle the existence of multiple album artwork files.

· Replace: The specified album art will replace any existing album art.
· Prepend: The specified album art will be placed in front of any existing album art.
· Append: The specified album art will be placed after any existing album art.
· Fallback: If the original input file contains artwork, Elastic Transcoder will use that artwork for the output. If the original input does not contain artwork, Elastic Transcoder will use the specified album art file.

· **Artwork** *(list)* –

The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20. Valid formats are .jpg and .png
· (dict) –

The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20.

To remove artwork or leave the artwork empty, you can either set Artwork to null, or set the Merge Policy to “Replace” and use an empty Artwork array.

To pass through existing artwork unchanged, set the Merge Policy to “Prepend”, “Append”, or “Fallback”, and use an empty Artwork array.

· InputKey (string) –

The name of the file to be used as album art. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by PipelineId; the InputBucket object in that pipeline identifies the bucket.

If the file name includes a prefix, for example, cooking/pie.jpg, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

· MaxWidth (string) –

The maximum width of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 4096, inclusive.

· MaxHeight (string) –

The maximum height of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 3072, inclusive.

· SizingPolicy (string) –

Specify one of the following values to control scaling of the output album art:

· Fit: Elastic Transcoder scales the output art so it matches the value that you specified in either MaxWidth or MaxHeight without exceeding the other value.

· Fill: Elastic Transcoder scales the output art so it matches the value that you specified in either MaxWidth or MaxHeight and matches or exceeds the other value. Elastic Transcoder centers the output art and then crops it in the dimension (if any) that exceeds the maximum value.

· Stretch: Elastic Transcoder stretches the output art to match the values that you specified for MaxWidth and MaxHeight. If the relative proportions of the input art and the output art are different, the output art will be distorted.

· Keep: Elastic Transcoder does not scale the output art. If either dimension of the input art exceeds the values that you specified for MaxWidth and MaxHeight, Elastic Transcoder crops the output art.

· ShrinkToFit: Elastic Transcoder scales the output art down so that its dimensions match the values that you spec-
ified for at least one of `MaxWidth` and `MaxHeight` without exceeding either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **ShrinkToFill** Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without dropping below either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **PaddingPolicy** *(string)*

  When you set `PaddingPolicy` to `Pad`, Elastic Transcoder may add white bars to the top and bottom and/or left and right sides of the output album art to make the total size of the output art match the values that you specified for `MaxWidth` and `MaxHeight`.

- **AlbumArtFormat** *(string)*

  The format of album art, if any. Valid formats are `.jpg` and `.png`.

- **Encryption** *(dict)*

  The encryption settings, if any, that you want Elastic Transcoder to apply to your artwork.

- **Mode** *(string)*

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  
  - **AES-CTR**: AES Counter Mode.
  
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  
  - **Key MD5**
  
  - **Initialization Vector**

  **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)*
The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Composition (list)** –

  You can create an output file that contains an excerpt from the input file. This excerpt, called a clip, can come from the beginning, middle, or end of the file. The Composition object contains settings for the clips that make up an output file. For the current release, you can only specify settings for a single clip per output file. The Composition object cannot be null.

  - **(dict)** –

    Settings for one clip in a composition. All jobs in a playlist must have the same clip settings.

    - **TimeSpan (dict)** –

      Settings that determine when a clip begins and how long it lasts.

      - **StartTime (string)** –

        The place in the input file where you want a clip to start. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder starts at the beginning of the input file.

      - **Duration (string)** –

        The duration of the clip. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder creates an output file from StartTime to the end of the file.

        If you specify a value longer than the duration of the input file, Elastic Transcoder transcodes the file and returns a warning.
Captions (dict) –

You can configure Elastic Transcoder to transcode captions, or subtitles, from one format to another. All captions must be in UTF-8. Elastic Transcoder supports two types of captions:

- **Embedded:** Embedded captions are included in the same file as the audio and video. Elastic Transcoder supports only one embedded caption per language, to a maximum of 300 embedded captions per file. Valid input values include: CEA-608 (EIA-608, first non-empty channel only), CEA-708 (EIA-708, first non-empty channel only), and mov-text. Valid outputs include: mov-text. Elastic Transcoder supports a maximum of one embedded format per output.

- **Sidecar:** Sidecar captions are kept in a separate metadata file from the audio and video data. Sidecar captions require a player that is capable of understanding the relationship between the video file and the sidecar file. Elastic Transcoder supports only one sidecar caption per language, to a maximum of 20 sidecar captions per file. Valid input values include: dfxp (first div element only), ebu-tt, scc, smpt, srt, ttml (first div element only), and webvtt. Valid outputs include: dfxp (first div element only), scc, srt, and webvtt.

If you want ttml or smpte-tt compatible captions, specify dfxp as your output format.

Elastic Transcoder does not support OCR (Optical Character Recognition), does not accept pictures as a valid input for captions, and is not available for audio-only transcoding. Elastic Transcoder does not preserve text formatting (for example, italics) during the transcoding process.

To remove captions or leave the captions empty, set Captions to null. To pass through existing captions unchanged, set the MergePolicy to MergeRetain, and pass in a null CaptionSources array.

For more information on embedded files, see the Subtitles Wikipedia page.

For more information on sidecar files, see the Extensible Metadata Platform and Sidecar file Wikipedia pages.

- **MergePolicy (string) –**

A policy that determines how Elastic Transcoder handles the existence of multiple captions.

- **MergeOverride:** Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the sidecar captions and ignores the embedded captions for that language.

- **MergeRetain:** Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the embedded captions and ignores
the sidecar captions for that language. If `CaptionSources` is empty, Elastic Transcoder omits all sidecar captions from the output files.

- **Override**: Elastic Transcoder transcodes only the sidecar captions that you specify in `CaptionSources`. `MergePolicy` cannot be null.

- **CaptionSources (list)** –

  Source files for the input sidecar captions used during the transcoding process. To omit all sidecar captions, leave `CaptionSources` blank.

  - **(dict)** –

    A source file for the input sidecar captions used during the transcoding process.

    - **Key (string)** –

      The name of the sidecar caption file that you want Elastic Transcoder to include in the output file.

    - **Language (string)** –

      A string that specifies the language of the caption. Specify this as one of:

      - 2-character ISO 639-1 code
      - 3-character ISO 639-2 code

      For more information on ISO language codes and language names, see the List of ISO 639-1 codes.

    - **TimeOffset (string)** –

      For clip generation or captions that do not start at the same time as the associated video file, the `TimeOffset` tells Elastic Transcoder how much of the video to encode before including captions.

      Specify the `TimeOffset` in the form [+-]SS.sss or [+-]HH:mm:SS.ss.

    - **Label (string)** –

      The label of the caption shown in the player when choosing a language. We recommend that you put the caption language name here, in the language of the captions.

- **Encryption (dict)** –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your caption sources.

  - **Mode (string)** –

    The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

    - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
    - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
· **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
· **AES-CTR**: AES Counter Mode.
· **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

· **Key**
· **Key MD5**
· **Initialization Vector**

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

· **Key** *(string)* –

The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

· **KeyMd5** *(string)* –

The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

· **Initialization Vector** *(string)* –

The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

· **CaptionFormats** *(list)* –

The array of file formats for the output captions. If you leave this value blank, Elastic Transcoder returns an error.

· **Format** *(string)* –

The format you specify determines whether Elastic Transcoder generates an embedded or sidecar caption
Valid Embedded Caption Formats: * for FLAC: None
- For MP3: None
- For MP4: mov-text
- For MPEG-TS: None
- For ogg: None
- For webm: None

Valid Sidecar Caption Formats: Elastic Transcoder supports dfxp (first div element only), scc, srt, and webvtt. If you want ttml or smpte-tt compatible captions, specify dfxp as your output format. * For FMP4: dfxp

Non-FMP4 outputs: All sidecar types
fmp4 captions have an extension of .ismt

Pattern (string) –

The prefix for caption filenames, in the form description -{language}, where:
- description is a description of the video.
- {language} is a literal value that Elastic Transcoder replaces with the two- or three-letter code for the language of the caption in the output file names.

If you don’t include {language} in the file name pattern, Elastic Transcoder automatically appends “{language} ” to the value that you specify for the description. In addition, Elastic Transcoder automatically appends the count to the end of the segment files.

For example, suppose you’re transcoding into srt format. When you enter “Sydney-{language}-sunrise”, and the language of the captions is English (en), the name of the first caption file will be Sydney-en-sunrise00000.srt.

Encryption (dict) –

The encryption settings, if any, that you want Elastic Transcoder to apply to your caption formats.

Mode (string) –

The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
- S3: Amazon S3 creates and manages the keys used for encrypting your files.
- S3-AWS-KMS: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
- AES-CTR: AES Counter Mode.
- AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following
settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

  **Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  \[128, 192, \text{or} 256\].

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Encryption** *(dict)* –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your output files. If you choose to use encryption, you must specify a mode to use. If you choose not to use encryption, Elastic Transcoder will write an unencrypted file to your Amazon S3 bucket.

- **Mode** *(string)* –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify **S3-AWS-KMS** and you don’t want to use the default key, you must add the
AWS-KMS key that you want to use to your pipeline.

- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –
  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  
  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –
  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –
  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AppliedColorSpaceConversion** *(string)* –
  If Elastic Transcoder used a preset with a ColorSpaceConversionMode to transcode the output file, the AppliedColorSpaceConversion parameter shows the conversion used. If no ColorSpaceConversionMode was defined in the preset, this parameter will not be included in the job response.

**Outputs** *(list)* –
Information about the output files. We recommend that you use the Outputs syntax for all jobs, even when you want Elastic Transcoder to transcode a file into only one format. Do not use both the Outputs and Output syntaxes in the same request. You can create a maximum of 30 outputs per job.

If you specify more than one output for a job, Elastic Transcoder creates the files for each output in the order in which you specify them in the job.

- (dict) –

  Warning: Outputs recommended instead.

If you specified one output for a job, information about that output. If you specified multiple outputs for a job, the Output object lists information about the first output. This duplicates the information that is listed for the first output in the Outputs object.

- **Id** *(string)* –

  A sequential counter, starting with 1, that identifies an output among the outputs from the current job. In the Output syntax, this value is always 1.

- **Key** *(string)* –

  The name to assign to the transcoded file. Elastic Transcoder saves the file in the Amazon S3 bucket specified by the OutputBucket object in the pipeline that is specified by the pipeline ID.

- **ThumbnailPattern** *(string)* –

  Whether you want Elastic Transcoder to create thumbnails for your videos and, if so, how you want Elastic Transcoder to name the files.

  If you don’t want Elastic Transcoder to create thumbnails, specify "".

  If you do want Elastic Transcoder to create thumbnails, specify the information that you want to include in the file name for each thumbnail. You can specify the following values in any sequence:

  - "{{count}}" *(Required)*: If you want to create thumbnails, you must include {count} in the ThumbnailPattern object. Wherever you specify {count}, Elastic Transcoder adds a five-digit sequence number (beginning with 00001) to thumbnail file names. The number indicates where a given thumbnail appears in the sequence of thumbnails for a transcoded file. 
    
    warning::If you specify a literal value and/or {resolution} but you omit {count}, Elastic Transcoder returns a validation error and does not create the job.

  - **Literal values** *(Optional)*: You can specify literal values anywhere in the ThumbnailPattern object. For example, you can include them as a file name prefix or as a delimiter between {resolution} and {count}.
· "{resolution}" (Optional): If you want Elastic Transcoder to include the resolution in the file name, include \{resolution\} in the ThumbnailPattern object. When creating thumbnails, Elastic Transcoder automatically saves the files in the format (.jpg or .png) that appears in the preset that you specified in the PresetID value of CreateJobOutput. Elastic Transcoder also appends the applicable file name extension.

· ThumbnailEncryption (dict) –

The encryption settings, if any, that you want Elastic Transcoder to apply to your thumbnail.

· Mode (string) –

The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

· S3: Amazon S3 creates and manages the keys used for encrypting your files.
· S3-AWS-KMS: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
· AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
· AES-CTR: AES Counter Mode.
· AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

· Key
· Key MD5
· Initialization Vector

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

· Key (string) –

The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

\[128, 192, \text{or} 256\,.

The key must also be encrypted by using the Amazon Key Management Service.

· KeyMd5 (string) –
The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –
  
The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Rotate** *(string)* –
  
The number of degrees clockwise by which you want Elastic Transcoder to rotate the output relative to the input. Enter one of the following values:

  auto, 0, 90, 180, 270

  The value `auto` generally works only if the file that you’re transcoding contains rotation metadata.

- **PresetId** *(string)* –
  
The value of the `Id` object for the preset that you want to use for this job. The preset determines the audio, video, and thumbnail settings that Elastic Transcoder uses for transcoding. To use a preset that you created, specify the preset ID that Elastic Transcoder returned in the response when you created the preset. You can also use the Elastic Transcoder system presets, which you can get with `ListPresets`.

- **SegmentDuration** *(string)* –
  
  Warning: (Outputs in Fragmented MP4 or MPEG-TS format only.)

  If you specify a preset in `PresetId` for which the value of `Container` is `fmp4` (Fragmented MP4) or `ts` (MPEG-TS), `SegmentDuration` is the target maximum duration of each segment in seconds. For HLSv3 format playlists, each media segment is stored in a separate `.ts` file. For HLSv4 and Smooth playlists, all media segments for an output are stored in a single file. Each segment is approximately the length of the `SegmentDuration`, though individual segments might be shorter or longer.

  The range of valid values is 1 to 60 seconds. If the duration of the video is not evenly divisible by `SegmentDuration`, the duration of the last segment is the remainder of total length/`SegmentDuration`.

  Elastic Transcoder creates an output-specific playlist for each output HLS output that you specify in `OutputKeys`. To add an output to the master playlist for this job, include it in the `OutputKeys` of the associated playlist.
· **Status** *(string)* –

The status of one output in a job. If you specified only one output for the job, **Outputs:Status** is always the same as **Job:Status**. If you specified more than one output:
· **Job:Status** and **Outputs:Status** for all of the outputs is Submitted until Elastic Transcoder starts to process the first output.
· When Elastic Transcoder starts to process the first output, **Outputs:Status** for that output and **Job:Status** both change to Progressing. For each output, the value of **Outputs:Status** remains Submitted until Elastic Transcoder starts to process the output.
· **Job:Status** remains Progressing until all of the outputs reach a terminal status, either Complete or Error.
· When all of the outputs reach a terminal status, **Job:Status** changes to Complete only if **Outputs:Status** for all of the outputs is Complete. If **Outputs:Status** for one or more outputs is Error, the terminal status for **Job:Status** is also Error.

The value of **Status** is one of the following: Submitted, Progressing, Complete, Cancelled, or Error.

· **StatusDetail** *(string)* –

Information that further explains **Status**.

· **Duration** *(integer)* –

Duration of the output file, in seconds.

· **Width** *(integer)* –

Specifies the width of the output file in pixels.

· **Height** *(integer)* –

Height of the output file, in pixels.

· **FrameRate** *(string)* –

Frame rate of the output file, in frames per second.

· **FileSize** *(integer)* –

File size of the output file, in bytes.

· **DurationMillis** *(integer)* –

Duration of the output file, in milliseconds.

· **Watermarks** *(list)* –

Information about the watermarks that you want Elastic Transcoder to add to the video during transcoding. You can specify up to four watermarks for each output. Settings for each watermark must be defined in the preset that you specify in **Preset** for the current output.

Watermarks are added to the output video in the sequence in which you list them in the job output; the first watermark in the list is added to the output video first, the second watermark in the list is added next, and so on. As a result, if the settings in a preset cause Elastic Transcoder to place all watermarks in the same location, the second watermark that you add will cover the first one, the third one will cover the second, and the fourth one will cover the third.
· **(dict)** –

  Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

· **PresetWatermarkId** *(string)* –

  The ID of the watermark settings that Elastic Transcoder uses to add watermarks to the video during transcoding. The settings are in the preset specified by Preset for the current output. In that preset, the value of Watermarks Id tells Elastic Transcoder which settings to use.

· **InputKey** *(string)* –

  The name of the .png or .jpg file that you want to use for the watermark. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by Pipeline; the Input Bucket object in that pipeline identifies the bucket.

  If the file name includes a prefix, for example, *logos/128x64.png*, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

· **Encryption** *(dict)* –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your watermarks.

· **Mode** *(string)* –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  · **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  · **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify **S3-AWS-KMS** and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  · **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  · **AES-CTR**: AES Counter Mode.
  · **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  · **Key**
  · **Key MD5**
  · **Initialization Vector**
Warning: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –
  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:
  
  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –
  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –
  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AlbumArt (dict)** –
  The album art to be associated with the output file, if any.

- **MergePolicy (string)** –
  A policy that determines how Elastic Transcoder will handle the existence of multiple album artwork files.
  - **Replace**: The specified album art will replace any existing album art.
  - **Prepend**: The specified album art will be placed in front of any existing album art.
  - **Append**: The specified album art will be placed after any existing album art.
  - **Fallback**: If the original input file contains artwork, Elastic Transcoder will use that artwork for the output. If the original input does not contain artwork, Elastic Transcoder will use the specified album art file.

- **Artwork (list)** –
  The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20. Valid formats are .jpg and .png.

- **(dict)** –
The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20.

To remove artwork or leave the artwork empty, you can either set Artwork to null, or set the Merge Policy to “Replace” and use an empty Artwork array.

To pass through existing artwork unchanged, set the Merge Policy to “Prepend”, “Append”, or “Fallback”, and use an empty Artwork array.

- **InputKey** *(string)* –

  The name of the file to be used as album art. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by PipelineId; the InputBucket object in that pipeline identifies the bucket.

  If the file name includes a prefix, for example, `cooking/pie.jpg`, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **MaxWidth** *(string)* –

  The maximum width of the output album art in pixels. If you specify `auto`, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 4096, inclusive.

- **MaxHeight** *(string)* –

  The maximum height of the output album art in pixels. If you specify `auto`, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 3072, inclusive.

- **SizingPolicy** *(string)* –

  Specify one of the following values to control scaling of the output album art:

  - **Fit**:
    Elastic Transcoder scales the output art so it matches the value that you specified in either `MaxWidth` or `MaxHeight` without exceeding the other value.

  - **Fill**:
    Elastic Transcoder scales the output art so it matches the value that you specified in either `MaxWidth` or `MaxHeight` and matches or exceeds the other value. Elastic Transcoder centers the output art and then crops it in the dimension (if any) that exceeds the maximum value.

  - **Stretch**:
    Elastic Transcoder stretches the output art to match the values that you specified for `MaxWidth` and `MaxHeight`. If the relative proportions of the input art and the output art are different, the output art will be distorted.

  - **Keep**:
    Elastic Transcoder does not scale the output art. If either dimension of the input art exceeds the values that you specified for `MaxWidth` and `MaxHeight`, Elastic Transcoder crops the output art.

  - **ShrinkToFit**:
    Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` with-
out exceeding either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **ShrinkToFill** Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without dropping below either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **PaddingPolicy** *(string)*

  When you set `PaddingPolicy` to `Pad`, Elastic Transcoder may add white bars to the top and bottom and/or left and right sides of the output album art to make the total size of the output art match the values that you specified for `MaxWidth` and `MaxHeight`.

- **AlbumArtFormat** *(string)*

  The format of album art, if any. Valid formats are `.jpg` and `.png`.

- **Encryption** *(dict)*

  The encryption settings, if any, that you want Elastic Transcoder to apply to your artwork.

- **Mode** *(string)*

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  **Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)*

  The data encryption key that you want Elastic Transcoder
to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

**KeyMd5 (string)**

The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

**InitializationVector (string)**

The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

**Composition (list)**

You can create an output file that contains an excerpt from the input file. This excerpt, called a clip, can come from the beginning, middle, or end of the file. The Composition object contains settings for the clips that make up an output file. For the current release, you can only specify settings for a single clip per output file. The Composition object cannot be null.

**(dict)**

Settings for one clip in a composition. All jobs in a playlist must have the same clip settings.

**TimeSpan (dict)**

Settings that determine when a clip begins and how long it lasts.

**StartTime (string)**

The place in the input file where you want a clip to start. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder starts at the beginning of the input file.

**Duration (string)**

The duration of the clip. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder creates an output file from StartTime to the end of the file.

If you specify a value longer than the duration of the input file, Elastic Transcoder transcodes the file and returns a warning message.
Captions (dict) –

You can configure Elastic Transcoder to transcode captions, or subtitles, from one format to another. All captions must be in UTF-8. Elastic Transcoder supports two types of captions:

- **Embedded**: Embedded captions are included in the same file as the audio and video. Elastic Transcoder supports only one embedded caption per language, to a maximum of 300 embedded captions per file. Valid input values include: CEA-608 (EIA-608, first non-empty channel only), CEA-708 (EIA-708, first non-empty channel only), and mov-text. Valid outputs include: mov-text. Elastic Transcoder supports a maximum of one embedded format per output.

- **Sidecar**: Sidecar captions are kept in a separate metadata file from the audio and video data. Sidecar captions require a player that is capable of understanding the relationship between the video file and the sidecar file. Elastic Transcoder supports only one sidecar caption per language, to a maximum of 20 sidecar captions per file. Valid input values include: dfxp (first div element only), ebu-tt, scc, smpte, srt, ttml (first div element only), and webvtt. Valid outputs include: dfxp (first div element only), scc, srt, and webvtt.

If you want ttml or smpte-tt compatible captions, specify dfxp as your output format.

Elastic Transcoder does not support OCR (Optical Character Recognition), does not accept pictures as a valid input for captions, and is not available for audio-only transcoding. Elastic Transcoder does not preserve text formatting (for example, italics) during the transcoding process.

To remove captions or leave the captions empty, set Captions to null. To pass through existing captions unchanged, set the MergePolicy to MergeRetain, and pass in a null CaptionSources array.

For more information on embedded files, see the Subtitles Wikipedia page.

For more information on sidecar files, see the Extensible Metadata Platform and Sidecar file Wikipedia pages.

- **MergePolicy (string)** –

A policy that determines how Elastic Transcoder handles the existence of multiple captions.

- **MergeOverride**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the sidecar captions and ignores the embedded captions for that language.

- **MergeRetain**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the embedded captions and ignores the sidecar captions for that language.
is empty, Elastic Transcoder omits all sidecar captions from the output files.

- **Override**: Elastic Transcoder transcodes only the sidecar captions that you specify in `CaptionSources`. `MergePolicy` cannot be null.

- **CaptionSources** *(list)*
  
  Source files for the input sidecar captions used during the transcoding process. To omit all sidecar captions, leave `CaptionSources` blank.

- **(dict)**
  
  A source file for the input sidecar captions used during the transcoding process.

- **Key** *(string)*
  
  The name of the sidecar caption file that you want Elastic Transcoder to include in the output file.

- **Language** *(string)*
  
  A string that specifies the language of the caption. Specify this as one of:
  
  - 2-character ISO 639-1 code
  - 3-character ISO 639-2 code
  
  For more information on ISO language codes and language names, see the List of ISO 639-1 codes.

- **TimeOffset** *(string)*
  
  For clip generation or captions that do not start at the same time as the associated video file, the `TimeOffset` tells Elastic Transcoder how much of the video to encode before including captions.

  Specify the `TimeOffset` in the form `[+-]SS.sss` or `[+-]HH:mm:SS.ss`.

- **Label** *(string)*
  
  The label of the caption shown in the player when choosing a language. We recommend that you put the caption language name here, in the language of the captions.

- **Encryption** *(dict)*
  
  The encryption settings, if any, that you want Elastic Transcoder to apply to your caption sources.

- **Mode** *(string)*
  
  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  
  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
· AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
· AES-CTR: AES Counter Mode.
· AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* —

The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* —

The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* —

The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **CaptionFormats** *(list)* —

The array of file formats for the output captions. If you leave this value blank, Elastic Transcoder returns an error.

- **Format** *(string)* —

The format you specify determines whether Elastic Transcoder generates an embedded or sidecar caption
Valid Embedded Caption Formats: * for FLAC: None  
For MP3: None  
For MP4: mov-text  
For MPEG-TS: None  
Forogg: None  
Forwebm: None  
Valid Sidecar Caption Formats: Elastic Transcoder supports dfxp (first div element only), scc, srt, and webvtt. If you want ttml or smpte-tt compatible captions, specify dfxp as your output format. * For FMP4: dfxp  
Non-FMP4 outputs: All sidecar types  
fmp4 captions have an extension of .ismt  
Pattern (string) –  
The prefix for caption filenames, in the form description - {language}, where:  
- description is a description of the video.  
- {language} is a literal value that Elastic Transcoder replaces with the two- or three-letter code for the language of the caption in the output file names.  
If you don’t include {language} in the file name pattern, Elastic Transcoder automatically appends “{language}” to the value that you specify for the description. In addition, Elastic Transcoder automatically appends the count to the end of the segment files.  
For example, suppose you’re transcoding into srt format.  
When you enter “Sydney-{language}-sunrise”, and the language of the captions is English (en), the name of the first caption file will be Sydney-en-sunrise00000.srt.  
Encryption (dict) –  
The encryption settings, if any, that you want Elastic Transcoder to apply to your caption formats.  
Mode (string) –  
The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:  
- S3: Amazon S3 creates and manages the keys used for encrypting your files.  
- S3-AWS-KMS: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.  
- AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.  
- AES-CTR: AES Counter Mode.  
- AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.  
For all three AES options, you must provide the following
settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

  **Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  \[
  128, 192, \text{or} 256
  \]

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Encryption** *(dict)* –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your output files. If you choose to use encryption, you must specify a mode to use. If you choose not to use encryption, Elastic Transcoder will write an unencrypted file to your Amazon S3 bucket.

- **Mode** *(string)* –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify **S3-AWS-KMS** and you don’t want to use the default key, you must add the
AWS-KMS key that you want to use to your pipeline.

- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to un-encrypt your data.

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AppliedColorSpaceConversion (string)** –

  If Elastic Transcoder used a preset with a ColorSpaceConversionMode to transcode the output file, the AppliedColorSpaceConversion parameter shows the conversion used. If no ColorSpaceConversionMode was defined in the preset, this parameter will not be included in the job response.

- **OutputKeyPrefix (string)** –
The value, if any, that you want Elastic Transcoder to prepend to the names of all files that this job creates, including output files, thumbnails, and playlists. We recommend that you add a / or some other delimiter to the end of the `OutputKeyPrefix`.

* **Playlists** *(list)*

<table>
<thead>
<tr>
<th>Warning:</th>
<th>Outputs in Fragmented MP4 or MPEG-TS format only.</th>
</tr>
</thead>
</table>

If you specify a preset in `PresetId` for which the value of `Container` is `fmp4` (Fragmented MP4) or `ts` (MPEG-TS), `Playlists` contains information about the master playlists that you want Elastic Transcoder to create.

The maximum number of master playlists in a job is 30.

- *(dict)*

  Use Only for Fragmented MP4 or MPEG-TS Outputs. If you specify a preset for which the value of `Container` is `fmp4` (Fragmented MP4) or `ts` (MPEG-TS), `Playlists` contains information about the master playlists that you want Elastic Transcoder to create. We recommend that you create only one master playlist per output format. The maximum number of master playlists in a job is 30.

  - **Name** *(string)*

    The name that you want Elastic Transcoder to assign to the master playlist, for example, `nyc-vacation.m3u8`. If the name includes a / character, the section of the name before the last / must be identical for all `Name` objects. If you create more than one master playlist, the values of all `Name` objects must be unique.

    **Note**: Elastic Transcoder automatically appends the relevant file extension to the file name (.m3u8 for HLSv3 and HLSv4 playlists, and .ism and .ismc for Smooth playlists). If you include a file extension in `Name`, the file name will have two extensions.

  - **Format** *(string)*

    The format of the output playlist. Valid formats include HLSv3, HLSv4, and Smooth.

  - **OutputKeys** *(list)*

    For each output in this job that you want to include in a master playlist, the value of the `Outputs:Key` object.

    - If your output is not HLS or does not have a segment duration set, the name of the output file is a concatenation of `OutputKeyPrefix` and `Outputs:Key`:
      `OutputKeyPrefix`*`Outputs:Key`*.

    - If your output is HLSv3 and has a segment duration set, or is not included in a playlist, Elastic Transcoder creates an output playlist file with a file extension of .m3u8, and a series of .ts files that include a five-digit sequential counter beginning with `00000`: 
      `OutputKeyPrefix`*`Outputs:Key`* .m3u8
      `OutputKeyPrefix`*`Outputs:Key`* 00000.ts
If your output is HLSv4, has a segment duration set, and is included in an HLSv4 playlist, Elastic Transcoder creates an output playlist file with a file extension of _v4.m3u8. If the output is video, Elastic Transcoder also creates an output file with an extension of _iframe.m3u8. OutputKeyPrefix"Outputs:Key"_v4.m3u8 OutputKeyPrefix"Outputs:Key"_iframe.m3u8 OutputKeyPrefix"Outputs:Key".ts
Elastic Transcoder automatically appends the relevant file extension to the file name. If you include a file extension in Output Key, the file name will have two extensions.

If you include more than one output in a playlist, any segment duration settings, clip settings, or caption settings must be the same for all outputs in the playlist. For Smooth playlists, the Audio:Profile, Video:Profile, and Video:FrameRate to Video:KeyframesMaxDist ratio must be the same for all outputs.

- (string) –
- HLSContentProtection (dict) –
  The HLS content protection settings, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.
- Method (string) –
  The content protection method for your output. The only valid value is: aes-128.
  This value will be written into the method attribute of the EXT-X-KEY metadata tag in the output playlist.
- Key (string) –
  If you want Elastic Transcoder to generate a key for you, leave this field blank.
  If you choose to supply your own key, you must encrypt the key by using AWS KMS. The key must be base64-encoded, and it must be one of the following bit lengths before being base64-encoded:
  128, 192, or 256.
- KeyMd5 (string) –
  If Elastic Transcoder is generating your key for you, you must leave this field blank.
  The MD5 digest of the key that you want Elastic Transcoder to use to encrypt your output file, and that you want Elastic Transcoder to use as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.
- InitializationVector (string) –
  If Elastic Transcoder is generating your key for you, you must leave this field blank.
  The series of random bits created by a random bit generator,
unique for every encryption operation, that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

- **LicenseAcquisitionUrl (string)** –

  The location of the license key required to decrypt your HLS playlist. The URL must be an absolute path, and is referenced in the URI attribute of the EXT-X-KEY metadata tag in the playlist file.

- **KeyStoragePolicy (string)** –

  Specify whether you want Elastic Transcoder to write your HLS license key to an Amazon S3 bucket. If you choose `WithVariantPlaylists`, `LicenseAcquisitionUrl` must be left blank and Elastic Transcoder writes your data key into the same bucket as the associated playlist.

- **PlayReadyDrm (dict)** –

  The DRM settings, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

- **Format (string)** –

  The type of DRM, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

- **Key (string)** –

  The DRM key for your file, provided by your DRM license provider. The key must be base64-encoded, and it must be one of the following bit lengths before being base64-encoded:

  `128, 192, 256`.

  The key must also be encrypted by using AWS KMS.

- **KeyMd5 (string)** –

  The MD5 digest of the key used for DRM on your file, and that you want Elastic Transcoder to use as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

- **KeyId (string)** –

  The ID for your DRM key, so that your DRM license provider knows which key to provide.

  The key ID must be provided in big endian, and Elastic Transcoder will convert it to little endian before inserting it into the PlayReady DRM headers. If you are unsure whether your license server provides your key ID in big or little endian, check with your DRM provider.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you want Elastic Transcoder to use to encrypt your files. The initialization vector must be base64-encoded, and it must be exactly 8 bytes
long before being base64-encoded. If no initialization vector is provided, Elastic Transcoder generates one for you.

- **LicenseAcquisitionUrl** *(string)* –
  The location of the license key required to play DRM content. The URL must be an absolute path, and is referenced by the PlayReady header. The PlayReady header is referenced in the protection header of the client manifest for Smooth Streaming outputs, and in the EXT-X-DXDRM and EXT-XDXDRMINFO metadata tags for HLS playlist outputs. An example URL looks like this: https://www.example.com/exampleKey/

- **Status** *(string)* –
  The status of the job with which the playlist is associated.

- **StatusDetail** *(string)* –
  Information that further explains the status.

* **Status** *(string)* –
  The status of the job: Submitted, Progressing, Complete, Cancelled, or Error.

* **UserMetadata** *(dict)* –
  User-defined metadata that you want to associate with an Elastic Transcoder job. You specify metadata in key/value pairs, and you can add up to 10 key/value pairs per job. Elastic Transcoder does not guarantee that key/value pairs will be returned in the same order in which you specify them.

Metadata keys and values must use characters from the following list:
- 0–9
- A–Z and a–z
- Space
- The following symbols: _, : /=+-@%

* **Timing** *(dict)* –
  Details about the timing of a job.

- **SubmitTimeMillis** *(integer)* –
  The time the job was submitted to Elastic Transcoder, in epoch milliseconds.

- **StartTimeMillis** *(integer)* –
  The time the job began transcoding, in epoch milliseconds.

- **FinishTimeMillis** *(integer)* –
  The time the job finished transcoding, in epoch milliseconds.

**read_pipeline(** **kwargs** **)***

The ReadPipeline operation gets detailed information about a pipeline.

**Request Syntax**
response = client.read_pipeline(
    Id='string'
)

**Parameters**

**Id (string)** – [REQUIRED]

The identifier of the pipeline to read.

**Return type**

`dict`

**Returns**

**Response Syntax**

```
{
    'Pipeline': {
        'Id': 'string',
        'Arn': 'string',
        'Name': 'string',
        'Status': 'string',
        'InputBucket': 'string',
        'OutputBucket': 'string',
        'Role': 'string',
        'AwsKmsKeyArn': 'string',
        'Notifications': {
            'Progressing': 'string',
            'Completed': 'string',
            'Warning': 'string',
            'Error': 'string'
        },
        'ContentConfig': {
            'Bucket': 'string',
            'StorageClass': 'string',
            'Permissions': [
                {
                    'GranteeType': 'string',
                    'Grantee': 'string',
                    'Access': [
                        'string',
                    ]
                }]
        },
        'ThumbnailConfig': {
            'Bucket': 'string',
            'StorageClass': 'string',
            'Permissions': [
                {
                    'GranteeType': 'string',
                    'Grantee': 'string',
                    'Access': [
                        'string',
                    ]
                }]
        }
    },
    'Warnings': [
        {
            'Code': 'string',
            
```
Response Structure

- (dict) –

The `ReadPipelineResponse` structure.

  - Pipeline (dict) –

    A section of the response body that provides information about the pipeline.

      * Id (string) –

        The identifier for the pipeline. You use this value to identify the pipeline in which you want to perform a variety of operations, such as creating a job or a preset.

      * Arn (string) –

        The Amazon Resource Name (ARN) for the pipeline.

      * Name (string) –

        The name of the pipeline. We recommend that the name be unique within the AWS account, but uniqueness is not enforced.

        Constraints: Maximum 40 characters

      * Status (string) –

        The current status of the pipeline:

        · Active: The pipeline is processing jobs.
        · Paused: The pipeline is not currently processing jobs.

      * InputBucket (string) –

        The Amazon S3 bucket from which Elastic Transcoder gets media files for transcoding and the graphics files, if any, that you want to use for watermarks.

      * OutputBucket (string) –

        The Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files, thumbnails, and playlists. Either you specify this value, or you specify both `ContentConfig` and `ThumbnailConfig`.

      * Role (string) –

        The IAM Amazon Resource Name (ARN) for the role that Elastic Transcoder uses to transcode jobs for this pipeline.

      * AwsKmsKeyArn (string) –

        The AWS Key Management Service (AWS KMS) key that you want to use with this pipeline.

        If you use either S3 or S3-AWS-KMS as your EncryptionMode, you don’t need to provide a key with your job because a default key, known as an AWS-KMS key, is created for you automatically. You need to provide an AWS-KMS key only if you want to use a non-default AWS-KMS key, or if you are using an EncryptionMode of AES-PKCS7, AES-CTR, or AES-GCM.
* **Notifications** *(dict)* –

The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify to report job status.

| Warning: | To receive notifications, you must also subscribe to the new topic in the Amazon SNS console. |

- **Progressing** *(optional)*: The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify when Elastic Transcoder has started to process the job.
- **Completed** *(optional)*: The Amazon SNS topic that you want to notify when Elastic Transcoder has finished processing the job.
- **Warning** *(optional)*: The Amazon SNS topic that you want to notify when Elastic Transcoder encounters a warning condition.
- **Error** *(optional)*: The Amazon SNS topic that you want to notify when Elastic Transcoder encounters an error condition.

* **ContentConfig** *(dict)* –

Information about the Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists. Either you specify both **ContentConfig** and **ThumbnailConfig**, or you specify **OutputBucket**.

- **Bucket**: The Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists.
- **Permissions**: A list of the users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access that you want them to have. *GranteeType*: The type of value that appears in the **Grantee** object: *Canonical*: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution.
- **Email**: The registered email address of an AWS account.
- **Group**: One of the following predefined Amazon S3 groups: **AllUsers**, **AuthenticatedUsers**, or **LogDelivery**.
- **Grantee**: The AWS user or group that you want to have access to transcoded files and playlists.
- **Access**: The permission that you want to give to the AWS user that is listed in `Grantee`. Valid values include: *READ*: The grantee can read the objects and metadata for objects that Elastic Transcoder adds to the Amazon S3 bucket.
  - **READ_ACP**: The grantee can read the object ACL for objects that Elastic Transcoder adds to the Amazon S3 bucket.
  - **WRITE_ACP**: The grantee can write the ACL for the objects that Elastic Transcoder adds to the Amazon S3 bucket.
  - **FULL_CONTROL**: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the objects that Elastic Transcoder adds to the Amazon S3 bucket.

- **StorageClass**: The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

- **Bucket** *(string)* –
  
The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the following are true:
  - You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.
  - You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.
  - You do not want to specify the permissions that Elastic Transcoder grants to the files.
  - You want to associate the transcoded files and thumbnails with the Amazon S3 Standard storage class.

  If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit `OutputBucket` and specify values for `ContentConfig` and `ThumbnailConfig` instead.

- **StorageClass** *(string)* –
  
The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

- **Permissions** *(list)* –
  
Optional. The `Permissions` object specifies which users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.

If you include `Permissions`, Elastic Transcoder grants only the permissions that you specify. It does not grant full permissions to the owner of the role specified by `Role`. If you want that user to have full control, you must explicitly grant full control to the user.

If you omit `Permissions`, Elastic Transcoder grants full...
control over the transcoded files and playlists to the owner of the role specified by Role, and grants no other permissions to any other user or group.

- (dict) –

  The Permission structure.

- **GranteeType (string)** –

  The type of value that appears in the Grantee object:

  - **Canonical**: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning:: A canonical user ID is not the same as an AWS account number.
  - **Email**: The registered email address of an AWS account.
  - **Group**: One of the following predefined Amazon S3 groups: AllUsers, AuthenticatedUsers, or LogDelivery.

- **Grantee (string)** –

  The AWS user or group that you want to have access to transcoded files and playlists. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.

- **Access (list)** –

  The permission that you want to give to the AWS user that is listed in Grantee. Valid values include:

  - **READ**: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **READ_ACP**: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **WRITE_ACP**: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **FULL_CONTROL**: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

- (string) –

  **ThumbnailConfig (dict)** –

  Information about the Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files. Either you specify both ContentConfig and ThumbnailConfig, or you specify OutputBucket.

  - **Bucket**: The Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files.
  - **Permissions**: A list of the users and/or predefined Amazon S3 groups you want to have access to thumbnail files, and the type of access that you want them to have. * GranteeType: The type of value that appears in the Grantee object: * Canonical: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning:: A canonical user ID is not the same as an AWS account number.
Email: The registered email address of an AWS account.

Group: One of the following predefined Amazon S3 groups: AllUsers, AuthenticatedUsers, or LogDelivery.

Grantee: The AWS user or group that you want to have access to thumbnail files.

Access: The permission that you want to give to the AWS user that is listed in Grantee. Valid values include: * READ: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

READ_ACP: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

WRITE_ACP: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

FULL_CONTROL: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

StorageClass: The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the thumbnails that it stores in your Amazon S3 bucket.

Bucket (string) –

The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the following are true:

- You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.
- You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.
- You do not want to specify the permissions that Elastic Transcoder grants to the files.
- You want to associate the transcoded files and thumbnails with the Amazon S3 Standard storage class.

If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit OutputBucket and specify values for ContentConfig and ThumbnailConfig instead.

StorageClass (string) –

The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

Permissions (list) –

Optional. The Permissions object specifies which users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.

If you include Permissions, Elastic Transcoder grants
only the permissions that you specify. It does not grant full permissions to the owner of the role specified by `Role`. If you want that user to have full control, you must explicitly grant full control to the user.

If you omit `Permissions`, Elastic Transcoder grants full control over the transcoded files and playlists to the owner of the role specified by `Role`, and grants no other permissions to any other user or group.

- `(dict)` —
  
  The `Permission` structure.

- **GranteeType** *(string)* —
  
  The type of value that appears in the Grantee object:
  - **Canonical**: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning:: A canonical user ID is not the same as an AWS account number.
  - **Email**: The registered email address of an AWS account.
  - **Group**: One of the following predefined Amazon S3 groups: `AllUsers`, `AuthenticatedUsers`, or `LogDelivery`.
  - **Grantee** *(string)* —
    
    The AWS user or group that you want to have access to transcoded files and playlists. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.

- **Access** *(list)* —
  
  The permission that you want to give to the AWS user that is listed in Grantee. Valid values include:
  - **READ**: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **READ_ACP**: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **WRITE_ACP**: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **FULL_CONTROL**: The grantee has `READ`, `READ_ACP`, and `WRITE_ACP` permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

- *(string)* —

- **Warnings** *(list)* —
  
  Elastic Transcoder returns a warning if the resources used by your pipeline are not in the same region as the pipeline.

Using resources in the same region, such as your Amazon S3 buckets, Amazon SNS notification topics, and AWS KMS key, reduces processing time and prevents cross-regional charges.

- *(dict)* —
  
  Elastic Transcoder returns a warning if the resources used by your pipeline are not in the same region as the pipeline.
Using resources in the same region, such as your Amazon S3 buckets, Amazon SNS notification topics, and AWS KMS key, reduces processing time and prevents cross-regional charges.

- **Code** *(string)* –
  The code of the cross-regional warning.
- **Message** *(string)* –
  The message explaining what resources are in a different region from the pipeline.

**Note:** AWS KMS keys must be in the same region as the pipeline.

### read_preset(**kwargs)**

The ReadPreset operation gets detailed information about a preset.

**Request Syntax**

```python
response = client.read_preset(
    Id='string'
)
```

**Parameters**

- **Id** *(string)* – [REQUIRED]
  The identifier of the preset for which you want to get detailed information.

**Return type**

**dict**

**Returns**

**Response Syntax**

```python
{
    'Preset': {
        'Id': 'string',
        'Arn': 'string',
        'Name': 'string',
        'Description': 'string',
        'Container': 'string',
        'Audio': {
            'Codec': 'string',
            'SampleRate': 'string',
            'BitRate': 'string',
            'Channels': 'string',
            'AudioPackingMode': 'string',
            'CodecOptions': {
                'Profile': 'string',
                'BitDepth': 'string',
                'BitOrder': 'string',
                'Signed': 'string'
            }
        },
        'Video': {
            'Codec': 'string',
            'CodecOptions': {
                'string': 'string'
            },
            'KeyframesMaxDist': 'string',
            'FixedGOP': 'string',
            'BitRate': 'string',
            'FrameRate': 'string',
        }
    }
}
```

Response Structure

- (dict) –
  The ReadPresetResponse structure.
    - Preset (dict) –
      A section of the response body that provides information about the preset.
        * Id (string) –
          Identifier for the new preset. You use this value to get settings for the preset or to delete it.
        * Arn (string) –
          The Amazon Resource Name (ARN) for the preset.
        * Name (string) –
          The name of the preset.
        * Description (string) –
          A description of the preset.
        * Container (string) –
          The container type for the output file. Valid values include flac.
flv, fmp4, gif, mp3, mp4, mpg, mxf, oga, ogg, ts, and webm.

* Audio (dict) –

A section of the response body that provides information about the audio preset values.

- Codec (string) –

  The audio codec for the output file. Valid values include aac, flac, mp2, mp3, pcm, and vorbis.

- SampleRate (string) –

  The sample rate of the audio stream in the output file, in Hertz. Valid values include:
  auto, 22050, 32000, 44100, 48000, 96000

  If you specify auto, Elastic Transcoder automatically detects the sample rate.

- BitRate (string) –

  The bit rate of the audio stream in the output file, in kilo-bits/second. Enter an integer between 64 and 320, inclusive.

- Channels (string) –

  The number of audio channels in the output file. The following values are valid:
  auto, 0, 1, 2

  One channel carries the information played by a single speaker. For example, a stereo track with two channels sends one channel to the left speaker, and the other channel to the right speaker. The output channels are organized into tracks. If you want Elastic Transcoder to automatically detect the number of audio channels in the input file and use that value for the output file, select auto.

  The output of a specific channel value and inputs are as follows:

  - auto channel specified, with any input: Pass through up to eight input channels.
  - 0 channels specified, with any input: Audio omitted from the output.
  - 1 channel specified, with at least one input channel: Mono sound.
  - 2 channels specified, with any input: Two identical mono channels or stereo. For more information about tracks, see Audio:AudioPackingMode.

  For more information about how Elastic Transcoder organizes channels and tracks, see Audio:AudioPackingMode.

- AudioPackingMode (string) –

  The method of organizing audio channels and tracks. Use Audio:Channels to specify the number of channels in your output, and Audio:AudioPackingMode to specify the number of tracks and their relation to the channels. If you do not specify an Audio:AudioPackingMode, Elastic Transcoder uses SingleTrack.
The following values are valid:

- **SingleTrack**
- **OneChannelPerTrack**
- **OneChannelPerTrackWithMOSTo8Tracks**

When you specify **SingleTrack**, Elastic Transcoder creates a single track for your output. The track can have up to eight channels. Use **SingleTrack** for all non-mxf containers.

The outputs of **SingleTrack** for a specific channel value and inputs are as follows:

- **0 channels with any input**: Audio omitted from the output
- **1, 2, or auto channels with no audio input**: Audio omitted from the output
- **1 channel with any input with audio**: One track with one channel, downmixed if necessary
- **2 channels with one track with one channel**: One track with two identical channels
- **2 or auto channels with two tracks with one channel each**: One track with two channels
- **2 or auto channels with one track with two channels**: One track with two channels
- **2 channels with one track with multiple channels**: One track with two channels
- **auto channels with one track with one channel**: One track with one channel
- **auto channels with one track with multiple channels**: One track with multiple channels

When you specify **OneChannelPerTrack**, Elastic Transcoder creates a new track for every channel in your output. Your output can have up to eight single-channel tracks.

The outputs of **OneChannelPerTrack** for a specific channel value and inputs are as follows:

- **0 channels with any input**: Audio omitted from the output
- **1, 2, or auto channels with no audio input**: Audio omitted from the output
- **1 channel with any input with audio**: One track with one channel, downmixed if necessary
- **2 channels with one track with one channel**: Two tracks with one identical channel each
- **2 or auto channels with two tracks with one channel each**: Two tracks with one channel each
- **2 or auto channels with one track with two channels**: Two tracks with one channel each
- **2 channels with one track with multiple channels**: Two tracks with one channel each
- **auto channels with one track with one channel**: One track with one channel
- **auto channels with one track with multiple channels**: Up to eight tracks with one channel each

When you specify **OneChannelPerTrackWithMOSTo8Tracks**, Elastic Transcoder creates eight single-channel tracks for your output. All tracks that do not contain audio data from an input channel are MOS, or Mit Out Sound, tracks.
The outputs of `OneChannelPerTrackWithMosTo8Tracks` for a specific channel value and inputs are as follows:

- **0 channels with any input**: Audio omitted from the output
- **1, 2, or auto channels with no audio input**: Audio omitted from the output
- **1 channel with any input with audio**: One track with one channel, downmixed if necessary, plus six MOS tracks
- **2 channels with one track with one channel**: Two tracks with one identical channel each, plus six MOS tracks
- **2 or auto channels with two tracks with one channel each**: Two tracks with one channel each, plus six MOS tracks
- **2 or auto channels with one track with two channels**: Two tracks with one channel each, plus six MOS tracks
- **2 channels with one track with multiple channels**: Two tracks with one channel each, plus six MOS tracks
- **auto channels with one track with one channel**: One track with one channel, plus seven MOS tracks
- **auto channels with one track with multiple channels**: Up to eight tracks with one channel each, plus MOS tracks until there are eight tracks in all

**CodecOptions (dict)** –

If you specified AAC for `Audio:Codec`, this is the AAC compression profile to use. Valid values include:

- `auto`, `AAC-LC`, `HE-AAC`, `HE-AACv2`

If you specify `auto`, Elastic Transcoder chooses a profile based on the bit rate of the output file.

**Profile (string)** –

You can only choose an audio profile when you specify AAC for the value of `Audio:Codec`.

Specify the AAC profile for the output file. Elastic Transcoder supports the following profiles:

- `auto`: If you specify `auto`, Elastic Transcoder will select the profile based on the bit rate selected for the output file.
- `AAC-LC`: The most common AAC profile. Use for bit rates larger than 64 kbps.
- `HE-AAC`: Not supported on some older players and devices. Use for bit rates between 40 and 80 kbps.
- `HE-AACv2`: Not supported on some players and devices. Use for bit rates less than 48 kbps.

All outputs in a `Smooth` playlist must have the same value for `Profile`.

**Note:** If you created any presets before AAC profiles were added, Elastic Transcoder automatically updated your presets to use AAC-LC. You can change the value as required.

**BitDepth (string)** –

You can only choose an audio bit depth when you specify `flac` or `pcm` for the value of `Audio:Codec`.

The bit depth of a sample is how many bits of information are included in the audio samples. The higher the bit depth, the
better the audio, but the larger the file.

Valid values are 16 and 24.

The most common bit depth is 24.

- **BitOrder (string)** –
  
  You can only choose an audio bit order when you specify pcm for the value of Audio:Codec.
  
  The order the bits of a PCM sample are stored in.
  
  The supported value is LittleEndian.

- **Signed (string)** –
  
  You can only choose whether an audio sample is signed when you specify pcm for the value of Audio:Codec.
  
  Whether audio samples are represented with negative and positive numbers (signed) or only positive numbers (unsigned).
  
  The supported value is Signed.

* **Video (dict)** –

  A section of the response body that provides information about the video preset values.

  - **Codec (string)** –
    
    The video codec for the output file. Valid values include gif, H.264, mpeg2, and vp8. You can only specify vp8 when the container type is webm, gif when the container type is gif, and mpeg2 when the container type is mpg.

  - **CodecOptions (dict)** –
    
    **Profile (H.264/VP8 Only)**
    
    The H.264 profile that you want to use for the output file. Elastic Transcoder supports the following profiles:
    
    - **baseline**: The profile most commonly used for videocasting and for mobile applications.
    - **main**: The profile used for standard-definition digital TV broadcasts.
    - **high**: The profile used for high-definition digital TV broadcasts and for Blu-ray discs.

    **Level (H.264 Only)**
    
    The H.264 level that you want to use for the output file. Elastic Transcoder supports the following levels:
    
    1, 1b, 1.1, 1.2, 1.3, 2, 2.1, 2.2, 2.3, 3.1, 3.2, 3.2.4, 4, 4.1

    **MaxReferenceFrames (H.264 Only)**
    
    Applicable only when the value of Video:Codec is H.264. The maximum number of previously decoded frames to use as a reference for decoding future frames. Valid values are integers 0 through 16, but we recommend that you not use a value greater than the following:
    
    Min(Floor(Maximum decoded picture buffer in macroblocks) *
256 / (Width in pixels * Height in pixels) * 16)

where Width in pixels and Height in pixels represent either MaxWidth and MaxHeight, or Resolution. Maximum decoded picture buffer in macroblocks depends on the value of the Level object. See the list below. (A macroblock is a block of pixels measuring 16x16.)

- 1 - 396
- 1b - 396
- 1.1 - 900
- 1.2 - 2376
- 1.3 - 2376
- 2 - 2376
- 2.1 - 4752
- 2.2 - 8100
- 3 - 8100
- 3.1 - 18000
- 3.2 - 20480
- 4 - 32768
- 4.1 - 32768

MaxBitRate (Optional, H.264/MPEG2/VP8 only)

The maximum number of bits per second in a video buffer; the size of the buffer is specified by BufferSize. Specify a value between 16 and 62,500. You can reduce the bandwidth required to stream a video by reducing the maximum bit rate, but this also reduces the quality of the video.

BufferSize (Optional, H.264/MPEG2/VP8 only)

The maximum number of bits in any x seconds of the output video. This window is commonly 10 seconds, the standard segment duration when you’re using FMP4 or MPEG-TS for the container type of the output video. Specify an integer greater than 0. If you specify MaxBitRate and omit BufferSize, Elastic Transcoder sets BufferSize to 10 times the value of MaxBitRate.

InterlacedMode (Optional, H.264/MPEG2 Only)

The interlace mode for the output video.

Interlaced video is used to double the perceived frame rate for a video by interlacing two fields (one field on every other line, the other field on the other lines) so that the human eye registers multiple pictures per frame. Interlacing reduces the bandwidth required for transmitting a video, but can result in blurred images and flickering.

Valid values include Progressive (no interlacing, top to bottom), TopFirst (top field first), BottomFirst (bottom field first), and Auto.

If InterlaceMode is not specified, Elastic Transcoder uses Progressive for the output. If Auto is specified, Elastic Transcoder interlaces the output.
**ColorSpaceConversionMode**  
(Optional, H.264/MPEG2 Only)

The color space conversion Elastic Transcoder applies to the output video. Color spaces are the algorithms used by the computer to store information about how to render color. Bt.601 is the standard for standard definition video, while Bt.709 is the standard for high definition video.

Valid values include None, Bt709toBt601, Bt601toBt709, and Auto.

If you chose Auto for ColorSpaceConversionMode and your output is interlaced, your frame rate is one of 23.97, 24, 25, 29.97, 50, or 60, your SegmentDuration is null, and you are using one of the resolution changes from the list below, Elastic Transcoder applies the following color space conversions:

- **Standard to HD, 720x480 to 1920x1080** - Elastic Transcoder applies Bt601ToBt709
- **Standard to HD, 720x576 to 1920x1080** - Elastic Transcoder applies Bt601ToBt709
- **HD to Standard, 1920x1080 to 720x480** - Elastic Transcoder applies Bt709ToBt601
- **HD to Standard, 1920x1080 to 720x576** - Elastic Transcoder applies Bt709ToBt601

**Note:** Elastic Transcoder may change the behavior of the ColorSpaceConversionMode Auto mode in the future. All outputs in a playlist must use the same ColorSpaceConversionMode.

If you do not specify a ColorSpaceConversionMode, Elastic Transcoder does not change the color space of a file. If you are unsure what ColorSpaceConversionMode was applied to your output file, you can check the AppliedColorSpaceConversion parameter included in your job response. If your job does not have an AppliedColorSpaceConversion in its response, no ColorSpaceConversionMode was applied.

**ChromaSubsampling**

The sampling pattern for the chroma (color) channels of the output video. Valid values include yuv420p and yuv422p.

- yuv420p samples the chroma information of every other horizontal and every other vertical line, yuv422p samples the color information of every horizontal line and every other vertical line.

**LoopCount (Gif Only)**

The number of times you want the output gif to loop. Valid values include Infinite and integers between 0 and 100, inclusive.

- (string)
- (string)
- KeyframesMaxDist (string)
Applicable only when the value of Video:Codec is one of H.264, MPEG2, or VP8.

The maximum number of frames between key frames. Key frames are fully encoded frames; the frames between key frames are encoded based, in part, on the content of the key frames. The value is an integer formatted as a string; valid values are between 1 (every frame is a key frame) and 100000, inclusive. A higher value results in higher compression but may also discernibly decrease video quality.

For Smooth outputs, the FrameRate must have a constant ratio to the KeyframesMaxDist. This allows Smooth playlists to switch between different quality levels while the file is being played.

For example, an input file can have a FrameRate of 30 with a KeyframesMaxDist of 90. The output file then needs to have a ratio of 1:3. Valid outputs would have FrameRate of 30, 25, and 10, and KeyframesMaxDist of 90, 75, and 30, respectively.

Alternately, this can be achieved by setting FrameRate to auto and having the same values for MaxFrameRate and KeyframesMaxDist.

- **FixedGOP (string)** –

  Applicable only when the value of Video:Codec is one of H.264, MPEG2, or VP8.

  Whether to use a fixed value for FixedGOP. Valid values are true and false:
  - true: Elastic Transcoder uses the value of KeyframesMaxDist for the distance between key frames (the number of frames in a group of pictures, or GOP).
  - false: The distance between key frames can vary.

  **Warning:** FixedGOP must be set to true for fmp4 containers.

- **BitRate (string)** –

  The bit rate of the video stream in the output file, in kilobits/second. Valid values depend on the values of Level and Profile. If you specify auto, Elastic Transcoder uses the detected bit rate of the input source. If you specify a value other than auto, we recommend that you specify a value less than or equal to the maximum H.264-compliant value listed for your level and profile:

  *Level - Maximum video bit rate in kilobits/second (baseline and main Profile) : maximum video bit rate in kilobits/second (high Profile)*

  - 1 - 64 : 80
  - 1b - 128 : 160
  - 1.1 - 192 : 240
  - 1.2 - 384 : 480
  - 1.3 - 768 : 960
FrameRate (string) –

The frames per second for the video stream in the output file. Valid values include:

- auto
- 10
- 15
- 23.97
- 24
- 25
- 29.97
- 30
- 60

If you specify auto, Elastic Transcoder uses the detected frame rate of the input source. If you specify a frame rate, we recommend that you perform the following calculation:

\[
\text{Frame rate} = \frac{\text{maximum recommended decoding speed in luma samples/second}}{\text{width in pixels} \times \text{height in pixels}}
\]

where:

- width in pixels and height in pixels represent the Resolution of the output video.
- maximum recommended decoding speed in Luma samples/second is less than or equal to the maximum value listed in the following table, based on the value that you specified for Level.

The maximum recommended decoding speed in Luma samples/second for each level is described in the following list (Level - Decoding speed):

- 1 - 380160
- 1b - 380160
- 1.1 - 76800
- 1.2 - 1536000
- 1.3 - 3041280
- 2 - 3041280
- 2.1 - 5068800
- 2.2 - 5184000
- 3 - 10368000
- 3.1 - 27648000
- 3.2 - 55296000
- 4 - 62914560
- 4.1 - 62914560

MaxFrameRate (string) –

If you specify auto for FrameRate, Elastic Transcoder uses the frame rate of the input video for the frame rate of the output video. Specify the maximum frame rate that you want Elastic Transcoder to use when the frame rate of the input video is greater than the desired maximum frame rate of the output video. Valid values include: 10, 15, 23.97, 24, 25, 29.97, 30, 60.

Resolution (string) –
Warning: To better control resolution and aspect ratio of output videos, we recommend that you use the values MaxWidth, MaxHeight, SizingPolicy, PaddingPolicy, and DisplayAspectRatio instead of Resolution and AspectRatio. The two groups of settings are mutually exclusive. Do not use them together.

The width and height of the video in the output file, in pixels. Valid values are auto and width x height:
- auto: Elastic Transcoder attempts to preserve the width and height of the input file, subject to the following rules.
- *width* x *height*: The width and height of the output video in pixels.

Note the following about specifying the width and height:
- The width must be an even integer between 128 and 4096, inclusive.
- The height must be an even integer between 96 and 3072, inclusive.
- If you specify a resolution that is less than the resolution of the input file, Elastic Transcoder rescales the output file to the lower resolution.
- If you specify a resolution that is greater than the resolution of the input file, Elastic Transcoder rescales the output to the higher resolution.
- We recommend that you specify a resolution for which the product of width and height is less than or equal to the applicable value in the following list (List - Max width x height value):
  - 1 - 25344
  - 1b - 25344

  - 1.2 - 101376
  - 1.3 - 101376
  - 2 - 101376
  - 2.1 - 202752
  - 2.2 - 404720
  - 3 - 404720
  - 3.1 - 921600
  - 3.2 - 1310720
  - 4 - 2097152
  - 4.1 - 2097152

AspectRatio (string) –

The display aspect ratio of the video in the output file. Valid
values include:

auto, 1:1, 4:3, 3:2, 16:9

If you specify auto, Elastic Transcoder tries to preserve the aspect ratio of the input file.

If you specify an aspect ratio for the output file that differs from aspect ratio of the input file, Elastic Transcoder adds pillarboxing (black bars on the sides) or letterboxing (black bars on the top and bottom) to maintain the aspect ratio of the active region of the video.

- **MaxWidth (string)** –

  The maximum width of the output video in pixels. If you specify auto, Elastic Transcoder uses 1920 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 128 and 4096.

- **MaxHeight (string)** –

  The maximum height of the output video in pixels. If you specify auto, Elastic Transcoder uses 1080 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 96 and 3072.

- **DisplayAspectRatio (string)** –

  The value that Elastic Transcoder adds to the metadata in the output file.

- **SizingPolicy (string)** –

  Specify one of the following values to control scaling of the output video:

  - **Fit**: Elastic Transcoder scales the output video so it matches the value that you specified in either MaxWidth or MaxHeight without exceeding the other value.
  - **Fill**: Elastic Transcoder scales the output video so it matches the value that you specified in either MaxWidth or MaxHeight and matches or exceeds the other value. Elastic Transcoder centers the output video and then crops it in the dimension (if any) that exceeds the maximum value.
  - **Stretch**: Elastic Transcoder stretches the output video to match the values that you specified for MaxWidth and MaxHeight. If the relative proportions of the input video and the output video are different, the output video will be distorted.
  - **Keep**: Elastic Transcoder does not scale the output video. If either dimension of the input video exceeds the values that you specified for MaxWidth and MaxHeight, Elastic Transcoder crops the output video.
  - **ShrinkToFit**: Elastic Transcoder scales the output video down so that its dimensions match the values that you specified for at least one of MaxWidth and MaxHeight without exceeding either value. If you specify this option, Elastic Transcoder does not scale the video up.
  - **ShrinkToFill**: Elastic Transcoder scales the output video down so that its dimensions match the values that you specified for at least one of MaxWidth and MaxHeight without exceeding either value. If you specify this option, Elastic Transcoder does not scale the video up.
dropping below either value. If you specify this option, Elastic Transcoder does not scale the video up.

- **PaddingPolicy** *(string)* –

  When you set `PaddingPolicy` to `Pad`, Elastic Transcoder may add black bars to the top and bottom and/or left and right sides of the output video to make the total size of the output video match the values that you specified for `MaxWidth` and `MaxHeight`.

- **Watermarks** *(list)* –

  Settings for the size, location, and opacity of graphics that you want Elastic Transcoder to overlay over videos that are transcoded using this preset. You can specify settings for up to four watermarks. Watermarks appear in the specified size and location, and with the specified opacity for the duration of the transcoded video.

  Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

  When you create a job that uses this preset, you specify the .png or .jpg graphics that you want Elastic Transcoder to include in the transcoded videos. You can specify fewer graphics in the job than you specify watermark settings in the preset, which allows you to use the same preset for up to four watermarks that have different dimensions.

- **(dict)** –

  Settings for the size, location, and opacity of graphics that you want Elastic Transcoder to overlay over videos that are transcoded using this preset. You can specify settings for up to four watermarks. Watermarks appear in the specified size and location, and with the specified opacity for the duration of the transcoded video.

  Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

  When you create a job that uses this preset, you specify the .png or .jpg graphics that you want Elastic Transcoder to include in the transcoded videos. You can specify fewer graphics in the job than you specify watermark settings in the preset, which allows you to use the same preset for up to four watermarks that have different dimensions.

- **Id** *(string)* – A unique identifier for the settings for one watermark. The value of `Id` can be up to 40 characters long.

- **MaxWidth** *(string)* –

  The maximum width of the watermark in one of the following formats:
  - number of pixels (px): The minimum value is 16 pixels, and the maximum value is the value of `MaxWidth`.
  - integer percentage (%): The range of valid values is 0 to 100. Use the value of `Target` to specify whether you want Elastic
Transcoder to include the black bars that are added by Elastic Transcoder, if any, in the calculation.
If you specify the value in pixels, it must be less than or equal to the value of MaxWidth.

- **MaxHeight** *(string)* –

  The maximum height of the watermark in one of the following formats:
  - number of pixels (px): The minimum value is 16 pixels, and the maximum value is the value of MaxHeight.
  - integer percentage (%): The range of valid values is 0 to 100.
  Use the value of Target to specify whether you want Elastic Transcoder to include the black bars that are added by Elastic Transcoder, if any, in the calculation.
  If you specify the value in pixels, it must be less than or equal to the value of MaxHeight.

- **SizingPolicy** *(string)* –

  A value that controls scaling of the watermark:
  - **Fit** : Elastic Transcoder scales the watermark so it matches the value that you specified in either MaxWidth or MaxHeight without exceeding the other value.
  - **Stretch** : Elastic Transcoder stretches the watermark to match the values that you specified for MaxWidth and MaxHeight. If the relative proportions of the watermark and the values of MaxWidth and MaxHeight are different, the watermark will be distorted.
  - **ShrinkToFit** : Elastic Transcoder scales the watermark down so that its dimensions match the values that you specified for at least one of MaxWidth and MaxHeight without exceeding either value. If you specify this option, Elastic Transcoder does not scale the watermark up.

- **HorizontalAlign** *(string)* –

  The horizontal position of the watermark unless you specify a non-zero value for HorizontalOffset:
  - **Left** : The left edge of the watermark is aligned with the left border of the video.
  - **Right** : The right edge of the watermark is aligned with the right border of the video.
  - **Center** : The watermark is centered between the left and right borders.

- **HorizontalOffset** *(string)* –

  The amount by which you want the horizontal position of the watermark to be offset from the position specified by HorizontalAlign:
  - number of pixels (px): The minimum value is 0 pixels, and the maximum value is the value of MaxWidth.
  - integer percentage (%): The range of valid values is 0 to 100.
  For example, if you specify Left for HorizontalAlign and 5px for HorizontalOffset, the left side of the watermark appears 5 pixels from the left border of the output video.

  HorizontalOffset is only valid when the value of
HorizontalAlign is Left or Right. If you specify an offset that causes the watermark to extend beyond the left or right border and Elastic Transcoder has not added black bars, the watermark is cropped. If Elastic Transcoder has added black bars, the watermark extends into the black bars. If the watermark extends beyond the black bars, it is cropped.

Use the value of Target to specify whether you want to include the black bars that are added by Elastic Transcoder, if any, in the offset calculation.

· VerticalAlign (string) –
  
The vertical position of the watermark unless you specify a non-zero value for VerticalOffset:
  · Top: The top edge of the watermark is aligned with the top border of the video.
  · Bottom: The bottom edge of the watermark is aligned with the bottom border of the video.
  · Center: The watermark is centered between the top and bottom borders.
  · VerticalOffset (string) – VerticalOffset

  The amount by which you want the vertical position of the watermark to be offset from the position specified by VerticalAlign:
  · number of pixels (px): The minimum value is 0 pixels, and the maximum value is the value of MaxHeight.
  · integer percentage (%): The range of valid values is 0 to 100. For example, if you specify Top for VerticalAlign and 5px for VerticalOffset, the top of the watermark appears 5 pixels from the top border of the output video.

VerticalOffset is only valid when the value of VerticalAlign is Top or Bottom.

If you specify an offset that causes the watermark to extend beyond the top or bottom border and Elastic Transcoder has not added black bars, the watermark is cropped. If Elastic Transcoder has added black bars, the watermark extends into the black bars. If the watermark extends beyond the black bars, it is cropped.

Use the value of Target to specify whether you want Elastic Transcoder to include the black bars that are added by Elastic Transcoder, if any, in the offset calculation.

· Opacity (string) –
  
  A percentage that indicates how much you want a watermark to obscure the video in the location where it appears. Valid values are 0 (the watermark is invisible) to 100 (the watermark completely obscures the video in the specified location). The datatype of Opacity is float.

Elastic Transcoder supports transparent .png graphics. If you use a transparent .png, the transparent portion of the video appears as if you had specified a value of 0 for Opacity. The .jpg file format doesn’t support transparency.

· Target (string) –
A value that determines how Elastic Transcoder interprets values that you specified for `HorizontalOffset`, `VerticalOffset`, `MaxWidth`, and `MaxHeight`:

- **Content**: `HorizontalOffset` and `VerticalOffset` values are calculated based on the borders of the video excluding black bars added by Elastic Transcoder, if any. In addition, `MaxWidth` and `MaxHeight`, if specified as a percentage, are calculated based on the borders of the video excluding black bars added by Elastic Transcoder, if any.

- **Frame**: `HorizontalOffset` and `VerticalOffset` values are calculated based on the borders of the video including black bars added by Elastic Transcoder, if any. In addition, `MaxWidth` and `MaxHeight`, if specified as a percentage, are calculated based on the borders of the video including black bars added by Elastic Transcoder, if any.

* **Thumbnails (dict)** –

A section of the response body that provides information about the thumbnail preset values, if any.

- **Format (string)** –

  The format of thumbnails, if any. Valid values are `jpg` and `png`.

  You specify whether you want Elastic Transcoder to create thumbnails when you create a job.

- **Interval (string)** –

  The approximate number of seconds between thumbnails. Specify an integer value.

- **Resolution (string)** –

  **Warning**: To better control resolution and aspect ratio of thumbnails, we recommend that you use the values `MaxWidth`, `MaxHeight`, `SizingPolicy`, and `PaddingPolicy` instead of `Resolution` and `AspectRatio`. The two groups of settings are mutually exclusive. Do not use them together.

  The width and height of thumbnail files in pixels. Specify a value in the format `*width* x *height*` where both values are even integers. The values cannot exceed the width and height that you specified in the `Video:Resolution` object.

- **AspectRatio (string)** –

  **Warning**: To better control resolution and aspect ratio of thumbnails, we recommend that you use the values `MaxWidth`, `MaxHeight`, `SizingPolicy`, and `PaddingPolicy` instead of `Resolution` and `AspectRatio`. The two groups of settings are mutually exclusive. Do not use them together.

  The aspect ratio of thumbnails. Valid values include:

  `auto`, `1:1`, `4:3`, `3:2`, `16:9`
If you specify `auto`, Elastic Transcoder tries to preserve the aspect ratio of the video in the output file.

- **MaxWidth (string)** –
  
The maximum width of thumbnails in pixels. If you specify auto, Elastic Transcoder uses 1920 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 32 and 4096.

- **MaxHeight (string)** –
  
The maximum height of thumbnails in pixels. If you specify auto, Elastic Transcoder uses 1080 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 32 and 3072.

- **SizingPolicy (string)** –
  
Specify one of the following values to control scaling of thumbnails:

- **Fit**: Elastic Transcoder scales thumbnails so they match the value that you specified in thumbnail MaxWidth or MaxHeight settings without exceeding the other value.

- **Fill**: Elastic Transcoder scales thumbnails so they match the value that you specified in thumbnail MaxWidth or MaxHeight settings and matches or exceeds the other value. Elastic Transcoder centers the image in thumbnails and then crops in the dimension (if any) that exceeds the maximum value.

- **Stretch**: Elastic Transcoder stretches thumbnails to match the values that you specified for thumbnail MaxWidth and MaxHeight settings. If the relative proportions of the input video and thumbnails are different, the thumbnails will be distorted.

- **Keep**: Elastic Transcoder does not scale thumbnails. If either dimension of the input video exceeds the values that you specified for thumbnail MaxWidth and MaxHeight settings, Elastic Transcoder crops the thumbnails.

- **ShrinkToFit**: Elastic Transcoder scales thumbnails down so that their dimensions match the values that you specified for at least one of thumbnail MaxWidth and MaxHeight without exceeding either value. If you specify this option, Elastic Transcoder does not scale thumbnails up.

- **ShrinkToFill**: Elastic Transcoder scales thumbnails down so that their dimensions match the values that you specified for at least one of MaxWidth and MaxHeight without dropping below either value. If you specify this option, Elastic Transcoder does not scale thumbnails up.

- **PaddingPolicy (string)** –
  
When you set PaddingPolicy to Pad, Elastic Transcoder may add black bars to the top and bottom and/or left and right sides of thumbnails to make the total size of the thumbnails match the values that you specified for thumbnail MaxWidth and MaxHeight settings.

- **Type (string)** –
  
Whether the preset is a default preset provided by Elastic Transcoder
(System) or a preset that you have defined (Custom).

test_role(**kwargs)

The TestRole operation tests the IAM role used to create the pipeline.

The TestRole action lets you determine whether the IAM role you are using has sufficient permissions to let Elastic Transcoder perform tasks associated with the transcoding process. The action attempts to assume the specified IAM role, checks read access to the input and output buckets, and tries to send a test notification to Amazon SNS topics that you specify.

Request Syntax

```python
response = client.test_role(
    Role='string',
    InputBucket='string',
    OutputBucket='string',
    Topics=['string'],
)
```

Parameters

- **Role (string)** – [REQUIRED]
  The IAM Amazon Resource Name (ARN) for the role that you want Elastic Transcoder to test.

- **InputBucket (string)** – [REQUIRED]
  The Amazon S3 bucket that contains media files to be transcoded. The action attempts to read from this bucket.

- **OutputBucket (string)** – [REQUIRED]
  The Amazon S3 bucket that Elastic Transcoder will write transcoded media files to. The action attempts to read from this bucket.

- **Topics (list)** – [REQUIRED]
  The ARNs of one or more Amazon Simple Notification Service (Amazon SNS) topics that you want the action to send a test notification to.

  - **(string)** –

Return type  dict

Returns

Response Syntax

```python
{
    'Success': 'string',
    'Messages': [
        'string',
    ]
}
```

Response Structure

- **(dict)** –

  The TestRoleResponse structure.

    - **Success (string)** –

      If the operation is successful, this value is `true`; otherwise, the value is `false`. 
– **Messages** (*list*) –

If the `Success` element contains `false`, this value is an array of one or more error messages that were generated during the test process.

* (string) –

**update_pipeline** (**kwargs**)

Use the `UpdatePipeline` operation to update settings for a pipeline.

**Warning:** When you change pipeline settings, your changes take effect immediately. Jobs that you have already submitted and that Elastic Transcoder has not started to process are affected in addition to jobs that you submit after you change settings.

**Request Syntax**

```python
response = client.update_pipeline(
    Id='string',
    Name='string',
    InputBucket='string',
    Role='string',
    AwsKmsKeyArn='string',
    Notifications={
        'Progressing': 'string',
        'Completed': 'string',
        'Warning': 'string',
        'Error': 'string'
    },
    ContentConfig={
        'Bucket': 'string',
        'StorageClass': 'string',
        'Permissions': [
            {'GranteeType': 'string',
             'Grantee': 'string',
             'Access': ['string',
                        ]},
         ]
    },
    ThumbnailConfig={
        'Bucket': 'string',
        'StorageClass': 'string',
        'Permissions': [
            {'GranteeType': 'string',
             'Grantee': 'string',
             'Access': ['string',
                        ]},
         ]
    }
)
```

**Parameters**

- **Id** *(string)* – [REQUIRED]
The ID of the pipeline that you want to update.

- **Name (string)** – The name of the pipeline. We recommend that the name be unique within the AWS account, but uniqueness is not enforced.

  Constraints: Maximum 40 characters

- **InputBucket (string)** – The Amazon S3 bucket in which you saved the media files that you want to transcode and the graphics that you want to use as watermarks.

- **Role (string)** – The IAM Amazon Resource Name (ARN) for the role that you want Elastic Transcoder to use to transcode jobs for this pipeline.

- **AwsKmsKeyArn (string)** – The AWS Key Management Service (AWS KMS) key that you want to use with this pipeline.

  If you use either S3 or S3-AWS-KMS as your Encryption:Mode, you don’t need to provide a key with your job because a default key, known as an AWS-KMS key, is created for you automatically. You need to provide an AWS-KMS key only if you want to use a non-default AWS-KMS key, or if you are using an Encryption:Mode of AES-PKCS7, AES-CTR, or AES-GCM.

- **Notifications (dict)** – The Amazon Simple Notification Service (Amazon SNS) topic or topics to notify in order to report job status.

  - **Progressing (string)** – The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify when Elastic Transcoder has started to process the job.
  
  - **Completed (string)** – The Amazon SNS topic that you want to notify when Elastic Transcoder has finished processing the job.
  
  - **Warning (string)** – The Amazon SNS topic that you want to notify when Elastic Transcoder encounters a warning condition.
  
  - **Error (string)** – The Amazon SNS topic that you want to notify when Elastic Transcoder encounters an error condition.

- **ContentConfig (dict)** – The optional ContentConfig object specifies information about the Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists: which bucket to use, which users you want to have access to the files, the type of access you want users to have, and the storage class that you want to assign to the files.

  If you specify values for ContentConfig, you must also specify values for ThumbnailConfig.

  If you specify values for ContentConfig and ThumbnailConfig, omit the OutputBucket object.

  - **Bucket** : The Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists.

  - **Permissions** (Optional): The Permissions object specifies which users you want to have access to transcoded files and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.

  - **Grantee Type**: Specify the type of value that appears in the Grantee object: * Canonical* : The value in the Grantee object is either the
canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. For more information about canonical user IDs, see Access Control List (ACL) Overview in the Amazon Simple Storage Service Developer Guide. For more information about using CloudFront origin access identities to require that users use CloudFront URLs instead of Amazon S3 URLs, see Using an Origin Access Identity to Restrict Access to Your Amazon S3 Content. .. warning:: A canonical user ID is not the same as an AWS account number.

- **Email**: The value in the `Grantee` object is the registered email address of an AWS account.
- **Group**: The value in the `Grantee` object is one of the following predefined Amazon S3 groups: `AllUsers`, `AuthenticatedUsers`, or `LogDelivery`.
- **Grantee**: The AWS user or group that you want to have access to transcoded files and playlists. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.
- **Access**: The permission that you want to give to the AWS user that you specified in `Grantee`. Permissions are granted on the files that Elastic Transcoder adds to the bucket, including playlists and video files. Valid values include: * `READ`: The grantee can read the objects and metadata for objects that Elastic Transcoder adds to the Amazon S3 bucket.
  - `READ_ACP`: The grantee can read the object ACL for objects that Elastic Transcoder adds to the Amazon S3 bucket.
  - `WRITE_ACP`: The grantee can write the ACL for the objects that Elastic Transcoder adds to the Amazon S3 bucket.
  - `FULL_CONTROL`: The grantee has `READ`, `READ_ACP`, and `WRITE_ACP` permissions for the objects that Elastic Transcoder adds to the Amazon S3 bucket.
- **StorageClass**: The Amazon S3 storage class, `Standard` or `ReducedRedundancy`, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

- **Bucket** *(string)* –

  The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the following are true:
  * You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.
  * You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.
  * You do not want to specify the permissions that Elastic Transcoder grants to the files.
  * You want to associate the transcoded files and thumbnails with the Amazon S3 Standard storage class.

If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit `OutputBucket` and specify values for `ContentConfig` and `ThumbnailConfig` instead.

- **StorageClass** *(string)* –

  The Amazon S3 storage class, `Standard` or `ReducedRedundancy`, that you want Elastic Transcoder to assign to the video files and playlists.
that it stores in your Amazon S3 bucket.

- **Permissions** *(list)* –

  Optional. The `Permissions` object specifies which users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.

  If you include `Permissions`, Elastic Transcoder grants only the permissions that you specify. It does not grant full permissions to the owner of the role specified by `Role`. If you want that user to have full control, you must explicitly grant full control to the user.

  If you omit `Permissions`, Elastic Transcoder grants full control over the transcoded files and playlists to the owner of the role specified by `Role`, and grants no other permissions to any other user or group.

  * *(dict)* –

**The Permission structure.**

  - **GranteeType**(string) –

    The type of value that appears in the `Grantee` object:

    - **Canonical**: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning::A canonical user ID is not the same as an AWS account number.
    - **Email**: The registered email address of an AWS account.
    - **Group**: One of the following predefined Amazon S3 groups: `AllUsers`, `AuthenticatedUsers`, or `LogDelivery`.

  - **Grantee**(string) –

    The AWS user or group that you want to have access to transcoded files and playlists. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.

  - **Access**(list) –

    The permission that you want to give to the AWS user that is listed in `Grantee`. Valid values include:

    - **READ**: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
    - **READ_ACP**: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
    - **WRITE_ACP**: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
    - **FULL_CONTROL**: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

  - **ThumbnailConfig**(dict) – The `ThumbnailConfig` object specifies several values, including the Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files, which users you want to have access to the files, the type of access you want users to have, and the storage class that you want to assign to
the files.

If you specify values for `ContentConfig`, you must also specify values for `ThumbnailConfig` even if you don’t want to create thumbnails.

If you specify values for `ContentConfig` and `ThumbnailConfig`, omit the `OutputBucket` object.

- **Bucket**: The Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files.
- **Permissions** (Optional): The `Permissions` object specifies which users and/or predefined Amazon S3 groups you want to have access to thumbnail files, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.
- **GranteeType**: Specify the type of value that appears in the `Grantee` object: *Canonical*: The value in the `Grantee` object is either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning:: A canonical user ID is not the same as an AWS account number.
- **Email**: The value in the `Grantee` object is the registered email address of an AWS account.
- **Group**: The value in the `Grantee` object is one of the following predefined Amazon S3 groups: `AllUsers`, `AuthenticatedUsers`, or `LogDelivery`.
- **Grantee**: The AWS user or group that you want to have access to thumbnail files. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.
- **Access**: The permission that you want to give to the AWS user that you specified in `Grantee`. Permissions are granted on the thumbnail files that Elastic Transcoder adds to the bucket. Valid values include: *READ*: The grantee can read the thumbnails and metadata for objects that Elastic Transcoder adds to the Amazon S3 bucket.
- **READ_ACP**: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
- **WRITE_ACP**: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
- **FULL_CONTROL**: The grantee has `READ`, `READ_ACP`, and `WRITE_ACP` permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
- **StorageClass**: The Amazon S3 storage class, `Standard` or `ReducedRedundancy`, that you want Elastic Transcoder to assign to the thumbnails that it stores in your Amazon S3 bucket.
- **Bucket** *(string)* –

The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the following are true:

* You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.
* You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.
* You do not want to specify the permissions that Elastic Transcoder grants to the files.
* You want to associate the transcoded files and thumbnails with the
Amazon S3 Standard storage class.
If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit OutputBucket and specify values for ContentConfig and ThumbnailConfig instead.

- **StorageClass** *(string)*

  The Amazon S3 storage class, **Standard** or **ReducedRedundancy**, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

- **Permissions** *(list)*

  Optional. The Permissions object specifies which users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.

  If you include Permissions, Elastic Transcoder grants only the permissions that you specify. It does not grant full permissions to the owner of the role specified by Role. If you want that user to have full control, you must explicitly grant full control to the user.

  If you omit Permissions, Elastic Transcoder grants full control over the transcoded files and playlists to the owner of the role specified by Role, and grants no other permissions to any other user or group.

  * *(dict)*

    The Permission structure.
    - **GranteeType** *(string)*

      The type of value that appears in the Grantee object:
      - **Canonical****: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. **Warning**: A canonical user ID is not the same as an AWS account number.
      - **Email****: The registered email address of an AWS account.
      - **Group****: One of the following predefined Amazon S3 groups: **AllUsers**, **AuthenticatedUsers**, or **LogDelivery**.
    - **Grantee** *(string)*

      The AWS user or group that you want to have access to transcoded files and playlists. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.
    - **Access** *(list)*

      The permission that you want to give to the AWS user that is listed in Grantee. Valid values include:
      - **READ****: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
      - **READ_ACP****: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
· **WRITE_ACP**: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
· **FULL_CONTROL**: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

**Return type** dict

**Returns**

**Response Syntax**

```py

```
Response Structure

- **(dict)** –
  When you update a pipeline, Elastic Transcoder returns the values that you specified in the request.

  - **Pipeline (dict)** –
    The pipeline (queue) that is used to manage jobs.
    - **Id (string)** –
      The identifier for the pipeline. You use this value to identify the pipeline in which you want to perform a variety of operations, such as creating a job or a preset.
    - **Arn (string)** –
      The Amazon Resource Name (ARN) for the pipeline.
    - **Name (string)** –
      The name of the pipeline. We recommend that the name be unique within the AWS account, but uniqueness is not enforced.
      Constraints: Maximum 40 characters
    - **Status (string)** –
      The current status of the pipeline:
      - **Active**: The pipeline is processing jobs.
      - **Paused**: The pipeline is not currently processing jobs.
    - **InputBucket (string)** –
      The Amazon S3 bucket from which Elastic Transcoder gets media files for transcoding and the graphics files, if any, that you want to use for watermarks.
    - **OutputBucket (string)** –
      The Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files, thumbnails, and playlists. Either you specify this value, or you specify both `ContentConfig` and `ThumbnailConfig`.
    - **Role (string)** –
      The IAM Amazon Resource Name (ARN) for the role that Elastic Transcoder uses to transcode jobs for this pipeline.
    - **AwsKmsKeyArn (string)** –
      The AWS Key Management Service (AWS KMS) key that you want to use with this pipeline.
      
      If you use either S3 or S3-AWS-KMS as your `Encryption:Mode`, you don’t need to provide a key with your job because a default key, known as an AWS-KMS key, is created for you automatically. You need to provide an AWS-KMS key only if you want to use a non-default AWS-KMS key, or if you are using an `Encryption:Mode` of AES-PKCS7, AES-CTR, or AES-GCM.
    - **Notifications (dict)** –
The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify to report job status.

**Warning:** To receive notifications, you must also subscribe to the new topic in the Amazon SNS console.

- **Progressing** (optional): The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify when Elastic Transcoder has started to process the job.
- **Completed** (optional): The Amazon SNS topic that you want to notify when Elastic Transcoder has finished processing the job.
- **Warning** (optional): The Amazon SNS topic that you want to notify when Elastic Transcoder encounters a warning condition.
- **Error** (optional): The Amazon SNS topic that you want to notify when Elastic Transcoder encounters an error condition.

- **Progressing** *(string)* –
  The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify when Elastic Transcoder has started to process the job.
- **Completed** *(string)* –
  The Amazon SNS topic that you want to notify when Elastic Transcoder has finished processing the job.
- **Warning** *(string)* –
  The Amazon SNS topic that you want to notify when Elastic Transcoder encounters a warning condition.
- **Error** *(string)* –
  The Amazon SNS topic that you want to notify when Elastic Transcoder encounters an error condition.

* **ContentConfig** *(dict)* –
  Information about the Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists. Either you specify both **ContentConfig** and **ThumbnailConfig**, or you specify **OutputBucket**.

  - **Bucket** : The Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists.
  - **Permissions** : A list of the users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access that you want them to have. *
    - **GranteeType**: The type of value that appears in the **Grantee** object: *
      - **Canonical**: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution.
    - **Email**: The registered email address of an AWS account.
    - **Group**: One of the following predefined Amazon S3 groups: **AllUsers**, **AuthenticatedUsers**, or **LogDelivery**.
    - **Grantee**: The AWS user or group that you want to have access to transcoded files and playlists.
    - **Access**: The permission that you want to give to the AWS user that is listed in **Grantee**. Valid values include: *

Chapter 3. API Reference
The grantee can read the objects and metadata for objects that Elastic Transcoder adds to the Amazon S3 bucket.

- **READ_ACP**: The grantee can read the object ACL for objects that Elastic Transcoder adds to the Amazon S3 bucket.
- **WRITE_ACP**: The grantee can write the ACL for the objects that Elastic Transcoder adds to the Amazon S3 bucket.
- **FULL_CONTROL**: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the objects that Elastic Transcoder adds to the Amazon S3 bucket.

- **StorageClass**: The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

- **Bucket** *(string)* –
  The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the following are true:
  - You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.
  - You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.
  - You do not want to specify the permissions that Elastic Transcoder grants to the files.
  - You want to associate the transcoded files and thumbnails with the Amazon S3 Standard storage class.

If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit **OutputBucket** and specify values for **ContentConfig** and **ThumbnailConfig** instead.

- **StorageClass** *(string)* –
  The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

- **Permissions** *(list)* –
  Optional. The **Permissions** object specifies which users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.

If you include **Permissions**, Elastic Transcoder grants only the permissions that you specify. It does not grant full permissions to the owner of the role specified by **Role**. If you want that user to have full control, you must explicitly grant full control to the user.

If you omit **Permissions**, Elastic Transcoder grants full control over the transcoded files and playlists to the owner of the role specified by **Role**, and grants no other permissions.
to any other user or group.

- (dict) –
  The Permission structure.

- GranteeType (string) –

  The type of value that appears in the Grantee object:
  - Canonical: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning:: A canonical user ID is not the same as an AWS account number.
  - Email: The registered email address of an AWS account.
  - Group: One of the following predefined Amazon S3 groups: AllUsers, AuthenticatedUsers, or LogDelivery.

- Grantee (string) –

  The AWS user or group that you want to have access to transcoded files and playlists. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.

- Access (list) –

  The permission that you want to give to the AWS user that is listed in Grantee. Valid values include:
  - READ: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - READ_ACP: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - WRITE_ACP: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - FULL_CONTROL: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

- (string) –

  * ThumbnailConfig (dict) –

  Information about the Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files. Either you specify both ContentConfig and ThumbnailConfig, or you specify OutputBucket.

  - Bucket: The Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files.
  - Permissions: A list of the users and/or predefined Amazon S3 groups you want to have access to thumbnail files, and the type of access that you want them to have. * GranteeType: The type of value that appears in the Grantee object: * Canonical: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning:: A canonical user ID is not the same as an AWS account number.
  - Email: The registered email address of an AWS account.
  - Group: One of the following predefined Amazon S3 groups: AllUsers, AuthenticatedUsers, or LogDelivery.

- (string) –
groups: AllUsers, AuthenticatedUsers, or LogDelivery.
· Grantee: The AWS user or group that you want to have access to thumbnail files.
· Access: The permission that you want to give to the AWS user that is listed in Grantee. Valid values include: *
  READ: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  READ_ACP: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  WRITE_ACP: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  FULL_CONTROL: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
· StorageClass: The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the thumbnails that it stores in your Amazon S3 bucket.
· Bucket (string) –
  The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the following are true:
  · You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.
  · You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.
  · You do not want to specify the permissions that Elastic Transcoder grants to the files.
  · You want to associate the transcoded files and thumbnails with the Amazon S3 Standard storage class.
  If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit OutputBucket and specify values for ContentConfig and ThumbnailConfig instead.
· StorageClass (string) –
  The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.
· Permissions (list) –
  Optional. The Permissions object specifies which users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.
  If you include Permissions, Elastic Transcoder grants only the permissions that you specify. It does not grant full permissions to the owner of the role specified by Role. If
you want that user to have full control, you must explicitly grant full control to the user.

If you omit Permissions, Elastic Transcoder grants full control over the transcoded files and playlists to the owner of the role specified by Role, and grants no other permissions to any other user or group.

- (dict) –
  The Permission structure.

- GranteeType (string) –
  The type of value that appears in the Grantee object:
  - Canonical: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning:: A canonical user ID is not the same as an AWS account number.
  - Email: The registered email address of an AWS account.
  - Group: One of the following predefined Amazon S3 groups: AllUsers, AuthenticatedUsers, or LogDelivery.

- Grantee (string) –
  The AWS user or group that you want to have access to transcoded files and playlists. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.

- Access (list) –
  The permission that you want to give to the AWS user that is listed in Grantee. Valid values include:
  - READ: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - READ_ACP: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - WRITE_ACP: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - FULL_CONTROL: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

- (string) –
  - Warnings (list) –
    Elastic Transcoder returns a warning if the resources used by your pipeline are not in the same region as the pipeline.

Using resources in the same region, such as your Amazon S3 buckets, Amazon SNS notification topics, and AWS KMS key, reduces processing time and prevents cross-regional charges.

- (dict) –
  Elastic Transcoder returns a warning if the resources used by your pipeline are not in the same region as the pipeline.

Using resources in the same region, such as your Amazon S3 buck-
ets, Amazon SNS notification topics, and AWS KMS key, reduces processing time and prevents cross-regional charges.

- **Code (string)** –
  
The code of the cross-regional warning.

- **Message (string)** –
  
The message explaining what resources are in a different region from the pipeline.

**Note:** AWS KMS keys must be in the same region as the pipeline.

### update_pipeline_notifications(**kwargs)**

With the UpdatePipelineNotifications operation, you can update Amazon Simple Notification Service (Amazon SNS) notifications for a pipeline.

When you update notifications for a pipeline, Elastic Transcoder returns the values that you specified in the request.

**Request Syntax**

```python
response = client.update_pipeline_notifications(
    Id='string',
    Notifications={
        'Progressing': 'string',
        'Completed': 'string',
        'Warning': 'string',
        'Error': 'string'
    }
)
```

**Parameters**

- **Id (string)** – [REQUIRED]
  
The identifier of the pipeline for which you want to change notification settings.

- **Notifications (dict)** – [REQUIRED]
  
The topic ARN for the Amazon Simple Notification Service (Amazon SNS) topic that you want to notify to report job status.

**Warning:** To receive notifications, you must also subscribe to the new topic in the Amazon SNS console.

- **Progressing**: The topic ARN for the Amazon Simple Notification Service (Amazon SNS) topic that you want to notify when Elastic Transcoder has started to process jobs that are added to this pipeline. This is the ARN that Amazon SNS returned when you created the topic.

- **Completed**: The topic ARN for the Amazon SNS topic that you want to notify when Elastic Transcoder has finished processing a job. This is the ARN that Amazon SNS returned when you created the topic.

- **Warning**: The topic ARN for the Amazon SNS topic that you want to notify when Elastic Transcoder encounters a warning condition. This is the ARN that Amazon SNS returned when you created the topic.

- **Error**: The topic ARN for the Amazon SNS topic that you want to notify when Elastic Transcoder encounters an error condition. This is the ARN that Amazon SNS returned when you created the topic.

- **Progressing (string)** –
The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify when Elastic Transcoder has started to process the job.

- **Completed** *(string)* –
  
  The Amazon SNS topic that you want to notify when Elastic Transcoder has finished processing the job.

- **Warning** *(string)* –
  
  The Amazon SNS topic that you want to notify when Elastic Transcoder encounters a warning condition.

- **Error** *(string)* –
  
  The Amazon SNS topic that you want to notify when Elastic Transcoder encounters an error condition.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Pipeline': {
        'Id': 'string',
        'Arn': 'string',
        'Name': 'string',
        'Status': 'string',
        'InputBucket': 'string',
        'OutputBucket': 'string',
        'Role': 'string',
        'AwsKmsKeyArn': 'string',
        'Notifications': {
            'Progressing': 'string',
            'Completed': 'string',
            'Warning': 'string',
            'Error': 'string'
        },
    },
    'ContentConfig': {
        'Bucket': 'string',
        'StorageClass': 'string',
        'Permissions': [
            {
                'GranteeType': 'string',
                'Grantee': 'string',
                'Access': ['string'],
            }
        ],
    },
    'ThumbnailConfig': {
        'Bucket': 'string',
        'StorageClass': 'string',
        'Permissions': [
            {
                'GranteeType': 'string',
                'Grantee': 'string',
                'Access': ['string'],
            }
        ],
    },
}
```
Response Structure

- (dict) –

The UpdatePipelineNotificationsResponse structure.

- Pipeline (dict) –

A section of the response body that provides information about the pipeline.

- **Id (string)** –

  The identifier for the pipeline. You use this value to identify the pipeline in which you want to perform a variety of operations, such as creating a job or a preset.

- **Arn (string)** –

  The Amazon Resource Name (ARN) for the pipeline.

- **Name (string)** –

  The name of the pipeline. We recommend that the name be unique within the AWS account, but uniqueness is not enforced.

  Constraints: Maximum 40 characters

- **Status (string)** –

  The current status of the pipeline:

  - **Active**: The pipeline is processing jobs.
  - **Paused**: The pipeline is not currently processing jobs.

- **InputBucket (string)** –

  The Amazon S3 bucket from which Elastic Transcoder gets media files for transcoding and the graphics files, if any, that you want to use for watermarks.

- **OutputBucket (string)** –

  The Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files, thumbnails, and playlists. Either you specify this value, or you specify both ContentConfig and ThumbnailConfig.

- **Role (string)** –

  The IAM Amazon Resource Name (ARN) for the role that Elastic Transcoder uses to transcode jobs for this pipeline.

- **AwsKmsKeyArn (string)** –

  The AWS Key Management Service (AWS KMS) key that you want to use with this pipeline.

  If you use either S3 or S3-AWS-KMS as your Encryption:Mode, you don’t need to provide a key with your job because a default key, known as an AWS-KMS key, is created for you automatically. You need to provide an AWS-KMS key only if you want to use a non-default AWS-KMS key, or if you are using an Encryption:Mode of AES-PKCS7, AES-CTR, or AES-GCM.
* **Notifications** *(dict)* –

The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify to report job status.

**Warning:** To receive notifications, you must also subscribe to the new topic in the Amazon SNS console.

- **Progressing** *(optional)*: The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify when Elastic Transcoder has started to process the job.
- **Completed** *(optional)*: The Amazon SNS topic that you want to notify when Elastic Transcoder has finished processing the job.
- **Warning** *(optional)*: The Amazon SNS topic that you want to notify when Elastic Transcoder encounters a warning condition.
- **Error** *(optional)*: The Amazon SNS topic that you want to notify when Elastic Transcoder encounters an error condition.

* **Progressing** *(string)* –

The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify when Elastic Transcoder has started to process the job.

- **Completed** *(string)* –

The Amazon SNS topic that you want to notify when Elastic Transcoder has finished processing the job.

- **Warning** *(string)* –

The Amazon SNS topic that you want to notify when Elastic Transcoder encounters a warning condition.

- **Error** *(string)* –

The Amazon SNS topic that you want to notify when Elastic Transcoder encounters an error condition.

* **ContentConfig** *(dict)* –

Information about the Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists. Either you specify both **ContentConfig** and **ThumbnailConfig**, or you specify **OutputBucket**.

- **Bucket** : The Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists.
- **Permissions** : A list of the users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access that you want them to have. *
  - **GranteeType** : The type of value that appears in the **Grantee** object:
    - **Canonical** : Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution.
    - **Email** : The registered email address of an AWS account.
    - **Group** : One of the following predefined Amazon S3 groups: **AllUsers**, **AuthenticatedUsers**, or **LogDelivery**.
    - **Grantee** : The AWS user or group that you want to have access to transcoded files and playlists.
· **Access**: The permission that you want to give to the AWS user that is listed in `Grantee`. Valid values include: *READ*: The grantee can read the objects and metadata for objects that Elastic Transcoder adds to the Amazon S3 bucket.
  - **READ_ACP**: The grantee can read the object ACL for objects that Elastic Transcoder adds to the Amazon S3 bucket.
  - **WRITE_ACP**: The grantee can write the ACL for the objects that Elastic Transcoder adds to the Amazon S3 bucket.
  - **FULL_CONTROL**: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the objects that Elastic Transcoder adds to the Amazon S3 bucket.

· **StorageClass**: The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

· **Bucket (string)** —
  The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the following are true:
  - You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.
  - You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.
  - You do not want to specify the permissions that Elastic Transcoder grants to the files.
  - You want to associate the transcoded files and thumbnails with the Amazon S3 Standard storage class.

  If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit `OutputBucket` and specify values for `ContentConfig` and `ThumbnailConfig` instead.

· **StorageClass (string)** —
  The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

· **Permissions (list)** —
  Optional. The `Permissions` object specifies which users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.

  If you include `Permissions`, Elastic Transcoder grants only the permissions that you specify. It does not grant full permissions to the owner of the role specified by `Role`. If you want that user to have full control, you must explicitly grant full control to the user.

  If you omit `Permissions`, Elastic Transcoder grants full
control over the transcoded files and playlists to the owner of the role specified by Role, and grants no other permissions to any other user or group.

· (dict) –

    The Permission structure.

· GranteeType (string) –

    The type of value that appears in the Grantee object:

    · Canonical: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning::A canonical user ID is not the same as an AWS account number.

    · Email: The registered email address of an AWS account.

    · Group: One of the following predefined Amazon S3 groups: AllUsers, AuthenticatedUsers, or LogDelivery.

· Grantee (string) –

    The AWS user or group that you want to have access to transcoded files and playlists. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.

· Access (list) –

    The permission that you want to give to the AWS user that is listed in Grantee. Valid values include:

    · READ: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

    · READ_ACP: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

    · WRITE_ACP: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

    · FULL_CONTROL: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

· (string) –

* ThumbnailConfig (dict) –

    Information about the Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files. Either you specify both ContentConfig and ThumbnailConfig, or you specify OutputBucket.

    · Bucket: The Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files.

    · Permissions: A list of the users and/or predefined Amazon S3 groups you want to have access to thumbnail files, and the type of access that you want them to have. * GranteeType: The type of value that appears in the Grantee object: * Canonical: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning::A canonical user ID is not the same as an AWS account number.
- **Email**: The registered email address of an AWS account.
- **Group**: One of the following predefined Amazon S3 groups: `AllUsers`, `AuthenticatedUsers`, or `LogDelivery`.
- **Grantee**: The AWS user or group that you want to have access to thumbnail files.
- **Access**: The permission that you want to give to the AWS user that is listed in Grantee. Valid values include: *READ*: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket. *READ_ACP*: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket. *WRITE_ACP*: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket. *FULL_CONTROL*: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
- **StorageClass**: The Amazon S3 storage class, `Standard` or `ReducedRedundancy`, that you want Elastic Transcoder to assign to the thumbnails that it stores in your Amazon S3 bucket.

**Bucket (string)** –

The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the following are true:
- You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.
- You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.
- You do not want to specify the permissions that Elastic Transcoder grants to the files.
- You want to associate the transcoded files and thumbnails with the Amazon S3 Standard storage class.

If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit `OutputBucket` and specify values for `ContentConfig` and `ThumbnailConfig` instead.

**StorageClass (string)** –

The Amazon S3 storage class, `Standard` or `ReducedRedundancy`, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

**Permissions (list)** –

Optional. The Permissions object specifies which users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.

If you include Permissions, Elastic Transcoder grants
only the permissions that you specify. It does not grant full permissions to the owner of the role specified by `Role`. If you want that user to have full control, you must explicitly grant full control to the user.

If you omit `Permissions`, Elastic Transcoder grants full control over the transcoded files and playlists to the owner of the role specified by `Role`, and grants no other permissions to any other user or group.

- `(dict)` –
  The `Permission` structure.

- `GranteeType (string)` –
  The type of value that appears in the `Grantee` object:
  - Canonical: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. **Warning:** A canonical user ID is not the same as an AWS account number.
  - Email: The registered email address of an AWS account.
  - Group: One of the following predefined Amazon S3 groups: `AllUsers`, `AuthenticatedUsers`, or `LogDelivery`.

- `Grantee (string)` –
  The AWS user or group that you want to have access to transoded files and playlists. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.

- `Access (list)` –
  The permission that you want to give to the AWS user that is listed in `Grantee`. Valid values include:
  - READ: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - READ_ACP: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - WRITE_ACP: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - FULL_CONTROL: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

- `(string)` –

### update_pipeline_status(**kwargs)

The `update_pipeline_status` operation pauses or reactivates a pipeline, so that the pipeline stops or restarts the processing of jobs.

Changing the pipeline status is useful if you want to cancel one or more jobs. You can’t cancel jobs after Elastic Transcoder has started processing them; if you pause the pipeline to which you submitted the jobs, you have more time to get the job IDs for the jobs that you want to cancel, and to send a `CancelJob` request.

**Request Syntax**
response = client.update_pipeline_status(
    Id='string',
    Status='string'
)

Parameters

- **Id** *(string)* – [REQUIRED]
  The identifier of the pipeline to update.

- **Status** *(string)* – [REQUIRED]
  The desired status of the pipeline:
  - *Active*: The pipeline is processing jobs.
  - *Paused*: The pipeline is not currently processing jobs.

Return type: **dict**

Returns

Response Syntax

```json
{
    'Pipeline': {
        'Id': 'string',
        'Arn': 'string',
        'Name': 'string',
        'Status': 'string',
        'InputBucket': 'string',
        'OutputBucket': 'string',
        'Role': 'string',
        'AwsKmsKeyArn': 'string',
        'Notifications': {
            'Progressing': 'string',
            'Completed': 'string',
            'Warning': 'string',
            'Error': 'string'
        },
        'ContentConfig': {
            'Bucket': 'string',
            'StorageClass': 'string',
            'Permissions': [
                {'GranteeType': 'string',
                 'Grantee': 'string',
                 'Access': ['string']}
            ],
        },
        'ThumbnailConfig': {
            'Bucket': 'string',
            'StorageClass': 'string',
            'Permissions': [
                {'GranteeType': 'string',
                 'Grantee': 'string',
                 'Access': ['string']}
            ],
        }
    }
}
```
Response Structure

* (dict) – When you update status for a pipeline, Elastic Transcoder returns the values that you specified in the request.
  - Pipeline (dict) –

  A section of the response body that provides information about the pipeline.
  * Id (string) –

    The identifier for the pipeline. You use this value to identify the pipeline in which you want to perform a variety of operations, such as creating a job or a preset.
  * Arn (string) –

    The Amazon Resource Name (ARN) for the pipeline.
  * Name (string) –

    The name of the pipeline. We recommend that the name be unique within the AWS account, but uniqueness is not enforced.

    Constraints: Maximum 40 characters
  * Status (string) –

    The current status of the pipeline:
    · Active: The pipeline is processing jobs.
    · Paused: The pipeline is not currently processing jobs.
  * InputBucket (string) –

    The Amazon S3 bucket from which Elastic Transcoder gets media files for transcoding and the graphics files, if any, that you want to use for watermarks.
  * OutputBucket (string) –

    The Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files, thumbnails, and playlists. Either you specify this value, or you specify both ContentConfig and ThumbnailConfig.
  * Role (string) –

    The IAM Amazon Resource Name (ARN) for the role that Elastic Transcoder uses to transcode jobs for this pipeline.
  * AwsKmsKeyArn (string) –

    The AWS Key Management Service (AWS KMS) key that you want to use with this pipeline.

    If you use either S3 or S3-AWS-KMS as your Encryption:Mode, you don’t need to provide a key with your job because a default key, known as an AWS-KMS key, is created for you automatically. You need to provide an AWS-KMS key only if you want to use a non-default AWS-KMS key, or if you are using an Encryption:Mode of AES-PKCS7, AES-CTR, or AES-GCM.
* **Notifications** *(dict)* –

The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify to report job status.

**Warning:** To receive notifications, you must also subscribe to the new topic in the Amazon SNS console.

- **Progressing** *(optional)*: The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify when Elastic Transcoder has started to process the job.
- **Completed** *(optional)*: The Amazon SNS topic that you want to notify when Elastic Transcoder has finished processing the job.
- **Warning** *(optional)*: The Amazon SNS topic that you want to notify when Elastic Transcoder encounters a warning condition.
- **Error** *(optional)*: The Amazon SNS topic that you want to notify when Elastic Transcoder encounters an error condition.

**ContentConfig** *(dict)* –

Information about the Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists. Either you specify both **ContentConfig** and **ThumbnailConfig**, or you specify **OutputBucket**.

- **Bucket**: The Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists.
- **Permissions**: A list of the users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access that you want them to have. *GranteeType: The type of value that appears in the Grantee object: *
  - **Canonical**: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution.
  - **Email**: The registered email address of an AWS account.
  - **Group**: One of the following predefined Amazon S3 groups: **AllUsers**, **AuthenticatedUsers**, or **LogDelivery**.
  - **Grantee**: The AWS user or group that you want to have access to transcoded files and playlists.
• **Access**: The permission that you want to give to the AWS user that is listed in `Grantee`. Valid values include: *READ*: The grantee can read the objects and metadata for objects that Elastic Transcoder adds to the Amazon S3 bucket.  
*READ_ACP*: The grantee can read the object ACL for objects that Elastic Transcoder adds to the Amazon S3 bucket.  
*WRITE_ACP*: The grantee can write the ACL for the objects that Elastic Transcoder adds to the Amazon S3 bucket.  
*FULL_CONTROL*: The grantee has **READ**, **READ_ACP**, and **WRITE_ACP** permissions for the objects that Elastic Transcoder adds to the Amazon S3 bucket.  
• **StorageClass**: The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

• **Bucket** (*string*) – The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the following are true:  
• You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.  
• You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.  
• You do not want to specify the permissions that Elastic Transcoder grants to the files.  
• You want to associate the transcoded files and thumbnails with the Amazon S3 Standard storage class.

If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit OutputBucket and specify values for `ContentConfig` and `ThumbnailConfig` instead.

• **StorageClass** (*string*) – The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

• **Permissions** (*list*) – Optional. The `Permissions` object specifies which users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.

If you include `Permissions`, Elastic Transcoder grants only the permissions that you specify. It does not grant full permissions to the owner of the role specified by `Role`. If you want that user to have full control, you must explicitly grant full control to the user.

If you omit `Permissions`, Elastic Transcoder grants full
control over the transoded files and playlists to the owner of the role specified by `Role`, and grants no other permissions to any other user or group.

- *(dict)* –
  The `Permission` structure.

- **GranteeType** *(string)* –
  The type of value that appears in the `Grantee` object:
  - `Canonical`: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning:: A canonical user ID is not the same as an AWS account number.
  - `Email`: The registered email address of an AWS account.
  - `Group`: One of the following predefined Amazon S3 groups: `AllUsers`, `AuthenticatedUsers`, or `LogDelivery`.

- **Grantee** *(string)* –
  The AWS user or group that you want to have access to transoded files and playlists. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.

- **Access** *(list)* –
  The permission that you want to give to the AWS user that is listed in `Grantee`. Valid values include:
  - `READ`: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - `READ_ACP`: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - `WRITE_ACP`: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - `FULL_CONTROL`: The grantee has `READ`, `READ_ACP`, and `WRITE_ACP` permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

- *(string)* –
  - **ThumbnailConfig** *(dict)* –
    Information about the Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files. Either you specify both `ContentConfig` and `ThumbnailConfig`, or you specify `OutputBucket`.
    - `Bucket`: The Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files.
    - `Permissions`: A list of the users and/or predefined Amazon S3 groups you want to have access to thumbnail files, and the type of access that you want them to have. * GranteeType: The type of value that appears in the `Grantee` object: * Canonical: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning:: A canonical user ID is not the same as an AWS account number.
· **Email**: The registered email address of an AWS account.

· **Group**: One of the following predefined Amazon S3 groups: **AllUsers**, **AuthenticatedUsers**, or **LogDelivery**.

· **Grantee**: The AWS user or group that you want to have access to thumbnail files.

· **Access**: The permission that you want to give to the AWS user that is listed in Grantee. Valid values include: 
  - **READ**: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **READ_ACP**: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **WRITE_ACP**: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
  - **FULL_CONTROL**: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

· **StorageClass**: The Amazon S3 storage class, **Standard** or **ReducedRedundancy**, that you want Elastic Transcoder to assign to the thumbnails that it stores in your Amazon S3 bucket.

· **Bucket** *(string)* –

  The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the following are true:
  - You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.
  - You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.
  - You do not want to specify the permissions that Elastic Transcoder grants to the files.
  - You want to associate the transcoded files and thumbnails with the Amazon S3 Standard storage class.

  If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit **OutputBucket** and specify values for **ContentConfig** and **ThumbnailConfig** instead.

· **StorageClass** *(string)* –

  The Amazon S3 storage class, **Standard** or **ReducedRedundancy**, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

· **Permissions** *(list)* –

  Optional. The Permissions object specifies which users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.

  If you include **Permissions**, Elastic Transcoder grants
Boto3 Documentation, Release 1.1.4

only the permissions that you specify. It does not grant full
permissions to the owner of the role specified by Role. If
you want that user to have full control, you must explicitly
grant full control to the user.

If you omit Permissions, Elastic Transcoder grants full
control over the transcoded files and playlists to the owner of
the role specified by Role, and grants no other permissions
to any other user or group.

· (dict) –
  The Permission structure.

· GranteeType (string) –
  The type of value that appears in the Grantee object:
  · Canonical: Either the canonical user ID for an AWS ac-
count or an origin access identity for an Amazon CloudFront
distribution. .. warning::A canonical user ID is not the same
  as an AWS account number.
  · Email: The registered email address of an AWS account.
  · Group: One of the following predefined Amazon S3
groups: AllUsers, AuthenticatedUsers, or
  LogDelivery.
  · Grantee (string) –
  The AWS user or group that you want to have access to
  transcoded files and playlists. To identify the user or group,
you can specify the canonical user ID for an AWS account, an
origin access identity for a CloudFront distribution, the regis-
tered email address of an AWS account, or a predefined Ama-
zon S3 group.

· Access (list) –
  The permission that you want to give to the AWS user that is
  listed in Grantee. Valid values include:
  · READ: The grantee can read the thumbnails and metadata for
    thumbnails that Elastic Transcoder adds to the Amazon S3
    bucket.
  · READ_ACP: The grantee can read the object ACL for thumb-
    nai s that Elastic Transcoder adds to the Amazon S3 bucket.
  · WRITE_ACP: The grantee can write the ACL for the thumb-
    nai s that Elastic Transcoder adds to the Amazon S3 bucket.
  · FULL_CONTROL: The grantee has READ, READ_ACP, and
    WRITE_ACP permissions for the thumbnails that Elas-
tic Transcoder adds to the Amazon S3 bucket.

Paginators

The available paginators are:
· ElasticTranscoder.Paginator.ListJobsByPipeline
· ElasticTranscoder.Paginator.ListJobsByStatus
· ElasticTranscoder.Paginator.ListPipelines
· ElasticTranscoder.Paginator.ListPresets

3.1. Services 2427
class ElasticTranscoderPaginator.ListJobsByPipeline

paginator = client.get_paginator('list_jobs_by_pipeline')

paginate(**kwargs)

Creates an iterator that will paginate through responses from
ElasticTranscoder.Client.list_jobs_by_pipeline().

Request Syntax

response_iterator = paginator.paginate(
    PipelineId='string',
    Ascending='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **PipelineId** (string) – [REQUIRED]
  The ID of the pipeline for which you want to get job information.
- **Ascending** (string) – To list jobs in chronological order by the date and time that
  they were submitted, enter true. To list jobs in reverse chronological order,
  enter false.
- **PaginationConfig** (dict) – A dictionary that provides parameters to control pagination.
  - **MaxItems** (integer) –
    The total number of items to return. If the total number of items available
    is more than the value specified in max-items then a NextToken will be
    provided in the output that you can use to resume pagination.
  - **PageSize** (integer) –
    The size of each page.
  - **StartingToken** (string) –
    A token to specify where to start paginating. This is the NextToken
    from a previous response.

Return type dict

Response Structure

- (dict) –

The ListJobsByPipelineResponse structure.
  - Jobs (list) –

An array of Job objects that are in the specified pipeline.

* (dict) –

A section of the response body that provides information about the job that is created.

  - Id (string) –

    The identifier that Elastic Transcoder assigned to the job. You use this value to get settings for the job or to delete the job.

  - Arn (string) –

    The Amazon Resource Name (ARN) for the job.

  - PipelineId (string) –

    The Id of the pipeline that you want Elastic Transcoder to use for transcoding. The pipeline determines several settings, including the Amazon S3 bucket from which Elastic Transcoder gets the files to transcode and the bucket into which Elastic Transcoder puts the transcoded files.

  - Input (dict) –

    A section of the request or response body that provides information about the file that is being transcoded.

    - Key (string) –

      The name of the file to transcode. Elsewhere in the body of the JSON block is the the ID of the pipeline to use for processing the job. The InputBucket object in that pipeline tells Elastic Transcoder which Amazon S3 bucket to get the file from.

      If the file name includes a prefix, such as
cooking/lasagna.mpg, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **FrameRate (string)** –

  The frame rate of the input file. If you want Elastic Transcoder to automatically detect the frame rate of the input file, specify auto. If you want to specify the frame rate for the input file, enter one of the following values:

  10, 15, 23.97, 24, 25, 29.97, 30, 60

  If you specify a value other than auto, Elastic Transcoder disables automatic detection of the frame rate.

- **Resolution (string)** –

  This value must be auto, which causes Elastic Transcoder to automatically detect the resolution of the input file.

- **AspectRatio (string)** –

  The aspect ratio of the input file. If you want Elastic Transcoder to automatically detect the aspect ratio of the input file, specify auto. If you want to specify the aspect ratio for the output file, enter one of the following values:

  1:1, 4:3, 3:2, 16:9

  If you specify a value other than auto, Elastic Transcoder disables automatic detection of the aspect ratio.

- **Interlaced (string)** –

  Whether the input file is interlaced. If you want Elastic Transcoder to automatically detect whether the input file is interlaced, specify auto. If you want to specify whether the input file is interlaced, enter one of the following values:

  true, false

  If you specify a value other than auto, Elastic Transcoder disables automatic detection of interlacing.

- **Container (string)** –

  The container type for the input file. If you want Elastic Transcoder to automatically detect the container type of the input file, specify auto. If you want to specify the container type for the input file, enter one of the following values:

  3gp, aac, asf, avi, divx, flv, m4a, mkv, mov, mp3, mp4, mpeg, mpeg-ps, mpeg-ts, mxf, ogg, vob, wav, webm

- **Encryption (dict)** –

  The encryption settings, if any, that are used for decrypting your input files. If your input file is encrypted, you must specify the mode that Elastic Transcoder will use to decrypt your file.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
- **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
- **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  \[128, 192, \text{or} 256\].

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **DetectedProperties (dict)** –

  The detected properties of the input file.

- **Width (integer)** –
The detected width of the input file, in pixels.
- **Height (integer)** –
  The detected height of the input file, in pixels.
- **FrameRate (string)** –
  The detected frame rate of the input file, in frames per second.
- **FileSize (integer)** –
  The detected file size of the input file, in bytes.
- **DurationMillis (integer)** –
  The detected duration of the input file, in milliseconds.
- **Output (dict)** –
  If you specified one output for a job, information about that output. If you specified multiple outputs for a job, the Output object lists information about the first output. This duplicates the information that is listed for the first output in the Outputs object.

**Warning:** Outputs recommended instead.

A section of the request or response body that provides information about the transcoded (target) file.
- **Id (string)** –
  A sequential counter, starting with 1, that identifies an output among the outputs from the current job. In the Output syntax, this value is always 1.
- **Key (string)** –
  The name to assign to the transcoded file. Elastic Transcoder saves the file in the Amazon S3 bucket specified by the `OutputBucket` object in the pipeline that is specified by the pipeline ID.
- **ThumbnailPattern (string)** –
  Whether you want Elastic Transcoder to create thumbnails for your videos and, if so, how you want Elastic Transcoder to name the files.

If you don’t want Elastic Transcoder to create thumbnails, specify ““.

If you do want Elastic Transcoder to create thumbnails, specify the information that you want to include in the file name for each thumbnail. You can specify the following values in any sequence:
- ““{count}“ (Required) : If you want to create thumbnails, you must include `{count}` in the ThumbnailPattern object. Wherever you specify `{count}`, Elastic Transcoder adds a five-digit sequence number (beginning with 00001) to thumbnail file names. The number indicates where a given thumbnail appears in the sequence of thumbnails for a transcoded file. .. warning::If you specify a literal value and/or `{resolution}` but you omit `{count}`, Elastic
Transcoder returns a validation error and does not create the job.

- **Literal values (Optional)**: You can specify literal values anywhere in the `ThumbnailPattern` object. For example, you can include them as a file name prefix or as a delimiter between `{resolution}` and `{count}`.

- **`{resolution}` (Optional)**: If you want Elastic Transcoder to include the resolution in the file name, include `{resolution}` in the `ThumbnailPattern` object. When creating thumbnails, Elastic Transcoder automatically saves the files in the format (.jpg or .png) that appears in the preset that you specified in the `PresetID` value of `CreateJobOutput`. Elastic Transcoder also appends the applicable file name extension.

- **ThumbnailEncryption (dict)** –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your thumbnail.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-
encoded:
128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Rotate (string)** –

  The number of degrees clockwise by which you want Elastic Transcoder to rotate the output relative to the input. Enter one of the following values:

  auto, 0, 90, 180, 270

  The value auto generally works only if the file that you’re transcoding contains rotation metadata.

- **PresetId (string)** –

  The value of the Id object for the preset that you want to use for this job. The preset determines the audio, video, and thumbnail settings that Elastic Transcoder uses for transcoding. To use a preset that you created, specify the preset ID that Elastic Transcoder returned in the response when you created the preset. You can also use the Elastic Transcoder system presets, which you can get with `ListPresets`.

- **SegmentDuration (string)** –

  **Warning:** (Outputs in Fragmented MP4 or MPEG-TS format only.)

  If you specify a preset in PresetId for which the value of Container is fmp4 (Fragmented MP4) or ts (MPEG-TS), SegmentDuration is the target maximum duration of each segment in seconds. For HLSv3 format playlists, each media segment is stored in a separate .ts file. For HLSv4 and Smooth playlists, all media segments for an output are stored in a single file. Each segment is approximately the length of the SegmentDuration, though individual segments might be shorter or longer.

  The range of valid values is 1 to 60 seconds. If the duration of the video is not evenly divisible by SegmentDuration
, the duration of the last segment is the remainder of total length/SegmentDuration.

Elastic Transcoder creates an output-specific playlist for each output HLS output that you specify in OutputKeys. To add an output to the master playlist for this job, include it in the OutputKeys of the associated playlist.

- **Status** *(string)* –

  The status of one output in a job. If you specified only one output for the job, Outputs:Status is always the same as Job:Status. If you specified more than one output:

  - Job:Status and Outputs:Status for all of the outputs is Submitted until Elastic Transcoder starts to process the first output.

  - When Elastic Transcoder starts to process the first output, Outputs:Status for that output and Job:Status both change to Progressing. For each output, the value of Outputs:Status remains Submitted until Elastic Transcoder starts to process the output.

  - Job:Status remains Progressing until all of the outputs reach a terminal status, either Complete or Error.

  - When all of the outputs reach a terminal status, Job:Status changes to Complete only if Outputs:Status for all of the outputs is Complete. If Outputs:Status for one or more outputs is Error, the terminal status for Job:Status is also Error.

  The value of Status is one of the following: Submitted, Progressing, Complete, Canceled, or Error.

- **StatusDetail** *(string)* –

  Information that further explains Status.

- **Duration** *(integer)* –

  Duration of the output file, in seconds.

- **Width** *(integer)* –

  Specifies the width of the output file in pixels.

- **Height** *(integer)* –

  Height of the output file, in pixels.

- **FrameRate** *(string)* –

  Frame rate of the output file, in frames per second.

- **FileSize** *(integer)* –

  File size of the output file, in bytes.

- **DurationMillis** *(integer)* –

  Duration of the output file, in milliseconds.

- **Watermarks** *(list)* –

  Information about the watermarks that you want Elastic Transcoder to add to the video during transcoding. You can specify up to four watermarks for each output. Settings for each watermark must be defined in the preset that you specify in Preset for the current output.

  Watermarks are added to the output video in the sequence in
which you list them in the job output the first watermark in the list is added to the output video first, the second watermark in the list is added next, and so on. As a result, if the settings in a preset cause Elastic Transcoder to place all watermarks in the same location, the second watermark that you add will cover the first one, the third one will cover the second, and the fourth one will cover the third.

- (dict) –
  Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

- PresetWatermarkId (string) –
  The ID of the watermark settings that Elastic Transcoder uses to add watermarks to the video during transcoding. The settings are in the preset specified by Preset for the current output. In that preset, the value of Watermarks Id tells Elastic Transcoder which settings to use.

- InputKey (string) –
  The name of the .png or .jpg file that you want to use for the watermark. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by Pipeline; the Input Bucket object in that pipeline identifies the bucket.

  If the file name includes a prefix, for example, logos/128x64.png, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- Encryption (dict) –
  The encryption settings, if any, that you want Elastic Transcoder to apply to your watermarks.

- Mode (string) –
  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - S3: Amazon S3 creates and manages the keys used for encrypting your files.
  - S3-AWS-KMS: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
  - AES-CTR: AES Counter Mode.
  - AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - Key
Warning: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –
The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

```
128, 192, or 256
```

The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –
The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –
The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AlbumArt** *(dict)* –
The album art to be associated with the output file, if any.

- **MergePolicy** *(string)* –
A policy that determines how Elastic Transcoder will handle the existence of multiple album artwork files.

- **Replace**: The specified album art will replace any existing album art.
- **Prepend**: The specified album art will be placed in front of any existing album art.
- **Append**: The specified album art will be placed after any existing album art.
- **Fallback**: If the original input file contains artwork, Elastic Transcoder will use that artwork for the output. If the original input does not contain artwork, Elastic Transcoder will use the specified album art file.

- **Artwork** *(list)* –
The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20. Valid formats are `.jpg` and `.png`
· (dict) –

The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20.

To remove artwork or leave the artwork empty, you can either set Artwork to null, or set the Merge Policy to “Replace” and use an empty Artwork array.

To pass through existing artwork unchanged, set the Merge Policy to “Prepend”, “Append”, or “Fallback”, and use an empty Artwork array.

· InputKey (string) –

The name of the file to be used as album art. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by PipelineId; the InputBucket object in that pipeline identifies the bucket.

If the file name includes a prefix, for example, cooking/pie.jpg, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

· MaxWidth (string) –

The maximum width of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 4096, inclusive.

· MaxHeight (string) –

The maximum height of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 3072, inclusive.

· SizingPolicy (string) –

Specify one of the following values to control scaling of the output album art:

· Fit: Elastic Transcoder scales the output art so it matches the value that you specified in either MaxWidth or MaxHeight without exceeding the other value.

· Fill: Elastic Transcoder scales the output art so it matches the value that you specified in either MaxWidth or MaxHeight and matches or exceeds the other value. Elastic Transcoder centers the output art and then crops it in the dimension (if any) that exceeds the maximum value.

· Stretch: Elastic Transcoder stretches the output art to match the values that you specified for MaxWidth and MaxHeight. If the relative proportions of the input art and the output art are different, the output art will be distorted.

· Keep: Elastic Transcoder does not scale the output art. If either dimension of the input art exceeds the values that you specified for MaxWidth and MaxHeight, Elastic Transcoder crops the output art.

· ShrinkToFit: Elastic Transcoder scales the output art down so that its dimensions match the values that you spec-
ified for at least one of `MaxWidth` and `MaxHeight` without exceeding either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **ShrinkToFit** Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without dropping below either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **PaddingPolicy** *(string)* –

  When you set `PaddingPolicy` to `Pad`, Elastic Transcoder may add white bars to the top and bottom and/or left and right sides of the output album art to make the total size of the output art match the values that you specified for `MaxWidth` and `MaxHeight`.

- **AlbumArtFormat** *(string)* –

  The format of album art, if any. Valid formats are `.jpg` and `.png`.

- **Encryption** *(dict)* –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your artwork.

- **Mode** *(string)* –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –
The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –
  
  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –
  
  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Composition (list)** –
  
  You can create an output file that contains an excerpt from the input file. This excerpt, called a clip, can come from the beginning, middle, or end of the file. The Composition object contains settings for the clips that make up an output file. For the current release, you can only specify settings for a single clip per output file. The Composition object cannot be null.

  - **(dict)** –
    
    Settings for one clip in a composition. All jobs in a playlist must have the same clip settings.

    - **StartTime (string)** –
      
      The place in the input file where you want a clip to start. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder starts at the beginning of the input file.

    - **Duration (string)** –
      
      The duration of the clip. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder creates an output file from StartTime to the end of the file.

      If you specify a value longer than the duration of the input file, Elastic Transcoder transcodes the file and returns a warning
Captions (dict) –

You can configure Elastic Transcoder to transcode captions, or subtitles, from one format to another. All captions must be in UTF-8. Elastic Transcoder supports two types of captions:

· **Embedded**: Embedded captions are included in the same file as the audio and video. Elastic Transcoder supports only one embedded caption per language, to a maximum of 300 embedded captions per file. Valid input values include: CEA-608 (EIA-608, first non-empty channel only), CEA-708 (EIA-708, first non-empty channel only), and mov-text. Valid outputs include: mov-text. Elastic Transcoder supports a maximum of one embedded format per output.

· **Sidecar**: Sidecar captions are kept in a separate metadata file from the audio and video data. Sidecar captions require a player that is capable of understanding the relationship between the video file and the sidecar file. Elastic Transcoder supports only one sidecar caption per language, to a maximum of 20 sidecar captions per file. Valid input values include: dfxp (first div element only), ebu-tt, scc, smpte, srt, ttml (first div element only), and webvtt. Valid outputs include: dfxp (first div element only), scc, srt, and webvtt.

If you want ttml or smpte-tt compatible captions, specify dfxp as your output format.

Elastic Transcoder does not support OCR (Optical Character Recognition), does not accept pictures as a valid input for captions, and is not available for audio-only transcoding. Elastic Transcoder does not preserve text formatting (for example, italics) during the transcoding process.

To remove captions or leave the captions empty, set Captions to null. To pass through existing captions unchanged, set the MergePolicy to MergeRetain, and pass in a null CaptionSources array.

For more information on embedded files, see the Subtitles Wikipedia page.

For more information on sidecar files, see the Extensible Metadata Platform and Sidecar file Wikipedia pages.

· **MergePolicy (string)** –

A policy that determines how Elastic Transcoder handles the existence of multiple captions.

· **MergeOverride**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the sidecar captions and ignores the embedded captions for that language.

· **MergeRetain**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the embedded captions and ignores...
the sidecar captions for that language. If `CaptionSources` is empty, Elastic Transcoder omits all sidecar captions from the output files.

- **Override:** Elastic Transcoder transcodes only the sidecar captions that you specify in `CaptionSources`. `MergePolicy` cannot be null.
- **CaptionSources** (*list*)
  Source files for the input sidecar captions used during the transcoding process. To omit all sidecar captions, leave `CaptionSources` blank.

  * **(dict)**
    A source file for the input sidecar captions used during the transcoding process.

    - **Key** (*string*)
      The name of the sidecar caption file that you want Elastic Transcoder to include in the output file.

    - **Language** (*string*)
      A string that specifies the language of the caption. Specify this as one of:
      - 2-character ISO 639-1 code
      - 3-character ISO 639-2 code
      For more information on ISO language codes and language names, see the List of ISO 639-1 codes.

    - **TimeOffset** (*string*)
      For clip generation or captions that do not start at the same time as the associated video file, the `TimeOffset` tells Elastic Transcoder how much of the video to encode before including captions.

      Specify the `TimeOffset` in the form `+[+-]SS.sss` or `[+-]HH:mm:SS.ss`.

    - **Label** (*string*)
      The label of the caption shown in the player when choosing a language. We recommend that you put the caption language name here, in the language of the captions.

  - **Encryption** (*dict*)
    The encryption settings, if any, that you want Elastic Transcoder to apply to your caption sources.

    - **Mode** (*string*)
      The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
      - **S3:** Amazon S3 creates and manages the keys used for encrypting your files.
      - **S3-AWS-KMS:** Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify **S3-AWS-KMS** and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
· AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
· AES-CTR: AES Counter Mode.
· AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –
  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –
  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Initialization Vector (string)** –
  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **CaptionFormats (list)** –
  The array of file formats for the output captions. If you leave this value blank, Elastic Transcoder returns an error.

- **(dict)** –
  The file format of the output captions. If you leave this value blank, Elastic Transcoder returns an error.

- **Format (string)** –
  The format you specify determines whether Elastic Transcoder generates an embedded or sidecar caption
for this output.

- **Valid Embedded Caption Formats:** *for FLAC*: None
  - *For MP3*: None
  - *For MP4*: mov-text
  - *For MPEG-TS*: None
  - *For ogg*: None
  - *For webm*: None
- **Valid Sidecar Caption Formats:** Elastic Transcoder supports dfxp (first div element only), scc, srt, and webvtt. If you want ttml or smpte-tt compatible captions, specify dfxp as your output format. *For FMP4*: dfxp
- **Non-FMP4 outputs**: All sidecar types
  - fmp4 captions have an extension of .ismt
- **Pattern** (*string*)
  - The prefix for caption filenames, in the form `description - {language}`, where:
    - *description* is a description of the video.
    - `{language}` is a literal value that Elastic Transcoder replaces with the two- or three-letter code for the language of the caption in the output file names.

If you don’t include `{language}` in the file name pattern, Elastic Transcoder automatically appends “`{language}`” to the value that you specify for the description. In addition, Elastic Transcoder automatically appends the count to the end of the segment files.

For example, suppose you’re transcoding into srt format. When you enter “Sydney-{language}-sunrise”, and the language of the captions is English (en), the name of the first caption file will be Sydney-en-sunrise00000.srt.

- **Encryption** (*dict*)
  - The encryption settings, if any, that you want Elastic Transcoder to apply to your caption formats.
- **Mode** (*string*)
  - The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify **S3-AWS-KMS** and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following
settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

| Warning: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data. |

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Encryption (dict)** –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your output files. If you choose to use encryption, you must specify a mode to use. If you choose not to use encryption, Elastic Transcoder will write an unencrypted file to your Amazon S3 bucket.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the
AWS-KMS key that you want to use to your pipeline.
- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:
- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –
  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –
  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –
  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AppliedColorSpaceConversion (string)** –
  If Elastic Transcoder used a preset with a ColorSpaceConversionMode to transcode the output file, the AppliedColorSpaceConversion parameter shows the conversion used. If no ColorSpaceConversionMode was defined in the preset, this parameter will not be included in the job response.

- **Outputs (list)** –
Information about the output files. We recommend that you use the Outputs syntax for all jobs, even when you want Elastic Transcoder to transcode a file into only one format. Do not use both the Outputs and Output syntaxes in the same request. You can create a maximum of 30 outputs per job.

If you specify more than one output for a job, Elastic Transcoder creates the files for each output in the order in which you specify them in the job.

- (dict) –
  
  **Warning:** Outputs recommended instead.
  
  If you specified one output for a job, information about that output. If you specified multiple outputs for a job, the Output object lists information about the first output. This duplicates the information that is listed for the first output in the Outputs object.

  - **Id (string) –**
    
    A sequential counter, starting with 1, that identifies an output among the outputs from the current job. In the Output syntax, this value is always 1.

  - **Key (string) –**
    
    The name to assign to the transcoded file. Elastic Transcoder saves the file in the Amazon S3 bucket specified by the OutputBucket object in the pipeline that is specified by the pipeline ID.

  - **ThumbnailPattern (string) –**
    
    Whether you want Elastic Transcoder to create thumbnails for your videos and, if so, how you want Elastic Transcoder to name the files.

    If you don't want Elastic Transcoder to create thumbnails, specify ""

    If you do want Elastic Transcoder to create thumbnails, specify the information that you want to include in the file name for each thumbnail. You can specify the following values in any sequence:

    - "{'count}" (Required): If you want to create thumbnails, you must include {count} in the ThumbnailPattern object. Wherever you specify {count}, Elastic Transcoder adds a five-digit sequence number (beginning with 00001) to thumbnail file names. The number indicates where a given thumbnail appears in the sequence of thumbnails for a transcoded file. .. warning::If you specify a literal value and/or {resolution} but you omit {count}, Elastic Transcoder returns a validation error and does not create the job.

      - **Literal values (Optional):** You can specify literal values anywhere in the ThumbnailPattern object. For example, you can include them as a file name prefix or as a delimiter.
between \{resolution\} and \{count\}.

- \{resolution\} \{Optional\}: If you want Elastic Transcoder to include the resolution in the file name, include \{resolution\} in the ThumbnailPattern object.

When creating thumbnails, Elastic Transcoder automatically saves the files in the format (.jpg or .png) that appears in the preset that you specified in the PresetID value of CreateJobOutput. Elastic Transcoder also appends the applicable file name extension.

- ThumbnailEncryption (dict) –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your thumbnail.

- Mode (string) –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - S3: Amazon S3 creates and manages the keys used for encrypting your files.
  - S3-AWS-KMS: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
  - AES-CTR: AES Counter Mode.
  - AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - Key
  - Key MD5
  - Initialization Vector

  **Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- Key (string) –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.
- **KeyMd5** *(string)* –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Initialization Vector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Rotate** *(string)* –

  The number of degrees clockwise by which you want Elastic Transcoder to rotate the output relative to the input. Enter one of the following values:

  - `auto`
  - `0`, `90`, `180`, `270`

  The value `auto` generally works only if the file that you’re transcoding contains rotation metadata.

- **PresetId** *(string)* –

  The value of the `Id` object for the preset that you want to use for this job. The preset determines the audio, video, and thumbnail settings that Elastic Transcoder uses for transcoding. To use a preset that you created, specify the preset ID that Elastic Transcoder returned in the response when you created the preset. You can also use the Elastic Transcoder system presets, which you can get with `ListPresets`.

- **SegmentDuration** *(string)* –

  **Warning:** (Outputs in Fragmented MP4 or MPEG-TS format only.)

  If you specify a preset in `PresetId` for which the value of `Container` is `fmp4` (Fragmented MP4) or `ts` (MPEG-TS), `SegmentDuration` is the target maximum duration of each segment in seconds. For HLSv3 format playlists, each media segment is stored in a separate `.ts` file. For HLSv4 and Smooth playlists, all media segments for an output are stored in a single file. Each segment is approximately the length of the `SegmentDuration`, though individual segments might be shorter or longer.

  The range of valid values is 1 to 60 seconds. If the duration of the video is not evenly divisible by `SegmentDuration`, the duration of the last segment is the remainder of total length/`SegmentDuration`.

  Elastic Transcoder creates an output-specific playlist for each output HLS output that you specify in `OutputKeys`. To add
an output to the master playlist for this job, include it in the
OutputKeys of the associated playlist.

- **Status (string)** –

  The status of one output in a job. If you specified only one output for the job, Outputs:Status is always the same as Job:Status. If you specified more than one output:
  - Job:Status and Outputs:Status for all of the outputs is Submitted until Elastic Transcoder starts to process the first output.
  - When Elastic Transcoder starts to process the first output, Outputs:Status for that output and Job:Status both change to Progressing. For each output, the value of Outputs:Status remains Submitted until Elastic Transcoder starts to process the output.
  - Job:Status remains Progressing until all of the outputs reach a terminal status, either Complete or Error.
  - When all of the outputs reach a terminal status, Job:Status changes to Complete only if Outputs:Status for all of the outputs is Complete. If Outputs:Status for one or more outputs is Error, the terminal status for Job:Status is also Error.

  The value of Status is one of the following: Submitted, Progressing, Complete, Canceled, or Error.

- **StatusDetail (string)** –

  Information that further explains Status.

- **Duration (integer)** –

  Duration of the output file, in seconds.

- **Width (integer)** –

  Specifies the width of the output file in pixels.

- **Height (integer)** –

  Height of the output file, in pixels.

- **FrameRate (string)** –

  Frame rate of the output file, in frames per second.

- **FileSize (integer)** –

  File size of the output file, in bytes.

- **DurationMillis (integer)** –

  Duration of the output file, in milliseconds.

- **Watermarks (list)** –

  Information about the watermarks that you want Elastic Transcoder to add to the video during transcoding. You can specify up to four watermarks for each output. Settings for each watermark must be defined in the preset that you specify in Preset for the current output.

  Watermarks are added to the output video in the sequence in which you list them in the job output. The first watermark in the list is added to the output video first, the second watermark in the list is added next, and so on. As a result, if the settings in a preset cause Elastic Transcoder to place all watermarks in the same location, the second watermark that you add will
cover the first one, the third one will cover the second, and the fourth one will cover the third.

- **(dict)**

  Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

- **PresetWatermarkId (string)**

  The ID of the watermark settings that Elastic Transcoder uses to add watermarks to the video during transcoding. The settings are in the preset specified by Preset for the current output. In that preset, the value of Watermarks Id tells Elastic Transcoder which settings to use.

- **InputKey (string)**

  The name of the .png or .jpg file that you want to use for the watermark. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by Pipeline; the Input Bucket object in that pipeline identifies the bucket.

  If the file name includes a prefix, for example, `logos/128x64.png`, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **Encryption (dict)**

  The encryption settings, if any, that you want Elastic Transcoder to apply to your watermarks.

  - **Mode (string)**

    The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

    - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
    - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
    - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
    - **AES-CTR**: AES Counter Mode.
    - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

    For all three AES options, you must provide the following settings, which must be base64-encoded:

    - **Key**
    - **Key MD5**
    - **Initialization Vector**
Warning: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** (*string*) –
  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** (*string*) –
  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** (*string*) –
  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AlbumArt** (*dict*) –
  The album art to be associated with the output file, if any.

- **MergePolicy** (*string*) –
  A policy that determines how Elastic Transcoder will handle the existence of multiple album artwork files.

  - Replace: The specified album art will replace any existing album art.
  - Prepend: The specified album art will be placed in front of any existing album art.
  - Append: The specified album art will be placed after any existing album art.
  - Fallback: If the original input file contains artwork, Elastic Transcoder will use that artwork for the output. If the original input does not contain artwork, Elastic Transcoder will use the specified album art file.

- **Artwork** (*list*) –
  The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20. Valid formats are .jpg and .png
The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20.

To remove artwork or leave the artwork empty, you can either set Artwork to null, or set the Merge Policy to “Replace” and use an empty Artwork array.

To pass through existing artwork unchanged, set the Merge Policy to “Prepend”, “Append”, or “Fallback”, and use an empty Artwork array.

- **InputKey (string)** –
  The name of the file to be used as album art. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by PipelineId; the InputBucket object in that pipeline identifies the bucket.

  If the file name includes a prefix, for example, `cooking/pie.jpg`, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **MaxWidth (string)** –
  The maximum width of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 4096, inclusive.

- **MaxHeight (string)** –
  The maximum height of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 3072, inclusive.

- **SizingPolicy (string)** –
  Specify one of the following values to control scaling of the output album art:

  - **Fit**: Elastic Transcoder scales the output art so it matches the value that you specified in either MaxWidth or MaxHeight without exceeding the other value.
  
  - **Fill**: Elastic Transcoder scales the output art so it matches the value that you specified in either MaxWidth or MaxHeight and matches or exceeds the other value. Elastic Transcoder centers the output art and then crops it in the dimension (if any) that exceeds the maximum value.
  
  - **Stretch**: Elastic Transcoder stretches the output art to match the values that you specified for MaxWidth and MaxHeight. If the relative proportions of the input art and the output art are different, the output art will be distorted.
  
  - **Keep**: Elastic Transcoder does not scale the output art. If either dimension of the input art exceeds the values that you specified for MaxWidth and MaxHeight, Elastic Transcoder crops the output art.
  
  - **ShrinkToFit**: Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of MaxWidth and MaxHeight with-
out exceeding either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **ShrinkToFit** Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without dropping below either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **PaddingPolicy** *(string)*

  When you set `PaddingPolicy` to `Pad`, Elastic Transcoder may add white bars to the top and bottom and/or left and right sides of the output album art to make the total size of the output art match the values that you specified for `MaxWidth` and `MaxHeight`.

- **AlbumArtFormat** *(string)*

  The format of album art, if any. Valid formats are `.jpg` and `.png`.

- **Encryption** *(dict)*

  The encryption settings, if any, that you want Elastic Transcoder to apply to your artwork.

- **Mode** *(string)*

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

  - **Key** *(string)*

    The data encryption key that you want Elastic Transcoder
to use to encrypt your output file, or that was used to en-
crypt your input file. The key must be base64-encoded and it
must be one of the following bit lengths before being base64-
encoded:

\[128, 192, \text{ or } 256\].

The key must also be encrypted by using the Amazon Key
Management Service.

- **KeyMd5 (string)** –
  
The MD5 digest of the key that you used to encrypt your in-
put file, or that you want Elastic Transcoder to use to encrypt
your output file. Elastic Transcoder uses the key digest as a
checksum to make sure your key was not corrupted in transit.
The key MD5 must be base64-encoded, and it must be exactly
16 bytes long before being base64-encoded.

- **InitializationVector (string)** –
  
The series of random bits created by a random bit genera-
tor, unique for every encryption operation, that you used to
encrypt your input files or that you want Elastic Transcoder
to use to encrypt your output files. The initialization vector
must be base64-encoded, and it must be exactly 16 bytes long
before being base64-encoded.

- **Composition (list)** –
  
You can create an output file that contains an excerpt from
the input file. This excerpt, called a clip, can come from the
beginning, middle, or end of the file. The Composition object
contains settings for the clips that make up an output file. For
the current release, you can only specify settings for a single
clip per output file. The Composition object cannot be null.

  - (dict) –
    
Settings for one clip in a composition. All jobs in a playlist
must have the same clip settings.

  - **TimeSpan (dict)** –
    
Settings that determine when a clip begins and how long it
lasts.

  - **StartTIme (string)** –
    
The place in the input file where you want a clip to start.
The format can be either HH:mm:ss.SSS (maximum value:
23:59:59.999; SSS is thousandths of a second) or sssss.SSS
(maximum value: 86399.999). If you don’t specify a value,
Elastic Transcoder starts at the beginning of the input file.

  - **Duration (string)** –
    
The duration of the clip. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder creates an output file from StartTime to the end of the file.

If you specify a value longer than the duration of the input file,
Elastic Transcoder transcodes the file and returns a warning
message.
Captions (dict) –
You can configure Elastic Transcoder to transcode captions, or subtitles, from one format to another. All captions must be in UTF-8. Elastic Transcoder supports two types of captions:

- **Embedded**: Embedded captions are included in the same file as the audio and video. Elastic Transcoder supports only one embedded caption per language, to a maximum of 300 embedded captions per file. Valid input values include: CEA-608 (EIA-608, first non-empty channel only), CEA-708 (EIA-708, first non-empty channel only), and mov-text. Valid outputs include: mov-text. Elastic Transcoder supports a maximum of one embedded format per output.

- **Sidecar**: Sidecar captions are kept in a separate metadata file from the audio and video data. Sidecar captions require a player that is capable of understanding the relationship between the video file and the sidecar file. Elastic Transcoder supports only one sidecar caption per language, to a maximum of 20 sidecar captions per file. Valid input values include: dfxp (first div element only), ebtt, scc, smp, srt, ttml (first div element only), and webvtt. Valid outputs include: dfxp (first div element only), scc, srt, and webvtt.

If you want ttml or smpte-tt compatible captions, specify dfxp as your output format.

Elastic Transcoder does not support OCR (Optical Character Recognition), does not accept pictures as a valid input for captions, and is not available for audio-only transcoding. Elastic Transcoder does not preserve text formatting (for example, italics) during the transcoding process.

To remove captions or leave the captions empty, set Captions to null. To pass through existing captions unchanged, set the MergePolicy to MergeRetain, and pass in a null CaptionSources array.

For more information on embedded files, see the Subtitles Wikipedia page.

For more information on sidecar files, see the Extensible Metadata Platform and Sidecar file Wikipedia pages.

- **MergePolicy (string)** –
A policy that determines how Elastic Transcoder handles the existence of multiple captions.

- **MergeOverride**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the sidecar captions and ignores the embedded captions for that language.

- **MergeRetain**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the embedded captions and ignores the sidecar captions for that language. If CaptionSources
is empty, Elastic Transcoder omits all sidecar captions from the output files.

- **Override:** Elastic Transcoder transcodes only the sidecar captions that you specify in `CaptionSources`. `MergePolicy` cannot be null.

- **CaptionSources** *(list)* –
  
  Source files for the input sidecar captions used during the transcoding process. To omit all sidecar captions, leave `CaptionSources` blank.

  *(dict)* –
  
  A source file for the input sidecar captions used during the transcoding process.

- **Key** *(string)* –
  
  The name of the sidecar caption file that you want Elastic Transcoder to include in the output file.

- **Language** *(string)* –
  
  A string that specifies the language of the caption. Specify this as one of:

  - 2-character ISO 639-1 code
  - 3-character ISO 639-2 code

  For more information on ISO language codes and language names, see the List of ISO 639-1 codes.

- **TimeOffset** *(string)* –
  
  For clip generation or captions that do not start at the same time as the associated video file, the `TimeOffset` tells Elastic Transcoder how much of the video to encode before including captions.

  Specify the `TimeOffset` in the form `[+-]SS.sss` or `[+-]HH:mm:SS.ss`.

- **Label** *(string)* –
  
  The label of the caption shown in the player when choosing a language. We recommend that you put the caption language name here, in the language of the captions.

- **Encryption** *(dict)* –
  
  The encryption settings, if any, that you want Elastic Transcoder to apply to your caption sources.

  - **Mode** *(string)* –
    
    The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

    - **S3:** Amazon S3 creates and manages the keys used for encrypting your files.
    - **S3-AWS-KMS:** Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
· **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
· **AES-CTR**: AES Counter Mode.
· **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

| Warning: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data. |

- **Key** *(string)* –

The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –

The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **CaptionFormats** *(list)* –

The array of file formats for the output captions. If you leave this value blank, Elastic Transcoder returns an error.

- **Format** *(dict)* –

The file format of the output captions. If you leave this value blank, Elastic Transcoder returns an error.

- **Format** *(string)* –

The format you specify determines whether Elastic Transcoder generates an embedded or sidecar caption.
Valid Embedded Caption Formats: * for FLAC : None
· For MP3 : None
· For MP4 : mov-text
· For MPEG-TS : None
· For ogg : None
· For webm : None

Valid Sidecar Caption Formats: Elastic Transcoder supports dfxp (first div element only), scc, srt, and webvtt. If you want ttml or smpte-tt compatible captions, specify dfxp as your output format. * For FMP4 : dfxp

Non-FMP4 outputs: All sidecar types

fmp4 captions have an extension of .ismt

Pattern (string) –

The prefix for caption filenames, in the form description -
{language}, where:
· description is a description of the video.
· {language} is a literal value that Elastic Transcoder replaces with the two- or three-letter code for the language of the caption in the output file names.

If you don’t include {language} in the file name pattern, Elastic Transcoder automatically appends “{language}” to the value that you specify for the description. In addition, Elastic Transcoder automatically appends the count to the end of the segment files.

For example, suppose you’re transcoding into srt format. When you enter “Sydney-{language}-sunrise”, and the language of the captions is English (en), the name of the first caption file will be Sydney-en-sunrise00000.srt.

Encryption (dict) –

The encryption settings, if any, that you want Elastic Transcoder to apply to your caption formats.

Mode (string) –

The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
· S3: Amazon S3 creates and manages the keys used for encrypting your files.
· S3-AWS-KMS: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
· AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
· AES-CTR: AES Counter Mode.
· AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following
settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

  **Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Encryption** *(dict)* –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your output files. If you choose to use encryption, you must specify a mode to use. If you choose not to use encryption, Elastic Transcoder will write an unencrypted file to your Amazon S3 bucket.

- **Mode** *(string)* –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3:** Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS:** Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify **S3-AWS-KMS** and you don’t want to use the default key, you must add the
AWS-KMS key that you want to use to your pipeline.

- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  \[128, 192, \text{ or } 256\].

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AppliedColorSpaceConversion** *(string)* –

  If Elastic Transcoder used a preset with a ColorSpaceConversionMode to transcode the output file, the AppliedColorSpaceConversion parameter shows the conversion used. If no ColorSpaceConversionMode was defined in the preset, this parameter will not be included in the job response.

- **OutputKeyPrefix** *(string)* –
The value, if any, that you want Elastic Transcoder to prepend to the names of all files that this job creates, including output files, thumbnails, and playlists. We recommend that you add a / or some other delimiter to the end of the `OutputKeyPrefix`.

- **Playlists (list)**

  **Warning:** Outputs in Fragmented MP4 or MPEG-TS format only.

  If you specify a preset in `PresetId` for which the value of `Container` is fmp4 (Fragmented MP4) or ts (MPEG-TS), `Playlists` contains information about the master playlists that you want Elastic Transcoder to create.

  The maximum number of master playlists in a job is 30.

- **Name (string)**

  The name that you want Elastic Transcoder to assign to the master playlist, for example, nyc-vacation.m3u8. If the name includes a / character, the section of the name before the last / must be identical for all `Name` objects. If you create more than one master playlist, the values of all `Name` objects must be unique.

  **Note:** Elastic Transcoder automatically appends the relevant file extension to the file name (.m3u8 for HLSv3 and HLSv4 playlists, and .ism and .ismc for Smooth playlists). If you include a file extension in `Name`, the file name will have two extensions.

- **Format (string)**

  The format of the output playlist. Valid formats include HLSv3, HLSv4, and Smooth.

- **OutputKeys (list)**

  For each output in this job that you want to include in a master playlist, the value of the Outputs:Key object.

  - If your output is not HLS or does not have a segment duration set, the name of the output file is a concatenation of `OutputKeyPrefix` and `Outputs:Key`: `OutputKeyPrefix``Outputs:Key```

  - If your output is HLSv3 and has a segment duration set, or is not included in a playlist, Elastic Transcoder creates an output playlist file with a file extension of .m3u8, and a series of .ts files that include a five-digit sequential counter beginning with 00000: `OutputKeyPrefix``Outputs:Key``.m3u8` `OutputKeyPrefix``Outputs:Key``.00000.ts`
· If your output is HLSv4, has a segment duration set, and is included in an HLSv4 playlist, Elastic Transcoder creates an output playlist file with a file extension of _v4.m3u8. If the output is video, Elastic Transcoder also creates an output file with an extension of _iframe.m3u8: OutputKeyPrefix"Outputs:Key"_v4.m3u8 OutputKeyPrefix"Outputs:Key"_iframe.m3u8 OutputKeyPrefix"Outputs:Key".ts

Elastic Transcoder automatically appends the relevant file extension to the file name. If you include a file extension in Output Key, the file name will have two extensions.

If you include more than one output in a playlist, any segment duration settings, clip settings, or caption settings must be the same for all outputs in the playlist. For Smooth playlists, the Audio:Profile, Video:Profile, and Video:FrameRate to Video:KeyframesMaxDist ratio must be the same for all outputs.

· (string) –
  · HLSContentProtection (dict) –

The HLS content protection settings, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

· Method (string) –

The content protection method for your output. The only valid value is: aes-128.

This value will be written into the method attribute of the EXT-X-KEY metadata tag in the output playlist.

· Key (string) –

If you want Elastic Transcoder to generate a key for you, leave this field blank.

If you choose to supply your own key, you must encrypt the key by using AWS KMS. The key must be base64-encoded, and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

· KeyMd5 (string) –

If Elastic Transcoder is generating your key for you, you must leave this field blank.

The MD5 digest of the key that you want Elastic Transcoder to use to encrypt your output file, and that you want Elastic Transcoder to use as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

· InitializationVector (string) –

If Elastic Transcoder is generating your key for you, you must leave this field blank.

The series of random bits created by a random bit generator,
unique for every encryption operation, that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

- **LicenseAcquisitionUrl (string)** –
  The location of the license key required to decrypt your HLS playlist. The URL must be an absolute path, and is referenced in the URI attribute of the EXT-X-KEY metadata tag in the playlist file.

- **KeyStoragePolicy (string)** –
  Specify whether you want Elastic Transcoder to write your HLS license key to an Amazon S3 bucket. If you choose **WithVariantPlaylists**, `LicenseAcquisitionUrl` must be left blank and Elastic Transcoder writes your data key into the same bucket as the associated playlist.

- **PlayReadyDrm (dict)** –
  The DRM settings, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

- **Format (string)** –
  The type of DRM, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

- **Key (string)** –
  The DRM key for your file, provided by your DRM license provider. The key must be base64-encoded, and it must be one of the following bit lengths before being base64-encoded: 128, 192, or 256.

The key must also be encrypted by using AWS KMS.

- **KeyMd5 (string)** –
  The MD5 digest of the key used for DRM on your file, and that you want Elastic Transcoder to use as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

- **KeyId (string)** –
  The ID for your DRM key, so that your DRM license provider knows which key to provide.

The key ID must be provided in big endian, and Elastic Transcoder will convert it to little endian before inserting it into the PlayReady DRM headers. If you are unsure whether your license server provides your key ID in big or little endian, check with your DRM provider.

- **InitializationVector (string)** –
  The series of random bits created by a random bit generator, unique for every encryption operation, that you want Elastic Transcoder to use to encrypt your files. The initialization vector must be base64-encoded, and it must be exactly 8 bytes
long before being base64-encoded. If no initialization vector is provided, Elastic Transcoder generates one for you.

- **LicenseAcquisitionUrl (string)** –

The location of the license key required to play DRM content. The URL must be an absolute path, and is referenced by the PlayReady header. The PlayReady header is referenced in the protection header of the client manifest for Smooth Streaming outputs, and in the EXT-X-DXDRM and EXT-XDXDRMINFO metadata tags for HLS playlist outputs. An example URL looks like this: 
https://www.example.com/exampleKey/

- **Status (string)** –

The status of the job with which the playlist is associated.

- **StatusDetail (string)** –

Information that further explains the status.

- **Status (string)** –

The status of the job: Submitted, Progressing, Complete, Canceled, or Error.

- **UserMetadata (dict)** –

User-defined metadata that you want to associate with an Elastic Transcoder job. You specify metadata in key/value pairs, and you can add up to 10 key/value pairs per job. Elastic Transcoder does not guarantee that key/value pairs will be returned in the same order in which you specify them.

Metadata keys and values must use characters from the following list:

- 0–9
- A–Z and a–z
- Space
- The following symbols: _ . : /=+-%@ ...
- (string) –
- (string) –
- **Timing (dict)** –

Details about the timing of a job.

- **SubmitTimeMillis (integer)** –

The time the job was submitted to Elastic Transcoder, in epoch milliseconds.

- **StartTimeMillis (integer)** –

The time the job began transcoding, in epoch milliseconds.

- **FinishTimeMillis (integer)** –

The time the job finished transcoding, in epoch milliseconds.

- **NextToken (string)** –

A token to resume pagination.
**paginate(**\*\*kwargs\*)**

Creates an iterator that will paginate through responses from `ElasticTranscoder.Client.list_jobs_by_status()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    Status='string',
    Ascending='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **Status (string)** – [REQUIRED]
  To get information about all of the jobs associated with the current AWS account that have a given status, specify the following status: Submitted, Progressing, Complete, Canceled, or Error.

- **Ascending (string)** – To list jobs in chronological order by the date and time that they were submitted, enter `true`. To list jobs in reverse chronological order, enter `false`.

- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize (integer)** –
    The size of each page.
  - **StartingToken (string)** –
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'Jobs': [
        {

Response Structure
• (dict) –

The ListJobsByStatusResponse structure.
• Jobs (list) –

An array of Job objects that have the specified status.
• (dict) –

A section of the response body that provides information about the job that is created.
• Id (string) –

The identifier that Elastic Transcoder assigned to the job. You use this value to get settings for the job or to delete the job.
• Arn (string) –

The Amazon Resource Name (ARN) for the job.
• PipelineId (string) –

The Id of the pipeline that you want Elastic Transcoder to use for transcoding. The pipeline determines several settings, including the Amazon S3 bucket from which Elastic Transcoder gets the files to transcode and the bucket into which Elastic Transcoder puts the transcoded files.
• Input (dict) –

A section of the request or response body that provides information about the file that is being transcoded.
• Key (string) –

The name of the file to transcode. Elsewhere in the body of the JSON block is the the ID of the pipeline to use for processing the job. The InputBucket object in that pipeline tells Elastic Transcoder which Amazon S3 bucket to get the file from.

If the file name includes a prefix, such as cooking/lasagna.mpg, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.
· **FrameRate** *(string)* –

The frame rate of the input file. If you want Elastic Transcoder to automatically detect the frame rate of the input file, specify `auto`. If you want to specify the frame rate for the input file, enter one of the following values:

```
10, 15, 23.97, 24, 25, 29.97, 30, 60
```

If you specify a value other than `auto`, Elastic Transcoder disables automatic detection of the frame rate.

· **Resolution** *(string)* –

This value must be `auto`, which causes Elastic Transcoder to automatically detect the resolution of the input file.

· **AspectRatio** *(string)* –

The aspect ratio of the input file. If you want Elastic Transcoder to automatically detect the aspect ratio of the input file, specify `auto`. If you want to specify the aspect ratio for the output file, enter one of the following values:

```
1:1, 4:3, 3:2, 16:9
```

If you specify a value other than `auto`, Elastic Transcoder disables automatic detection of the aspect ratio.

· **Interlaced** *(string)* –

Whether the input file is interlaced. If you want Elastic Transcoder to automatically detect whether the input file is interlaced, specify `auto`. If you want to specify whether the input file is interlaced, enter one of the following values:

```
true, false
```

If you specify a value other than `auto`, Elastic Transcoder disables automatic detection of interlacing.

· **Container** *(string)* –

The container type for the input file. If you want Elastic Transcoder to automatically detect the container type of the input file, specify `auto`. If you want to specify the container type for the input file, enter one of the following values:

```
3gp, aac, asf, avi, divx, flv, m4a, mkv, mov, mp3, mp4, mpeg, mpeg-ps, mpeg-ts, mxf, ogg, vob, wav, webm
```

· **Encryption** *(dict)* –

The encryption settings, if any, that are used for decrypting your input files. If your input file is encrypted, you must specify the mode that Elastic Transcoder will use to decrypt your file.

· **Mode** *(string)* –

The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

· **S3**: Amazon S3 creates and manages the keys used for encrypting your files.

· **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are...
used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.

- AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
- AES-CTR: AES Counter Mode.
- AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **DetectedProperties** *(dict)* –

  The detected properties of the input file.

- **Width** *(integer)* –

  The detected width of the input file, in pixels.

- **Height** *(integer)* –

  The detected height of the input file, in pixels.
- **FrameRate** *(string)* –
  The detected frame rate of the input file, in frames per second.
- **FileSize** *(integer)* –
  The detected file size of the input file, in bytes.
- **DurationMillis** *(integer)* –
  The detected duration of the input file, in milliseconds.
- **Output** *(dict)* –
  If you specified one output for a job, information about that output. If you specified multiple outputs for a job, the Output object lists information about the first output. This duplicates the information that is listed for the first output in the Outputs object.

  **Warning:** Outputs recommended instead.

A section of the request or response body that provides information about the transcoded (target) file.

- **Id** *(string)* –
  A sequential counter, starting with 1, that identifies an output among the outputs from the current job. In the Output syntax, this value is always 1.

- **Key** *(string)* –
  The name to assign to the transcoded file. Elastic Transcoder saves the file in the Amazon S3 bucket specified by the `OutputBucket` object in the pipeline that is specified by the pipeline ID.

- **ThumbnailPattern** *(string)* –
  Whether you want Elastic Transcoder to create thumbnails for your videos and, if so, how you want Elastic Transcoder to name the files.

  If you don’t want Elastic Transcoder to create thumbnails, specify "".

  If you do want Elastic Transcoder to create thumbnails, specify the information that you want to include in the file name for each thumbnail. You can specify the following values in any sequence:

  - **"{count}" (Required)**: If you want to create thumbnails, you must include `{count}` in the `ThumbnailPattern` object. Wherever you specify `{count}`, Elastic Transcoder adds a five-digit sequence number (beginning with 00001) to thumbnail file names. The number indicates where a given thumbnail appears in the sequence of thumbnails for a transcoded file. .. warning:: If you specify a literal value and/or `{resolution}` but you omit `{count}`, Elastic Transcoder returns a validation error and does not create the job.

  - **Literal values (Optional)**: You can specify literal values anywhere in the `ThumbnailPattern` object. For example,
you can include them as a file name prefix or as a delimiter between \{resolution\} and \{count\}.

- \{resolution\}\{ (Optional) \: If you want Elastic Transcoder to include the resolution in the file name, include \{resolution\} in the ThumbnailPattern object.

When creating thumbnails, Elastic Transcoder automatically saves the files in the format (.jpg or .png) that appears in the preset that you specified in the PresetID value of CreateJobOutput. Elastic Transcoder also appends the applicable file name extension.

- ThumbnailEncryption (dict) –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your thumbnail.

- Mode (string) –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  - S3: Amazon S3 creates and manages the keys used for encrypting your files.
  - S3-AWS-KMS: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
  - AES-CTR: AES Counter Mode.
  - AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:
  - Key
  - Key MD5
  - Initialization Vector

| Warning: | For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data. |

- Key (string) –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key
Management Service.

- **KeyMd5** *(string)* –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Rotate** *(string)* –

  The number of degrees clockwise by which you want Elastic Transcoder to rotate the output relative to the input. Enter one of the following values:

  auto, 0, 90, 180, 270

  The value `auto` generally works only if the file that you’re transcoding contains rotation metadata.

- **PresetId** *(string)* –

  The value of the `Id` object for the preset that you want to use for this job. The preset determines the audio, video, and thumbnail settings that Elastic Transcoder uses for transcoding. To use a preset that you created, specify the preset ID that Elastic Transcoder returned in the response when you created the preset. You can also use the Elastic Transcoder system presets, which you can get with `ListPresets`.

- **SegmentDuration** *(string)* –

  Warning: (Outputs in Fragmented MP4 or MPEG-TS format only.

If you specify a preset in `PresetId` for which the value of `Container` is `fmp4` (Fragmented MP4) or `ts` (MPEG-TS), `SegmentDuration` is the target maximum duration of each segment in seconds. For HLSv3 format playlists, each media segment is stored in a separate `.ts` file. For HLSv4 and Smooth playlists, all media segments for an output are stored in a single file. Each segment is approximately the length of the `SegmentDuration`, though individual segments might be shorter or longer.

The range of valid values is 1 to 60 seconds. If the duration of the video is not evenly divisible by `SegmentDuration`, the duration of the last segment is the remainder of total length/`SegmentDuration`.

Elastic Transcoder creates an output-specific playlist for each output HLS output that you specify in `OutputKeys`. To add
an output to the master playlist for this job, include it in the OutputKeys of the associated playlist.

- **Status (string)**

  The status of one output in a job. If you specified only one output for the job, Outputs:Status is always the same as Job:Status. If you specified more than one output:
  - Job:Status and Outputs:Status for all of the outputs is Submitted until Elastic Transcoder starts to process the first output.
  - When Elastic Transcoder starts to process the first output, Outputs:Status for that output and Job:Status both change to Progressing. For each output, the value of Outputs:Status remains Submitted until Elastic Transcoder starts to process the output.
  - Job:Status remains Progressing until all of the outputs reach a terminal status, either Complete or Error.
  - When all of the outputs reach a terminal status, Job:Status changes to Complete only if Outputs:Status for all of the outputs is Complete. If Outputs:Status for one or more outputs is Error, the terminal status for Job:Status is also Error.
  
  The value of Status is one of the following: Submitted, Progressing, Complete, Canceled, or Error.

- **StatusDetail (string)**

  Information that further explains Status.

- **Duration (integer)**

  Duration of the output file, in seconds.

- **Width (integer)**

  Specifies the width of the output file in pixels.

- **Height (integer)**

  Height of the output file, in pixels.

- **FrameRate (string)**

  Frame rate of the output file, in frames per second.

- **FileSize (integer)**

  File size of the output file, in bytes.

- **DurationMillis (integer)**

  Duration of the output file, in milliseconds.

- **Watermarks (list)**

  Information about the watermarks that you want Elastic Transcoder to add to the video during transcoding. You can specify up to four watermarks for each output. Settings for each watermark must be defined in the preset that you specify in Preset for the current output.

  Watermarks are added to the output video in the sequence in which you list them in the job output: the first watermark in the list is added to the output video first, the second watermark in the list is added next, and so on. As a result, if the settings in a preset cause Elastic Transcoder to place all watermarks in the same location, the second watermark that you add will
cover the first one, the third one will cover the second, and the fourth one will cover the third.

- *(dict)*

Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

- **PresetWatermarkId** *(string)*

The ID of the watermark settings that Elastic Transcoder uses to add watermarks to the video during transcoding. The settings are in the preset specified by Preset for the current output. In that preset, the value of Watermarks Id tells Elastic Transcoder which settings to use.

- **InputKey** *(string)*

The name of the .png or .jpg file that you want to use for the watermark. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by Pipeline; the Input Bucket object in that pipeline identifies the bucket.

If the file name includes a prefix, for example, logos/128x64.png, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **Encryption** *(dict)*

The encryption settings, if any, that you want Elastic Transcoder to apply to your watermarks.

- **Mode** *(string)*

The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

- **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
- **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**
Warning: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –
  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:
  
  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –
  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –
  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AlbumArt (dict)** –
  The album art to be associated with the output file, if any.

- **MergePolicy (string)** –
  A policy that determines how Elastic Transcoder will handle the existence of multiple album artwork files.
  
  - **Replace**: The specified album art will replace any existing album art.
  
  - **Prepend**: The specified album art will be placed in front of any existing album art.
  
  - **Append**: The specified album art will be placed after any existing album art.
  
  - **Fallback**: If the original input file contains artwork, Elastic Transcoder will use that artwork for the output. If the original input does not contain artwork, Elastic Transcoder will use the specified album art file.

- **Artwork (list)** –
  The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20. Valid formats are .jpg and .png

- **(dict)** –
The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20.

To remove artwork or leave the artwork empty, you can either set Artwork to null, or set the Merge Policy to “Replace” and use an empty Artwork array.

To pass through existing artwork unchanged, set the Merge Policy to “Prepend”, “Append”, or “Fallback”, and use an empty Artwork array.

- **InputKey (string)** –
  The name of the file to be used as album art. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by PipelineId; the InputBucket object in that pipeline identifies the bucket.

  If the file name includes a prefix, for example, cooking/pie.jpg, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **MaxWidth (string)** –
  The maximum width of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 4096, inclusive.

- **MaxHeight (string)** –
  The maximum height of the output album art in pixels. If you specify auto, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 3072, inclusive.

- **SizingPolicy (string)** –
  Specify one of the following values to control scaling of the output album art:

  - **Fit**: Elastic Transcoder scales the output art so it matches the value that you specified in either MaxWidth or MaxHeight without exceeding the other value.
  
  - **Fill**: Elastic Transcoder scales the output art so it matches the value that you specified in either MaxWidth or MaxHeight and matches or exceeds the other value. Elastic Transcoder centers the output art and then crops it in the dimension (if any) that exceeds the maximum value.
  
  - **Stretch**: Elastic Transcoder stretches the output art to match the values that you specified for MaxWidth and MaxHeight. If the relative proportions of the input art and the output art are different, the output art will be distorted.
  
  - **Keep**: Elastic Transcoder does not scale the output art. If either dimension of the input art exceeds the values that you specified for MaxWidth and MaxHeight, Elastic Transcoder crops the output art.
  
  - **ShrinkToFit**: Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of MaxWidth and MaxHeight with-
out exceeding either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **ShrinkToFit** Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of MaxWidth and MaxHeight without dropping below either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **PaddingPolicy** *(string)*

  When you set PaddingPolicy to Pad, Elastic Transcoder may add white bars to the top and bottom and/or left and right sides of the output album art to make the total size of the output art match the values that you specified for MaxWidth and MaxHeight.

- **AlbumArtFormat** *(string)*

  The format of album art, if any. Valid formats are .jpg and .png.

- **Encryption** *(dict)*

  The encryption settings, if any, that you want Elastic Transcoder to apply to your artwork.

- **Mode** *(string)*

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  - **Key MD5**
  - **Initialization Vector**

  **Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

  - **Key** *(string)*

    The data encryption key that you want Elastic Transcoder to use. This key is required for all AES encryption modes.

  - **Key MD5** *(string)*

    The MD5 hash of the encryption key. This is optional but can help verify the integrity of the key.

  - **Initialization Vector** *(string)*

    The initialization vector that is used to start the encryption process. This is optional but can help prevent attacks on your data.
to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

128, 192, or 256.

The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Composition (list)** –

  You can create an output file that contains an excerpt from the input file. This excerpt, called a clip, can come from the beginning, middle, or end of the file. The Composition object contains settings for the clips that make up an output file. For the current release, you can only specify settings for a single clip per output file. The Composition object cannot be null.

  - **(dict)** –

    Settings for one clip in a composition. All jobs in a playlist must have the same clip settings.

  - **TimeSpan (dict)** –

    Settings that determine when a clip begins and how long it lasts.

  - **StartTime (string)** –

    The place in the input file where you want a clip to start. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder starts at the beginning of the input file.

  - **Duration (string)** –

    The duration of the clip. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder creates an output file from StartTime to the end of the file.

    If you specify a value longer than the duration of the input file, Elastic Transcoder transcodes the file and returns a warning message.
Captions (dict) –

You can configure Elastic Transcoder to transcode captions, or subtitles, from one format to another. All captions must be in UTF-8. Elastic Transcoder supports two types of captions:

- **Embedded**: Embedded captions are included in the same file as the audio and video. Elastic Transcoder supports only one embedded caption per language, to a maximum of 300 embedded captions per file. Valid input values include: CEA-608 (EIA-608, first non-empty channel only), CEA-708 (EIA-708, first non-empty channel only), and mov-text. Valid outputs include: mov-text. Elastic Transcoder supports a maximum of one embedded format per output.

- **Sidecar**: Sidecar captions are kept in a separate metadata file from the audio and video data. Sidecar captions require a player that is capable of understanding the relationship between the video file and the sidecar file. Elastic Transcoder supports only one sidecar caption per language, to a maximum of 20 sidecar captions per file. Valid input values include: dfxp (first div element only), ebtt, scc, spt, ttml (first div element only), and webvtt. Valid outputs include: dfxp (first div element only), scc, srt, and webvtt.

If you want ttml or smpte-tt compatible captions, specify dfxp as your output format.

Elastic Transcoder does not support OCR (Optical Character Recognition), does not accept pictures as a valid input for captions, and is not available for audio-only transcoding. Elastic Transcoder does not preserve text formatting (for example, italics) during the transcoding process.

To remove captions or leave the captions empty, set Captions to null. To pass through existing captions unchanged, set the MergePolicy to MergeRetain, and pass in a null CaptionSources array.

For more information on embedded files, see the Subtitles Wikipedia page.

For more information on sidecar files, see the Extensible Metadata Platform and Sidecar file Wikipedia pages.

- **MergePolicy (string)** –

  A policy that determines how Elastic Transcoder handles the existence of multiple captions.

- **MergeOverride**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the sidecar captions and ignores the embedded captions for that language.

- **MergeRetain**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the embedded captions and ignores the sidecar captions for that language.
is empty, Elastic Transcoder omits all sidecar captions from the output files.

- **Override**: Elastic Transcoder transcodes only the sidecar captions that you specify in `CaptionSources`. `MergePolicy` cannot be null.

- **CaptionSources** *(list)* –
  
  Source files for the input sidecar captions used during the transcoding process. To omit all sidecar captions, leave `CaptionSources` blank.

  - **(dict)** –
    
    A source file for the input sidecar captions used during the transcoding process.

  - **Key** *(string)* –
    
    The name of the sidecar caption file that you want Elastic Transcoder to include in the output file.

  - **Language** *(string)* –
    
    A string that specifies the language of the caption. Specify this as one of:

    - 2-character ISO 639-1 code
    - 3-character ISO 639-2 code

    For more information on ISO language codes and language names, see the List of ISO 639-1 codes.

  - **TimeOffset** *(string)* –
    
    For clip generation or captions that do not start at the same time as the associated video file, the `TimeOffset` tells Elastic Transcoder how much of the video to encode before including captions.

    Specify the `TimeOffset` in the form `[+-]SS.sss` or `[+-]HH:mm:SS.sss`.

  - **Label** *(string)* –
    
    The label of the caption shown in the player when choosing a language. We recommend that you put the caption language name here, in the language of the captions.

  - **Encryption** *(dict)* –
    
    The encryption settings, if any, that you want Elastic Transcoder to apply to your caption sources.

  - **Mode** *(string)* –
    
    The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

    - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
    - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify `S3-AWS-KMS` and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)**

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  \[ 128, 192, \text{ or } 256 \].

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)**

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)**

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **CaptionFormats (list)**

  The array of file formats for the output captions. If you leave this value blank, Elastic Transcoder returns an error.

- **(dict)**

  The file format of the output captions. If you leave this value blank, Elastic Transcoder returns an error.

- **Format (string)**

  The format you specify determines whether Elastic Transcoder generates an embedded or sidecar caption
Valid Embedded Caption Formats:  * for FLAC: None
  * For MP3: None
  * For MP4: mov-text
  * For MPEG-TS: None
  * For ogg: None
  * For webm: None

Valid Sidecar Caption Formats: Elastic Transcoder supports dfxp (first div element only), scc, srt, and webvtt. If you want ttml or smpte-tt compatible captions, specify dfxp as your output format. * For FMP4: dfxp

Non-FMP4 outputs: All sidecar types
  * fmp4 captions have an extension of .ismt

Pattern (string) –

The prefix for caption filenames, in the form description -
{language}, where:

  * description is a description of the video.
  * {language} is a literal value that Elastic Transcoder replaces with the two- or three-letter code for the language of the caption in the output file names.

If you don’t include {language} in the file name pattern, Elastic Transcoder automatically appends “{language} “ to the value that you specify for the description. In addition, Elastic Transcoder automatically appends the count to the end of the segment files.

For example, suppose you’re transcoding into srt format. When you enter “Sydney-{language}-sunrise”, and the language of the captions is English (en), the name of the first caption file will be Sydney-en-sunrise00000.srt.

Encryption (dict) –

The encryption settings, if any, that you want Elastic Transcoder to apply to your caption formats.

Mode (string) –

The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  * S3: Amazon S3 creates and manages the keys used for encrypting your files.
  * S3-AWS-KMS: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  * AES-CBC-PKCS7: A padded cipher-block mode of operation originally used for HLS files.
  * AES-CTR: AES Counter Mode.
  * AES-GCM: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following
settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Encryption (dict)** –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your output files. If you choose to use encryption, you must specify a mode to use. If you choose not to use encryption, Elastic Transcoder will write an unencrypted file to your Amazon S3 bucket.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the
AWS-KMS key that you want to use to your pipeline.

- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AppliedColorSpaceConversion (string)** –

  If Elastic Transcoder used a preset with a ColorSpaceConversionMode to transcode the output file, the AppliedColorSpaceConversion parameter shows the conversion used. If no ColorSpaceConversionMode was defined in the preset, this parameter will not be included in the job response.

- **Outputs (list)** –
Information about the output files. We recommend that you use the Outputs syntax for all jobs, even when you want Elastic Transcoder to transcode a file into only one format. Do not use both the Outputs and Output syntaxes in the same request. You can create a maximum of 30 outputs per job.

If you specify more than one output for a job, Elastic Transcoder creates the files for each output in the order in which you specify them in the job.

- (dict) –

**Warning:** Outputs recommended instead.

If you specified one output for a job, information about that output. If you specified multiple outputs for a job, the Output object lists information about the first output. This duplicates the information that is listed for the first output in the Outputs object.

- **Id (string)** –

  A sequential counter, starting with 1, that identifies an output among the outputs from the current job. In the Output syntax, this value is always 1.

- **Key (string)** –

  The name to assign to the transcoded file. Elastic Transcoder saves the file in the Amazon S3 bucket specified by the OutputBucket object in the pipeline that is specified by the pipeline ID.

- **ThumbnailPattern (string)** –

  Whether you want Elastic Transcoder to create thumbnails for your videos and, if so, how you want Elastic Transcoder to name the files.

If you don’t want Elastic Transcoder to create thumbnails, specify “".

If you do want Elastic Transcoder to create thumbnails, specify the information that you want to include in the file name for each thumbnail. You can specify the following values in any sequence:

- **"{count}" (Required)** : If you want to create thumbnails, you must include {count} in the ThumbnailPattern object. Wherever you specify {count}, Elastic Transcoder adds a five-digit sequence number (beginning with 00001 ) to thumbnail file names. The number indicates where a given thumbnail appears in the sequence of thumbnails for a transcoded file. .. warning::If you specify a literal value and/or {resolution} but you omit {count}, Elastic Transcoder returns a validation error and does not create the job.

- **Literal values (Optional)** : You can specify literal values anywhere in the ThumbnailPattern object. For example, you can include them as a file name prefix or as a delimiter
between \{resolution\} and \{count\}.

- \{resolution\} \(\text{``(Optional)''}\): If you want Elastic Transcoder to include the resolution in the file name, include \{resolution\} in the ThumbnailPattern object.

When creating thumbnails, Elastic Transcoder automatically saves the files in the format (.jpg or .png) that appears in the preset that you specified in the \texttt{PresetID} value of \texttt{CreateJobOutput}. Elastic Transcoder also appends the applicable file name extension.

- **ThumbnailEncryption (dict)** —
  
The encryption settings, if any, that you want Elastic Transcoder to apply to your thumbnail.

- **Mode (string)** —
  
The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  
  - **AES-CTR**: AES Counter Mode.
  
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following settings, which must be base64-encoded:

  - **Key**
  
  - **Key MD5**
  
  - **Initialization Vector**

    **Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key (string)** —
  
The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  \[ 128, 192, \text{or} 256 \].

  The key must also be encrypted by using the Amazon Key Management Service.
· **KeyMd5** *(string)* –

The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

· **InitializationVector** *(string)* –

The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

· **Rotate** *(string)* –

The number of degrees clockwise by which you want Elastic Transcoder to rotate the output relative to the input. Enter one of the following values:

`auto`, 0, 90, 180, 270

The value `auto` generally works only if the file that you’re transcoding contains rotation metadata.

· **PresetId** *(string)* –

The value of the `Id` object for the preset that you want to use for this job. The preset determines the audio, video, and thumbnail settings that Elastic Transcoder uses for transcoding. To use a preset that you created, specify the preset ID that Elastic Transcoder returned in the response when you created the preset. You can also use the Elastic Transcoder system presets, which you can get with `ListPresets`.

· **SegmentDuration** *(string)* –

**Warning:** (Outputs in Fragmented MP4 or MPEG-TS format only.)

If you specify a preset in *PresetId* for which the value of *Container* is *fmp4* (Fragmented MP4) or *ts* (MPEG-TS), *SegmentDuration* is the target maximum duration of each segment in seconds. For HLSv3 format playlists, each media segment is stored in a separate `.ts` file. For HLSv4 and Smooth playlists, all media segments for an output are stored in a single file. Each segment is approximately the length of the `SegmentDuration`, though individual segments might be shorter or longer.

The range of valid values is 1 to 60 seconds. If the duration of the video is not evenly divisible by `SegmentDuration`, the duration of the last segment is the remainder of total length/`SegmentDuration`.

Elastic Transcoder creates an output-specific playlist for each output HLS output that you specify in `OutputKeys`. To add
an output to the master playlist for this job, include it in the OutputKeys of the associated playlist.

- **Status (string)** –

  The status of one output in a job. If you specified only one output for the job, Outputs:Status is always the same as Job:Status. If you specified more than one output:

  - Job:Status and Outputs:Status for all of the outputs is Submitted until Elastic Transcoder starts to process the first output.

  - When Elastic Transcoder starts to process the first output, Outputs:Status for that output and Job:Status both change to Progressing. For each output, the value of Outputs:Status remains Submitted until Elastic Transcoder starts to process the output.

  - Job:Status remains Progressing until all of the outputs reach a terminal status, either Complete or Error.

  - When all of the outputs reach a terminal status, Job:Status changes to Complete only if Outputs:Status for all of the outputs is Complete. If Outputs:Status for one or more outputs is Error, the terminal status for Job:Status is also Error.

  The value of Status is one of the following: Submitted, Progressing, Complete, Canceled, or Error.

- **StatusDetail (string)** –

  Information that further explains Status.

- **Duration (integer)** –

  Duration of the output file, in seconds.

- **Width (integer)** –

  Specifies the width of the output file in pixels.

- **Height (integer)** –

  Height of the output file, in pixels.

- **FrameRate (string)** –

  Frame rate of the output file, in frames per second.

- **FileSize (integer)** –

  File size of the output file, in bytes.

- **DurationMillis (integer)** –

  Duration of the output file, in milliseconds.

- **Watermarks (list)** –

  Information about the watermarks that you want Elastic Transcoder to add to the video during transcoding. You can specify up to four watermarks for each output. Settings for each watermark must be defined in the preset that you specify in Preset for the current output.

  Watermarks are added to the output video in the sequence in which you list them in the job output. The first watermark in the list is added to the output video first, the second watermark in the list is added next, and so on. As a result, if the settings in a preset cause Elastic Transcoder to place all watermarks in the same location, the second watermark that you add will
cover the first one, the third one will cover the second, and the fourth one will cover the third.

- **(dict)** –

  Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

- **PresetWatermarkId (string)** –

  The ID of the watermark settings that Elastic Transcoder uses to add watermarks to the video during transcoding. The settings are in the preset specified by Preset for the current output. In that preset, the value of Watermarks Id tells Elastic Transcoder which settings to use.

- **InputKey (string)** –

  The name of the .png or .jpg file that you want to use for the watermark. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by Pipeline; the Input Bucket object in that pipeline identifies the bucket.

  If the file name includes a prefix, for example, logos/128x64.png, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **Encryption (dict)** –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your watermarks.

  - **Mode (string)** –

    The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

    - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
    - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
    - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
    - **AES-CTR**: AES Counter Mode.
    - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

    For all three AES options, you must provide the following settings, which must be base64-encoded:

    - **Key**
    - **Key MD5**
    - **Initialization Vector**
Warning: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* —
  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* —
  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* —
  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AlbumArt** *(dict)* —
  The album art to be associated with the output file, if any.

- **MergePolicy** *(string)* —
  A policy that determines how Elastic Transcoder will handle the existence of multiple album artwork files.

  - Replace: The specified album art will replace any existing album art.
  - Prepend: The specified album art will be placed in front of any existing album art.
  - Append: The specified album art will be placed after any existing album art.
  - Fallback: If the original input file contains artwork, Elastic Transcoder will use that artwork for the output. If the original input does not contain artwork, Elastic Transcoder will use the specified album art file.

- **Artwork** *(list)* —
  The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20. Valid formats are .jpg and .png.
The file to be used as album art. There can be multiple artworks associated with an audio file, to a maximum of 20.

To remove artwork or leave the artwork empty, you can either set `Artwork` to null, or set the `Merge Policy` to “Replace” and use an empty `Artwork` array.

To pass through existing artwork unchanged, set the `Merge Policy` to “Prepend”, “Append”, or “Fallback”, and use an empty `Artwork` array.

- **InputKey (string)** –

  The name of the file to be used as album art. To determine which Amazon S3 bucket contains the specified file, Elastic Transcoder checks the pipeline specified by `PipelineId`; the `InputBucket` object in that pipeline identifies the bucket.

  If the file name includes a prefix, for example, `cooking/pie.jpg`, include the prefix in the key. If the file isn’t in the specified bucket, Elastic Transcoder returns an error.

- **MaxWidth (string)** –

  The maximum width of the output album art in pixels. If you specify `auto`, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 4096, inclusive.

- **MaxHeight (string)** –

  The maximum height of the output album art in pixels. If you specify `auto`, Elastic Transcoder uses 600 as the default value. If you specify a numeric value, enter an even integer between 32 and 3072, inclusive.

- **SizingPolicy (string)** –

  Specify one of the following values to control scaling of the output album art:

  - **Fit**: Elastic Transcoder scales the output art so it matches the value that you specified in either `MaxWidth` or `MaxHeight` without exceeding the other value.
  - **Fill**: Elastic Transcoder scales the output art so it matches the value that you specified in either `MaxWidth` or `MaxHeight` and matches or exceeds the other value. Elastic Transcoder centers the output art and then crops it in the dimension (if any) that exceeds the maximum value.
  - **Stretch**: Elastic Transcoder stretches the output art to match the values that you specified for `MaxWidth` and `MaxHeight`. If the relative proportions of the input art and the output art are different, the output art will be distorted.
  - **Keep**: Elastic Transcoder does not scale the output art. If either dimension of the input art exceeds the values that you specified for `MaxWidth` and `MaxHeight`, Elastic Transcoder crops the output art.
  - **ShrinkToFit**: Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` with-
out exceeding either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **ShrinkToFill** Elastic Transcoder scales the output art down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without dropping below either value. If you specify this option, Elastic Transcoder does not scale the art up.

- **PaddingPolicy** *(string)* —
  When you set `PaddingPolicy` to `Pad`, Elastic Transcoder may add white bars to the top and bottom and/or left and right sides of the output album art to make the total size of the output art match the values that you specified for `MaxWidth` and `MaxHeight`.

- **AlbumArtFormat** *(string)* —
  The format of album art, if any. Valid formats are .jpg and .png.

- **Encryption** *(dict)* —
  The encryption settings, if any, that you want Elastic Transcoder to apply to your artwork.

- **Mode** *(string)* —
  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify **S3-AWS-KMS** and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning:** For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* —
  The data encryption key that you want Elastic Transcoder
to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

\[128, 192, \text{or } 256\].

The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Composition** *(list)* –

  You can create an output file that contains an excerpt from the input file. This excerpt, called a clip, can come from the beginning, middle, or end of the file. The Composition object contains settings for the clips that make up an output file. For the current release, you can only specify settings for a single clip per output file. The Composition object cannot be null.

  - **(dict)** –

    Settings for one clip in a composition. All jobs in a playlist must have the same clip settings.

  - **TimeSpan** *(dict)* –

    Settings that determine when a clip begins and how long it lasts.

  - **StartTime** *(string)* –

    The place in the input file where you want a clip to start. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder starts at the beginning of the input file.

  - **Duration** *(string)* –

    The duration of the clip. The format can be either HH:mm:ss.SSS (maximum value: 23:59:59.999; SSS is thousandths of a second) or sssss.SSS (maximum value: 86399.999). If you don’t specify a value, Elastic Transcoder creates an output file from StartTime to the end of the file.

    If you specify a value longer than the duration of the input file, Elastic Transcoder transcodes the file and returns a warning message.
· **Captions** *(dict)* –

You can configure Elastic Transcoder to transcode captions, or subtitles, from one format to another. All captions must be in UTF-8. Elastic Transcoder supports two types of captions:

- **Embedded**: Embedded captions are included in the same file as the audio and video. Elastic Transcoder supports only one embedded caption per language, to a maximum of 300 embedded captions per file. Valid input values include: CEA-608 (EIA-608, first non-empty channel only), CEA-708 (EIA-708, first non-empty channel only), and mov-text. Valid outputs include: mov-text. Elastic Transcoder supports a maximum of one embedded format per output.

- **Sidecar**: Sidecar captions are kept in a separate metadata file from the audio and video data. Sidecar captions require a player that is capable of understanding the relationship between the video file and the sidecar file. Elastic Transcoder supports only one sidecar caption per language, to a maximum of 20 sidecar captions per file. Valid input values include: dfxp (first div element only), ebu-tt, scc, smpte, srt, ttml (first div element only), and webvtt. Valid outputs include: dfxp (first div element only), scc, srt, and webvtt.

If you want ttml or smpte-tt compatible captions, specify dfxp as your output format.

Elastic Transcoder does not support OCR (Optical Character Recognition), does not accept pictures as a valid input for captions, and is not available for audio-only transcoding. Elastic Transcoder does not preserve text formatting (for example, italics) during the transcoding process.

To remove captions or leave the captions empty, set Captions to null. To pass through existing captions unchanged, set the **MergePolicy** to MergeRetain, and pass in a null **CaptionSources** array.

For more information on embedded files, see the Subtitles Wikipedia page.

For more information on sidecar files, see the Extensible Metadata Platform and Sidecar file Wikipedia pages.

- **MergePolicy** *(string)* –

A policy that determines how Elastic Transcoder handles the existence of multiple captions.

- **MergeOverride**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the sidecar captions and ignores the embedded captions for that language.

- **MergeRetain**: Elastic Transcoder transcodes both embedded and sidecar captions into outputs. If captions for a language are embedded in the input file and also appear in a sidecar file, Elastic Transcoder uses the embedded captions and ignores the sidecar captions for that language.
is empty, Elastic Transcoder omits all sidecar captions from the output files.

- **Override**: Elastic Transcoder transcodes only the sidecar captions that you specify in `CaptionSources`. `MergePolicy` cannot be null.

- **CaptionSources** (list) –
  
  Source files for the input sidecar captions used during the transcoding process. To omit all sidecar captions, leave `CaptionSources` blank.
  
  (dict) –
  
  A source file for the input sidecar captions used during the transcoding process.
  
  - **Key** (string) –
    
    The name of the sidecar caption file that you want Elastic Transcoder to include in the output file.
  
  - **Language** (string) –
    
    A string that specifies the language of the caption. Specify this as one of:
    
    - 2-character ISO 639-1 code
    - 3-character ISO 639-2 code
    
    For more information on ISO language codes and language names, see the List of ISO 639-1 codes.

  - **TimeOffset** (string) –
    
    For clip generation or captions that do not start at the same time as the associated video file, the `TimeOffset` tells Elastic Transcoder how much of the video to encode before including captions.
    
    Specify the `TimeOffset` in the form `[+-]SS.sss` or `[+-]HH:mm:SS.ss`.

  - **Label** (string) –
    
    The label of the caption shown in the player when choosing a language. We recommend that you put the caption language name here, in the language of the captions.

  - **Encryption** (dict) –
    
    The encryption settings, if any, that you want Elastic Transcoder to apply to your caption sources.

  - **Mode** (string) –
    
    The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

    - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
    - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Key</strong></td>
<td>The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded: 128, 192, or 256. The key must also be encrypted by using the Amazon Key Management Service.</td>
</tr>
<tr>
<td><strong>KeyMD5</strong></td>
<td>The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.</td>
</tr>
<tr>
<td><strong>InitializationVector</strong></td>
<td>The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.</td>
</tr>
<tr>
<td><strong>CaptionFormats</strong></td>
<td>The array of file formats for the output captions. If you leave this value blank, Elastic Transcoder returns an error.</td>
</tr>
<tr>
<td><strong>Format</strong></td>
<td>The file format of the output captions. If you leave this value blank, Elastic Transcoder returns an error.</td>
</tr>
</tbody>
</table>

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.
for this output.

- **Valid Embedded Caption Formats:**
  - *for FLAC*: None
  - *for MP3*: None
  - *for MP4*: mov-text
  - *for MPEG-TS*: None
  - *for ogg*: None
  - *for webm*: None

- **Valid Sidecar Caption Formats:**
  Elastic Transcoder supports dfxp (first div element only), scc, srt, and webvtt. If you want ttml or smpte-tt compatible captions, specify dfxp as your output format. *For FMP4*: dfxp

- **Non-FMP4 outputs**: All sidecar types
  - *fmp4* captions have an extension of `.ismt`

- **Pattern** *(string)* –
  The prefix for caption filenames, in the form `description` - `{language}`, where:
  - `description` is a description of the video.
  - `{language}` is a literal value that Elastic Transcoder replaces with the two- or three-letter code for the language of the caption in the output file names.

  If you don’t include `{language}` in the file name pattern, Elastic Transcoder automatically appends “{language}” to the value that you specify for the description. In addition, Elastic Transcoder automatically appends the count to the end of the segment files.

  For example, suppose you’re transcoding into srt format. When you enter “Sydney-{language}-sunrise”, and the language of the captions is English (en), the name of the first caption file will be Sydney-en-sunrise00000.srt.

- **Encryption** *(dict)* –
  The encryption settings, if any, that you want Elastic Transcoder to apply to your caption formats.

- **Mode** *(string)* –
  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:
  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the AWS-KMS key that you want to use to your pipeline.
  - **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
  - **AES-CTR**: AES Counter Mode.
  - **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

  For all three AES options, you must provide the following
settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

| Warning: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data. |

- **Key (string)** –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5 (string)** –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector (string)** –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **Encryption (dict)** –

  The encryption settings, if any, that you want Elastic Transcoder to apply to your output files. If you choose to use encryption, you must specify a mode to use. If you choose not to use encryption, Elastic Transcoder will write an unencrypted file to your Amazon S3 bucket.

- **Mode (string)** –

  The specific server-side encryption mode that you want Elastic Transcoder to use when decrypting your input files or encrypting your output files. Elastic Transcoder supports the following options:

  - **S3**: Amazon S3 creates and manages the keys used for encrypting your files.
  - **S3-AWS-KMS**: Amazon S3 calls the Amazon Key Management Service, which creates and manages the keys that are used for encrypting your files. If you specify S3-AWS-KMS and you don’t want to use the default key, you must add the
AWS-KMS key that you want to use to your pipeline.

- **AES-CBC-PKCS7**: A padded cipher-block mode of operation originally used for HLS files.
- **AES-CTR**: AES Counter Mode.
- **AES-GCM**: AES Galois Counter Mode, a mode of operation that is an authenticated encryption format, meaning that a file, key, or initialization vector that has been tampered with will fail the decryption process.

For all three AES options, you must provide the following settings, which must be base64-encoded:

- **Key**
- **Key MD5**
- **Initialization Vector**

**Warning**: For the AES modes, your private encryption keys and your unencrypted data are never stored by AWS; therefore, it is important that you safely manage your encryption keys. If you lose them, you won’t be able to unencrypt your data.

- **Key** *(string)* –

  The data encryption key that you want Elastic Transcoder to use to encrypt your output file, or that was used to encrypt your input file. The key must be base64-encoded and it must be one of the following bit lengths before being base64-encoded:

  $$128, 192, \text{ or } 256.$$

  The key must also be encrypted by using the Amazon Key Management Service.

- **KeyMd5** *(string)* –

  The MD5 digest of the key that you used to encrypt your input file, or that you want Elastic Transcoder to use to encrypt your output file. Elastic Transcoder uses the key digest as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **InitializationVector** *(string)* –

  The series of random bits created by a random bit generator, unique for every encryption operation, that you used to encrypt your input files or that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes long before being base64-encoded.

- **AppliedColorSpaceConversion** *(string)* –

  If Elastic Transcoder used a preset with a ColorSpaceConversionMode to transcode the output file, the AppliedColorSpaceConversion parameter shows the conversion used. If no ColorSpaceConversionMode was defined in the preset, this parameter will not be included in the job response.

- **OutputKeyPrefix** *(string)* –
The value, if any, that you want Elastic Transcoder to prepend to the names of all files that this job creates, including output files, thumbnails, and playlists. We recommend that you add a / or some other delimiter to the end of the `OutputKeyPrefix`.

- **Playlists (list)** –

<table>
<thead>
<tr>
<th>Warning: Outputs in Fragmented MP4 or MPEG-TS format only.</th>
</tr>
</thead>
</table>

If you specify a preset in `PresetId` for which the value of `Container` is `fmp4` (Fragmented MP4) or `ts` (MPEG-TS), `Playlists` contains information about the master playlists that you want Elastic Transcoder to create.

The maximum number of master playlists in a job is 30.

- **(dict)** –

  Use Only for Fragmented MP4 or MPEG-TS Outputs. If you specify a preset for which the value of `Container` is `fmp4` (Fragmented MP4) or `ts` (MPEG-TS), `Playlists` contains information about the master playlists that you want Elastic Transcoder to create. We recommend that you create only one master playlist per output format. The maximum number of master playlists in a job is 30.

  - **Name (string)** –

    The name that you want Elastic Transcoder to assign to the master playlist, for example, nyc-vacation.m3u8. If the name includes a / character, the section of the name before the last / must be identical for all `Name` objects. If you create more than one master playlist, the values of all `Name` objects must be unique.

    | Note: Elastic Transcoder automatically appends the relevant file extension to the file name (.m3u8 for HLSv3 and HLSv4 playlists, and .ism and .ismc for Smooth playlists). If you include a file extension in `Name`, the file name will have two extensions. |
    |---------------------------------------------------------------|

  - **Format (string)** –

    The format of the output playlist. Valid formats include HLSv3, HLSv4, and Smooth.

  - **OutputKeys (list)** –

    For each output in this job that you want to include in a master playlist, the value of the Outputs:Key object.

    - If your output is not HLS or does not have a segment duration set, the name of the output file is a concatenation of `OutputKeyPrefix` and `Outputs:Key`: `OutputKeyPrefix``Outputs:Key``.

    - If your output is HLSv3 and has a segment duration set, or is not included in a playlist, Elastic Transcoder creates an output playlist file with a file extension of .m3u8, and a series of .ts files that include a five-digit sequential counter beginning with 00000: `OutputKeyPrefix``Outputs:Key``m3u8``00000.ts`
· If your output is HLSv4, has a segment duration set, and is included in an HLSv4 playlist, Elastic Transcoder creates an output playlist file with a file extension of _v4.m3u8. If the output is video, Elastic Transcoder also creates an output file with an extension of _iframe.m3u8. The output files associated with this playlist.

· **HlsContentProtection (dict)** –

  The HLS content protection settings, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

· **Method (string)** –

  The content protection method for your output. The only valid value is: aes-128.

  This value will be written into the method attribute of the EXT-X-KEY metadata tag in the output playlist.

· **Key (string)** –

  If you want Elastic Transcoder to generate a key for you, leave this field blank.

  If you choose to supply your own key, you must encrypt the key by using AWS KMS. The key must be base64-encoded, and it must be one of the following bit lengths before being base64-encoded:

  128, 192, or 256.

· **KeyMd5 (string)** –

  If Elastic Transcoder is generating your key for you, you must leave this field blank.

  The MD5 digest of the key that you want Elastic Transcoder to use to encrypt your output file, and that you want Elastic Transcoder to use as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

· **InitializationVector (string)** –

  If Elastic Transcoder is generating your key for you, you must leave this field blank.

  The series of random bits created by a random bit generator,
unique for every encryption operation, that you want Elastic Transcoder to use to encrypt your output files. The initialization vector must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

- **LicenseAcquisitionUrl** *(string)* –

  The location of the license key required to decrypt your HLS playlist. The URL must be an absolute path, and is referenced in the URI attribute of the EXT-X-KEY metadata tag in the playlist file.

- **KeyStoragePolicy** *(string)* –

  Specify whether you want Elastic Transcoder to write your HLS license key to an Amazon S3 bucket. If you choose `WithVariantPlaylists`, `LicenseAcquisitionUrl` must be left blank and Elastic Transcoder writes your data key into the same bucket as the associated playlist.

- **PlayReadyDrm** *(dict)* –

  The DRM settings, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

  - **Format** *(string)* –

    The type of DRM, if any, that you want Elastic Transcoder to apply to the output files associated with this playlist.

  - **Key** *(string)* –

    The DRM key for your file, provided by your DRM license provider. The key must be base64-encoded, and it must be one of the following bit lengths before being base64-encoded: 128, 192, or 256.

    The key must also be encrypted by using AWS KMS.

  - **KeyMd5** *(string)* –

    The MD5 digest of the key used for DRM on your file, and that you want Elastic Transcoder to use as a checksum to make sure your key was not corrupted in transit. The key MD5 must be base64-encoded, and it must be exactly 16 bytes before being base64-encoded.

  - **KeyId** *(string)* –

    The ID for your DRM key, so that your DRM license provider knows which key to provide.

    The key ID must be provided in big endian, and Elastic Transcoder will convert it to little endian before inserting it into the PlayReady DRM headers. If you are unsure whether your license server provides your key ID in big or little endian, check with your DRM provider.

  - **InitializationVector** *(string)* –

    The series of random bits created by a random bit generator, unique for every encryption operation, that you want Elastic Transcoder to use to encrypt your files. The initialization vector must be base64-encoded, and it must be exactly 8 bytes...
long before being base64-encoded. If no initialization vector is provided, Elastic Transcoder generates one for you.

- **LicenseAcquisitionUrl (string)** –
  
The location of the license key required to play DRM content. The URL must be an absolute path, and is referenced by the PlayReady header. The PlayReady header is referenced in the protection header of the client manifest for Smooth Streaming outputs, and in the EXT-X-DXDRM and EXT-XDXDRMMINFO metadata tags for HLS playlist outputs. An example URL looks like this: https://www.example.com/exampleKey/

- **Status (string)** –
  
The status of the job with which the playlist is associated.

- **StatusDetail (string)** –
  
Information that further explains the status.

- **Status (string)** –
  
The status of the job: Submitted, Progressing, Complete, Canceled, or Error.

- **UserMetadata (dict)** –
  
User-defined metadata that you want to associate with an Elastic Transcoder job. You specify metadata in key/value pairs, and you can add up to 10 key/value pairs per job. Elastic Transcoder does not guarantee that key/value pairs will be returned in the same order in which you specify them.

Metadata keys and values must use characters from the following list:

- 0-9
- A-Z and a-z
- Space
- The following symbols: __,:/=+-%@ (string) –
- (string) –
- **Timing (dict)** –
  
Details about the timing of a job.

- **SubmitTimeMillis (integer)** –
  
The time the job was submitted to Elastic Transcoder, in epoch milliseconds.

- **StartTimeMillis (integer)** –
  
The time the job began transcoding, in epoch milliseconds.

- **FinishTimeMillis (integer)** –
  
The time the job finished transcoding, in epoch milliseconds.

- **NextToken (string)** –
  
A token to resume pagination.

class ElasticTranscoder.Paginator.ListPipelines

    paginator = client.get_paginotor('list_pipelines')

3.1. Services 2511
paginate(**kwargs)

Creates an iterator that will paginate through responses from ElasticTranscoder.Client.list_pipelines().

Request Syntax

response_iterator = paginator.paginate(
    Ascending='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **Ascending** (string) – To list pipelines in chronological order by the date and time that they were created, enter **true**. To list pipelines in reverse chronological order, enter **false**.
- **PaginationConfig** (dict) – A dictionary that provides parameters to control pagination.
  - **MaxItems** (integer) – The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** (integer) – The size of each page.
  - **StartingToken** (string) – A token to specify where to start paginating. This is the NextToken from a previous response.

Returns

Response Syntax

```python
{
    'Pipelines': [
        {
            'Id': 'string',
            'Arn': 'string',
            'Name': 'string',
            'Status': 'string',
            'InputBucket': 'string',
            'OutputBucket': 'string',
            'Role': 'string',
            'AwsKmsKeyArn': 'string',
            'Notifications': {
                'Progressing': 'string',
                'Completed': 'string',
                'Warning': 'string',
                'Error': 'string'
            },
            'ContentConfig': {
                'Bucket': 'string',
                'StorageClass': 'string',
            }
        }
    ]
}
```
'Permissions': [
    {
        'GranteeType': 'string',
        'Grantee': 'string',
        'Access': [
            'string',
        ],
    },
],
'ThumbnailConfig': {
    'Bucket': 'string',
    'StorageClass': 'string',

        {
            'GranteeType': 'string',
            'Grantee': 'string',
            'Access': [
                'string',
            ],
        },
    ],
},
'NextToken': 'string'

Response Structure

- (dict) –
  A list of the pipelines associated with the current AWS account.
  - Pipelines (list) –
    An array of Pipeline objects.
      * (dict) –
        The pipeline (queue) that is used to manage jobs.
          - Id (string) –
            The identifier for the pipeline. You use this value to identify
            the pipeline in which you want to perform a variety of opera-
            tions, such as creating a job or a preset.
          - Arn (string) –
            The Amazon Resource Name (ARN) for the pipeline.
          - Name (string) –
            The name of the pipeline. We recommend that the name be
            unique within the AWS account, but uniqueness is not en-
            forced.
            Constraints: Maximum 40 characters
          - Status (string) –
            The current status of the pipeline:
              - Active: The pipeline is processing jobs.
              - Paused: The pipeline is not currently processing jobs.
              - InputBucket (string) –
The Amazon S3 bucket from which Elastic Transcoder gets media files for transcoding and the graphics files, if any, that you want to use for watermarks.

- **OutputBucket** *(string)* –
  The Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files, thumbnails, and playlists. Either you specify this value, or you specify both `ContentConfig` and `ThumbnailConfig`.

- **Role** *(string)* –
  The IAM Amazon Resource Name (ARN) for the role that Elastic Transcoder uses to transcode jobs for this pipeline.

- **AwsKmsKeyArn** *(string)* –
  The AWS Key Management Service (AWS KMS) key that you want to use with this pipeline.

  If you use either S3 or S3-AWS-KMS as your `Encryption:Mode`, you don’t need to provide a key with your job because a default key, known as an AWS-KMS key, is created for you automatically. You need to provide an AWS-KMS key only if you want to use a non-default AWS-KMS key, or if you are using an `Encryption:Mode` of AES-PKCS7, AES-CTR, or AES-GCM.

- **Notifications** *(dict)* –
  The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify to report job status.

  **Warning:** To receive notifications, you must also subscribe to the new topic in the Amazon SNS console.

  - **Progressing** *(optional)*: The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify when Elastic Transcoder has started to process the job.
  - **Completed** *(optional)*: The Amazon SNS topic that you want to notify when Elastic Transcoder has finished processing the job.
  - **Warning** *(optional)*: The Amazon SNS topic that you want to notify when Elastic Transcoder encounters a warning condition.
  - **Error** *(optional)*: The Amazon SNS topic that you want to notify when Elastic Transcoder encounters an error condition.

- **Progressing** *(string)* –
  The Amazon Simple Notification Service (Amazon SNS) topic that you want to notify when Elastic Transcoder has started to process the job.

- **Completed** *(string)* –
  The Amazon SNS topic that you want to notify when Elastic Transcoder has finished processing the job.

- **Warning** *(string)* –
  The Amazon SNS topic that you want to notify when Elastic Transcoder encounters a warning condition.

- **Error** *(string)* –
The Amazon SNS topic that you want to notify when Elastic Transcoder encounters an error condition.

- **ContentConfig (dict)** –

  Information about the Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists. Either you specify both `ContentConfig` and `ThumbnailConfig`, or you specify `OutputBucket`.

- **Bucket**: The Amazon S3 bucket in which you want Elastic Transcoder to save transcoded files and playlists.

- **Permissions**: A list of the users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access that you want them to have.

  - **GranteeType**: The type of value that appears in the `Grantee` object:
    - **Canonical**: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution.

- **Email**: The registered email address of an AWS account.

- **Group**: One of the following predefined Amazon S3 groups: `AllUsers`, `AuthenticatedUsers`, or `LogDelivery`.

- **Grantee**: The AWS user or group that you want to have access to transcoded files and playlists.

- **Access**: The permission that you want to give to the AWS user that is listed in `Grantee`. Valid values include:
  - **READ**: The grantee can read the objects and metadata for objects that Elastic Transcoder adds to the Amazon S3 bucket.
  - **READ_ACP**: The grantee can read the object ACL for objects that Elastic Transcoder adds to the Amazon S3 bucket.
  - **WRITE_ACP**: The grantee can write the ACL for the objects that Elastic Transcoder adds to the Amazon S3 bucket.
  - **FULL_CONTROL**: The grantee has **READ**, **READ_ACP**, and **WRITE_ACP** permissions for the objects that Elastic Transcoder adds to the Amazon S3 bucket.

- **StorageClass**: The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

- **Bucket (string)** –

  The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the following are true:

  - You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.
  - You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.
  - You do not want to specify the permissions that Elastic Transcoder grants to the files.
  - You want to associate the transcoded files and thumbnails with the Amazon S3 Standard storage class.

  If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit Out-
putBucket and specify values for ContentConfig and
ThumbnailConfig instead.

- **StorageClass (string)** –
  The Amazon S3 storage class, Standard or
  ReducedRedundancy, that you want Elastic Transcoder
to assign to the video files and playlists that it stores in your
Amazon S3 bucket.

- **Permissions (list)** –
  Optional. The Permissions object specifies which users
  and/or predefined Amazon S3 groups you want to have access
to transcoded files and playlists, and the type of access you
want them to have. You can grant permissions to a maximum
of 30 users and/or predefined Amazon S3 groups.

  If you include Permissions, Elastic Transcoder grants
  only the permissions that you specify. It does not grant full
  permissions to the owner of the role specified by Role. If
  you want that user to have full control, you must explicitly
  grant full control to the user.

  If you omit Permissions, Elastic Transcoder grants full
  control over the transcoded files and playlists to the owner
  of the role specified by Role, and grants no other permissions
to any other user or group.

  - **(dict)** –
    The Permission structure.

  - **GranteeType (string)** –
    The type of value that appears in the Grantee object:

    - **Canonical**: Either the canonical user ID for an AWS ac-
      count or an origin access identity for an Amazon CloudFront
distribution. .. warning:: A canonical user ID is not the same
      as an AWS account number.

    - **Email**: The registered email address of an AWS account.

    - **Group**: One of the following predefined Amazon S3
groups: AllUsers, AuthenticatedUsers, or
      LogDelivery.

  - **Grantee (string)** –
    The AWS user or group that you want to have access to
    transcoded files and playlists. To identify the user or group,
you can specify the canonical user ID for an AWS account, an
origin access identity for a CloudFront distribution, the regis-
tered email address of an AWS account, or a predefined Ama-
zon S3 group.

  - **Access (list)** –
    The permission that you want to give to the AWS user that is
    listed in Grantee. Valid values include:

    - **READ**: The grantee can read the thumbnails and metadata for
      thumbnails that Elastic Transcoder adds to the Amazon S3
      bucket.

    - **READ_ACP**: The grantee can read the object ACL for thumb-
      nAILS that Elastic Transcoder adds to the Amazon S3 bucket.
WRITE_ACP: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

FULL_CONTROL: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

(string) –

ThumbnailConfig (dict) –

Information about the Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files. Either you specify both ContentConfig and ThumbnailConfig, or you specify OutputBucket.

Bucket: The Amazon S3 bucket in which you want Elastic Transcoder to save thumbnail files.

Permissions: A list of the users and/or predefined Amazon S3 groups you want to have access to thumbnail files, and the type of access that you want them to have. * GranteeType: The type of value that appears in the Grantee object:

Canonical: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning:: A canonical user ID is not the same as an AWS account number.

Email: The registered email address of an AWS account.

Group: One of the following predefined Amazon S3 groups: AllUsers, AuthenticatedUsers, or LogDelivery.

Grantee: The AWS user or group that you want to have access to thumbnail files.

Access: The permission that you want to give to the AWS user that is listed in Grantee. Valid values include:

READ: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

READ_ACP: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

WRITE_ACP: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

FULL_CONTROL: The grantee has READ, READ_ACP, and WRITE_ACP permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

StorageClass: The Amazon S3 storage class, Standard or ReducedRedundancy, that you want Elastic Transcoder to assign to the thumbnails that it stores in your Amazon S3 bucket.

Bucket (string) –

The Amazon S3 bucket in which you want Elastic Transcoder to save the transcoded files. Specify this value when all of the following are true:

You want to save transcoded files, thumbnails (if any), and playlists (if any) together in one bucket.

You do not want to specify the users or groups who have access to the transcoded files, thumbnails, and playlists.

You do not want to specify the permissions that Elastic Transcoder grants to the files.

You want to associate the transcoded files and thumbnails
with the Amazon S3 Standard storage class.
If you want to save transcoded files and playlists in one bucket and thumbnails in another bucket, specify which users can access the transcoded files or the permissions the users have, or change the Amazon S3 storage class, omit OutputBucket and specify values for ContentConfig and ThumbnailConfig instead.

- **StorageClass** *(string)*

  The Amazon S3 storage class, *Standard* or *ReducedRedundancy*, that you want Elastic Transcoder to assign to the video files and playlists that it stores in your Amazon S3 bucket.

- **Permissions** *(list)*

  Optional. The Permissions object specifies which users and/or predefined Amazon S3 groups you want to have access to transcoded files and playlists, and the type of access you want them to have. You can grant permissions to a maximum of 30 users and/or predefined Amazon S3 groups.

  If you include Permissions, Elastic Transcoder grants only the permissions that you specify. It does not grant full permissions to the owner of the role specified by Role. If you want that user to have full control, you must explicitly grant full control to the user.

  If you omit Permissions, Elastic Transcoder grants full control over the transcoded files and playlists to the owner of the role specified by Role, and grants no other permissions to any other user or group.

- **(dict)**

  The Permission structure.

- **GranteeType** *(string)*

  The type of value that appears in the Grantee object:

  - **Canonical**: Either the canonical user ID for an AWS account or an origin access identity for an Amazon CloudFront distribution. .. warning::A canonical user ID is not the same as an AWS account number.
  - **Email**: The registered email address of an AWS account.
  - **Group**: One of the following predefined Amazon S3 groups: AllUsers, AuthenticatedUsers, or LogDelivery.

- **Grantee** *(string)*

  The AWS user or group that you want to have access to transcoded files and playlists. To identify the user or group, you can specify the canonical user ID for an AWS account, an origin access identity for a CloudFront distribution, the registered email address of an AWS account, or a predefined Amazon S3 group.

- **Access** *(list)*

  The permission that you want to give to the AWS user that is listed in Grantee. Valid values include:
- **READ**: The grantee can read the thumbnails and metadata for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
- **READ_ACP**: The grantee can read the object ACL for thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
- **WRITE_ACP**: The grantee can write the ACL for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.
- **FULL_CONTROL**: The grantee has **READ**, **READ_ACP**, and **WRITE_ACP** permissions for the thumbnails that Elastic Transcoder adds to the Amazon S3 bucket.

```
(string) –

- **NextToken** *(string)* –
  A token to resume pagination.
```

```python
class ElasticTranscoder.Paginator.ListPresets

paginator = client.get_paginator('list_presets')

paginate(**kwargs)

Creates an iterator that will paginate through responses from
ElasticTranscoder.Client.list_presets().

Request Syntax

```
response_iterator = paginator.paginate(
    Ascending='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **Ascending** *(string)* – To list presets in chronological order by the date and time
  that they were created, enter **true**. To list presets in reverse chronological
  order, enter **false**.
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagi-
  nation.
  - **MaxItems** *(integer)* –

    The total number of items to return. If the total number of items available
    is more than the value specified in **max-items** then a **NextToken** will be
    provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –

    The size of each page.
  - **StartingToken** *(string)* –

    A token to specify where to start paginating. This is the **NextToken**
    from a previous response.

Return type  **dict**

Returns

Response Syntax

```json
{
  'Presets': [

          'Resolution': 'string',
          'AspectRatio': 'string'
        }
      }
    }
  ]
}
```
Response Structure

- *(dict)* –
  The `ListPresetsResponse` structure.
  - **Presets** *(list)* –
    An array of `Preset` objects.
    - *(dict)* –
      Presets are templates that contain most of the settings for transcoding media files from one format to another. Elastic Transcoder includes some default presets for common formats, for example, several iPod and iPhone versions. You can also create your own presets for formats that aren’t included among the default presets. You specify which preset you want to use when you create a job.
        - **Id** *(string)* –
            Identifier for the new preset. You use this value to get settings for the preset or to delete it.
        - **Arn** *(string)* –
            The Amazon Resource Name (ARN) for the preset.
        - **Name** *(string)* –
            The name of the preset.
        - **Description** *(string)* –
            A description of the preset.
        - **Container** *(string)* –
            The container type for the output file. Valid values include `flac`, `flv`, `fmp4`, `gif`, `mp3`, `mp4`, `mpg`, `mxf`, `oga`, `ogg`, `ts`, and `webm`.
        - **Audio** *(dict)* –
            A section of the response body that provides information about the audio preset values.
            - **Codec** *(string)* –
                The audio codec for the output file. Valid values include `aac`, `flac`, `mp2`, `mp3`, `pcm`, and `vorbis`.
            - **SampleRate** *(string)* –
                The sample rate of the audio stream in the output file, in Hertz. Valid values include:
                `auto`, `22050`, `32000`, `44100`, `48000`, `96000`
                If you specify `auto`, Elastic Transcoder automatically detects the sample rate.
· **BitRate (string)** –
  The bit rate of the audio stream in the output file, in kilo-
  bits/second. Enter an integer between 64 and 320, inclusive.

· **Channels (string)** –
  The number of audio channels in the output file. The follow-
  ing values are valid:
  
  auto, 0, 1, 2

  One channel carries the information played by a single
  speaker. For example, a stereo track with two channels sends
  one channel to the left speaker, and the other channel to the
  right speaker. The output channels are organized into tracks.
  If you want Elastic Transcoder to automatically detect the
  number of audio channels in the input file and use that value
  for the output file, select *auto*.

  The output of a specific channel value and inputs are as fol-
  lows:
  
  · **auto channel specified, with any input**: Pass through up to
    eight input channels.
  
  · **0 channels specified, with any input**: Audio omitted from
    the output.
  
  · **1 channel specified, with at least one input channel**: Mono
    sound.
  
  · **2 channels specified, with any input**: Two identical mono
    channels or stereo. For more information about tracks, see
    `Audio:AudioPackingMode`

  For more information about how Elastic Transcoder organizes
  channels and tracks, see `Audio:AudioPackingMode`.

· **AudioPackingMode (string)** –
  The method of organizing audio channels and tracks. Use
  `Audio:Channels` to specify the number of channels in
  your output, and `Audio:AudioPackingMode` to specify
  the number of tracks and their relation to the channels. If you
  do not specify an `Audio:AudioPackingMode`, Elastic
  Transcoder uses **SingleTrack**.

  The following values are valid:

  *SingleTrack*, *OneChannelPerTrack*, and
  *OneChannelPerTrackWithMosTo8Tracks*

  When you specify **SingleTrack**, Elastic Transcoder cre-
  ates a single track for your output. The track can have up to
  eight channels. Use **SingleTrack** for all non-mxf contain-
  ers.

  The outputs of **SingleTrack** for a specific channel value
  and inputs are as follows:

  · **0 channels with any input**: Audio omitted from the output
  
  · **1, 2, or auto channels with no audio input**: Audio
    omitted from the output
  
  · **1 channel with any input with audio**: One track with one
    channel, downmixed if necessary
· 2 channels with one track with one channel: One track with two identical channels
· 2 or auto channels with two tracks with one channel each: One track with two channels
· 2 or auto channels with one track with two channels: One track with two channels
· 2 channels with one track with multiple channels: One track with two channels
· auto channels with one track with one channel: One track with one channel
· auto channels with one track with multiple channels: One track with multiple channels

When you specify OneChannelPerTrack, Elastic Transcoder creates a new track for every channel in your output. Your output can have up to eight single-channel tracks.

The outputs of OneChannelPerTrack for a specific channel value and inputs are as follows:
· 0 channels with any input: Audio omitted from the output
· 1, 2, or auto channels with no audio input: Audio omitted from the output
· 1 channel with any input with audio: One track with one channel, downmixed if necessary
· 2 channels with one track with one channel: Two tracks with one identical channel each
· 2 or auto channels with two tracks with one channel each: Two tracks with one channel each
· 2 or auto channels with one track with two channels: Two tracks with one channel each
· 2 channels with one track with multiple channels: Two tracks with one channel each
· auto channels with one track with multiple channels: One track with one channel
· auto channels with one track with multiple channels: Up to eight tracks with one channel each

When you specify OneChannelPerTrackWithMosTo8Tracks, Elastic Transcoder creates eight single-channel tracks for your output. All tracks that do not contain audio data from an input channel are MOS, or Mit Out Sound, tracks.

The outputs of OneChannelPerTrackWithMosTo8Tracks for a specific channel value and inputs are as follows:
· 0 channels with any input: Audio omitted from the output
· 1, 2, or auto channels with no audio input: Audio omitted from the output
· 1 channel with any input with audio: One track with one channel, downmixed if necessary, plus six MOS tracks
· 2 channels with one track with one channel: Two tracks with one identical channel each, plus six MOS tracks
· 2 or auto channels with two tracks with one channel each: Two tracks with one channel each, plus six MOS tracks
· 2 or auto channels with one track with two channels: Two tracks with one channel each, plus six MOS tracks
· 2 channels with one track with multiple channels: Two tracks with one channel each, plus six MOS tracks
· **auto channels with one track with one channel:** One track with one channel, plus seven MOS tracks
· **auto channels with one track with multiple channels:** Up to eight tracks with one channel each, plus MOS tracks until there are eight tracks in all

- **CodecOptions (dict)** –
  
  If you specified AAC for **Audio:Codec**, this is the AAC compression profile to use. Valid values include:

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto, AAC-LC, HE-AAC, HE-AACv2</td>
</tr>
</tbody>
</table>

  If you specify **auto**, Elastic Transcoder chooses a profile based on the bit rate of the output file.

- **Profile (string)** –

  You can only choose an audio profile when you specify AAC for the value of **Audio:Codec**.

  Specify the AAC profile for the output file. Elastic Transcoder supports the following profiles:

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto: If you specify <strong>auto</strong>, Elastic Transcoder will select the profile based on the bit rate selected for the output file.</td>
</tr>
<tr>
<td>AAC-LC: The most common AAC profile. Use for bit rates larger than 64 kbps.</td>
</tr>
<tr>
<td>HE-AAC: Not supported on some older players and devices. Use for bit rates between 40 and 80 kbps.</td>
</tr>
<tr>
<td>HE-AACv2: Not supported on some players and devices. Use for bit rates less than 48 kbps.</td>
</tr>
</tbody>
</table>

  All outputs in a **Smooth** playlist must have the same value for **Profile**.

  **Note:** If you created any presets before AAC profiles were added, Elastic Transcoder automatically updated your presets to use AAC-LC. You can change the value as required.

- **BitDepth (string)** –

  You can only choose an audio bit depth when you specify **flac** or **pcm** for the value of **Audio:Codec**.

  The bit depth of a sample is how many bits of information are included in the audio samples. The higher the bit depth, the better the audio, but the larger the file.

  Valid values are **16** and **24**.

  The most common bit depth is **24**.

- **BitOrder (string)** –

  You can only choose an audio bit order when you specify **pcm** for the value of **Audio:Codec**.

  The order the bits of a PCM sample are stored in.

  The supported value is **LittleEndian**.

- **Signed (string)** –

  You can only choose whether an audio sample is signed when you specify **pcm** for the value of **Audio:Codec**.
Whether audio samples are represented with negative and positive numbers (signed) or only positive numbers (unsigned).

The supported value is **Signed**.

- **Video (dict)** –
  
  A section of the response body that provides information about the video preset values.

- **Codec (string)** –
  
  The video codec for the output file. Valid values include **gif**, **H.264**, **mpeg2**, and **vp8**. You can only specify **vp8** when the container type is **webm**, **gif** when the container type is **gif**, and **mpeg2** when the container type is **mpg**.

- **CodecOptions (dict)** –

  - **Profile (H.264/VP8 Only)**
    
    The H.264 profile that you want to use for the output file. Elastic Transcoder supports the following profiles:
    - **baseline**: The profile most commonly used for videoconferencing and for mobile applications.
    - **main**: The profile used for standard-definition digital TV broadcasts.
    - **high**: The profile used for high-definition digital TV broadcasts and for Blu-ray discs.

  - **Level (H.264 Only)**
    
    The H.264 level that you want to use for the output file. Elastic Transcoder supports the following levels:
    
    1, 1b, 1.1, 1.2, 1.3, 2, 2.1, 2.2, 3, 3.1, 3.2, 4, 4, 1

  - **MaxReferenceFrames (H.264 Only)**
    
    Applicable only when the value of Video:Codec is H.264. The maximum number of previously decoded frames to use as a reference for decoding future frames. Valid values are integers 0 through 16, but we recommend that you not use a value greater than the following:
    
    \[
    \text{Min(Floor(Minimum decoded picture buffer in macroblocks * 256 / (Width in pixels * Height in pixels)), 16)}
    \]

    where **Width in pixels** and **Height in pixels** represent either MaxWidth and MaxHeight, or Resolution. **Maximum decoded picture buffer in macroblocks** depends on the value of the **Level** object. See the list below. (A macroblock is a block of pixels measuring 16x16.)

    - 1 - 396
    - 1b - 396
    - 1.1 - 900
    - 1.2 - 2376
    - 1.3 - 2376
    - 2 - 2376
    - 2.1 - 4752
    - 2.2 - 8100
    - 3 - 8100
MaxBitRate (Optional, H.264/MPEG2/VP8 only)

The maximum number of bits per second in a video buffer; the size of the buffer is specified by BufferSize. Specify a value between 16 and 62,500. You can reduce the bandwidth required to stream a video by reducing the maximum bit rate, but this also reduces the quality of the video.

BufferSize (Optional, H.264/MPEG2/VP8 only)

The maximum number of bits in any x seconds of the output video. This window is commonly 10 seconds, the standard segment duration when you’re using FMP4 or MPEG-TS for the container type of the output video. Specify an integer greater than 0. If you specify MaxBitRate and omit BufferSize, Elastic Transcoder sets BufferSize to 10 times the value of MaxBitRate.

InterlacedMode (Optional, H.264/MPEG2 Only)

The interlace mode for the output video.

Interlaced video is used to double the perceived frame rate for a video by interlacing two fields (one field on every other line, the other field on the other lines) so that the human eye registers multiple pictures per frame. Interlacing reduces the bandwidth required for transmitting a video, but can result in blurred images and flickering.

Valid values include Progressive (no interlacing, top to bottom), TopFirst (top field first), BottomFirst (bottom field first), and Auto.

If InterlaceMode is not specified, Elastic Transcoder uses Progressive for the output. If Auto is specified, Elastic Transcoder interlaces the output.

ColorSpaceConversionMode (Optional, H.264/MPEG2 Only)

The color space conversion Elastic Transcoder applies to the output video. Color spaces are the algorithms used by the computer to store information about how to render color. Bt.601 is the standard for standard definition video, while Bt.709 is the standard for high definition video.

Valid values include None, Bt709toBt601, Bt601toBt709, and Auto.

If you chose Auto for ColorSpaceConversionMode and your output is interlaced, your frame rate is one of 23.97, 24, 25, 29.97, 50, or 60, your SegmentDuration is null, and you are using one of the resolution changes from the list below, Elastic Transcoder applies the following color space conversions:
· Standard to HD, 720x480 to 1920x1080 - Elastic Transcoder applies Bt601ToBt709
· Standard to HD, 720x576 to 1920x1080 - Elastic Transcoder applies Bt601ToBt709
· HD to Standard, 1920x1080 to 720x480 - Elastic Transcoder applies Bt709ToBt601
· HD to Standard, 1920x1080 to 720x576 - Elastic Transcoder applies Bt709ToBt601

Note: Elastic Transcoder may change the behavior of the ColorSpaceConversionMode Auto mode in the future. All outputs in a playlist must use the same ColorSpaceConversionMode.

If you do not specify a ColorSpaceConversionMode, Elastic Transcoder does not change the color space of a file. If you are unsure what ColorSpaceConversionMode was applied to your output file, you can check the AppliedColorSpaceConversion parameter included in your job response. If your job does not have an AppliedColorSpaceConversion in its response, no ColorSpaceConversionMode was applied.

ChromaSubsampling
The sampling pattern for the chroma (color) channels of the output video. Valid values include yuv420p and yuv422p.

yuv420p samples the chroma information of every other horizontal and every other vertical line, yuv422p samples the color information of every horizontal line and every other vertical line.

LoopCount (Gif Only)
The number of times you want the output gif to loop. Valid values include Infinite and integers between 0 and 100, inclusive.
· (string) –
· (string) –
· KeyframesMaxDist (string) –

Applicable only when the value of Video:Codec is one of H.264, MPEG2, or VP8.

The maximum number of frames between key frames. Key frames are fully encoded frames; the frames between key frames are encoded based, in part, on the content of the key frames. The value is an integer formatted as a string; valid values are between 1 (every frame is a key frame) and 100000, inclusive. A higher value results in higher compression but may also discernibly decrease video quality.

For Smooth outputs, the FrameRate must have a constant ratio to the KeyframesMaxDist. This allows Smooth playlists to switch between different quality levels while the file is being played.

For example, an input file can have a FrameRate of 30 with a KeyframesMaxDist of 90. The output file then needs to
have a ratio of 1:3. Valid outputs would have FrameRate of 30, 25, and 10, and KeyframesMaxDist of 90, 75, and 30, respectively.

Alternately, this can be achieved by setting FrameRate to auto and having the same values for MaxFrameRate and KeyframesMaxDist.

- **FixedGOP (string)** –
  Applicable only when the value of Video:Codec is one of H.264, MPEG2, or VP8.
  Whether to use a fixed value for FixedGOP. Valid values are true and false:
  - true: Elastic Transcoder uses the value of KeyframesMaxDist for the distance between key frames (the number of frames in a group of pictures, or GOP).
  - false: The distance between key frames can vary.

  **Warning:** FixedGOP must be set to true for fmp4 containers.

- **BitRate (string)** –
  The bit rate of the video stream in the output file, in kilo-bits/second. Valid values depend on the values of Level and Profile. If you specify auto, Elastic Transcoder uses the detected bit rate of the input source. If you specify a value other than auto, we recommend that you specify a value less than or equal to the maximum H.264-compliant value listed for your level and profile:
  
  Level - Maximum video bit rate in kilobits/second
  (baseline and main Profile): maximum video bit rate in kilobits/second (high Profile)

  - 1 - 64 : 80
  - 1b - 128 : 160
  - 1.1 - 192 : 240
  - 1.2 - 384 : 480
  - 1.3 - 768 : 960
  - 2 - 2000 : 2500
  - 3 - 10000 : 12500
  - 3.1 - 14000 : 17500
  - 3.2 - 20000 : 25000
  - 4 - 20000 : 25000
  - 4.1 - 50000 : 62500

- **FrameRate (string)** –
  The frames per second for the video stream in the output file. Valid values include:
  
  auto, 10, 15, 23.97, 24, 25, 29.97, 30, 60

  If you specify auto, Elastic Transcoder uses the detected frame rate of the input source. If you specify a frame rate, we recommend that you perform the following calculation:
  
  Frame rate = maximum recommended decoding speed in luma
samples/second / (width in pixels * height in pixels)

where:

- `width in pixels` and `height in pixels` represent the Resolution of the output video.
- `maximum recommended decoding speed in Luma samples/second` is less than or equal to the maximum value listed in the following table, based on the value that you specified for Level.

The maximum recommended decoding speed in Luma samples/second for each level is described in the following list:

<table>
<thead>
<tr>
<th>Level</th>
<th>Decoding speed</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

- **MaxFrameRate (string)** –

If you specify `auto` for FrameRate, Elastic Transcoder uses the frame rate of the input video for the frame rate of the output video. Specify the maximum frame rate that you want Elastic Transcoder to use when the frame rate of the input video is greater than the desired maximum frame rate of the output video. Valid values include: 10, 15, 23.97, 24, 25, 29.97, 30, 60.

- **Resolution (string)** –

**Warning:** To better control resolution and aspect ratio of output videos, we recommend that you use the values MaxWidth, MaxHeight, SizingPolicy, PaddingPolicy, and DisplayAspectRatio instead of Resolution and AspectRatio. The two groups of settings are mutually exclusive. Do not use them together.

The width and height of the video in the output file, in pixels. Valid values are `auto` and `width x height`:

- `auto`: Elastic Transcoder attempts to preserve the width and height of the input file, subject to the following rules.
- `*width* x *height*`: The width and height of the output video in pixels.

Note the following about specifying the width and height:

- The width must be an even integer between 128 and 4096, inclusive.
- The height must be an even integer between 96 and 3072,
inclusive.

- If you specify a resolution that is less than the resolution of the input file, Elastic Transcoder rescales the output file to the lower resolution.
- If you specify a resolution that is greater than the resolution of the input file, Elastic Transcoder rescales the output to the higher resolution.
- We recommend that you specify a resolution for which the product of width and height is less than or equal to the applicable value in the following list (List\footnote{Max width x height value}):
  - 1 - 25344
  - 1b - 25344
  - 1.1 - 101376
  - 1.2 - 101376
  - 1.3 - 101376
  - 2 - 101376
  - 2.1 - 202752
  - 2.2 - 404720
  - 3 - 404720
  - 3.1 - 921600
  - 3.2 - 1310720
  - 4 - 2097152
  - 4.1 - 2097152

- \texttt{AspectRatio} (string) –

\begin{center}
\begin{tabular}{|l|}
\hline
\textbf{Warning:} To better control resolution and aspect ratio of output videos, we recommend that you use the values \texttt{MaxWidth}, \texttt{MaxHeight}, \texttt{SizingPolicy}, \texttt{PaddingPolicy}, and \texttt{DisplayAspectRatio} instead of \texttt{Resolution} and \texttt{AspectRatio}. The two groups of settings are mutually exclusive. Do not use them together. \\
\hline
\end{tabular}
\end{center}

The display aspect ratio of the video in the output file. Valid values include:

\texttt{auto}, 1:1, 4:3, 3:2, 16:9

If you specify \texttt{auto}, Elastic Transcoder tries to preserve the aspect ratio of the input file.

If you specify an aspect ratio for the output file that differs from aspect ratio of the input file, Elastic Transcoder adds pillarboxing (black bars on the sides) or letterboxing (black bars on the top and bottom) to maintain the aspect ratio of the active region of the video.

- \texttt{MaxWidth} (string) –

The maximum width of the output video in pixels. If you specify \texttt{auto}, Elastic Transcoder uses 1920 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 128 and 4096.

- \texttt{MaxHeight} (string) –

The maximum height of the output video in pixels. If you
specify `auto`, Elastic Transcoder uses 1080 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 96 and 3072.

- **DisplayAspectRatio** *(string)* –

  The value that Elastic Transcoder adds to the metadata in the output file.

- **SizingPolicy** *(string)* –

  Specify one of the following values to control scaling of the output video:
  - **Fit**: Elastic Transcoder scales the output video so it matches the value that you specified in either `MaxWidth` or `MaxHeight` without exceeding the other value.
  - **Fill**: Elastic Transcoder scales the output video so it matches the value that you specified in either `MaxWidth` or `MaxHeight` and matches or exceeds the other value. Elastic Transcoder centers the output video and then crops it in the dimension (if any) that exceeds the maximum value.
  - **Stretch**: Elastic Transcoder stretches the output video to match the values that you specified for `MaxWidth` and `MaxHeight`. If the relative proportions of the input video and the output video are different, the output video will be distorted.
  - **Keep**: Elastic Transcoder does not scale the output video. If either dimension of the input video exceeds the values that you specified for `MaxWidth` and `MaxHeight`, Elastic Transcoder crops the output video.
  - **ShrinkToFit**: Elastic Transcoder scales the output video down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without exceeding either value. If you specify this option, Elastic Transcoder does not scale the video up.
  - **ShrinkToFill**: Elastic Transcoder scales the output video down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without dropping below either value. If you specify this option, Elastic Transcoder does not scale the video up.

- **PaddingPolicy** *(string)* –

  When you set `PaddingPolicy` to `Pad`, Elastic Transcoder may add black bars to the top and bottom and/or left and right sides of the output video to make the total size of the output video match the values that you specified for `MaxWidth` and `MaxHeight`.

- **Watermarks** *(list)* –

  Settings for the size, location, and opacity of graphics that you want Elastic Transcoder to overlay over videos that are transcoded using this preset. You can specify settings for up to four watermarks. Watermarks appear in the specified size and location, and with the specified opacity for the duration of the transcoded video.

  Watermarks can be in `.png` or `.jpg` format. If you want to display a watermark that is not rectangular, use the `.png` format,
which supports transparency.

When you create a job that uses this preset, you specify the .png or .jpg graphics that you want Elastic Transcoder to include in the transcoded videos. You can specify fewer graphics in the job than you specify watermark settings in the preset, which allows you to use the same preset for up to four watermarks that have different dimensions.

- **(dict)** –

  Settings for the size, location, and opacity of graphics that you want Elastic Transcoder to overlay over videos that are transcoded using this preset. You can specify settings for up to four watermarks. Watermarks appear in the specified size and location, and with the specified opacity for the duration of the transcoded video.

  Watermarks can be in .png or .jpg format. If you want to display a watermark that is not rectangular, use the .png format, which supports transparency.

  When you create a job that uses this preset, you specify the .png or .jpg graphics that you want Elastic Transcoder to include in the transcoded videos. You can specify fewer graphics in the job than you specify watermark settings in the preset, which allows you to use the same preset for up to four watermarks that have different dimensions.

- **Id (string)** – A unique identifier for the settings for one watermark. The value of Id can be up to 40 characters long.

- **MaxWidth (string)** –

  The maximum width of the watermark in one of the following formats:

  - number of pixels (px): The minimum value is 16 pixels, and the maximum value is the value of MaxWidth.
  - integer percentage (%): The range of valid values is 0 to 100. Use the value of Target to specify whether you want Elastic Transcoder to include the black bars that are added by Elastic Transcoder, if any, in the calculation.

  If you specify the value in pixels, it must be less than or equal to the value of MaxWidth.

- **MaxHeight (string)** –

  The maximum height of the watermark in one of the following formats:

  - number of pixels (px): The minimum value is 16 pixels, and the maximum value is the value of MaxHeight.
  - integer percentage (%): The range of valid values is 0 to 100. Use the value of Target to specify whether you want Elastic Transcoder to include the black bars that are added by Elastic Transcoder, if any, in the calculation.

  If you specify the value in pixels, it must be less than or equal to the value of MaxHeight.

- **SizingPolicy (string)** –

  A value that controls scaling of the watermark:

  - **Fit**: Elastic Transcoder scales the watermark so it matches
the value that you specified in either `MaxWidth` or `MaxHeight` without exceeding the other value.

- **Stretch**: Elastic Transcoder stretches the watermark to match the values that you specified for `MaxWidth` and `MaxHeight`. If the relative proportions of the watermark and the values of `MaxWidth` and `MaxHeight` are different, the watermark will be distorted.

- **ShrinkToFit**: Elastic Transcoder scales the watermark down so that its dimensions match the values that you specified for at least one of `MaxWidth` and `MaxHeight` without exceeding either value. If you specify this option, Elastic Transcoder does not scale the watermark up.

- **HorizontalAlign** *(string)* –

  The horizontal position of the watermark unless you specify a non-zero value for `HorizontalOffset`:

  - **Left**: The left edge of the watermark is aligned with the left border of the video.
  - **Right**: The right edge of the watermark is aligned with the right border of the video.
  - **Center**: The watermark is centered between the left and right borders.

- **HorizontalOffset** *(string)* –

  The amount by which you want the horizontal position of the watermark to be offset from the position specified by `HorizontalAlign`:

  - number of pixels (px): The minimum value is 0 pixels, and the maximum value is the value of `MaxWidth`.
  - integer percentage (%): The range of valid values is 0 to 100. For example, if you specify Left for `HorizontalAlign` and 5px for `HorizontalOffset`, the left side of the watermark appears 5 pixels from the left border of the output video.

  `HorizontalOffset` is only valid when the value of `HorizontalAlign` is Left or Right. If you specify an offset that causes the watermark to extend beyond the left or right border and Elastic Transcoder has not added black bars, the watermark is cropped. If Elastic Transcoder has added black bars, the watermark extends into the black bars. If the watermark extends beyond the black bars, it is cropped.

  Use the value of `Target` to specify whether you want to include the black bars that are added by Elastic Transcoder, if any, in the offset calculation.

- **VerticalAlign** *(string)* –

  The vertical position of the watermark unless you specify a non-zero value for `VerticalOffset`:

  - **Top**: The top edge of the watermark is aligned with the top border of the video.
  - **Bottom**: The bottom edge of the watermark is aligned with the bottom border of the video.
  - **Center**: The watermark is centered between the top and bottom borders.
· **VerticalOffset** *(string)* – VerticalOffset

The amount by which you want the vertical position of the watermark to be offset from the position specified by VerticalAlign:

- number of pixels (px): The minimum value is 0 pixels, and the maximum value is the value of MaxHeight.
- integer percentage (%): The range of valid values is 0 to 100.
  For example, if you specify Top for VerticalAlign and 5px for VerticalOffset, the top of the watermark appears 5 pixels from the top border of the output video.

**VerticalOffset** is only valid when the value of VerticalAlign is Top or Bottom.

If you specify an offset that causes the watermark to extend beyond the top or bottom border and Elastic Transcoder has not added black bars, the watermark is cropped. If Elastic Transcoder has added black bars, the watermark extends into the black bars. If the watermark extends beyond the black bars, it is cropped.

Use the value of Target to specify whether you want Elastic Transcoder to include the black bars that are added by Elastic Transcoder, if any, in the offset calculation.

· **Opacity** *(string)* –

A percentage that indicates how much you want a watermark to obscure the video in the location where it appears. Valid values are 0 (the watermark is invisible) to 100 (the watermark completely obscures the video in the specified location). The datatype of Opacity is float.

Elastic Transcoder supports transparent .png graphics. If you use a transparent .png, the transparent portion of the video appears as if you had specified a value of 0 for Opacity. The .jpg file format doesn’t support transparency.

· **Target** *(string)* –

A value that determines how Elastic Transcoder interprets values that you specified for HorizontalOffset, VerticalOffset, MaxWidth, and MaxHeight:

- **Content** : HorizontalOffset and VerticalOffset values are calculated based on the borders of the video excluding black bars added by Elastic Transcoder, if any. In addition, MaxWidth and MaxHeight, if specified as a percentage, are calculated based on the borders of the video excluding black bars added by Elastic Transcoder, if any.

- **Frame** : HorizontalOffset and VerticalOffset values are calculated based on the borders of the video including black bars added by Elastic Transcoder, if any. In addition, MaxWidth and MaxHeight, if specified as a percentage, are calculated based on the borders of the video including black bars added by Elastic Transcoder, if any.

· **Thumbnails** *(dict)* –

A section of the response body that provides information about the thumbnail preset values, if any.
- **Format** *(string)* –
  The format of thumbnails, if any. Valid values are `jpg` and `png`.
  You specify whether you want Elastic Transcoder to create thumbnails when you create a job.

- **Interval** *(string)* –
  The approximate number of seconds between thumbnails. Specify an integer value.

- **Resolution** *(string)* –

  **Warning:** To better control resolution and aspect ratio of thumbnails, we recommend that you use the values `MaxWidth`, `MaxHeight`, `SizingPolicy`, and `PaddingPolicy` instead of `Resolution` and `AspectRatio`. The two groups of settings are mutually exclusive. Do not use them together.

  The width and height of thumbnail files in pixels. Specify a value in the format `*width* x *height*` where both values are even integers. The values cannot exceed the width and height that you specified in the `Video:Resolution` object.

- **AspectRatio** *(string)* –

  **Warning:** To better control resolution and aspect ratio of thumbnails, we recommend that you use the values `MaxWidth`, `MaxHeight`, `SizingPolicy`, and `PaddingPolicy` instead of `Resolution` and `AspectRatio`. The two groups of settings are mutually exclusive. Do not use them together.

  The aspect ratio of thumbnails. Valid values include:
  
  `auto`, `1:1`, `4:3`, `3:2`, `16:9`

  If you specify `auto`, Elastic Transcoder tries to preserve the aspect ratio of the video in the output file.

- **MaxWidth** *(string)* –
  The maximum width of thumbnails in pixels. If you specify `auto`, Elastic Transcoder uses 1920 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 32 and 4096.

- **MaxHeight** *(string)* –
  The maximum height of thumbnails in pixels. If you specify `auto`, Elastic Transcoder uses 1080 (Full HD) as the default value. If you specify a numeric value, enter an even integer between 32 and 3072.

- **SizingPolicy** *(string)* –
  Specify one of the following values to control scaling of thumbnails:
· **Fit**: Elastic Transcoder scales thumbnails so they match the value that you specified in thumbnail MaxWidth or MaxHeight settings without exceeding the other value.

· **Fill**: Elastic Transcoder scales thumbnails so they match the value that you specified in thumbnail MaxWidth or MaxHeight settings and matches or exceeds the other value. Elastic Transcoder centers the image in thumbnails and then crops in the dimension (if any) that exceeds the maximum value.

· **Stretch**: Elastic Transcoder stretches thumbnails to match the values that you specified for thumbnail MaxWidth and MaxHeight settings. If the relative proportions of the input video and thumbnails are different, the thumbnails will be distorted.

· **Keep**: Elastic Transcoder does not scale thumbnails. If either dimension of the input video exceeds the values that you specified for thumbnail MaxWidth and MaxHeight settings, Elastic Transcoder crops the thumbnails.

· **ShrinkToFit**: Elastic Transcoder scales thumbnails down so that their dimensions match the values that you specified for at least one of thumbnail MaxWidth and MaxHeight without exceeding either value. If you specify this option, Elastic Transcoder does not scale thumbnails up.

· **ShrinkToFill**: Elastic Transcoder scales thumbnails down so that their dimensions match the values that you specified for at least one of MaxWidth and MaxHeight without dropping below either value. If you specify this option, Elastic Transcoder does not scale thumbnails up.

· **PaddingPolicy** *(string)* –

When you set PaddingPolicy to Pad, Elastic Transcoder may add black bars to the top and bottom and/or left and right sides of thumbnails to make the total size of the thumbnails match the values that you specified for thumbnail MaxWidth and MaxHeight settings.

· **Type** *(string)* –

Whether the preset is a default preset provided by Elastic Transcoder (System) or a preset that you have defined (Custom).

- **NextToken** *(string)* –

A token to resume pagination.

### Waiters

The available waiters are:

- `ElasticTranscoder.Waiter.JobComplete`

```python
class ElasticTranscoder.Waiter.JobComplete

waiter = client.get_waiter('job_complete')
```
**wait(**kwargs)**

Polls `ElasticTranscoder.Client.read_job()` every 30 seconds until a successful state is reached. An error is returned after 120 failed checks.

**Request Syntax**

```python
waiter.wait(
  Id='string'
)
```

**Parameters**  
Id *(string)* – [REQUIRED]  
The identifier of the job for which you want to get detailed information.  

**Returns**  
None

**ElasticLoadBalancing**

**Table of Contents**

- ElasticLoadBalancing
  - Client
  - Paginators

**Client**

```python
import boto3

client = boto3.client('elb')
```

These are the available methods:

- `add_tags()`
- `apply_security_groups_to_load_balancer()`
- `attach_load_balancer_to_subnets()`
- `can_paginate()`
- `configure_health_check()`
- `create_app_cookie_stickiness_policy()`
- `create_lb_cookie_stickiness_policy()`
- `create_load_balancer()`
- `create_load_balancer_listeners()`
- `create_load_balancer_policy()`
- `delete_load_balancer()`
- `delete_load_balancer_listeners()`
- `delete_load_balancer_policy()`
- `deregister_instances_from_load_balancer()`
- `describe_instance_health()`
- `describe_load_balancer_attributes()`
- `describe_load_balancer_policies()`
- `describe_load_balancer_policy_types()`
- `describe_load_balancers()`
add_tags(**kwargs)

Adds the specified tags to the specified load balancer. Each load balancer can have a maximum of 10 tags. Each tag consists of a key and an optional value. If a tag with the same key is already associated with the load balancer, `AddTags` updates its value.

For more information, see Tag Your Load Balancer in the *Elastic Load Balancing Developer Guide*.

**Request Syntax**

```python
response = client.add_tags(
    LoadBalancerNames=[
        'string',
    ],
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

**Parameters**

- **LoadBalancerNames (list)** – [REQUIRED]
  
  The name of the load balancer. You can specify one load balancer only.
  
  - (string) –

- **Tags (list)** – [REQUIRED]

  The tags.
  
  - (dict) –

  Information about a tag.
  
  - **Key (string)** – [REQUIRED]
    
    The key of the tag.
  
  - **Value (string)** –

    The value of the tag.

**Return type** dict

**Returns**

**Response Syntax**

```python
{}
```

**Response Structure**
apply_security_groups_to_load_balancer(**kwargs)

Associates one or more security groups with your load balancer in a virtual private cloud (VPC). The specified security groups override the previously associated security groups.

For more information, see Security Groups for Load Balancers in a VPC in the Elastic Load Balancing Developer Guide.

Request Syntax

```
response = client.apply_security_groups_to_load_balancer(
    LoadBalancerName='string',
    SecurityGroups=[
        'string',
    ],
)
```

Parameters

- **LoadBalancerName (string)** – [REQUIRED]
  - The name of the load balancer.
- **SecurityGroups (list)** – [REQUIRED]
  - The IDs of the security groups to associate with the load balancer. Note that you cannot specify the name of the security group.
  - * (string) –

Return type  dict

Returns

Response Syntax

```
{
    'SecurityGroups': [
        'string',
    ]
}
```

Response Structure

- **(dict)** –
  - **SecurityGroups (list)** –
    - The IDs of the security groups associated with the load balancer.
    - * (string) –

attach_load_balancer_to_subnets(**kwargs)

Adds one or more subnets to the set of configured subnets for the specified load balancer.

The load balancer evenly distributes requests across all registered subnets. For more information, see Add or Remove Subnets for Your Load Balancer in a VPC in the Elastic Load Balancing Developer Guide.

Request Syntax

```
response = client.attach_load_balancer_to_subnets(
    LoadBalancerName='string',
    Subnets=[
        'string',
    ],
)
```
Parameters

- **LoadBalancerName** *(string) – [REQUIRED]*
  The name of the load balancer.
- **Subnets** *(list) – [REQUIRED]*
  The IDs of the subnets to add for the load balancer. You can add only one subnet per Availability Zone.
  - *(string) –

Return type  dict

Returns

Response Syntax

```
{
    'Subnets': [  
        'string',
    ]
}
```

Response Structure

- *(dict) –
  - **Subnets** *(list) –
    The IDs of the subnets attached to the load balancer.
    * *(string) –

`can_paginate` *(operation_name)*

Check if an operation can be paginated.

Parameters **operation_name** *(string) –* The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

Returns `True` if the operation can be paginated, `False` otherwise.

`configure_health_check` (**kwargs)**

Specifies the health check settings to use when evaluating the health state of your back-end instances.

For more information, see `Configure Health Checks` in the `Elastic Load Balancing Developer Guide` .

Request Syntax

```python
response = client.configure_health_check(
    LoadBalancerName='string',
    HealthCheck={
        'Target': 'string',
        'Interval': 123,
        'Timeout': 123,
        'UnhealthyThreshold': 123,
        'HealthyThreshold': 123
    }
)
```

Parameters

- **LoadBalancerName** *(string) – [REQUIRED]*
  The name of the load balancer.
• **HealthCheck (dict)** – **[REQUIRED]**

  The configuration information for the new health check.

  – **Target (string)** – **[REQUIRED]**

    The instance being checked. The protocol is either TCP, HTTP, HTTPS, or SSL. The range of valid ports is one (1) through 65535.

    TCP is the default, specified as a TCP: port pair, for example “TCP:5000”. In this case, a health check simply attempts to open a TCP connection to the instance on the specified port. Failure to connect within the configured timeout is considered unhealthy.

    SSL is also specified as SSL: port pair, for example, SSL:5000.

    For HTTP/HTTPS, you must include a ping path in the string. HTTP is specified as a HTTP:port://PathToPing; grouping, for example “HTTP:80/weather/us/wa/seattle”. In this case, a HTTP GET request is issued to the instance on the given port and path. Any answer other than “200 OK” within the timeout period is considered unhealthy.

    The total length of the HTTP ping target must be 1024 16-bit Unicode characters or less.

  – **Interval (integer)** – **[REQUIRED]**

    The approximate interval, in seconds, between health checks of an individual instance.

  – **Timeout (integer)** – **[REQUIRED]**

    The amount of time, in seconds, during which no response means a failed health check.

    This value must be less than the **Interval** value.

  – **UnhealthyThreshold (integer)** – **[REQUIRED]**

    The number of consecutive health check failures required before moving the instance to the **Unhealthy** state.

  – **HealthyThreshold (integer)** – **[REQUIRED]**

    The number of consecutive health checks successes required before moving the instance to the **Healthy** state.

**Return type** dict

**Returns**

**Response Syntax**

```
{  
    'HealthCheck': {  
        'Target': 'string',  
        'Interval': 123,  
        'Timeout': 123,  
        'UnhealthyThreshold': 123,  
        'HealthyThreshold': 123  
    }  
}
```

**Response Structure**

• (dict) –

  – **HealthCheck (dict)** –

    The updated health check.
**Target** *(string)* – 

The instance being checked. The protocol is either TCP, HTTP, HTTPS, or SSL. The range of valid ports is one (1) through 65535.

TCP is the default, specified as a TCP: port pair, for example “TCP:5000”. In this case, a health check simply attempts to open a TCP connection to the instance on the specified port. Failure to connect within the configured timeout is considered unhealthy.

SSL is also specified as SSL: port pair, for example, SSL:5000.

For HTTP/HTTPS, you must include a ping path in the string. HTTP is specified as a HTTP:port;/;PathToPing; grouping, for example “HTTP:80/weather/us/wa/seattle”. In this case, a HTTP GET request is issued to the instance on the given port and path. Any answer other than “200 OK” within the timeout period is considered unhealthy.

The total length of the HTTP ping target must be 1024 16-bit Unicode characters or less.

**Interval** *(integer)* – 

The approximate interval, in seconds, between health checks of an individual instance.

**Timeout** *(integer)* –

The amount of time, in seconds, during which no response means a failed health check.

This value must be less than the **Interval** value.

**UnhealthyThreshold** *(integer)* –

The number of consecutive health check failures required before moving the instance to the **Unhealthy** state.

**HealthyThreshold** *(integer)* –

The number of consecutive health checks successes required before moving the instance to the **Healthy** state.

---

**create_app_cookie_stickiness_policy** (**kwargs**)

Generates a stickiness policy with sticky session lifetimes that follow that of an application-generated cookie. This policy can be associated only with HTTP/HTTPS listeners.

This policy is similar to the policy created by CreateLBCookieStickinessPolicy, except that the lifetime of the special Elastic Load Balancing cookie, AWSELB, follows the lifetime of the application-generated cookie specified in the policy configuration. The load balancer only inserts a new stickiness cookie when the application response includes a new application cookie.

If the application cookie is explicitly removed or expires, the session stops being sticky until a new application cookie is issued.

For more information, see Application-Controlled Session Stickiness in the Elastic Load Balancing Developer Guide.

**Request Syntax**

```python
response = client.create_app_cookie_stickiness_policy(
    LoadBalancerName='string',
    PolicyName='string',
)
```
CookieName='string'
)

Parameters

- **LoadBalancerName** *(string)* – [REQUIRED]
  The name of the load balancer.

- **PolicyName** *(string)* – [REQUIRED]
  The name of the policy being created. This name must be unique within the set of policies for this load balancer.

- **CookieName** *(string)* – [REQUIRED]
  The name of the application cookie used for stickiness.

Return type  dict

Returns

Response Syntax

```
{}
```

Response Structure

- *(dict)* –

create_lb_cookie_stickiness_policy(**kwargs)**
Generates a stickiness policy with sticky session lifetimes controlled by the lifetime of the browser (user-agent) or a specified expiration period. This policy can be associated only with HTTP/HTTPS listeners.

When a load balancer implements this policy, the load balancer uses a special cookie to track the back-end server instance for each request. When the load balancer receives a request, it first checks to see if this cookie is present in the request. If so, the load balancer sends the request to the application server specified in the cookie. If not, the load balancer sends the request to a server that is chosen based on the existing load-balancing algorithm.

A cookie is inserted into the response for binding subsequent requests from the same user to that server. The validity of the cookie is based on the cookie expiration time, which is specified in the policy configuration.

For more information, see Duration-Based Session Stickiness in the Elastic Load Balancing Developer Guide.

Request Syntax

```python
response = client.create_lb_cookie_stickiness_policy(
    LoadBalancerName='string',
    PolicyName='string',
    CookieExpirationPeriod=123
)
```

Parameters

- **LoadBalancerName** *(string)* – [REQUIRED]
  The name of the load balancer.

- **PolicyName** *(string)* – [REQUIRED]
  The name of the policy being created. This name must be unique within the set of policies for this load balancer.

- **CookieExpirationPeriod** *(integer)* – The time period, in seconds, after which the cookie should be considered stale. If you do not specify this parameter, the sticky session lasts for the duration of the browser session.
Return type: dict

Returns:

Response Syntax

{}

Response Structure

- (dict) –

**create_load_balancer(**kwargs)

Creates a load balancer.

If the call completes successfully, a new load balancer is created with a unique Domain Name Service (DNS) name. The load balancer receives incoming traffic and routes it to the registered instances. For more information, see How Elastic Load Balancing Works in the *Elastic Load Balancing Developer Guide*.

You can create up to 20 load balancers per region per account. You can request an increase for the number of load balancers for your account. For more information, see Elastic Load Balancing Limits in the *Elastic Load Balancing Developer Guide*.

Request Syntax

```python
def create_load_balancer(**kwargs):
    response = client.create_load_balancer(
        LoadBalancerName='string',
        Listeners=[
            {'Protocol': 'string',
             'LoadBalancerPort': 123,
             'InstanceProtocol': 'string',
             'InstancePort': 123,
             'SSLCertificateId': 'string'},
        ],
        AvailabilityZones=[
            'string',
        ],
        Subnets=[
            'string',
        ],
        SecurityGroups=[
            'string',
        ],
        Scheme='string',
        Tags=[
            {'Key': 'string',
             'Value': 'string'},
        ],
    )
```

Parameters:

- **LoadBalancerName** *(string)* – [REQUIRED]

  The name of the load balancer.
This name must be unique within your AWS account, must have a maximum of 32 characters, must contain only alphanumeric characters or hyphens, and cannot begin or end with a hyphen.

- **Listeners** ([required])
  - The listeners.
  
  For more information, see Listeners for Your Load Balancer in the Elastic Load Balancing Developer Guide.
  - (dict) –

  Information about a listener.

  For information about the protocols and the ports supported by Elastic Load Balancing, see Listener Configurations for Elastic Load Balancing in the Elastic Load Balancing Developer Guide.
  - **Protocol** ([required])
    - The load balancer transport protocol to use for routing: HTTP, HTTPS, TCP, or SSL.
  - **LoadBalancerPort** ([required])
    - The port on which the load balancer is listening. The supported ports are: 25, 80, 443, 465, 587, and 1024-65535.
  - **InstanceProtocol**
    - The protocol to use for routing traffic to back-end instances: HTTP, HTTPS, TCP, or SSL.
    
    If the front-end protocol is HTTP, HTTPS, TCP, or SSL, `InstanceProtocol` must be at the same protocol.
    
    If there is another listener with the same `InstancePort` whose `InstanceProtocol` is secure, (HTTPS or SSL), the listener's `InstanceProtocol` must also be secure.
    
    If there is another listener with the same `InstancePort` whose `InstanceProtocol` is HTTP or TCP, the listener's `InstanceProtocol` must be HTTP or TCP.
  - **InstancePort** ([required])
    - The port on which the instance is listening.
  - **SSLCertificateId**
    - The Amazon Resource Name (ARN) of the server certificate.

- **AvailabilityZones** ([list]) – One or more Availability Zones from the same region as the load balancer. Traffic is equally distributed across all specified Availability Zones.

  You must specify at least one Availability Zone.

  You can add more Availability Zones after you create the load balancer using EnableAvailabilityZonesForLoadBalancer.
  - (string) –

- **Subnets** ([list]) – The IDs of the subnets in your VPC to attach to the load balancer. Specify one subnet per Availability Zone specified in AvailabilityZones.
  - (string) –

- **SecurityGroups** ([list]) – The IDs of the security groups to assign to the load balancer.
  - (string) –
• **Scheme** *(string)* – The type of a load balancer. Valid only for load balancers in a VPC.

By default, Elastic Load Balancing creates an Internet-facing load balancer with a publicly resolvable DNS name, which resolves to public IP addresses. For more information about Internet-facing and Internal load balancers, see Internet-facing and Internal Load Balancers in the *Elastic Load Balancing Developer Guide*.

Specify `internal` to create an internal load balancer with a DNS name that resolves to private IP addresses.

• **Tags** *(list)* – A list of tags to assign to the load balancer.

For more information about tagging your load balancer, see Tagging in the *Elastic Load Balancing Developer Guide*.

  – *(dict)* – Information about a tag.
    * **Key** *(string)* – [REQUIRED]
      The key of the tag.
    * **Value** *(string)* –
      The value of the tag.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
  'DNSName': 'string'
}
```

**Response Structure**

• *(dict)* –
  – **DNSName** *(string)* –
    The DNS name of the load balancer.

`create_load_balancer_listeners (**kwargs)`

Creates one or more listeners for the specified load balancer. If a listener with the specified port does not already exist, it is created; otherwise, the properties of the new listener must match the properties of the existing listener.

For more information, see Add a Listener to Your Load Balancer in the *Elastic Load Balancing Developer Guide*.

**Request Syntax**

```python
response = client.create_load_balancer_listeners(
  LoadBalancerName='string',
  Listeners=[
    {'Protocol': 'string',
     'LoadBalancerPort': 123,
     'InstanceProtocol': 'string',
     'InstancePort': 123,
     'SSLCertificateId': 'string'
    },
  ],
)```

2546 Chapter 3. API Reference
Parameters

- **LoadBalancerName (string)** – [REQUIRED]
  The name of the load balancer.

- **Listeners (list)** – [REQUIRED]
  The listeners.
  - *(dict)* –
    Information about a listener.

For information about the protocols and the ports supported by Elastic Load Balancing, see `Listener Configurations for Elastic Load Balancing` in the `Elastic Load Balancing Developer Guide`.

- **Protocol (string)** – [REQUIRED]
  The load balancer transport protocol to use for routing: HTTP, HTTPS, TCP, or SSL.

- **LoadBalancerPort (integer)** – [REQUIRED]
  The port on which the load balancer is listening. The supported ports are: 25, 80, 443, 465, 587, and 1024-65535.

- **InstanceProtocol (string)** –
  The protocol to use for routing traffic to back-end instances: HTTP, HTTPS, TCP, or SSL.

  If the front-end protocol is HTTP, HTTPS, TCP, or SSL, `InstanceProtocol` must be at the same protocol.

  If there is another listener with the same `InstancePort` whose `InstanceProtocol` is secure, (HTTPS or SSL), the listener's `InstanceProtocol` must also be secure.

  If there is another listener with the same `InstancePort` whose `InstanceProtocol` is HTTP or TCP, the listener's `InstanceProtocol` must be HTTP or TCP.

- **InstancePort (integer)** – [REQUIRED]
  The port on which the instance is listening.

- **SSLCertificateId (string)** –
  The Amazon Resource Name (ARN) of the server certificate.

Return type: dict

Response Syntax

```python
{}
```

Response Structure

- *(dict)* –

**create_load_balancer_policy(**kwargs**)**

Creates a policy with the specified attributes for the specified load balancer.

Policies are settings that are saved for your load balancer and that can be applied to the front-end listener or the back-end application server, depending on the policy type.
Request Syntax

```python
response = client.create_load_balancer_policy(
    LoadBalancerName='string',
    PolicyName='string',
    PolicyTypeName='string',
    PolicyAttributes=[
        {'AttributeName': 'string',
         'AttributeValue': 'string'},
    ],
)
```

Parameters

- **LoadBalancerName**(string) – [REQUIRED]
  The name of the load balancer.

- **PolicyName**(string) – [REQUIRED]
  The name of the load balancer policy to be created. This name must be unique within the set of policies for this load balancer.

- **PolicyTypeName**(string) – [REQUIRED]
  The name of the base policy type. To get the list of policy types, use DescribeLoadBalancerPolicyTypes.

- **PolicyAttributes**(list) – The attributes for the policy.
  - (dict) – Information about a policy attribute.
    * **AttributeName**(string) –
      The name of the attribute.
    * **AttributeValue**(string) –
      The value of the attribute.

Return type  dict
Returns

Response Syntax

```python
{}
```

Response Structure

- (dict) –
  
  **delete_load_balancer**(\**kwargs\)
  Deletes the specified load balancer.

  If you are attempting to recreate a load balancer, you must reconfigure all settings. The DNS name associated with a deleted load balancer are no longer usable. The name and associated DNS record of the deleted load balancer no longer exist and traffic sent to any of its IP addresses is no longer delivered to back-end instances.

  If the load balancer does not exist or has already been deleted, the call to **DeleteLoadBalancer** still succeeds.

Request Syntax
response = client.delete_load_balancer(
    LoadBalancerName='string'
)

Parameters  

LoadBalancerName (string) – [REQUIRED]
The name of the load balancer.

Return type  

dict

Returns

Response Syntax

{}

Response Structure

• (dict) –

delete_load_balancer_listeners (**kwargs)
Deletes the specified listeners from the specified load balancer.

Request Syntax

response = client.delete_load_balancer_listeners(
    LoadBalancerName='string',
    LoadBalancerPorts=[
        123,
    ],
)

Parameters

• LoadBalancerName (string) – [REQUIRED]
The name of the load balancer.

• LoadBalancerPorts (list) – [REQUIRED]
The client port numbers of the listeners.

  – (integer) –

Return type  

dict

Returns

Response Syntax

{}

Response Structure

• (dict) –

delete_load_balancer_policy (**kwargs)
Deletes the specified policy from the specified load balancer. This policy must not be enabled for any listeners.

Request Syntax

response = client.delete_load_balancer_policy(
    LoadBalancerName='string',
    PolicyName='string'
)

Parameters
- **LoadBalancerName** *(string)* – [REQUIRED]
  The name of the load balancer.
- **PolicyName** *(string)* – [REQUIRED]
  The name of the policy.

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{}
```

**Response Structure**

- *(dict)* –

```python
deregister_instances_from_load_balancer(**kwargs)
```

Deregisters the specified instances from the specified load balancer. After the instance is deregistered, it no longer receives traffic from the load balancer.

You can use DescribeLoadBalancers to verify that the instance is deregistered from the load balancer.

For more information, see Deregister and Register Amazon EC2 Instances in the *Elastic Load Balancing Developer Guide*.

**Request Syntax**

```python
response = client.deregister_instances_from_load_balancer(
    LoadBalancerName='string',
    Instances=[
        {'InstanceId': 'string'},
    ],
)
```

**Parameters**

- **LoadBalancerName** *(string)* – [REQUIRED]
  The name of the load balancer.
- **Instances** *(list)* – [REQUIRED]
  The IDs of the instances.
  - *(dict)* –
    The ID of a back-end instance.
    - **InstanceId** *(string)* –
      The ID of the instance.

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'Instances': [
        {'InstanceId': 'string'}
    ],
}
```
Response Structure
- (dict) –
  - **Instances** (list) –
    The remaining instances registered with the load balancer.
      * (dict) –
        The ID of a back-end instance.
          - **InstanceId** (string) –
            The ID of the instance.

describe_instance_health(**kwargs)
Describes the state of the specified instances registered with the specified load balancer. If no instances are specified, the call describes the state of all instances registered with the load balancer, not including any terminated instances.

Request Syntax
```python
response = client.describe_instance_health(
    LoadBalancerName='string',
    Instances=[
        {
            'InstanceId': 'string'
        },
    ]
)
```

Parameters
- **LoadBalancerName** (string) – [REQUIRED]
  The name of the load balancer.
- **Instances** (list) – The IDs of the instances.
  - (dict) –
    The ID of a back-end instance.
      - **InstanceId** (string) –
        The ID of the instance.

Return type
dict

Returns

Response Syntax
```python
{
    'InstanceStates': [
        {
            'InstanceId': 'string',
            'State': 'string',
            'ReasonCode': 'string',
            'Description': 'string'
        },
    ]
}
```

Response Structure
- (dict) –
  - **InstanceStates** (list) –
    Information about the health of the instances.
* (dict) –

Information about the state of a back-end instance.
- **InstanceId** *(string)* –
  The ID of the instance.
- **State** *(string)* –
  The current state of the instance.
  Valid values: InService | OutOfService | Unknown
- **ReasonCode** *(string)* –
  Information about the cause of OutOfService instances. Specifically, whether the cause is Elastic Load Balancing or the instance.
  Valid values: ELB | Instance | N/A
- **Description** *(string)* –
  A description of the instance state. This string can contain one or more of the following messages.
  - N/A
  - A transient error occurred. Please try again later.
  - Instance has failed at least the UnhealthyThreshold number of health checks consecutively.
  - Instance has not passed the configured HealthyThreshold number of health checks consecutively.
  - Instance registration is still in progress.
  - Instance is in the EC2 Availability Zone for which LoadBalancer is not configured to route traffic to.
  - Instance is not currently registered with the LoadBalancer.
  - Instance deregistration currently in progress.
  - Disable Availability Zone is currently in progress.
  - Instance is in pending state.
  - Instance is in stopped state.
  - Instance is in terminated state.

**describe_load_balancer_attributes(****kwargs**
)

Describes the attributes for the specified load balancer.

**Request Syntax**

```python
response = client.describe_load_balancer_attributes(
    LoadBalancerName='string'
)
```

**Parameters**  **LoadBalancerName** *(string)* – [REQUIRED]

The name of the load balancer.

**Return type**  dict
Returns

Response Syntax

```
{
    'LoadBalancerAttributes': {
        'CrossZoneLoadBalancing': {
            'Enabled': True|False
        },
        'AccessLog': {
            'Enabled': True|False,
            'S3BucketName': 'string',
            'EmitInterval': 123,
            'S3BucketPrefix': 'string'
        },
        'ConnectionDraining': {
            'Enabled': True|False,
            'Timeout': 123
        },
        'ConnectionSettings': {
            'IdleTimeout': 123
        },
        'AdditionalAttributes': [
            {
                'Key': 'string',
                'Value': 'string'
            }
        ]
    }
}
```

Response Structure

- (dict) –
  - **LoadBalancerAttributes** (dict) –
    Information about the load balancer attributes.
    - **CrossZoneLoadBalancing** (dict) –
      If enabled, the load balancer routes the request traffic evenly across all back-end instances regardless of the Availability Zones.
      For more information, see Enable Cross-Zone Load Balancing in the Elastic Load Balancing Developer Guide.
      - **Enabled** (boolean) –
        Specifies whether cross-zone load balancing is enabled for the load balancer.
    - **AccessLog** (dict) –
      If enabled, the load balancer captures detailed information of all requests and delivers the information to the Amazon S3 bucket that you specify.
      For more information, see Enable Access Logs in the Elastic Load Balancing Developer Guide.
      - **Enabled** (boolean) –
        Specifies whether access log is enabled for the load balancer.
      - **S3BucketName** (string) –

3.1. Services
The name of the Amazon S3 bucket where the access logs are stored.

- **EmitInterval** (integer)

  The interval for publishing the access logs. You can specify an interval of either 5 minutes or 60 minutes.

  Default: 60 minutes

- **S3BucketPrefix** (string)

  The logical hierarchy you created for your Amazon S3 bucket, for example `my-bucket-prefix/prod`. If the prefix is not provided, the log is placed at the root level of the bucket.

* **ConnectionDraining** (dict)

  If enabled, the load balancer allows existing requests to complete before the load balancer shifts traffic away from a deregistered or unhealthy back-end instance.

  For more information, see [Enable Connection Draining](#) in the Elastic Load Balancing Developer Guide.

  - **Enabled** (boolean)

    Specifies whether connection draining is enabled for the load balancer.

  - **Timeout** (integer)

    The maximum time, in seconds, to keep the existing connections open before deregistering the instances.

* **ConnectionSettings** (dict)

  If enabled, the load balancer allows the connections to remain idle (no data is sent over the connection) for the specified duration.

  By default, Elastic Load Balancing maintains a 60-second idle connection timeout for both front-end and back-end connections of your load balancer. For more information, see [Configure Idle Connection Timeout](#) in the Elastic Load Balancing Developer Guide.

  - **IdleTimeout** (integer)

    The time, in seconds, that the connection is allowed to be idle (no data has been sent over the connection) before it is closed by the load balancer.

* **AdditionalAttributes** (list)

  This parameter is reserved.

  - **(dict)**

    This data type is reserved.

  - **Key** (string)

    This parameter is reserved.

  - **Value** (string)

    This parameter is reserved.

### describe_load_balancer_policies (**kwargs)**

Describes the specified policies.

If you specify a load balancer name, the action returns the descriptions of all policies created for the load balancer. If you specify a policy name associated with your load balancer, the action returns the description of that policy. If you don’t specify a load balancer name, the action returns descriptions of the
specified sample policies, or descriptions of all sample policies. The names of the sample policies have the ELBSample- prefix.

**Request Syntax**

```python
response = client.describe_load_balancer_policies(
    LoadBalancerName='string',
    PolicyNames=[
        'string',
    ]
)
```

**Parameters**

- **LoadBalancerName** *(string)* – The name of the load balancer.
- **PolicyNames** *(list)* – The names of the policies.

**Return type** *dict*

**Returns**

**Response Syntax**

```json
{
    'PolicyDescriptions': [
        {
            'PolicyName': 'string',
            'PolicyTypeName': 'string',
            'PolicyAttributeDescriptions': [
                {
                    'AttributeName': 'string',
                    'AttributeValue': 'string'
                },
            ],
        },
    ]
}
```

**Response Structure**

- *(dict)* –
  - **PolicyDescriptions** *(list)* –
    
    Information about the policies.

- *(dict)* –
  
  Information about a policy.

  - **PolicyName** *(string)* –
    
    The name of the policy.

  - **PolicyTypeName** *(string)* –
    
    The name of the policy type.

  - **PolicyAttributeDescriptions** *(list)* –
    
    The policy attributes.

- *(dict)* –
  
  Information about a policy attribute.

  - **AttributeName** *(string)* –
    
    The name of the attribute.
- `AttributeValue (string)` –
  The value of the attribute.

**describe_load_balancer_policy_types (**kwargs**)
Describes the specified load balancer policy types.

You can use these policy types with CreateLoadBalancerPolicy to create policy configurations for a load balancer.

**Request Syntax**

```python
response = client.describe_load_balancer_policy_types(
    PolicyTypeNames=[
        'string',
    ]
)
```

**Parameters**
- `PolicyTypeNames (list)` – The names of the policy types. If no names are specified, describes all policy types defined by Elastic Load Balancing.

**Return type**
- `dict` –

**Returns**

**Response Syntax**

```python
{
    'PolicyTypeDescriptions': [
        {
            'PolicyTypeName': 'string',
            'Description': 'string',
            'PolicyAttributeTypeDescriptions': [
                {
                    'AttributeName': 'string',
                    'AttributeType': 'string',
                    'Description': 'string',
                    'DefaultValue': 'string',
                    'Cardinality': 'string'
                }
            ]
        }
    ]
}
```

**Response Structure**

- `(dict)` –
  - `PolicyTypeDescriptions (list)` –
    Information about the policy types.
    - `(dict)` –
      Information about a policy type.
      - `PolicyTypeName (string)` –
        The name of the policy type.
      - `Description (string)` –
        A description of the policy type.
      - `PolicyAttributeTypeDescriptions (list)` –
The description of the policy attributes associated with the policies defined by Elastic Load Balancing.

- (dict) –
  
  Information about a policy attribute type.
  
  - **AttributeName** (string) –
    
    The name of the attribute.
  
  - **AttributeType** (string) –
    
    The type of the attribute. For example, Boolean or Integer.
  
  - **Description** (string) –
    
    A description of the attribute.
  
  - **DefaultValue** (string) –
    
    The default value of the attribute, if applicable.
  
  - **Cardinality** (string) –
    
    The cardinality of the attribute.

Valid values:

- ONE(1) : Single value required
- ZERO_OR_ONE(0..1) : Up to one value can be supplied
- ZERO_OR_MORE(0..*) : Optional. Multiple values are allowed
- ONE_OR_MORE(1..*0) : Required. Multiple values are allowed

```python
describe_load_balancers(**kwargs)
```

Describes the specified the load balancers. If no load balancers are specified, the call describes all of your load balancers.

**Request Syntax**

```python
response = client.describe_load_balancers(
    LoadBalancerNames=[
        'string',
    ],
    Marker='string',
    PageSize=123
)
```

**Parameters**

- **LoadBalancerNames** (list) – The names of the load balancers.
  
  - (string) –
  
- **Marker** (string) – The marker for the next set of results. (You received this marker from a previous call.)

**PageSize** (integer) – The maximum number of results to return with this call (a number from 1 to 400). The default is 400.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'LoadBalancerDescriptions': [
    
```
'LoadBalancerName': 'string',
'DNSName': 'string',
'CanonicalHostedZoneName': 'string',
'CanonicalHostedZoneNameID': 'string',

},

'NextMarker': 'string'

**Response Structure**

- *(dict)* –
  - **LoadBalancerDescriptions** *(list)* –
    Information about the load balancers.
      - *(dict)* –
        Information about a load balancer.
          - **LoadBalancerName** *(string)* –
            The name of the load balancer.
          - **DNSName** *(string)* –
            The external DNS name of the load balancer.
          - **CanonicalHostedZoneName** *(string)* –
            The Amazon Route 53 hosted zone associated with the load balancer.
            For more information, see Using Domain Names With Elastic Load Balancing in the Elastic Load Balancing Developer Guide.
          - **CanonicalHostedZoneNameID** *(string)* –
            The ID of the Amazon Route 53 hosted zone name associated with the load balancer.
          - **ListenerDescriptions** *(list)* –
            The listeners for the load balancer.
              - *(dict)* –
                The policies enabled for a listener.
              - **Listener** *(dict)* –
                Information about a listener.

For information about the protocols and the ports supported by Elastic Load Balancing, see Listener Configurations for Elastic Load Balancing in the Elastic Load Balancing Developer Guide.

- **Protocol** *(string)* –
The load balancer transport protocol to use for routing: HTTP, HTTPS, TCP, or SSL.

- **LoadBalancerPort** *(integer)*

  The port on which the load balancer is listening. The supported ports are: 25, 80, 443, 465, 587, and 1024-65535.

- **InstanceProtocol** *(string)*

  The protocol to use for routing traffic to back-end instances: HTTP, HTTPS, TCP, or SSL.
  
  If the front-end protocol is HTTP, HTTPS, TCP, or SSL, **InstanceProtocol** must be at the same protocol.
  
  If there is another listener with the same **InstancePort** whose **InstanceProtocol** is secure, (HTTPS or SSL), the listener’s **InstanceProtocol** must also be secure.
  
  If there is another listener with the same **InstancePort** whose **InstanceProtocol** is HTTP or TCP, the listener’s **InstanceProtocol** must be HTTP or TCP.

- **InstancePort** *(integer)*

  The port on which the instance is listening.

- **SSLCertificateId** *(string)*

  The Amazon Resource Name (ARN) of the server certificate.

- **PolicyNames** *(list)*

  The policies. If there are no policies enabled, the list is empty.

- **Policies** *(dict)*

  Information about a policy for application-controlled session stickiness.

  - **PolicyName** *(string)*

    The mnemonic name for the policy being created. The name must be unique within a set of policies for this load balancer.

  - **CookieName** *(string)*

    The name of the application cookie used for stickiness.

- **LBCookieStickinessPolicies** *(list)*

  The stickiness policies created using CreateLCookieStickinessPolicy.

  *(dict)*

  Information about a policy for duration-based session stickiness.

  - **PolicyName** *(string)*

    The name for the policy being created. The name must be unique within the set of policies for this load balancer.
· **CookieExpirationPeriod** *(integer)* –
  The time period, in seconds, after which the cookie should be considered stale. If this parameter is not specified, the stickiness session lasts for the duration of the browser session.

· **OtherPolicies** *(list)* –
  The policies other than the stickiness policies.
  *(string)* –

· **BackendServerDescriptions** *(list)* –
  Information about the back-end servers.
  *(dict)* –
  Information about the configuration of a back-end server.

· **InstancePort** *(integer)* –
  The port on which the back-end server is listening.

· **PolicyNames** *(list)* –
  The names of the policies enabled for the back-end server.
  *(string)* –

· **AvailabilityZones** *(list)* –
  The Availability Zones for the load balancer.
  *(string)* –

· **Subnets** *(list)* –
  The IDs of the subnets for the load balancer.
  *(string)* –

· **VPCId** *(string)* –
  The ID of the VPC for the load balancer.

· **Instances** *(list)* –
  The IDs of the instances for the load balancer.
  *(dict)* –
  The ID of a back-end instance.

· **InstanceId** *(string)* –
  The ID of the instance.

· **HealthCheck** *(dict)* –
  Information about the health checks conducted on the load balancer.

· **Target** *(string)* –
  The instance being checked. The protocol is either TCP, HTTP, HTTPS, or SSL. The range of valid ports is one (1) through 65535.

TCP is the default, specified as a TCP: port pair, for example “TCP:5000”. In this case, a health check simply attempts to open a TCP connection to the instance on the specified port. Failure to connect within the configured timeout is considered unhealthy.

SSL is also specified as SSL: port pair, for example, SSL:5000.
For HTTP/HTTPS, you must include a ping path in the string. HTTP is specified as a HTTP:port:/PathToPing: grouping, for example “HTTP:80/weather/us/wa/seattle”. In this case, a HTTP GET request is issued to the instance on the given port and path. Any answer other than “200 OK” within the timeout period is considered unhealthy.

The total length of the HTTP ping target must be 1024 16-bit Unicode characters or less.

- **Interval (integer)** –
  The approximate interval, in seconds, between health checks of an individual instance.

- **Timeout (integer)** –
  The amount of time, in seconds, during which no response means a failed health check.

  This value must be less than the Interval value.

- **UnhealthyThreshold (integer)** –
  The number of consecutive health check failures required before moving the instance to the Unhealthy state.

- **HealthyThreshold (integer)** –
  The number of consecutive health checks successes required before moving the instance to the Healthy state.

- **SourceSecurityGroup (dict)** –
  The security group that you can use as part of your inbound rules for your load balancer’s back-end application instances. To only allow traffic from load balancers, add a security group rule to your back end instance that specifies this source security group as the inbound source.

- **OwnerAlias (string)** –
  The owner of the security group.

- **GroupName (string)** –
  The name of the security group.

- **SecurityGroups (list)** –
  The security groups for the load balancer. Valid only for load balancers in a VPC.

- **CreatedTime (datetime)** –
  The date and time the load balancer was created.

- **Scheme (string)** –
  The type of load balancer. Valid only for load balancers in a VPC.

  If Scheme is internet-facing, the load balancer has a public DNS name that resolves to a public IP address.

  If Scheme is internal, the load balancer has a public DNS name that resolves to a private IP address.

- **NextMarker (string)** –
The marker to use when requesting the next set of results. If there are no additional results, the string is empty.

```python
describe_tags(**kwargs)
```

Describes the tags associated with the specified load balancers.

**Request Syntax**

```python
response = client.describe_tags(
    LoadBalancerNames=[
        'string',
    ]
)
```

**Parameters**

- **LoadBalancerNames (list)** – [REQUIRED]
  The names of the load balancers.

**Return type**

- **dict** –

**Returns**

**Response Syntax**

```python
{
    'TagDescriptions': [
        {
            'LoadBalancerName': 'string',
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                },
            ],
        },
    ]
}
```

**Response Structure**

- **(dict)** –
  - **TagDescriptions (list)** –
    Information about the tags.
    - **(dict)** –
      The tags associated with a load balancer.
      - **LoadBalancerName (string)** –
        The name of the load balancer.
      - **Tags (list)** –
        The tags.
      - **(dict)** –
        Information about a tag.
      - **Key (string)** –
        The key of the tag.
      - **Value (string)** –
        The value of the tag.
**detach_load_balancer_from_subnets** (**kwargs)**

Removes the specified subnets from the set of configured subnets for the load balancer.

After a subnet is removed, all EC2 instances registered with the load balancer in the removed subnet go into the `OutOfService` state. Then, the load balancer balances the traffic among the remaining routable subnets.

**Request Syntax**

```python
response = client.detach_load_balancer_from_subnets(
    LoadBalancerName='string',
    Subnets=['string'],
)
```

**Parameters**

- **LoadBalancerName (string)** – [REQUIRED]
  
  The name of the load balancer.

- **Subnets (list)** – [REQUIRED]
  
  The IDs of the subnets.

  - (string) –

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'Subnets': ['string'],
}
```

**Response Structure**

- (dict) –
  
  - **Subnets (list)** –
    
    The IDs of the remaining subnets for the load balancer.

  - (string) –

**disable_availability_zones_for_load_balancer** (**kwargs**)

Removes the specified Availability Zones from the set of Availability Zones for the specified load balancer.

There must be at least one Availability Zone registered with a load balancer at all times. After an Availability Zone is removed, all instances registered with the load balancer that are in the removed Availability Zone go into the `OutOfService` state. Then, the load balancer attempts to equally balance the traffic among its remaining Availability Zones.

For more information, see Disable an Availability Zone from a Load-Balanced Application in the Elastic Load Balancing Developer Guide.

**Request Syntax**

```python
response = client.disable_availability_zones_for_load_balancer(
    LoadBalancerName='string',
    AvailabilityZones=['string'],
)
```
Parameters

- **LoadBalancerName** (*string*) – [REQUIRED]
The name of the load balancer.
- **AvailabilityZones** (*list*) – [REQUIRED]
The Availability Zones.
  - (*string*) –

Return type: dict

Returns

Response Syntax

```python
{
    'AvailabilityZones': [
        'string',
    ]
}
```

Response Structure

- (*dict*) –
  - **AvailabilityZones** (*list*) –
    The remaining Availability Zones for the load balancer.
    - (*string*) –

`enable_availability_zones_for_load_balancer(**kwargs)`

Adds the specified Availability Zones to the set of Availability Zones for the specified load balancer.

The load balancer evenly distributes requests across all its registered Availability Zones that contain instances.

For more information, see Add Availability Zone in the Elastic Load Balancing Developer Guide.

Request Syntax

```python
response = client.enable_availability_zones_for_load_balancer(
    LoadBalancerName='string',
    AvailabilityZones=['string',
                      'string',
    ]
)
```

Parameters

- **LoadBalancerName** (*string*) – [REQUIRED]
The name of the load balancer.
- **AvailabilityZones** (*list*) – [REQUIRED]
The Availability Zones. These must be in the same region as the load balancer.
  - (*string*) –

Return type: dict

Returns

Response Syntax
Response Structure
• (dict) –
  – AvailabilityZones (list) –
    The updated list of Availability Zones for the load balancer.
  * (string) –

generate_presigned_url (ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)
Generate a presigned url given a client, its method, and arguments

Parameters
• ClientMethod (string) – The client method to presign for
• Params (dict) – The parameters normally passed to ClientMethod.
• ExpiresIn (int) – The number of seconds the presigned url is valid for. By
default it expires in an hour (3600 seconds)
• HttpMethod (string) – The http method to use on the generated url. By default,
  the http method is whatever is used in the method’s model.

Returns The presigned url

get_paginator (operation_name)
Create a paginator for an operation.

Parameters operation_name (string) – The operation name. This is the same name as
the method name on the client. For example, if the method name is create_foo,
and you’d normally invoke the operation as client.create_foo(**kwargs),
if the create_foo operation can be paginated, you can use the call
client.get_paginator("create_foo").

Raises OperationNotPageableError Raised if the operation is not pageable. You can use
the client.can_paginate method to check if an operation is pageable.

Return type L{botocore.paginate.Paginator}

Returns A paginator object.

get_waiter (waiter_name)

modify_load_balancer_attributes (**kwargs)
Modifies the attributes of the specified load balancer.

You can modify the load balancer attributes, such as AccessLogs, ConnectionDraining, and
CrossZoneLoadBalancing by either enabling or disabling them. Or, you can modify the load bal-
cancer attribute ConnectionSettings by specifying an idle connection timeout value for your load
balancer.

For more information, see the following in the Elastic Load Balancing Developer Guide :
• Cross-Zone Load Balancing
• Connection Draining
• Access Logs
• Idle Connection Timeout

Request Syntax

response = client.modify_load_balancer_attributes(
    LoadBalancerName='string',
    LoadBalancerAttributes={
        'CrossZoneLoadBalancing': {
            'Enabled': True|False
        }
    }
)
{'AccessLog': {
    'Enabled': True|False,
    'S3BucketName': 'string',
    'EmitInterval': 123,
    'S3BucketPrefix': 'string'
},
'ConnectionDraining': {
    'Enabled': True|False,
    'Timeout': 123
},
'ConnectionSettings': {
    'IdleTimeout': 123
},
'AdditionalAttributes': [
    {
        'Key': 'string',
        'Value': 'string'
    }
]}

Parameters

- **LoadBalancerName** *(string)* – [REQUIRED]
  
The name of the load balancer.
- **LoadBalancerAttributes** *(dict)* – [REQUIRED]
  
The attributes of the load balancer.
  - **CrossZoneLoadBalancing** *(dict)* –
    
    If enabled, the load balancer routes the request traffic evenly across all back-end instances regardless of the Availability Zones.

    For more information, see Enable Cross-Zone Load Balancing in the Elastic Load Balancing Developer Guide.

    - **Enabled** *(boolean)* – [REQUIRED]
      
      Specifies whether cross-zone load balancing is enabled for the load balancer.

    - **AccessLog** *(dict)* –
      
      If enabled, the load balancer captures detailed information of all requests and delivers the information to the Amazon S3 bucket that you specify.

      For more information, see Enable Access Logs in the Elastic Load Balancing Developer Guide.

      - **Enabled** *(boolean)* – [REQUIRED]
        
        Specifies whether access log is enabled for the load balancer.

      - **S3BucketName** *(string)* –
        
        The name of the Amazon S3 bucket where the access logs are stored.

      - **EmitInterval** *(integer)* –
        
        The interval for publishing the access logs. You can specify an interval of either 5 minutes or 60 minutes.

        Default: 60 minutes
S3BucketPrefix (string) –

The logical hierarchy you created for your Amazon S3 bucket, for example my-bucket-prefix/prod. If the prefix is not provided, the log is placed at the root level of the bucket.

ConnectionDraining (dict) –

If enabled, the load balancer allows existing requests to complete before the load balancer shifts traffic away from a deregistered or unhealthy backend instance.

For more information, see Enable Connection Draining in the Elastic Load Balancing Developer Guide.

* Enabled (boolean) – [REQUIRED]

Specifies whether connection draining is enabled for the load balancer.

* Timeout (integer) –

The maximum time, in seconds, to keep the existing connections open before deregistering the instances.

ConnectionSettings (dict) –

If enabled, the load balancer allows the connections to remain idle (no data is sent over the connection) for the specified duration.

By default, Elastic Load Balancing maintains a 60-second idle connection timeout for both front-end and back-end connections of your load balancer. For more information, see Configure Idle Connection Timeout in the Elastic Load Balancing Developer Guide.

* IdleTimeout (integer) – [REQUIRED]

The time, in seconds, that the connection is allowed to be idle (no data has been sent over the connection) before it is closed by the load balancer.

AdditionalAttributes (list) –

This parameter is reserved.

* (dict) –

This data type is reserved.

  - Key (string) –

    This parameter is reserved.

  - Value (string) –

    This parameter is reserved.

Return type  dict

Response Syntax

```json
{
    'LoadBalancerName': 'string',
    'LoadBalancerAttributes': {
        'CrossZoneLoadBalancing': { 'Enabled': True|False },
        'AccessLog': { 'Enabled': True|False, 'S3BucketName': 'string',
```
Response Structure

- LoadBalancerName (string) –
  The name of the load balancer.
- LoadBalancerAttributes (dict) –
  The attributes for a load balancer.
  * CrossZoneLoadBalancing (dict) –
    If enabled, the load balancer routes the request traffic evenly across all back-end instances regardless of the Availability Zones.
    For more information, see Enable Cross-Zone Load Balancing in the Elastic Load Balancing Developer Guide .
    - Enabled (boolean) –
      Specifies whether cross-zone load balancing is enabled for the load balancer.
  * AccessLog (dict) –
    If enabled, the load balancer captures detailed information of all requests and delivers the information to the Amazon S3 bucket that you specify.
    For more information, see Enable Access Logs in the Elastic Load Balancing Developer Guide .
    - Enabled (boolean) –
      Specifies whether access log is enabled for the load balancer.
    - S3BucketName (string) –
      The name of the Amazon S3 bucket where the access logs are stored.
    - EmitInterval (integer) –
      The interval for publishing the access logs. You can specify an interval of either 5 minutes or 60 minutes.
      Default: 60 minutes
    - S3BucketPrefix (string) –

```json
{
    'EmitInterval': 123,
    'S3BucketPrefix': 'string'
},
'S3BucketName': 'string',
'ConnectionDraining': {
    'Enabled': True|False,
    'Timeout': 123
},
'ConnectionSettings': {
    'IdleTimeout': 123
},
'AdditionalAttributes': [
    {
        'Key': 'string',
        'Value': 'string'
    }
}
}
The logical hierarchy you created for your Amazon S3 bucket, for example my-bucket-prefix/prod. If the prefix is not provided, the log is placed at the root level of the bucket.

* ConnectionDraining (dict) –

If enabled, the load balancer allows existing requests to complete before the load balancer shifts traffic away from a deregistered or unhealthy back-end instance.

For more information, see Enable Connection Draining in the Elastic Load Balancing Developer Guide.

- **Enabled** (boolean) –
  Specifies whether connection draining is enabled for the load balancer.
- **Timeout** (integer) –
  The maximum time, in seconds, to keep the existing connections open before deregistering the instances.

* ConnectionSettings (dict) –

If enabled, the load balancer allows the connections to remain idle (no data is sent over the connection) for the specified duration.

By default, Elastic Load Balancing maintains a 60-second idle connection timeout for both front-end and back-end connections of your load balancer. For more information, see Configure Idle Connection Timeout in the Elastic Load Balancing Developer Guide.

- **IdleTimeout** (integer) –
  The time, in seconds, that the connection is allowed to be idle (no data has been sent over the connection) before it is closed by the load balancer.

* AdditionalAttributes (list) –

This parameter is reserved.

- (dict) –
  This data type is reserved.
- **Key** (string) –
  This parameter is reserved.
- **Value** (string) –
  This parameter is reserved.

**register_instances_with_load_balancer(**

`register_instances_with_load_balancer(**kwargs)` adds the specified instances to the specified load balancer.

The instance must be a running instance in the same network as the load balancer (EC2-Classic or the same VPC). If you have EC2-Classic instances and a load balancer in a VPC with ClassicLink enabled, you can link the EC2-Classic instances to that VPC and then register the linked EC2-Classic instances with the load balancer in the VPC.

Note that `register_instance_with_load_balancer` completes when the request has been registered. Instance registration happens shortly afterwards. To check the state of the registered instances, use `describe_load_balancers` or `describe_instance_health`.

After the instance is registered, it starts receiving traffic and requests from the load balancer. Any instance that is not in one of the Availability Zones registered for the load balancer is moved to the
OutOfService state. If an Availability Zone is added to the load balancer later, any instances registered with the load balancer move to the InService state.

If you stop an instance registered with a load balancer and then start it, the IP addresses associated with the instance changes. Elastic Load Balancing cannot recognize the new IP address, which prevents it from routing traffic to the instances. We recommend that you use the following sequence: stop the instance, deregister the instance, start the instance, and then register the instance. To deregister instances from a load balancer, use DeregisterInstancesFromLoadBalancer.

For more information, see Deregister and Register EC2 Instances in the Elastic Load Balancing Developer Guide.

Request Syntax

```python
response = client.register_instances_with_load_balancer(
    LoadBalancerName='string',
    Instances=[
        {
            'InstanceId': 'string'
        },
    ]
)
```

Parameters

- **LoadBalancerName** (*string*) – [REQUIRED]
  The name of the load balancer.
- **Instances** (*list*) – [REQUIRED]
  The IDs of the instances.
  - *(dict)* –
    The ID of a back-end instance.
    - **InstanceId** (*string*) –
      The ID of the instance.

Return type  *dict*

Returns

Response Syntax

```python
{
    'Instances': [
        {
            'InstanceId': 'string'
        },
    ]
}
```

Response Structure

- *(dict)* –
  - **Instances** (*list*) –
    The updated list of instances for the load balancer.
    - *(dict)* –
      The ID of a back-end instance.
      - **InstanceId** (*string*) –
        The ID of the instance.
**remove_tags**(**kwargs**)

Removes one or more tags from the specified load balancer.

**Request Syntax**

```python
response = client.remove_tags(
    LoadBalancerNames=[
        'string',
    ],
    Tags=[
        {
            'Key': 'string'
        },
    ]
)
```

**Parameters**

- **LoadBalancerNames** (*list*) – [REQUIRED]
  
  The name of the load balancer. You can specify a maximum of one load balancer name.
  
  - * (string) –

- **Tags** (*list*) – [REQUIRED]
  
  The list of tag keys to remove.
  
  - * (dict) –
    
    The key of a tag.
    
    * **Key** (*string*) –
      
      The name of the key.

**Return type** dict

**Returns**

**Response Syntax**

```python
{}
```

**Response Structure**

- * (dict) –

**set_load_balancer_listener_ssl_certificate**(**kwargs**)

Sets the certificate that terminates the specified listener’s SSL connections. The specified certificate replaces any prior certificate that was used on the same load balancer and port.

For more information about updating your SSL certificate, see [Updating an SSL Certificate for a Load Balancer](Elastic Load Balancing Developer Guide).

**Request Syntax**

```python
response = client.set_load_balancer_listener_ssl_certificate(
    LoadBalancerName='string',
    LoadBalancerPort=123,
    SSLCertificateId='string'
)
```

**Parameters**

- **LoadBalancerName** (*string*) – [REQUIRED]
  
  The name of the load balancer.
• **LoadBalancerPort** (*integer*) – [REQUIRED]
  The port that uses the specified SSL certificate.

• **SSLCertificateId** (*string*) – [REQUIRED]
  The Amazon Resource Name (ARN) of the SSL certificate.

---

**Return type**
dict

**Returns**

**Response Syntax**

```{}
```

**Response Structure**

* (dict) –

`set_load_balancer_policies_for_backend_server(**kwargs)`

Replaces the set of policies associated with the specified port on which the back-end server is listening with a new set of policies. At this time, only the back-end server authentication policy type can be applied to the back-end ports; this policy type is composed of multiple public key policies.

Each time you use `SetLoadBalancerPoliciesForBackendServer` to enable the policies, use the `PolicyNames` parameter to list the policies that you want to enable.

You can use `DescribeLoadBalancers` or `DescribeLoadBalancerPolicies` to verify that the policy is associated with the back-end server.

**Request Syntax**

```python
response = client.set_load_balancer_policies_for_backend_server(
    LoadBalancerName='string',
    InstancePort=123,
    PolicyNames=[
        'string',
    ]
)
```

**Parameters**

* **LoadBalancerName** (*string*) – [REQUIRED]
  The name of the load balancer.

* **InstancePort** (*integer*) – [REQUIRED]
  The port number associated with the back-end server.

* **PolicyNames** (*list*) – [REQUIRED]
  The names of the policies. If the list is empty, then all current polices are removed from the back-end server.

---

**Return type**
dict

**Returns**

**Response Syntax**

```{}
```

**Response Structure**

* (dict) –
set_load_balancer_policies_of_listener(**kwargs)
Associates, updates, or disables a policy with a listener for the specified load balancer. You can associate multiple policies with a listener.

Request Syntax

response = client.set_load_balancer_policies_of_listener(
    LoadBalancerName='string',
    LoadBalancerPort=123,
    PolicyNames=['string',
                 ]
)

Parameters

- **LoadBalancerName** *(string)* – [REQUIRED]
The name of the load balancer.
- **LoadBalancerPort** *(integer)* – [REQUIRED]
The external port of the load balancer for the policy.
- **PolicyNames** *(list)* – [REQUIRED]
The names of the policies. If the list is empty, the current policy is removed from the listener.

Return type: dict

Returns

Response Syntax

{}  

Response Structure

- *(dict)* –

Paginators

The available paginators are:

- ElasticLoadBalancingPaginator.DescribeLoadBalancers

class ElasticLoadBalancingPaginator.DescribeLoadBalancers

    paginator = client.get_paginator('describe_load_balancers')

paginate(**kwargs)

Creates an iterator that will paginate through responses from ElasticLoadBalancing.Client.describe_load_balancers().

Request Syntax

response_iterator = paginator.paginate(
    LoadBalancerNames=['string',
                      ],
    PaginationConfig={}
{'MaxItems': 123,
'PageSize': 123,
'StartingToken': 'string'
}
}

Parameters

- **LoadBalancerNames (list)** – The names of the load balancers.
  - **(string)** –
- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize (integer)** –
    The size of each page.
  - **StartingToken (string)** –
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type dict

Returns

**Response Syntax**

```json
{
    'LoadBalancerDescriptions': [
        {
            'LoadBalancerName': 'string',
            'DNSName': 'string',

                    },
                    'PolicyNames': [
                        'string'
                    ]
                }
            ],
            'Policies': {
                'AppCookieStickinessPolicies': [
                    {
                        'PolicyName': 'string',
                        'CookieName': 'string'
                    }
                ],
                'LBCookieStickinessPolicies': [
                    {
```

Response Structure

* (dict) –
  - LoadBalancerDescriptions (list) –
    Information about the load balancers.
  * (dict) –
    Information about a load balancer.
      - LoadBalancerName (string) –
The name of the load balancer.

- **DNSName** *(string)*  
The external DNS name of the load balancer.

- **CanonicalHostedZoneName** *(string)*  
The Amazon Route 53 hosted zone associated with the load balancer.

- **CanonicalHostedZoneNameID** *(string)*  
The ID of the Amazon Route 53 hosted zone name associated with the load balancer.

- **ListenerDescriptions** *(list)*  
The listeners for the load balancer.

  - **Listener** *(dict)*  
    Information about a listener.

    For information about the protocols and the ports supported by Elastic Load Balancing, see [Listener Configurations for Elastic Load Balancing](https://docs.aws.amazon.com/elasticloadbalancing/latest/dg/listener-configurations.html) in the [Elastic Load Balancing Developer Guide](https://docs.aws.amazon.com/elasticloadbalancing/latest/dg/).  

    - **Protocol** *(string)*  
      The load balancer transport protocol to use for routing: HTTP, HTTPS, TCP, or SSL.

    - **LoadBalancerPort** *(integer)*  
      The port on which the load balancer is listening. The supported ports are: 25, 80, 443, 465, 587, and 1024-65535.

    - **InstanceProtocol** *(string)*  
      The protocol to use for routing traffic to back-end instances: HTTP, HTTPS, TCP, or SSL.

      If the front-end protocol is HTTP, HTTPS, TCP, or SSL, `InstanceProtocol` must be at the same protocol.

      If there is another listener with the same `InstancePort` whose `InstanceProtocol` is secure, (HTTPS or SSL), the listener's `InstanceProtocol` must also be secure.

      If there is another listener with the same `InstancePort` whose `InstanceProtocol` is HTTP or TCP, the listener's `InstanceProtocol` must be HTTP or TCP.

    - **InstancePort** *(integer)*  
      The port on which the instance is listening.

    - **SSLCertificateId** *(string)*  
      The Amazon Resource Name (ARN) of the server certificate.

    - **PolicyNames** *(list)*  
      The policies. If there are no policies enabled, the list is empty.
- **(string)** –
- **Policies (dict)** –
  The policies defined for the load balancer.
- **AppCookieStickinessPolicies (list)** –
  The stickiness policies created using CreateAppCookieStickinessPolicy.
- **(dict)** –
  Information about a policy for application-controlled session stickiness.
  - **PolicyName (string)** –
    The mnemonic name for the policy being created. The name must be unique within a set of policies for this load balancer.
  - **CookieName (string)** –
    The name of the application cookie used for stickiness.
- **LBCookieStickinessPolicies (list)** –
  The stickiness policies created using CreateLBCookieStickinessPolicy.
- **(dict)** –
  Information about a policy for duration-based session stickiness.
  - **PolicyName (string)** –
    The name for the policy being created. The name must be unique within the set of policies for this load balancer.
  - **CookieExpirationPeriod (integer)** –
    The time period, in seconds, after which the cookie should be considered stale. If this parameter is not specified, the stickiness session lasts for the duration of the browser session.
- **OtherPolicies (list)** –
  The policies other than the stickiness policies.
  - **(string)** –
  - **BackendServerDescriptions (list)** –
    Information about the back-end servers.
    - **(dict)** –
      Information about the configuration of a back-end server.
      - **InstancePort (integer)** –
        The port on which the back-end server is listening.
      - **PolicyNames (list)** –
        The names of the policies enabled for the back-end server.
        - **(string)** –
        - **AvailabilityZones (list)** –
          The Availability Zones for the load balancer.
          - **(string)** –
          - **Subnets (list)** –
            The IDs of the subnets for the load balancer.
· **VPCId** *(string)* –
  
The ID of the VPC for the load balancer.

· **Instances** *(list)* –
  
The IDs of the instances for the load balancer.

· **InstanceId** *(string)* –
  
The ID of a back-end instance.

· **HealthCheck** *(dict)* –
  
Information about the health checks conducted on the load balancer.

· **Target** *(string)* –
  
The instance being checked. The protocol is either TCP, HTTP, HTTPS, or SSL. The range of valid ports is one (1) through 65535.

TCP is the default, specified as a TCP: port pair, for example “TCP:5000”. In this case, a health check simply attempts to open a TCP connection to the instance on the specified port. Failure to connect within the configured timeout is considered unhealthy.

SSL is also specified as SSL: port pair, for example, SSL:5000.

For HTTP/HTTPS, you must include a ping path in the string. HTTP is specified as a HTTP:port;/;PathToPing; grouping, for example “HTTP:80/weather/us/wa/seattle”. In this case, a HTTP GET request is issued to the instance on the given port and path. Any answer other than “200 OK” within the timeout period is considered unhealthy.

The total length of the HTTP ping target must be 1024 16-bit Unicode characters or less.

· **Interval** *(integer)* –
  
The approximate interval, in seconds, between health checks of an individual instance.

· **Timeout** *(integer)* –
  
The amount of time, in seconds, during which no response means a failed health check.

  This value must be less than the Interval value.

· **UnhealthyThreshold** *(integer)* –
  
The number of consecutive health check failures required before moving the instance to the Unhealthy state.

· **HealthyThreshold** *(integer)* –
  
The number of consecutive health checks successes required before moving the instance to the Healthy state.

· **SourceSecurityGroup** *(dict)* –
  
The security group that you can use as part of your inbound rules for your load balancer’s back-end application instances.
To only allow traffic from load balancers, add a security group rule to your back end instance that specifies this source security group as the inbound source.

- **OwnerAlias (string)** –
  The owner of the security group.

- **GroupName (string)** –
  The name of the security group.

- **SecurityGroups (list)** –
  The security groups for the load balancer. Valid only for load balancers in a VPC.

- **CreatedAtTime (datetime)** –
  The date and time the load balancer was created.

- **Scheme (string)** –
  The type of load balancer. Valid only for load balancers in a VPC.

  - If `Scheme` is `internet-facing`, the load balancer has a public DNS name that resolves to a public IP address.
  - If `Scheme` is `internal`, the load balancer has a public DNS name that resolves to a private IP address.

- **NextToken (string)** –
  A token to resume pagination.

---

**EMR**

---

**Client**

**class** `EMR.Client`

A low-level client representing Amazon Elastic MapReduce (EMR):

```python
import boto3

client = boto3.client('emr')
```

These are the available methods:

- `add_instance_groups()`
- `add_job_flow_steps()`
- `add_tags()`
- `can_paginate()`
- `describe_cluster()`
add_instance_groups (**kwargs)

AddInstanceGroups adds an instance group to a running cluster.

Request Syntax

response = client.add_instance_groups(
    InstanceGroups=[
        {
            'Name': 'string',
            'Market': 'ON_DEMAND'|'SPOT',
            'InstanceRole': 'MASTER'|'CORE'|'TASK',
            'BidPrice': 'string',
            'InstanceType': 'string',
            'InstanceCount': 123,
            'Configurations': [
                {
                    'Classification': 'string',
                    'Configurations': {'... recursive ...'},
                    'Properties': {
                        'string': 'string'
                    }
                }
            ],
            JobFlowId='string'
        }
    ],
    JobFlowId='string'
)

Parameters

* InstanceGroups (list) – [REQUIRED]
  
  Instance Groups to add.

  - (dict) –

  Configuration defining a new instance group.

  * Name (string) –

  Friendly name given to the instance group.

  * Market (string) –

  Market type of the Amazon EC2 instances used to create a cluster node.
* InstanceRole (string) – [REQUIRED]

The role of the instance group in the cluster.

* BidPrice (string) –

Bid price for each Amazon EC2 instance in the instance group when launching nodes as Spot Instances, expressed in USD.

* InstanceType (string) – [REQUIRED]

The Amazon EC2 instance type for all instances in the instance group.

* InstanceCount (integer) – [REQUIRED]

Target number of instances for the instance group.

* Configurations (list) –

Note: Amazon EMR releases 4.x or later.

The list of configurations supplied for an EMR cluster instance group. You can specify a separate configuration for each instance group (master, core, and task).

- (dict) –

  Note: Amazon EMR releases 4.x or later.

  Specifies a hardware and software configuration of the EMR cluster. This includes configurations for applications and software bundled with Amazon EMR. The Configuration object is a JSON object which is defined by a classification and a set of properties. Configurations can be nested, so a configuration may have its own Configuration objects listed.

  - Classification (string) –

    The classification of a configuration. For more information see, Amazon EMR Configurations.

  - Configurations (list) –

    A list of configurations you apply to this configuration object.

  - Properties (dict) –

    A set of properties supplied to the Configuration object.

    - (string) –
      - (string) –

* JobFlowId (string) – [REQUIRED]

Job flow in which to add the instance groups.

Return type  dict

Returns

Response Syntax

```python
{
    'JobFlowId': 'string',
    'InstanceGroupIds': [ 'string',
                          ]
}
```

Response Structure
Output from an AddInstanceGroups call.

- **JobFlowId** *(string)*
  The job flow ID in which the instance groups are added.

- **InstanceGroupIds** *(list)*
  Instance group IDs of the newly created instance groups.

**add_job_flow_steps(**kwargs)**

AddJobFlowSteps adds new steps to a running job flow. A maximum of 256 steps are allowed in each job flow.

If your job flow is long-running (such as a Hive data warehouse) or complex, you may require more than 256 steps to process your data. You can bypass the 256-step limitation in various ways, including using the SSH shell to connect to the master node and submitting queries directly to the software running on the master node, such as Hive and Hadoop. For more information on how to do this, go to [Add More than 256 Steps to a Job Flow](https://docs.aws.amazon.com/elasticmapreduce/latest/developerguide/amazon-elastic-mapreduce-add-more-than-256-steps.html) in the Amazon Elastic MapReduce Developer's Guide.

A step specifies the location of a JAR file stored either on the master node of the job flow or in Amazon S3. Each step is performed by the main function of the main class of the JAR file. The main class can be specified either in the manifest of the JAR or by using the MainFunction parameter of the step.

Elastic MapReduce executes each step in the order listed. For a step to be considered complete, the main function must exit with a zero exit code and all Hadoop jobs started while the step was running must have completed and run successfully.

You can only add steps to a job flow that is in one of the following states: STARTING, BOOTSTRAPPING, RUNNING, or WAITING.

**Request Syntax**

```python
response = client.add_job_flow_steps(
    JobFlowId='string',
    Steps=[
        {
            'Name': 'string',
            'ActionOnFailure': 'TERMINATE_JOB_FLOW'|'TERMINATE_CLUSTER'|'CANCEL_AND_WAIT'|'CONTINUE',
            'HadoopJarStep': {
                'Properties': [
                    {
                        'Key': 'string',
                        'Value': 'string'
                    }
                ],
                'Jar': 'string',
                'MainClass': 'string',
                'Args': [
                    'string'
                ]
            }
        },
    ]
)
```

**Parameters**

- **JobFlowId** *(string)* – [REQUIRED]
A string that uniquely identifies the job flow. This identifier is returned by RunJobFlow and can also be obtained from ListClusters.

- **Steps (list)** – [REQUIRED]

  A list of StepConfig to be executed by the job flow.
  - (dict) –

    - **Name (string)** – [REQUIRED]
      The name of the job flow step.
    - **ActionOnFailure (string)** –
      The action to take if the job flow step fails.
    - **HadoopJarStep (dict)** – [REQUIRED]
      The JAR file used for the job flow step.
        - **Properties (list)** –
          A list of Java properties that are set when the step runs. You can use these properties to pass key value pairs to your main function.
        - (dict) –
          A key value pair.
        - **Key (string)** –
          The unique identifier of a key value pair.
        - **Value (string)** –
          The value part of the identified key.
        - **Jar (string)** – [REQUIRED]
          A path to a JAR file run during the step.
        - **MainClass (string)** –
          The name of the main class in the specified Java file. If not specified, the JAR file should specify a Main-Class in its manifest file.
        - **Args (list)** –
          A list of command line arguments passed to the JAR file’s main function when executed.

    Return type  dict

    Returns

    **Response Syntax**

    ```
    {
      'StepIds': [
        'string',
      ]
    }
    ```

    **Response Structure**
    - (dict) –
      The output for the AddJobFlowSteps operation.
      - **StepIds (list)** –
        The identifiers of the list of steps added to the job flow.
add_tags (**kwargs)

Add tags to an Amazon EMR resource. Tags make it easier to associate clusters in various ways, such as grouping clusters to track your Amazon EMR resource allocation costs. For more information, see Tagging Amazon EMR Resources.

Request Syntax

```python
response = client.add_tags(
    ResourceId='string',
    Tags=[
        {'Key': 'string',
         'Value': 'string'},
    ],
)
```

Parameters

- **ResourceId** (*string*) – [REQUIRED]
  
The Amazon EMR resource identifier to which tags will be added. This value must be a cluster identifier.

- **Tags** (*list*) – [REQUIRED]
  
  A list of tags to associate with a cluster and propagate to Amazon EC2 instances. Tags are user-defined key/value pairs that consist of a required key string with a maximum of 128 characters, and an optional value string with a maximum of 256 characters.

  ```python
  { 'Key': 'string',
    'Value': 'string'
  },
  }
  ```

Return type **dict**

Returns

Response Syntax

```python
{}
```

Response Structure

- **(dict)** –

  This output indicates the result of adding tags to a resource.

**can_paginate** (*operation_name*)

Check if an operation can be paginated.
Parameters **operation_name** (*string*) – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

Returns True if the operation can be paginated, False otherwise.

describe_cluster(**kwargs)**

Provides cluster-level details including status, hardware and software configuration, VPC settings, and so on. For information about the cluster steps, see ListSteps.

Request Syntax

```python
response = client.describe_cluster(
    ClusterId='string'
)
```

Parameters **ClusterId** (*string*) – [REQUIRED]

The identifier of the cluster to describe.

Return type dict

Returns

Response Syntax

```python
{
    'Cluster': {
        'Id': 'string',
        'Name': 'string',
        'Status': {
            'State': 'STARTING'|'BOOTSTRAPPING'|'RUNNING'|'WAITING'|'TERMINATING'|'TERMINATED'|'TERMINATED_WITH_ERRORS',
            'StateChangeReason': {
                'Code': 'INTERNAL_ERROR'|'VALIDATION_ERROR'|'INSTANCE_FAILURE'|'BOOTSTRAP_FAILURE'|'USER_REQUEST'|'STEP_FAILURE'|'ALL_STEPS_COMPLETED',
                'Message': 'string'
            },
            'Timeline': {
                'CreationDateTime': datetime(2015, 1, 1),
                'ReadyDateTime': datetime(2015, 1, 1),
                'EndDateTime': datetime(2015, 1, 1)
            }
        },
        'Ec2InstanceAttributes': {
            'Ec2KeyName': 'string',
            'Ec2SubnetId': 'string',
            'Ec2AvailabilityZone': 'string',
            'IamInstanceProfile': 'string',
            'EmrManagedMasterSecurityGroup': 'string',
            'EmrManagedSlaveSecurityGroup': 'string',
            'AdditionalMasterSecurityGroups': [
                'string',
            ],
            'AdditionalSlaveSecurityGroups': [
                'string',
            ],
            'LogUri': 'string',
            'RequestedAmiVersion': 'string',
            'RunningAmiVersion': 'string',
            'ReleaseLabel': 'string',
        },
        'LogUri': 'string',
        'RequestedAmiVersion': 'string',
        'RunningAmiVersion': 'string',
        'ReleaseLabel': 'string',
    }
}
```
Response Structure

- `(dict)` –
  This output contains the description of the cluster.
  
  - **Cluster (dict)**
    
    This output contains the details for the requested cluster.
    
    - **Id (string)** –
      
      The unique identifier for the cluster.
    
    - **Name (string)** –
      
      The name of the cluster.
    
    - **Status (dict)** –
      
      The current status details about the cluster.
      
      - **State (string)** –
        
        The current state of the cluster.
      
      - **StateChangeReason (dict)** –
        
        The reason for the cluster status change.
      
      - **Code (string)** –
        
        The programmatic code for the state change reason.
- **Message** *(string)* –
  The descriptive message for the state change reason.

- **Timeline** *(dict)* –
  A timeline that represents the status of a cluster over the lifetime of the cluster.

- **CreationDateTime** *(datetime)* –
  The creation date and time of the cluster.

- **ReadyDateTime** *(datetime)* –
  The date and time when the cluster was ready to execute steps.

- **EndDateTime** *(datetime)* –
  The date and time when the cluster was terminated.

- **Ec2InstanceAttributes** *(dict)* –
  Provides information about the EC2 instances in a cluster grouped by category. For example, key name, subnet ID, IAM instance profile, and so on.

  - **Ec2KeyName** *(string)* –
    The name of the Amazon EC2 key pair to use when connecting with SSH into the master node as a user named “hadoop”.

  - **Ec2SubnetId** *(string)* –
    To launch the job flow in Amazon VPC, set this parameter to the identifier of the Amazon VPC subnet where you want the job flow to launch. If you do not specify this value, the job flow is launched in the normal AWS cloud, outside of a VPC.

    Amazon VPC currently does not support cluster compute quadruple extra large (cc1.4xlarge) instances. Thus, you cannot specify the cc1.4xlarge instance type for nodes of a job flow launched in a VPC.

  - **Ec2AvailabilityZone** *(string)* –
    The Availability Zone in which the cluster will run.

  - **IamInstanceProfile** *(string)* –
    The IAM role that was specified when the job flow was launched. The EC2 instances of the job flow assume this role.

  - **EmrManagedMasterSecurityGroup** *(string)* –
    The identifier of the Amazon EC2 security group (managed by Amazon Elastic MapReduce) for the master node.

  - **EmrManagedSlaveSecurityGroup** *(string)* –
    The identifier of the Amazon EC2 security group (managed by Amazon Elastic MapReduce) for the slave nodes.

  - **AdditionalMasterSecurityGroups** *(list)* –
    A list of additional Amazon EC2 security group IDs for the master node.

  - **AdditionalSlaveSecurityGroups** *(list)* –
    A list of additional Amazon EC2 security group IDs for the slave nodes.
* **LogUri** *(string)* –
  The path to the Amazon S3 location where logs for this cluster are stored.

* **RequestedAmiVersion** *(string)* –
  The AMI version requested for this cluster.

* **RunningAmiVersion** *(string)* –
  The AMI version running on this cluster.

* **ReleaseLabel** *(string)* –
  The release label for the Amazon EMR release. For Amazon EMR 3.x and 2.x AMIs, use amiVersion instead of ReleaseLabel.

* **AutoTerminate** *(boolean)* –
  Specifies whether the cluster should terminate after completing all steps.

* **TerminationProtected** *(boolean)* –
  Indicates whether Amazon EMR will lock the cluster to prevent the EC2 instances from being terminated by an API call or user intervention, or in the event of a cluster error.

* **VisibleToAllUsers** *(boolean)* –
  Indicates whether the job flow is visible to all IAM users of the AWS account associated with the job flow. If this value is set to `true`, all IAM users of that AWS account can view and manage the job flow if they have the proper policy permissions set. If this value is `false`, only the IAM user that created the cluster can view and manage it. This value can be changed using the SetVisibleToAllUsers action.

* **Applications** *(list)* –
  The applications installed on this cluster.
  
  · *(dict)* –
    An application is any Amazon or third-party software that you can add to the cluster. This structure contains a list of strings that indicates the software to use with the cluster and accepts a user argument list. Amazon EMR accepts and forwards the argument list to the corresponding installation script as bootstrap action argument. For more information, see Launch a Job Flow on the MapR Distribution for Hadoop. Currently supported values are:
    · “mapr-m3” - launch the job flow using MapR M3 Edition.
    · “mapr-m5” - launch the job flow using MapR M5 Edition.
    · “mapr” with the user arguments specifying “–edition,m3” or “–edition,m5” - launch the job flow using MapR M3 or M5 Edition, respectively.

  **Note:** In Amazon EMR releases 4.0 and greater, the only accepted parameter is the application name. To pass arguments to applications, you supply a configuration for each application.

  · **Name** *(string)* –
    The name of the application.

  · **Version** *(string)* –
The version of the application.

- **Args (list)** –
  Arguments for Amazon EMR to pass to the application.
  - *(string)* –
  - **AdditionalInfo (dict)** –
    This option is for advanced users only. This is meta information about third-party applications that third-party vendors use for testing purposes.
    - *(string)* –
    - *(string)* –

* **Tags (list)** –
A list of tags associated with a cluster.
  - *(dict)* –
    A key/value pair containing user-defined metadata that you can associate with an Amazon EMR resource. Tags make it easier to associate clusters in various ways, such as grouping clusters to track your Amazon EMR resource allocation costs. For more information, see *Tagging Amazon EMR Resources*.
    - **Key (string)** –
      A user-defined key, which is the minimum required information for a valid tag. For more information, see *Tagging Amazon EMR Resources*.
    - **Value (string)** –
      A user-defined value, which is optional in a tag. For more information, see *Tagging Amazon EMR Resources*.

* **ServiceRole (string)** –
  The IAM role that will be assumed by the Amazon EMR service to access AWS resources on your behalf.

* **NormalizedInstanceHours (integer)** –
  An approximation of the cost of the job flow, represented in m1.small/hours. This value is incremented one time for every hour an m1.small instance runs. Larger instances are weighted more, so an EC2 instance that is roughly four times more expensive would result in the normalized instance hours being incremented by four. This result is only an approximation and does not reflect the actual billing rate.

* **MasterPublicDnsName (string)** –
  The public DNS name of the master EC2 instance.

* **Configurations (list)** –

  **Note:** Amazon EMR releases 4.x or later.

  The list of Configurations supplied to the EMR cluster.
  - *(dict)* –

  **Note:** Amazon EMR releases 4.x or later.

  Specifies a hardware and software configuration of the EMR.
This includes configurations for applications and software bundled with Amazon EMR. The Configuration object is a JSON object which is defined by a classification and a set of properties. Configurations can be nested, so a configuration may have its own Configuration objects listed.

- **Classification (string)** –
  The classification of a configuration. For more information see, Amazon EMR Configurations.

- **Configurations (list)** –
  A list of configurations you apply to this configuration object.

- **Properties (dict)** –
  A set of properties supplied to the Configuration object.

```
describe_job_flows(**kwargs)
```

This API is deprecated and will eventually be removed. We recommend you use ListClusters, DescribeCluster, ListSteps, ListInstanceGroups and ListBootstrapActions instead.

DescribeJobFlows returns a list of job flows that match all of the supplied parameters. The parameters can include a list of job flow IDs, job flow states, and restrictions on job flow creation date and time.

Regardless of supplied parameters, only job flows created within the last two months are returned.

If no parameters are supplied, then job flows matching either of the following criteria are returned:

- Job flows created and completed in the last two weeks
- Job flows created within the last two months that are in one of the following states: RUNNING, WAITING, SHUTTING_DOWN, STARTING

Amazon Elastic MapReduce can return a maximum of 512 job flow descriptions.

**Request Syntax**

```python
response = client.describe_job_flows(
    CreatedAfter=datetime(2015, 1, 1),
    CreatedBefore=datetime(2015, 1, 1),
    JobFlowIds=[
        'string',
    ],
    JobFlowStates=[
        'STARTING','BOOTSTRAPPING','RUNNING','WAITING','SHUTTING_DOWN','TERMINATED','COMPLETED'
    ]
)
```

**Parameters**

- **CreatedAfter (datetime)** – Return only job flows created after this date and time.
- **CreatedBefore (datetime)** – Return only job flows created before this date and time.
- **JobFlowIds (list)** – Return only job flows whose job flow ID is contained in this list.
  - **(string)** –
- **JobFlowStates (list)** – Return only job flows whose state is contained in this list.
  - **(string)** –

  The type of instance.

  A small instance
A large instance

Return type  dict

Returns

Response Syntax

```python
{
    'JobFlows': [ {
        'JobFlowId': 'string',
        'Name': 'string',
        'LogUri': 'string',

Response Structure

* (dict) –

The output for the DescribeJobFlows operation.

  – **JobFlows** (list) –

    A list of job flows matching the parameters supplied.

    * (dict) –

      A description of a job flow.

      · **JobFlowId** (string) –
The job flow identifier.

- **Name (string)** –
  The name of the job flow.

- **LogUri (string)** –
  The location in Amazon S3 where log files for the job are stored.

- **AmiVersion (string)** –
  The version of the AMI used to initialize Amazon EC2 instances in the job flow. For a list of AMI versions currently supported by Amazon ElasticMapReduce, go to AMI Versions Supported in Elastic MapReduce in the Amazon Elastic MapReduce Developer Guide.

- **ExecutionStatusDetail (dict)** –
  Describes the execution status of the job flow.

  - **State (string)** –
    The state of the job flow.

  - **CreationDateTime (datetime)** –
    The creation date and time of the job flow.

  - **StartDateTime (datetime)** –
    The start date and time of the job flow.

  - **ReadyDateTime (datetime)** –
    The date and time when the job flow was ready to start running bootstrap actions.

  - **EndDateTime (datetime)** –
    The completion date and time of the job flow.

  - **LastStateChangeReason (string)** –
    Description of the job flow last changed state.

- **Instances (dict)** –
  Describes the Amazon EC2 instances of the job flow.

  - **MasterInstanceType (string)** –
    The Amazon EC2 master node instance type.

  - **MasterPublicDnsName (string)** –
    The DNS name of the master node.

  - **MasterInstanceId (string)** –
    The Amazon EC2 instance identifier of the master node.

  - **SlaveInstanceType (string)** –
    The Amazon EC2 slave node instance type.

  - **InstanceCount (integer)** –
    The number of Amazon EC2 instances in the cluster. If the value is 1, the same instance serves as both the master and slave node. If the value is greater than 1, one instance is the master node and all others are slave nodes.

- **InstanceGroups (list)** –
  Details about the job flow’s instance groups.
Detailed information about an instance group.

- **InstanceGroupId** *(string)* –
  Unique identifier for the instance group.

- **Name** *(string)* –
  Friendly name for the instance group.

- **Market** *(string)* –
  Market type of the Amazon EC2 instances used to create a cluster node.

- **InstanceRole** *(string)* –
  Instance group role in the cluster

- **BidPrice** *(string)* –
  Bid price for EC2 Instances when launching nodes as Spot Instances, expressed in USD.

- **InstanceType** *(string)* –
  Amazon EC2 Instance type.

- **InstanceRequestCount** *(integer)* –
  Target number of instances to run in the instance group.

- **InstanceRunningCount** *(integer)* –
  Actual count of running instances.

- **State** *(string)* –
  State of instance group. The following values are deprecated: STARTING, TERMINATED, and FAILED.

- **LastStateChangeReason** *(string)* –
  Details regarding the state of the instance group.

- **CreationDateTime** *(datetime)* –
  The date/time the instance group was created.

- **StartDateTime** *(datetime)* –
  The date/time the instance group was started.

- **ReadyDateTime** *(datetime)* –
  The date/time the instance group was available to the cluster.

- **EndDateTime** *(datetime)* –
  The date/time the instance group was terminated.

- **NormalizedInstanceHours** *(integer)* –
  An approximation of the cost of the job flow, represented in m1.small/hours. This value is incremented once for every hour an m1.small runs. Larger instances are weighted more, so an Amazon EC2 instance that is roughly four times more expensive would result in the normalized instance hours being incremented by four. This result is only an approximation and does not reflect the actual billing rate.

- **Ec2KeyName** *(string)* –
  The name of an Amazon EC2 key pair that can be used to ssh to the master node of job flow.
- **Ec2SubnetId** *(string)* –
  
  For job flows launched within Amazon Virtual Private Cloud, this value specifies the identifier of the subnet where the job flow was launched.

- **Placement** *(dict)* –
  
  The Amazon EC2 Availability Zone for the job flow.

  - **AvailabilityZone** *(string)* –
    
    The Amazon EC2 Availability Zone for the job flow.

- **KeepJobFlowAliveWhenNoSteps** *(boolean)* –
  
  Specifies whether the job flow should terminate after completing all steps.

- **TerminationProtected** *(boolean)* –
  
  Specifies whether the Amazon EC2 instances in the cluster are protected from termination by API calls, user intervention, or in the event of a job flow error.

- **HadoopVersion** *(string)* –
  
  The Hadoop version for the job flow.

- **Steps** *(list)* –
  
  A list of steps run by the job flow.

  - *(dict)* –
    
    Combines the execution state and configuration of a step.

  - **StepConfig** *(dict)* –
    
    The step configuration.

  - **Name** *(string)* –
    
    The name of the job flow step.

  - **ActionOnFailure** *(string)* –
    
    The action to take if the job flow step fails.

- **HadoopJarStep** *(dict)* –
  
  The JAR file used for the job flow step.

- **Properties** *(list)* –
  
  A list of Java properties that are set when the step runs. You can use these properties to pass key value pairs to your main function.

  - *(dict)* –
    
    A key value pair.

  - **Key** *(string)* –
    
    The unique identifier of a key value pair.

  - **Value** *(string)* –
    
    The value part of the identified key.

  - **Jar** *(string)* –
    
    A path to a JAR file run during the step.

  - **MainClass** *(string)* –
    
    The name of the main class in the specified Java file. If not specified, the JAR file should specify a Main-Class in its manifest file.
· **Args** *(list)* –
  A list of command line arguments passed to the JAR file’s main function when executed.
· *(string)* –
  · **ExecutionStatusDetail** *(dict)* –
    The description of the step status.
· **State** *(string)* –
  The state of the job flow step.
· **CreationDateTime** *(datetime)* –
  The creation date and time of the step.
· **StartDateTime** *(datetime)* –
  The start date and time of the step.
· **EndDateTime** *(datetime)* –
  The completion date and time of the step.
· **LastStateChangeReason** *(string)* –
  A description of the step’s current state.
· **BootstrapActions** *(list)* –
  A list of the bootstrap actions run by the job flow.
· *(dict)* –
  Reports the configuration of a bootstrap action in a job flow.
· **BootstrapActionConfig** *(dict)* –
  A description of the bootstrap action.
· **Name** *(string)* –
  The name of the bootstrap action.
· **ScriptBootstrapAction** *(dict)* –
  The script run by the bootstrap action.
· **Path** *(string)* –
  Location of the script to run during a bootstrap action. Can be either a location in Amazon S3 or on a local file system.
· **Args** *(list)* –
  A list of command line arguments to pass to the bootstrap action script.
· *(string)* –
  · **SupportedProducts** *(list)* –
    A list of strings set by third party software when the job flow is launched. If you are not using third party software to manage the job flow this value is empty.
· *(string)* –
  · **VisibleToAllUsers** *(boolean)* –
    Specifies whether the job flow is visible to all IAM users of the AWS account associated with the job flow. If this value is set to `true`, all IAM users of that AWS account can view and (if they have the proper policy permissions set) manage the job flow. If it is set to `false`, only the IAM user that created the job flow can view and manage it. This value can be changed using the SetVisibleToAllUsers action.
· **JobFlowRole** *(string)* –

  The IAM role that was specified when the job flow was launched. The EC2 instances of the job flow assume this role.

· **ServiceRole** *(string)* –

  The IAM role that will be assumed by the Amazon EMR service to access AWS resources on your behalf.

**describe_step(** **kwargs** **)**

Provides more detail about the cluster step.

**Request Syntax**

```python
response = client.describe_step(
    ClusterId='string',
    StepId='string'
)
```

**Parameters**

- **ClusterId** *(string)* – [REQUIRED]
  
  The identifier of the cluster with steps to describe.

- **StepId** *(string)* – [REQUIRED]
  
  The identifier of the step to describe.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Step': {
        'Id': 'string',
        'Name': 'string',
        'Config': {
            'Jar': 'string',
            'Properties': {
                'string': 'string'
            },
            'MainClass': 'string',
            'Args': [
                'string',
            ],
        },
        'ActionOnFailure': 'TERMINATE_JOB_FLOW'|'TERMINATE_CLUSTER'|'CANCEL_AND_WAIT'|'CONTINUE',
        'Status': {
            'State': 'PENDING'|'RUNNING'|'COMPLETED'|'CANCELLED'|'FAILED'|'INTERRUPTED',
            'StateChangeReason': {
                'Code': 'NONE',
                'Message': 'string'
            },
            'Timeline': {
                'CreationDateTime': datetime(2015, 1, 1),
                'StartDateTime': datetime(2015, 1, 1),
                'EndDateTime': datetime(2015, 1, 1)
            }
        }
    },
}
```
Response Structure

- (dict) –
  This output contains the description of the cluster step.
  - Step (dict) –
    The step details for the requested step identifier.
    - Id (string) –
      The identifier of the cluster step.
    - Name (string) –
      The name of the cluster step.
    - Config (dict) –
      The Hadoop job configuration of the cluster step.
      - Jar (string) –
        The path to the JAR file that runs during the step.
      - Properties (dict) –
        The list of Java properties that are set when the step runs. You can use these properties to pass key value pairs to your main function.
        - (string) –
        - (string) –
        - MainClass (string) –
          The name of the main class in the specified Java file. If not specified, the JAR file should specify a main class in its manifest file.
        - Args (list) –
          The list of command line arguments to pass to the JAR file’s main function for execution.
        - (string) –
    - ActionOnFailure (string) –
      This specifies what action to take when the cluster step fails. Possible values are TERMINATE_CLUSTER, CANCEL_AND_WAIT, and CONTINUE.
    - Status (dict) –
      The current execution status details of the cluster step.
      - State (string) –
        The execution state of the cluster step.
      - StateChangeReason (dict) –
        The reason for the step execution status change.
      - Code (string) –
        The programmable code for the state change reason. Note: Currently, the service provides no code for the state change.
      - Message (string) –
        The descriptive message for the state change reason.
      - Timeline (dict) –
        The timeline of the cluster step status over time.
      - CreationDateTime (datetime) –
The date and time when the cluster step was created.

- **StartDateTime** *(datetime)* –

The date and time when the cluster step execution started.

- **EndDateDateTime** *(datetime)* –

The date and time when the cluster step execution completed or failed.

`generate_presigned_url` *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

**Parameters**

- **ClientMethod** *(string)* – The client method to presign for
- **Params** *(dict)* – The parameters normally passed to `ClientMethod`
- **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns** The presigned url

`get_paginator` *(operation_name)*

Create a paginator for an operation.

**Parameters**

- **operation_name** *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

**Raises** `OperationNotPageableError` Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

**Return type** `botocore.paginate.Paginator`

**Returns** A paginator object.

`get_waiter` *(waiter_name)*

`list_bootstrap_actions` (**kwargs**)

Provides information about the bootstrap actions associated with a cluster.

**Request Syntax**

```python
response = client.list_bootstrap_actions(
    ClusterId='string',
    Marker='string'
)
```

**Parameters**

- **ClusterId** *(string)* – [REQUIRED]

  The cluster identifier for the bootstrap actions to list.

- **Marker** *(string)* – The pagination token that indicates the next set of results to retrieve.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'BootstrapActions': [
        {'Name': 'string',
```
Response Structure

- **(dict)** –
  This output contains the bootstrap actions detail.
  - **BootstrapActions (list)** –
    The bootstrap actions associated with the cluster.
    - **(dict)** –
      An entity describing an executable that runs on a cluster.
      - **Name (string)** –
        The name of the command.
      - **ScriptPath (string)** –
        The Amazon S3 location of the command script.
      - **Args (list)** –
        Arguments for Amazon EMR to pass to the command for execution.
      - **Marker (string)** –
        The pagination token that indicates the next set of results to retrieve.

`list_clusters(**kwargs)`

Provides the status of all clusters visible to this AWS account. Allows you to filter the list of clusters based on certain criteria; for example, filtering by cluster creation date and time or by status. This call returns a maximum of 50 clusters per call, but returns a marker to track the paging of the cluster list across multiple ListClusters calls.

Request Syntax

```python
response = client.list_clusters(
    CreatedAfter=datetime(2015, 1, 1),
    CreatedBefore=datetime(2015, 1, 1),
    ClusterStates=['STARTING'|'BOOTSTRAPPING'|'RUNNING'|'WAITING'|'TERMINATING'|'TERMINATED'|'TERMINATED_WITH_ERRORS',
                   ],
    Marker='string'
)
```

Parameters

- **CreatedAfter (datetime)** – The creation date and time beginning value filter for listing clusters.
- **CreatedBefore (datetime)** – The creation date and time end value filter for listing clusters.
- **ClusterStates (list)** – The cluster state filters to apply when listing clusters.
  - **(string)** –
- **Marker (string)** – The pagination token that indicates the next set of results to retrieve.
Return type  dict

Returns

Response Syntax

```python
{
    'Clusters': [
        {
            'Id': 'string',
            'Name': 'string',
            'Status': {
                'State': 'STARTING'|'BOOTSTRAPPING'|'RUNNING'|'WAITING'|'TERMINATING'|'TERMINATED'|'TERMINATED_WITH_ERRORS',
                'StateChangeReason': {
                    'Code': 'INTERNAL_ERROR'|'VALIDATION_ERROR'|'INSTANCE_FAILURE'|'BOOTSTRAP_FAILURE'|'USER_REQUEST'|'STEP_FAILURE'|'ALL_STEPS_COMPLETED',
                    'Message': 'string'
                },
                'Timeline': {
                    'CreationDateTime': datetime(2015, 1, 1),
                    'ReadyDateTime': datetime(2015, 1, 1),
                    'EndDateTime': datetime(2015, 1, 1)
                }
            },
            'NormalizedInstanceHours': 123
        },
        'Marker': 'string'
    }
}
```

Response Structure

- (dict) –
  This contains a ClusterSummaryList with the cluster details; for example, the cluster IDs, names, and status.

  - Clusters (list) –
    The list of clusters for the account based on the given filters.
    - (dict) –
      The summary description of the cluster.
      - Id (string) –
        The unique identifier for the cluster.
      - Name (string) –
        The name of the cluster.
      - Status (dict) –
        The details about the current status of the cluster.
        - State (string) –
          The current state of the cluster.
        - StateChangeReason (dict) –
          The reason for the cluster status change.
          - Code (string) –
            The programmatic code for the state change reason.
          - Message (string) –
            The descriptive message for the state change reason.
· **Timeline (dict)** –
  A timeline that represents the status of a cluster over the lifetime of the cluster.

· **CreationDateTime (datetime)** –
  The creation date and time of the cluster.

· **ReadyDateTime (datetime)** –
  The date and time when the cluster was ready to execute steps.

· **EndDateTime (datetime)** –
  The date and time when the cluster was terminated.

· **NormalizedInstanceHours (integer)** –
  An approximation of the cost of the job flow, represented in m1.small/hours. This value is incremented one time for every hour an m1.small instance runs. Larger instances are weighted more, so an EC2 instance that is roughly four times more expensive would result in the normalized instance hours being incremented by four. This result is only an approximation and does not reflect the actual billing rate.

   – **Marker (string)** –
     The pagination token that indicates the next set of results to retrieve.

**list_instance_groups (**kwargs**)**

Provides all available details about the instance groups in a cluster.

**Request Syntax**

```python
response = client.list_instance_groups(
    ClusterId='string',
    Marker='string'
)
```

**Parameters**

- **ClusterId (string)** – [REQUIRED]
  The identifier of the cluster for which to list the instance groups.

- **Marker (string)** – The pagination token that indicates the next set of results to retrieve.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'InstanceGroups': [
        {'Id': 'string',
         'Name': 'string',
         'Market': 'ON_DEMAND'|'SPOT',
         'InstanceGroupType': 'MASTER'|'CORE'|'TASK',
         'BidPrice': 'string',
         'InstanceType': 'string',
         'RequestedInstanceCount': 123,
         'RunningInstanceCount': 123,
         'Status': {
             'State': 'PROVISIONING'|'BOOTSTRAPPING'|'RUNNING'|'RESIZING'|'SUSPENDED'|'TERMINATING'|'TERMINATED'|'ARRESTED'|'SHUTTING_DOWN'|'ENDED',
```
'StateChangeReason': {
    'Code': 'INTERNAL_ERROR'|'VALIDATION_ERROR'|'INSTANCE_FAILURE'|
    'Message': 'string'
},
'Timeline': {
    'CreationDateTime': datetime(2015, 1, 1),
    'ReadyDateTime': datetime(2015, 1, 1),
    'EndDateTime': datetime(2015, 1, 1)
},
'Configurations': [
    {
        'Classification': 'string',
        'Configurations': {'... recursive ...'},
        'Properties': {
            'string': 'string'
        }
    },
    
},
'Marker': 'string'

Response Structure
• (dict) –
  This input determines which instance groups to retrieve.
  – InstanceGroups (list) –
    The list of instance groups for the cluster and given filters.
    • (dict) –
      This entity represents an instance group, which is a group of in-
      stances that have common purpose. For example, CORE instance
group is used for HDFS.
        • Id (string) –
          The identifier of the instance group.
        • Name (string) –
          The name of the instance group.
        • Market (string) –
          The marketplace to provision instances for this group. Valid
          values are ON_DEMAND or SPOT.
        • InstanceGroupType (string) –
          The type of the instance group. Valid values are MASTER,
          CORE or TASK.
        • BidPrice (string) –
          The bid price for each EC2 instance in the instance group
          when launching nodes as Spot Instances, expressed in USD.
        • InstanceType (string) –
          The EC2 instance type for all instances in the instance group.
        • RequestedInstanceCount (integer) –
          The target number of instances for the instance group.
- **RunningInstanceCount** *(integer)* –
  The number of instances currently running in this instance group.

- **Status** *(dict)* –
  The current status of the instance group.
  - **State** *(string)* –
    The current state of the instance group.

- **StateChangeReason** *(dict)* –
  The status change reason details for the instance group.
  - **Code** *(string)* –
    The programmable code for the state change reason.
  - **Message** *(string)* –
    The status change reason description.
  - **Timeline** *(dict)* –
    The timeline of the instance group status over time.
  - **CreationDateTime** *(datetime)* –
    The creation date and time of the instance group.
  - **ReadyDateTime** *(datetime)* –
    The date and time when the instance group became ready to perform tasks.
  - **EndDateTime** *(datetime)* –
    The date and time when the instance group terminated.

- **Configurations** *(list)* –
  Note: Amazon EMR releases 4.x or later.

  The list of configurations supplied for an EMR cluster instance group. You can specify a separate configuration for each instance group (master, core, and task).

- **(dict)** –
  Note: Amazon EMR releases 4.x or later.

  Specifies a hardware and software configuration of the EMR cluster. This includes configurations for applications and software bundled with Amazon EMR. The Configuration object is a JSON object which is defined by a classification and a set of properties. Configurations can be nested, so a configuration may have its own Configuration objects listed.

  - **Classification** *(string)* –
    The classification of a configuration. For more information see, Amazon EMR Configurations.

  - **Configurations** *(list)* –
    A list of configurations you apply to this configuration object.

  - **Properties** *(dict)* –
    A set of properties supplied to the Configuration object.

  - **(string)** –
list_instances(**kwargs)

Provides information about the cluster instances that Amazon EMR provisions on behalf of a user when it creates the cluster. For example, this operation indicates when the EC2 instances reach the Ready state, when instances become available to Amazon EMR to use for jobs, and the IP addresses for cluster instances, etc.

**Request Syntax**

```python
response = client.list_instances(
    ClusterId='string',
    InstanceGroupId='string',
    InstanceGroupTypes=[
        'MASTER'|'CORE'|'TASK',
    ],
    Marker='string'
)
```

**Parameters**

- **ClusterId** *(string)* – [REQUIRED]
  
  The identifier of the cluster for which to list the instances.
  
- **InstanceGroupId** *(string)* – The identifier of the instance group for which to list the instances.
  
- **InstanceGroupTypes** *(list)* – The type of instance group for which to list the instances.
  
  - *(string)* –
  
- **Marker** *(string)* – The pagination token that indicates the next set of results to retrieve.

**Return type** dict

**Returns**

**Response Syntax**

```json
{}

'Instances': [
    {
        'Id': 'string',
        'Ec2InstanceId': 'string',
        'PublicDnsName': 'string',
        'PublicIpAddress': 'string',
        'PrivateDnsName': 'string',
        'PrivateIpAddress': 'string',
        'Status': {
            'State': 'AWAITING_FULFILLMENT'|'PROVISIONING'|'BOOTSTRAPPING'|'RUNNING'|'TERMINATED',
            'StateChangeReason': {
                'Code': 'INTERNAL_ERROR'|'VALIDATION_ERROR'|'INSTANCE_FAILURE'|'BOOTSTRAP_FAILURE'|'CLUSTER_TERMINATED',
                'Message': 'string'
            },
            'Timeline': {
                'CreationDateTime': datetime(2015, 1, 1),
                'ReadyDateTime': datetime(2015, 1, 1),
                'EndDateTime': datetime(2015, 1, 1)
            }
        }
    }
]
```
Response Structure

- (dict) –
  This output contains the list of instances.
  - Instances (list) –
    The list of instances for the cluster and given filters.
    - (dict) –
      Represents an EC2 instance provisioned as part of cluster.
      - Id (string) –
        The unique identifier for the instance in Amazon EMR.
      - Ec2InstanceId (string) –
        The unique identifier of the instance in Amazon EC2.
      - PublicDnsName (string) –
        The public DNS name of the instance.
      - PublicIpAddress (string) –
        The public IP address of the instance.
      - PrivateDnsName (string) –
        The private DNS name of the instance.
      - PrivateIpAddress (string) –
        The private IP address of the instance.
      - Status (dict) –
        The current status of the instance.
        - State (string) –
          The current state of the instance.
        - StateChangeReason (dict) –
          The details of the status change reason for the instance.
          - Code (string) –
            The programmable code for the state change reason.
          - Message (string) –
            The status change reason description.
          - Timeline (dict) –
            The timeline of the instance status over time.
          - CreationDateTime (datetime) –
            The creation date and time of the instance.
          - ReadyDateTime (datetime) –
            The date and time when the instance was ready to perform tasks.
          - EndDateTime (datetime) –
            The date and time when the instance was terminated.
list_steps(**kwargs)

Provides a list of steps for the cluster.

Request Syntax

```python
response = client.list_steps(
    ClusterId='string',
    StepStates=[
        'PENDING'|'RUNNING'|'COMPLETED'|'CANCELLED'|'FAILED'|'INTERRUPTED',
    ],
    StepIds=[
        'string',
    ],
    Marker='string'
)
```

Parameters

- **ClusterId** *(string)* – [REQUIRED]
  The identifier of the cluster for which to list the steps.
- **StepStates** *(list)* – The filter to limit the step list based on certain states.
  - *(string)* –
- **StepIds** *(list)* – The filter to limit the step list based on the identifier of the steps.
  - *(string)* –
- **Marker** *(string)* – The pagination token that indicates the next set of results to retrieve.

Return type

dict

Returns

Response Syntax

```json
{
    'Steps': [
        {
            'Id': 'string',
            'Name': 'string',
            'Config': {
                'Jar': 'string',
                'Properties': {
                    'string': 'string'
                },
                'MainClass': 'string',
                'Args': [
                    'string',
                ],
            },
            'ActionOnFailure': 'TERMINATE_JOB_FLOW'|'TERMINATE_CLUSTER'|'CANCEL_AND_WAIT'|'CONTINUE',
            'Status': {
                'State': 'PENDING'|'RUNNING'|'COMPLETED'|'CANCELLED'|'FAILED'|'INTERRUPTED',
                'StateChangeReason': {
                    'Code': 'NONE',
                    'Message': 'string'
                },
                'Timeline': {
                    'CreationDateTime': datetime(2015, 1, 1),
                }
            }
        }
    ]
}
```
Response Structure

- (dict) –

  This output contains the list of steps.

  - Steps (list) –

    The filtered list of steps for the cluster.

    * (dict) –

      The summary of the cluster step.

      - Id (string) –

        The identifier of the cluster step.

      - Name (string) –

        The name of the cluster step.

      - Config (dict) –

        The Hadoop job configuration of the cluster step.

      - Jar (string) –

        The path to the JAR file that runs during the step.

      - Properties (dict) –

        The list of Java properties that are set when the step runs. You can use these properties to pass key value pairs to your main function.

        * (string) –

        * (string) –

        - MainClass (string) –

        The name of the main class in the specified Java file. If not specified, the JAR file should specify a main class in its manifest file.

      - Args (list) –

        The list of command line arguments to pass to the JAR file’s main function for execution.

        * (string) –

        - ActionOnFailure (string) –

        This specifies what action to take when the cluster step fails. Possible values are TERMINATE_CLUSTER, CANCEL_AND_WAIT, and CONTINUE.

      - Status (dict) –

        The current execution status details of the cluster step.

      - State (string) –

        The execution state of the cluster step.

      - StateChangeReason (dict) –
The reason for the step execution status change.
- **Code** *(string)* –
  The programmable code for the state change reason. Note: Currently, the service provides no code for the state change.
- **Message** *(string)* –
  The descriptive message for the state change reason.
- **Timeline** *(dict)* –
  The timeline of the cluster step status over time.
  - **CreationDateTime** *(datetime)* –
    The date and time when the cluster step was created.
  - **StartDateTime** *(datetime)* –
    The date and time when the cluster step execution started.
  - **EndDateTime** *(datetime)* –
    The date and time when the cluster step execution completed or failed.
- **Marker** *(string)* –
  The pagination token that indicates the next set of results to retrieve.

**modify_instance_groups(***kwargs*)**
ModifyInstanceGroups modifies the number of nodes and configuration settings of an instance group. The input parameters include the new target instance count for the group and the instance group ID. The call will either succeed or fail atomically.

**Request Syntax**

```python
response = client.modify_instance_groups(
    InstanceGroups=[
        {
            'InstanceGroupId': 'string',
            'InstanceCount': 123,
            'EC2InstanceIdsToTerminate': ['string'],
        },
    ]
)
```

**Parameters**
- **InstanceGroups** *(list)* – Instance groups to change.
  - *(dict)* –
    Modify an instance group size.
    - **InstanceGroupId** *(string)* – [REQUIRED]
      Unique ID of the instance group to expand or shrink.
    - **InstanceCount** *(integer)* –
      Target size for the instance group.
    - **EC2InstanceIdsToTerminate** *(list)* –
      The EC2 Instancelds to terminate. For advanced users only. Once you terminate the instances, the instance group will not return to its original requested size.

**Returns**
- **None**
**remove_tags(**kwargs**)

Removes tags from an Amazon EMR resource. Tags make it easier to associate clusters in various ways, such as grouping clusters to track your Amazon EMR resource allocation costs. For more information, see Tagging Amazon EMR Resources.

The following example removes the stack tag with value Prod from a cluster:

**Request Syntax**

```python
response = client.remove_tags(
    ResourceId='string',
    TagKeys=['string'],
)
```

**Parameters**

- **ResourceId (string)** – [REQUIRED]
  
The Amazon EMR resource identifier from which tags will be removed. This value must be a cluster identifier.

- **TagKeys (list)** – [REQUIRED]
  
  A list of tag keys to remove from a resource.

**Return type** dict

**Returns**

**Response Syntax**

```python
{}
```

**Response Structure**

- (dict) –

  This output indicates the result of removing tags from a resource.

**run_job_flow(**kwargs**)

RunJobFlow creates and starts running a new job flow. The job flow will run the steps specified. Once the job flow completes, the cluster is stopped and the HDFS partition is lost. To prevent loss of data, configure the last step of the job flow to store results in Amazon S3. If the JobFlowInstancesConfig KeepJobFlowAliveWhenNoSteps parameter is set to TRUE, the job flow will transition to the WAITING state rather than shutting down once the steps have completed.

For additional protection, you can set the JobFlowInstancesConfig TerminationProtected parameter to TRUE to lock the job flow and prevent it from being terminated by API call, user intervention, or in the event of a job flow error.

A maximum of 256 steps are allowed in each job flow.

If your job flow is long-running (such as a Hive data warehouse) or complex, you may require more than 256 steps to process your data. You can bypass the 256-step limitation in various ways, including using the SSH shell to connect to the master node and submitting queries directly to the software running on the master node, such as Hive and Hadoop. For more information on how to do this, go to Add More than 256 Steps to a Job Flow in the Amazon Elastic MapReduce Developer’s Guide.

For long running job flows, we recommend that you periodically store your results.

**Request Syntax**
response = client.run_job_flow(
    Name='string',
    LogUri='string',
    AdditionalInfo='string',
    AmiVersion='string',
    ReleaseLabel='string',
    Instances={

VisibleToAllUsers=True|False,
JobFlowRole='string',
ServiceRole='string',
Tags=[  
  {
    'Key': 'string',
    'Value': 'string'
  },
]
Parameters

- **Name** *(string)* – [REQUIRED]
  The name of the job flow.
- **LogUri** *(string)* – The location in Amazon S3 to write the log files of the job flow. If a value is not provided, logs are not created.
- **AdditionalInfo** *(string)* – A JSON string for selecting additional features.
- **AmiVersion** *(string)*

  **Note:** For Amazon EMR releases 3.x and 2.x. For Amazon EMR releases 4.x and greater, use ReleaseLabel.

  The version of the Amazon Machine Image (AMI) to use when launching Amazon EC2 instances in the job flow. The following values are valid:
  - The version number of the AMI to use, for example, “2.0.”
  If the AMI supports multiple versions of Hadoop (for example, AMI 1.0 supports both Hadoop 0.18 and 0.20) you can use the JobFlowInstancesConfig HadoopVersion parameter to modify the version of Hadoop from the defaults shown above.

  For details about the AMI versions currently supported by Amazon Elastic MapReduce, go to AMI Versions Supported in Elastic MapReduce in the Amazon Elastic MapReduce Developer’s Guide.
- **ReleaseLabel** *(string)*

  **Note:** Amazon EMR releases 4.x or later.

  The release label for the Amazon EMR release. For Amazon EMR 3.x and 2.x AMIs, use amiVersion instead of ReleaseLabel.
- **Instances** *(dict)* – [REQUIRED]

  A specification of the number and type of Amazon EC2 instances on which to run the job flow.
  - **MasterInstanceType** *(string)* –
    The EC2 instance type of the master node.
  - **SlaveInstanceType** *(string)* –
    The EC2 instance type of the slave nodes.
  - **InstanceCount** *(integer)* –
    The number of Amazon EC2 instances used to execute the job flow.
  - **InstanceGroups** *(list)* –
    Configuration for the job flow’s instance groups.
    
    **(dict)** –
    Configuration defining a new instance group.
    - **Name** *(string)* –
      Friendly name given to the instance group.
    - **Market** *(string)* –
      Market type of the Amazon EC2 instances used to create a cluster node.
- **InstanceRole** *(string)* – [REQUIRED]
  The role of the instance group in the cluster.
- **BidPrice** *(string)* –
  Bid price for each Amazon EC2 instance in the instance group when launching nodes as Spot Instances, expressed in USD.
- **InstanceType** *(string)* – [REQUIRED]
  The Amazon EC2 instance type for all instances in the instance group.
- **InstanceCount** *(integer)* – [REQUIRED]
  Target number of instances for the instance group.
- **Configurations** *(list)* –

  **Note:** Amazon EMR releases 4.x or later.

  The list of configurations supplied for an EMR cluster instance group. You can specify a separate configuration for each instance group (master, core, and task).
- *(dict)* –

  **Note:** Amazon EMR releases 4.x or later.

  Specifies a hardware and software configuration of the EMR cluster. This includes configurations for applications and software bundled with Amazon EMR. The Configuration object is a JSON object which is defined by a classification and a set of properties. Configurations can be nested, so a configuration may have its own Configuration objects listed.
- **Classification** *(string)* –
  The classification of a configuration. For more information see, Amazon EMR Configurations .
- **Configurations** *(list)* –
  A list of configurations you apply to this configuration object.
- **Properties** *(dict)* –
  A set of properties supplied to the Configuration object.
- *(string)* –
- *(string)* –
  - **Ec2KeyName** *(string)* –
    The name of the Amazon EC2 key pair that can be used to ssh to the master node as the user called “hadoop.”
  - **Placement** *(dict)* –
    The Availability Zone the job flow will run in.
    - **AvailabilityZone** *(string)* – [REQUIRED]
      The Amazon EC2 Availability Zone for the job flow.
  - **KeepJobFlowAliveWhenNoSteps** *(boolean)* –
    Specifies whether the job flow should be kept alive after completing all steps.
  - **TerminationProtected** *(boolean)* –
Specifies whether to lock the job flow to prevent the Amazon EC2 instances from being terminated by API call, user intervention, or in the event of a job flow error.

- **HadoopVersion** (*string*)
  
  The Hadoop version for the job flow. Valid inputs are “0.18” (deprecated), “0.20” (deprecated), “0.20.205” (deprecated), “1.0.3”, “2.2.0”, or “2.4.0”. If you do not set this value, the default of 0.18 is used, unless the AmiVersion parameter is set in the RunJobFlow call, in which case the default version of Hadoop for that AMI version is used.

- **Ec2SubnetId** (*string*)
  
  To launch the job flow in Amazon Virtual Private Cloud (Amazon VPC), set this parameter to the identifier of the Amazon VPC subnet where you want the job flow to launch. If you do not specify this value, the job flow is launched in the normal Amazon Web Services cloud, outside of an Amazon VPC.

  Amazon VPC currently does not support cluster compute quadruple extra large (cc1.4xlarge) instances. Thus you cannot specify the cc1.4xlarge instance type for nodes of a job flow launched in a Amazon VPC.

- **EmrManagedMasterSecurityGroup** (*string*)
  
  The identifier of the Amazon EC2 security group (managed by Amazon ElasticMapReduce) for the master node.

- **EmrManagedSlaveSecurityGroup** (*string*)
  
  The identifier of the Amazon EC2 security group (managed by Amazon ElasticMapReduce) for the slave nodes.

- **AdditionalMasterSecurityGroups** (*list*)
  
  A list of additional Amazon EC2 security group IDs for the master node.

  * (*string*)

- **AdditionalSlaveSecurityGroups** (*list*)
  
  A list of additional Amazon EC2 security group IDs for the slave nodes.

  * (*string*)

- **Steps** (*list*) — A list of steps to be executed by the job flow.

    * **Name** (*string*) — [REQUIRED]
      
      The name of the job flow step.

    * **ActionOnFailure** (*string*) —
      
      The action to take if the job flow step fails.

    * **HadoopJarStep** (*dict*) — [REQUIRED]
      
      The JAR file used for the job flow step.

      - **Properties** (*list*) — A list of Java properties that are set when the step runs. You can use these properties to pass key value pairs to your main function.

        * (*dict*) — A key value pair.

        * **Key** (*string*) —
          
          The unique identifier of a key value pair.
· **Value (string)** –
  The value part of the identified key.
· **Jar (string)** – [REQUIRED]
  A path to a JAR file run during the step.
· **MainClass (string)** –
  The name of the main class in the specified Java file. If not specified, the JAR file should specify a Main-Class in its manifest file.
· **Args (list)** –
  A list of command line arguments passed to the JAR file’s main function when executed.
· (string) –

**BootstrapActions (list)** – A list of bootstrap actions that will be run before Hadoop is started on the cluster nodes.
  – (dict) –
    Configuration of a bootstrap action.
      * **Name (string)** – [REQUIRED]
        The name of the bootstrap action.
      * **ScriptBootstrapAction (dict)** – [REQUIRED]
        The script run by the bootstrap action.
          · **Path (string)** – [REQUIRED]
            Location of the script to run during a bootstrap action. Can be either a location in Amazon S3 or on a local file system.
          · **Args (list)** –
            A list of command line arguments to pass to the bootstrap action script.
          · (string) –

**SupportedProducts (list)** –

**Note:** For Amazon EMR releases 3.x and 2.x. For Amazon EMR releases 4.x and greater, use Applications.

A list of strings that indicates third-party software to use with the job flow. For more information, go to Use Third Party Applications with Amazon EMR. Currently supported values are:
  – “mapr-m5” - launch the job flow using MapR M5 Edition.
  – (string) –

**NewSupportedProducts (list)** –

**Note:** For Amazon EMR releases 3.x and 2.x. For Amazon EMR releases 4.x and greater, use Applications.

A list of strings that indicates third-party software to use with the job flow that accepts a user argument list. EMR accepts and forwards the argument list to the corresponding installation script as bootstrap action arguments. For more information, see Launch a Job Flow on the MapR Distribution for Hadoop. Currently supported values are:
  – “mapr-m3” - launch the cluster using MapR M3 Edition.
- “mapr-m5” - launch the cluster using MapR M5 Edition.
- “mapr” with the user arguments specifying “--edition,m3” or “--edition,m5” - launch the job flow using MapR M3 or M5 Edition respectively.
- “mapr-m7” - launch the cluster using MapR M7 Edition.
- “hunk” - launch the cluster with the Hunk Big Data Analytics Platform.
- “hue” - launch the cluster with Hue installed.
- “spark” - launch the cluster with Apache Spark installed.
- “ganglia” - launch the cluster with the Ganglia Monitoring System installed.

- (dict)
  The list of supported product configurations which allow user-supplied arguments. EMR accepts these arguments and forwards them to the corresponding installation script as bootstrap action arguments.
    * Name (string)
      The name of the product configuration.
    * Args (list)
      The list of user-supplied arguments.
        - (string)

• Applications (list)

Note: Amazon EMR releases 4.x or later.

A list of applications for the cluster. Valid values are: “Hadoop”, “Hive”, “Mahout”, “Pig”, and “Spark.” They are case insensitive.

- (dict)

An application is any Amazon or third-party software that you can add to the cluster. This structure contains a list of strings that indicates the software to use with the cluster and accepts a user argument list. Amazon EMR accepts and forwards the argument list to the corresponding installation script as bootstrap action argument. For more information, see Launch a Job Flow on the MapR Distribution for Hadoop . Currently supported values are:
    * “mapr-m3” - launch the job flow using MapR M3 Edition.
    * “mapr-m5” - launch the job flow using MapR M5 Edition.
    * “mapr” with the user arguments specifying “--edition,m3” or “--edition,m5” - launch the job flow using MapR M3 or M5 Edition respectively.

Note: In Amazon EMR releases 4.0 and greater, the only accepted parameter is the application name. To pass arguments to applications, you supply a configuration for each application.

    * Name (string)
      The name of the application.
    * Version (string)
      The version of the application.
    * Args (list)
      Arguments for Amazon EMR to pass to the application.
        - (string)
* **AdditionalInfo (dict)** –
  This option is for advanced users only. This is meta information about third-party applications that third-party vendors use for testing purposes.
  - *(string)* –
  - *(string)* –

- **Configurations (list)** –

  **Note:** Amazon EMR releases 4.x or later.

  The list of configurations supplied for the EMR cluster you are creating.
  - *(dict)* –

  **Note:** Amazon EMR releases 4.x or later.

  Specifies a hardware and software configuration of the EMR cluster. This includes configurations for applications and software bundled with Amazon EMR. The Configuration object is a JSON object which is defined by a classification and a set of properties. Configurations can be nested, so a configuration may have its own Configuration objects listed.

  * **Classification (string)** –
    The classification of a configuration. For more information see, Amazon EMR Configurations.

  * **Configurations (list)** –
    A list of configurations you apply to this configuration object.

  * **Properties (dict)** –
    A set of properties supplied to the Configuration object.
    - *(string)* –
    - *(string)* –

  - **VisibleToAllUsers (boolean)** – Whether the job flow is visible to all IAM users of the AWS account associated with the job flow. If this value is set to true, all IAM users of that AWS account can view and (if they have the proper policy permissions set) manage the job flow. If it is set to false, only the IAM user that created the job flow can view and manage it.

  - **JobFlowRole (string)** – An IAM role for the job flow. The EC2 instances of the job flow assume this role. The default role is EMRJobflowDefault. In order to use the default role, you must have already created it using the CLI.

  - **ServiceRole (string)** – The IAM role that will be assumed by the Amazon EMR service to access AWS resources on your behalf.

  - **Tags (list) (string)** – A list of tags to associate with a cluster and propagate to Amazon EC2 instances.
    - *(dict)* –

    A key/value pair containing user-defined metadata that you can associate with an Amazon EMR resource. Tags make it easier to associate clusters in various ways, such as grouping clusters to track your Amazon EMR resource allocation costs. For more information, see Tagging Amazon EMR Resources.

    * **Key (string)** –
      A user-defined key, which is the minimum required information for a valid tag. For more information, see Tagging Amazon EMR Resources.
* **Value** *(string)* – A user-defined value, which is optional in a tag. For more information, see Tagging Amazon EMR Resources.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'JobFlowId': 'string'
}
```

**Response Structure**

- *(dict)* – The result of the RunJobFlow operation.
  - **JobFlowId** *(string)* – An unique identifier for the job flow.

**set_termination_protection**(**kwargs**)

SetTerminationProtection locks a job flow so the Amazon EC2 instances in the cluster cannot be terminated by user intervention, an API call, or in the event of a job-flow error. The cluster still terminates upon successful completion of the job flow. Calling SetTerminationProtection on a job flow is analogous to calling the Amazon EC2 DisableAPITermination API on all of the EC2 instances in a cluster.

SetTerminationProtection is used to prevent accidental termination of a job flow and to ensure that in the event of an error, the instances will persist so you can recover any data stored in their ephemeral instance storage.

To terminate a job flow that has been locked by setting SetTerminationProtection to `true`, you must first unlock the job flow by a subsequent call to SetTerminationProtection in which you set the value to `false`.

For more information, go to Protecting a Job Flow from Termination in the Amazon Elastic MapReduce Developer's Guide.

**Request Syntax**

```python
response = client.set_termination_protection(
    JobFlowIds=[
        'string',
    ],
    TerminationProtected=True|False
)
```

**Parameters**

- **JobFlowIds** *(list)* – [REQUIRED]
  A list of strings that uniquely identify the job flows to protect. This identifier is returned by RunJobFlow and can also be obtained from DescribeJobFlows.
  - *(string)* –
- **TerminationProtected** *(boolean)* – [REQUIRED]
  A Boolean that indicates whether to protect the job flow and prevent the Amazon EC2 instances in the cluster from shutting down due to API calls, user intervention, or job-flow error.

**Returns** None
**set_visible_to_all_users(**kwargs)**

Sets whether all AWS Identity and Access Management (IAM) users under your account can access the specified job flows. This action works on running job flows. You can also set the visibility of a job flow when you launch it using the `VisibleToAllUsers` parameter of `RunJobFlow`. The `SetVisibleToAllUsers` action can be called only by an IAM user who created the job flow or the AWS account that owns the job flow.

**Request Syntax**

```python
response = client.set_visible_to_all_users(
    JobFlowIds=['string'],
    VisibleToAllUsers=True|False
)
```

**Parameters**

- **JobFlowIds** *(list) – [REQUIRED]*
  Identifiers of the job flows to receive the new visibility setting.
  
- **VisibleToAllUsers** *(boolean) – [REQUIRED]*
  Whether the specified job flows are visible to all IAM users of the AWS account associated with the job flow. If this value is set to True, all IAM users of that AWS account can view and, if they have the proper IAM policy permissions set, manage the job flows. If it is set to False, only the IAM user that created a job flow can view and manage it.

**Returns** None

**terminate_job_flows(**kwargs)**

TerminateJobFlows shuts a list of job flows down. When a job flow is shut down, any step not yet completed is canceled and the EC2 instances on which the job flow is running are stopped. Any log files not already saved are uploaded to Amazon S3 if a LogUri was specified when the job flow was created.

The maximum number of JobFlows allowed is 10. The call to `TerminateJobFlows` is asynchronous. Depending on the configuration of the job flow, it may take up to 5-20 minutes for the job flow to completely terminate and release allocated resources, such as Amazon EC2 instances.

**Request Syntax**

```python
response = client.terminate_job_flows(
    JobFlowIds=['string'],
)
```

**Parameters**

- **JobFlowIds** *(list) – [REQUIRED]*
  A list of job flows to be shutdown.

**Returns** None

**Paginators**

The available paginators are:

- EMR.Paginator.ListBootstrapActions

3.1. Services 2621
class EMR.Paginator.ListBootstrapActions

paginator = client.get_paginator('list_bootstrap_actions')

paginate(**kwargs)

Creates an iterator that will paginate through responses from EMR.Client.list_bootstrap_actions().

Request Syntax

response_iterator = paginator.paginate(
    ClusterId='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **ClusterId (string)** – [REQUIRED]
  The cluster identifier for the bootstrap actions to list.
- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize (integer)** –
    The size of each page.
  - **StartingToken (string)** –
    A token to specify where to start paginating. This is the NextToken from a previous response.

Returns

dict

Response Syntax

{
    'BootstrapActions': [
        {
            'Name': 'string',
            'ScriptPath': 'string',
            'Args': [
                'string',
            ],
        },
    ]
}
Response Structure

- **(dict)** –
  
  This output contains the bootstrap actions detail.

  - **BootstrapActions (list)** –
    
    The bootstrap actions associated with the cluster.

    * **(dict)** –
      
      An entity describing an executable that runs on a cluster.

      - **Name (string)** –
        
        The name of the command.

      - **ScriptPath (string)** –
        
        The Amazon S3 location of the command script.

      - **Args (list)** –
        
        Arguments for Amazon EMR to pass to the command for execution.

    - **NextToken (string)** –
      
      A token to resume pagination.

```python
class EMR.Paginator.ListClusters

paginataor = client.get_paginator('list_clusters')

paginate(**kwargs)

Creates an iterator that will paginate through responses from EMR.Client.list_clusters().

Request Syntax

```python
response_iterator = paginataor.paginate(
    CreatedAfter=datetime(2015, 1, 1),
    CreatedBefore=datetime(2015, 1, 1),
    ClusterStates=['STARTING'|'BOOTSTRAPPING'|'RUNNING'|'WAITING'|'TERMINATING'|'TERMINATED'|'TERMINATED_WITH_ERRORS',
    ],
    PaginationConfig=
    { 'MaxItems': 123,
      'PageSize': 123,
      'StartingToken': 'string'
    }
)
```

Parameters

- **CreatedAfter (datetime)** – The creation date and time beginning value filter for listing clusters.
- **CreatedBefore (datetime)** – The creation date and time end value filter for listing clusters.
- **ClusterStates (list)** – The cluster state filters to apply when listing clusters.
• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  – **MaxItems** *(integer)* –

  The total number of items to return. If the total number of items available is more than the value specified in `max-items` then a `NextToken` will be provided in the output that you can use to resume pagination.

  – **PageSize** *(integer)* –

  The size of each page.

  – **StartingToken** *(string)* –

  A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Returns**

**dict**

**Response Syntax**

```python
{
    'Clusters': [
        {
            'Id': 'string',
            'Name': 'string',
            'Status': {
                'State': 'STARTING'|'BOOTSTRAPPING'|'RUNNING'|'WAITING'|'TERMINATING'|'TERMINATED'|'TERMINATED_WITH_ERRORS',
                'StateChangeReason': {
                    'Code': 'INTERNAL_ERROR'|'VALIDATION_ERROR'|'INSTANCE_FAILURE'|'BOOTSTRAP_FAILURE'|'USER_REQUEST'|'STEP_FAILURE'|'ALL_STEPS_COMPLETED',
                    'Message': 'string'
                },
                'Timeline': {
                    'CreationDateTime': datetime(2015, 1, 1),
                    'ReadyDateTime': datetime(2015, 1, 1),
                    'EndDateTime': datetime(2015, 1, 1)
                }
            },
            'NormalizedInstanceHours': 123
        },
        
        'NextToken': 'string'
    ]
}
```

**Response Structure**

• *(dict)* –

This contains a ClusterSummaryList with the cluster details; for example, the cluster IDs, names, and status.

  – **Clusters** *(list)* –

  The list of clusters for the account based on the given filters.

    • *(dict)* –

    The summary description of the cluster.

      • **Id** *(string)* –

      The unique identifier for the cluster.

      • **Name** *(string)* –

      The name of the cluster.
- **Status** *(dict)* —
  The details about the current status of the cluster.

- **State** *(string)* —
  The current state of the cluster.

- **StateChangeReason** *(dict)* —
  The reason for the cluster status change.

- **Code** *(string)* —
  The programmatic code for the state change reason.

- **Message** *(string)* —
  The descriptive message for the state change reason.

- **Timeline** *(dict)* —
  A timeline that represents the status of a cluster over the lifetime of the cluster.

- **CreationDateTime** *(datetime)* —
  The creation date and time of the cluster.

- **ReadyDateTime** *(datetime)* —
  The date and time when the cluster was ready to execute steps.

- **EndDateTime** *(datetime)* —
  The date and time when the cluster was terminated.

- **NormalizedInstanceHours** *(integer)* —
  An approximation of the cost of the job flow, represented in m1.small/hours. This value is incremented one time for every hour an m1.small instance runs. Larger instances are weighted more, so an EC2 instance that is roughly four times more expensive would result in the normalized instance hours being incremented by four. This result is only an approximation and does not reflect the actual billing rate.

- **NextToken** *(string)* —
  A token to resume pagination.

```python
class EMR.Paginator.ListInstanceGroups

paginator = client.get_paginator('list_instance_groups')

paginate(**kwargs)

Creates an iterator that will paginate through responses from EMR.Client.list_instance_groups().

Request Syntax

response_iterator = paginator.paginate(
    ClusterId='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```
Parameters

- **ClusterId (string)** – [REQUIRED]
  
  The identifier of the cluster for which to list the instance groups.

- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  
  - **MaxItems (integer)** –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  
  - **PageSize (integer)** –
    
    The size of each page.
  
  - **StartingToken (string)** –
    
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict

Returns

Response Syntax

```
{
    'InstanceGroups': [  
        {
            'Id': 'string',
            'Name': 'string',
            'Market': 'ON_DEMAND'|'SPOT',
            'InstanceGroupType': 'MASTER'|'CORE'|'TASK',
            'BidPrice': 'string',
            'InstanceType': 'string',
            'RequestedInstanceCount': 123,
            'RunningInstanceCount': 123,
            'Status': {
                'State': 'PROVISIONING'|'BOOTSTRAPPING'|'RUNNING'|'RESIZING'|'SUSPENDED'|'TERMINATING'|'TERMINATED'|'ARRESTED'|'SHUTTING_DOWN'|'ENDED',
                'StateChangeReason': {
                'Code': 'INTERNAL_ERROR'|'VALIDATION_ERROR'|'INSTANCE_FAILURE'|'CLUSTER_TERMINATED',
                    'Message': 'string'
                },
                'Timeline': {
                    'CreationDateTime': datetime(2015, 1, 1),
                    'ReadyDateTime': datetime(2015, 1, 1),
                    'EndDateTime': datetime(2015, 1, 1)
                }
            },
            'Configurations': [  
                {
                    'Classification': 'string',
                    'Configurations': '{... recursive ...}',
                    'Properties': {
                        'string': 'string'
                    }
                },
                ],
            },
        },
    ],
    'NextToken': 'string'
}
```
Response Structure

- (dict) –

This input determines which instance groups to retrieve.

- **InstanceGroups** (list) –

The list of instance groups for the cluster and given filters.

- * (dict) –

This entity represents an instance group, which is a group of instances that have common purpose. For example, CORE instance group is used for HDFS.

  - **Id** (string) –
    The identifier of the instance group.
  
  - **Name** (string) –
    The name of the instance group.
  
  - **Market** (string) –
    The marketplace to provision instances for this group. Valid values are ON_DEMAND or SPOT.
  
  - **InstanceGroupType** (string) –
    The type of the instance group. Valid values are MASTER, CORE or TASK.
  
  - **BidPrice** (string) –
    The bid price for each EC2 instance in the instance group when launching nodes as Spot Instances, expressed in USD.
  
  - **InstanceType** (string) –
    The EC2 instance type for all instances in the instance group.
  
  - **RequestedInstanceCount** (integer) –
    The target number of instances for the instance group.
  
  - **RunningInstanceCount** (integer) –
    The number of instances currently running in this instance group.
  
  - **Status** (dict) –
    The current status of the instance group.
  
  - **State** (string) –
    The current state of the instance group.
  
  - **StateChangeReason** (dict) –
    The status change reason details for the instance group.

  - **Code** (string) –
    The programmable code for the state change reason.
  
  - **Message** (string) –
    The status change reason description.
  
  - **Timeline** (dict) –
    The timeline of the instance group status over time.
  
  - **CreationDateTime** (datetime) –
    The creation date and time of the instance group.
- **ReadyDateTime** *(datetime)* –
  The date and time when the instance group became ready to perform tasks.
- **EndDateTime** *(datetime)* –
  The date and time when the instance group terminated.
- **Configurations** *(list)* –

  **Note:** Amazon EMR releases 4.x or later.

  The list of configurations supplied for an EMR cluster instance group. You can specify a separate configuration for each instance group (master, core, and task).

  **Note:** Amazon EMR releases 4.x or later.

  Specifies a hardware and software configuration of the EMR cluster. This includes configurations for applications and software bundled with Amazon EMR. The Configuration object is a JSON object which is defined by a classification and a set of properties. Configurations can be nested, so a configuration may have its own Configuration objects listed.

  - **Classification** *(string)* –
    The classification of a configuration. For more information see, [Amazon EMR Configurations](#).
  - **Configurations** *(list)* –
    A list of configurations you apply to this configuration object.
  - **Properties** *(dict)* –
    A set of properties supplied to the Configuration object.
    - *(string)* –
    - *(string)* –

  - **NextToken** *(string)* –
    A token to resume pagination.

```python
class EMR.Paginator.ListInstances

paginator = client.get_paginator('list_instances')

paginate(**kwargs)

Creates an iterator that will paginate through responses from `EMR.Client.list_instances()`.

Request Syntax

```
response_iterator = paginator.paginate(
    ClusterId='string',
    InstanceGroupId='string',
    InstanceGroupTypes=['MASTER'|'CORE'|'TASK',
    ],
    PaginationConfig={
        'MaxItems': 123,
    },
```
```
Parameters

- **ClusterId** *(string)* – [REQUIRED]
  The identifier of the cluster for which to list the instances.
- **InstanceGroupId** *(string)* – The identifier of the instance group for which to list the instances.
- **InstanceGroupTypes** *(list)* – The type of instance group for which to list the instances.
  - *(string)* –
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –
    The size of each page.
  - **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

Return type  **dict**

Returns

Response Syntax

```json
{
    'Instances': [ {
        'Id': 'string',
        'Ec2InstanceId': 'string',
        'PublicDnsName': 'string',
        'PublicIpAddress': 'string',
        'PrivateDnsName': 'string',
        'PrivateIpAddress': 'string',
        'Status': {
            'State': 'AWAITING_FULFILLMENT'|'PROVISIONING'|'BOOTSTRAPPING'|'RUNNING'|'TERMINATED',
            'StateChangeReason': { 
                'Code': 'INTERNAL_ERROR'|'VALIDATION_ERROR'|'INSTANCE_FAILURE'|'BOOTSTRAP_FAILURE'|'CLUSTER_TERMINATED',
                'Message': 'string'
            },
            'Timeline': {
                'CreationDateTime': datetime(2015, 1, 1),
                'ReadyDateTime': datetime(2015, 1, 1),
                'EndDateTime': datetime(2015, 1, 1)
            }
        }
    },
    ]
    'NextToken': 'string'
}
```
Response Structure

- (dict) –
  
  This output contains the list of instances.
  
  - Instances (list) –
    
    The list of instances for the cluster and given filters.
    
    * (dict) –
      
      Represents an EC2 instance provisioned as part of cluster.
      
      - Id (string) –
        
        The unique identifier for the instance in Amazon EMR.
      
      - Ec2InstanceId (string) –
        
        The unique identifier of the instance in Amazon EC2.
      
      - PublicDnsName (string) –
        
        The public DNS name of the instance.
      
      - PublicIpAddress (string) –
        
        The public IP address of the instance.
      
      - PrivateDnsName (string) –
        
        The private DNS name of the instance.
      
      - PrivateIpAddress (string) –
        
        The private IP address of the instance.
      
      - Status (dict) –
        
        The current status of the instance.
      
      - State (string) –
        
        The current state of the instance.
      
      - StateChangeReason (dict) –
        
        The details of the status change reason for the instance.
      
      - Code (string) –
        
        The programmable code for the state change reason.
      
      - Message (string) –
        
        The status change reason description.
      
      - Timeline (dict) –
        
        The timeline of the instance status over time.
      
      - CreationDateTime (datetime) –
        
        The creation date and time of the instance.
      
      - ReadyDateTime (datetime) –
        
        The date and time when the instance was ready to perform tasks.
      
      - EndDateTime (datetime) –
        
        The date and time when the instance was terminated.
    
    - NextToken (string) –
      
      A token to resume pagination.

class EMR.Paginator.ListSteps
paginator = client.get_paginator('list_steps')

**paginate(**kwargs

Creates an iterator that will paginate through responses from EMR.Client.list_steps().

**Request Syntax**

response_iterator = paginator.paginate(
    ClusterId='string',
    StepStates=[
        'PENDING'|'RUNNING'|'COMPLETED'|'CANCELLED'|'FAILED'|'INTERRUPTED',
    ],
    StepIds=[
        'string',
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

**Parameters**

- **ClusterId** *(string)* – [REQUIRED]
  
  The identifier of the cluster for which to list the steps.

- **StepStates** *(list)* – The filter to limit the step list based on certain states.
  
  - *(string)*

- **StepIds** *(list)* – The filter to limit the step list based on the identifier of the steps.
  
  - *(string)*

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  - **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

  - **PageSize** *(integer)* –
    
    The size of each page.

  - **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** *dict*

**Returns**

**Response Syntax**

```
{
    'Steps': [
        {
            'Id': 'string',
            'Name': 'string',
            'Config': {
                'Jar': 'string',
                'Properties': {
                    'string': 'string'
                }
            }
        }
    ]
}
```
Response Structure

- (dict) –

This output contains the list of steps.

- Steps (list) –

The filtered list of steps for the cluster.

  - (dict) –

The summary of the cluster step.

  - Id (string) –

The identifier of the cluster step.

  - Name (string) –

The name of the cluster step.

  - Config (dict) –

The Hadoop job configuration of the cluster step.

  - Jar (string) –

The path to the JAR file that runs during the step.

  - Properties (dict) –

The list of Java properties that are set when the step runs. You can use these properties to pass key value pairs to your main function.

  - (string) –
  - (string) –

  - MainClass (string) –

The name of the main class in the specified Java file. If not specified, the JAR file should specify a main class in its manifest file.

  - Args (list) –
The list of command line arguments to pass to the JAR file’s main function for execution.

- (string) –
- **ActionOnFailure** (string) –
  This specifies what action to take when the cluster step fails. Possible values are TERMINATE.CLUSTER, CANCEL_AND_WAIT, and CONTINUE.
- **Status** (dict) –
  The current execution status details of the cluster step.
- **State** (string) –
  The execution state of the cluster step.
- **StateChangeReason** (dict) –
  The reason for the step execution status change.
- **Code** (string) –
  The programmable code for the state change reason. Note: Currently, the service provides no code for the state change.
- **Message** (string) –
  The descriptive message for the state change reason.
- **Timeline** (dict) –
  The timeline of the cluster step status over time.
- **CreationDateTime** (datetime) –
  The date and time when the cluster step was created.
- **StartDateTime** (datetime) –
  The date and time when the cluster step execution started.
- **EndDateTime** (datetime) –
  The date and time when the cluster step execution completed or failed.
- **NextToken** (string) –
  A token to resume pagination.

### Waiters

The available waiters are:

- **EMR.Waiter.ClusterRunning**

```python
class EMR.Waiter.ClusterRunning

waiter = client.get_waiter('cluster_running')

wait(**kwargs)
```

Polls `EMR.Client.describe_cluster()` every 30 seconds until a successful state is reached. An error is returned after 60 failed checks.

### Request Syntax
waiter.wait(
    ClusterId='string'
)

Parameters
ClusterId (string) – [REQUIRED]
   The identifier of the cluster to describe.

Returns
   None

Glacier

Table of Contents
- Glacier
  - Client
  - Service Resource
  - Account
  - Archive
  - Job
  - MultipartUpload
  - Notification
  - Vault

Client

class Glacier.Client
   A low-level client representing Amazon Glacier:

   import boto3

   client = boto3.client('glacier')

These are the available methods:
- abort_multipart_upload()
- abort_vault_lock()
- add_tags_to_vault()
- can_paginate()
- complete_multipart_upload()
- complete_vault_lock()
- create_vault()
- delete_archive()
- delete_vault()
- delete_vault_access_policy()
- delete_vault_notifications()
- describe_job()
- describe_vault()
- generate_presigned_url()
- get_data_retrieval_policy()
- get_job_output()
- get_paginators()
- get_vault_access_policy()
- get_vault_lock()
abort_multipart_upload(**kwargs)

This operation aborts a multipart upload identified by the upload ID.

After the Abort Multipart Upload request succeeds, you cannot upload any more parts to the multipart upload or complete the multipart upload. Aborting a completed upload fails. However, aborting an already-aborted upload will succeed, for a short time. For more information about uploading a part and completing a multipart upload, see UploadMultipartPart and CompleteMultipartUpload.

This operation is idempotent.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Working with Archives in Amazon Glacier and Abort Multipart Upload in the Amazon Glacier Developer Guide.

Request Syntax

```python
response = client.abort_multipart_upload(
    vaultName='string',
    uploadId='string'
)
```

Parameters

- **accountId (string)** – The `AccountId` value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos“-apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to “-” by default if no value is not specified.

- **vaultName (string)** – [REQUIRED]

  The name of the vault.

- **uploadId (string)** – [REQUIRED]

  The upload ID of the multipart upload to delete.

Returns None
**abort_vault_lock(**kwargs)**

This operation aborts the vault locking process if the vault lock is not in the **Locked** state. If the vault lock is in the **Locked** state when this operation is requested, the operation returns an **AccessDeniedException** error. Aborting the vault locking process removes the vault lock policy from the specified vault.

A vault lock is put into the **InProgress** state by calling **InitiateVaultLock**. A vault lock is put into the **Locked** state by calling **CompleteVaultLock**. You can get the state of a vault lock by calling **GetVaultLock**. For more information about the vault locking process, see Amazon Glacier Vault Lock. For more information about vault lock policies, see Amazon Glacier Access Control with Vault Lock Policies.

This operation is idempotent. You can successfully invoke this operation multiple times, if the vault lock is in the **InProgress** state or if there is no policy associated with the vault.

**Request Syntax**

```python
response = client.abort_vault_lock(
    vaultName='string'
)
```

**Parameters**

- **accountId** (**string**) – The AccountId value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single apos”-”apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to “.” by default if no value is not specified.

- **vaultName** (**string**) – [REQUIRED]
  
  The name of the vault.

**Returns**

None

**add_tags_to_vault(**kwargs)**

This operation adds the specified tags to a vault. Each tag is composed of a key and a value. Each vault can have up to 10 tags. If your request would cause the tag limit for the vault to be exceeded, the operation throws the **LimitExceededException** error. If a tag already exists on the vault under a specified key, the existing key value will be overwritten. For more information about tags, see Tagging Amazon Glacier Resources.

**Request Syntax**

```python
response = client.add_tags_to_vault(
    vaultName='string',
    Tags={
        'string': 'string'
    }
)
```

**Parameters**

- **accountId** (**string**) – The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos”-”apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to “.” by default if no value is not specified.

- **vaultName** (**string**) – [REQUIRED]
  
  The name of the vault.

**Returns**

None
• **vaultName** *(string)* – [REQUIRED]

  The name of the vault.

• **Tags** *(dict)* – The tags to add to the vault. Each tag is composed of a key and a value. The value can be an empty string.

  – *(string)* –

  Returns None

**can_paginate**(operation_name)

Check if an operation can be paginated.

**Parameters**

  operation_name *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginators("create_foo")`.

**Returns**

  True if the operation can be paginated, False otherwise.

**complete_multipart_upload**(**kwargs)

You call this operation to inform Amazon Glacier that all the archive parts have been uploaded and that Amazon Glacier can now assemble the archive from the uploaded parts. After assembling and saving the archive to the vault, Amazon Glacier returns the URI path of the newly created archive resource. Using the URI path, you can then access the archive. After you upload an archive, you should save the archive ID returned to retrieve the archive at a later point. You can also get the vault inventory to obtain a list of archive IDs in a vault. For more information, see InitiateJob.

In the request, you must include the computed SHA256 tree hash of the entire archive you have uploaded. For information about computing a SHA256 tree hash, see Computing Checksums. On the server side, Amazon Glacier also constructs the SHA256 tree hash of the assembled archive. If the values match, Amazon Glacier saves the archive to the vault; otherwise, it returns an error, and the operation fails. The ListParts operation returns a list of parts uploaded for a specific multipart upload. It includes checksum information for each uploaded part that can be used to debug a bad checksum issue.

Additionally, Amazon Glacier also checks for any missing content ranges when assembling the archive, if missing content ranges are found, Amazon Glacier returns an error and the operation fails.

Complete Multipart Upload is an idempotent operation. After your first successful complete multipart upload, if you call the operation again within a short period, the operation will succeed and return the same archive ID. This is useful in the event you experience a network issue that causes an aborted connection or receive a 500 server error, in which case you can repeat your Complete Multipart Upload request and get the same archive ID without creating duplicate archives. Note, however, that after the multipart upload completes, you cannot call the List Parts operation and the multipart upload will not appear in List Multipart Uploads response, even if idempotent complete is possible.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Uploading Large Archives in Parts (Multipart Upload) and Complete Multipart Upload in the Amazon Glacier Developer Guide.

**Request Syntax**

```python
response = client.complete_multipart_upload(
    vaultName='string',
    uploadId='string',
    archiveSize='string',
)```

3.1. Services

2637
Parameters

- **accountId (string)** – The `AccountId` value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos’’apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to “-” by default if no value is not specified.

- **vaultName (string)** – [REQUIRED]
  
  The name of the vault.

- **uploadId (string)** – [REQUIRED]
  
  The upload ID of the multipart upload.

- **archiveSize (string)** – The total size, in bytes, of the entire archive. This value should be the sum of all the sizes of the individual parts that you uploaded.

- **checksum (string)** – The SHA256 tree hash of the entire archive. It is the tree hash of SHA256 tree hash of the individual parts. If the value you specify in the request does not match the SHA256 tree hash of the final assembled archive as computed by Amazon Glacier, Amazon Glacier returns an error and the request fails.
  
  Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.

Return type  dict

Returns

Response Syntax

```json
{
    'location': 'string',
    'checksum': 'string',
    'archiveId': 'string'
}
```

Response Structure

- **(dict)** –  

  Contains the Amazon Glacier response to your request.

  For information about the underlying REST API, go to `Upload Archive`. For conceptual information, go to `Working with Archives in Amazon Glacier`.

  - `location (string)` –  

    The relative URI path of the newly added archive resource.

  - `checksum (string)` –  

    The checksum of the archive computed by Amazon Glacier.

  - `archiveId (string)` –  

    The ID of the archive. This value is also included as part of the location.

`complete_vault_lock (**kwargs)`

This operation completes the vault locking process by transitioning the vault lock from the **InProgress** state to the **Locked** state, which causes the vault lock policy to become unchangeable. A vault lock is put into the **InProgress** state by calling `InitiateVaultLock`. You can obtain the state of the vault lock
by calling GetVaultLock. For more information about the vault locking process, Amazon Glacier Vault Lock.

This operation is idempotent. This request is always successful if the vault lock is in the Locked state and the provided lock ID matches the lock ID originally used to lock the vault.

If an invalid lock ID is passed in the request when the vault lock is in the Locked state, the operation returns an AccessDeniedException error. If an invalid lock ID is passed in the request when the vault lock is in the InProgress state, the operation throws an InvalidParameter error.

Request Syntax

```python
response = client.complete_vault_lock(
    vaultName='string',
    lockId='string'
)
```

Parameters

- **accountId (string)** – The AccountId value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single apos''-apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to “-” by default if no value is not specified.

- **vaultName (string)** – [REQUIRED]
  The name of the vault.

- **lockId (string)** – [REQUIRED]
  The lockId value is the lock ID obtained from a InitiateVaultLock request.

Returns

None

create_vault(**kwargs)**

This operation creates a new vault with the specified name. The name of the vault must be unique within a region for an AWS account. You can create up to 1,000 vaults per account. If you need to create more vaults, contact Amazon Glacier.

You must use the following guidelines when naming a vault.

- Names can be between 1 and 255 characters long.
- Allowed characters are a-z, A-Z, 0-9, _ (underscore), - (hyphen), and . (period).

This operation is idempotent.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Creating a Vault in Amazon Glacier and Create Vault in the Amazon Glacier Developer Guide.

Request Syntax

```python
response = client.create_vault(
    vaultName='string'
)
```

Parameters
• **accountId** *(string)* – The `AccountId` value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single apos”-“ apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens (apos-apos) in the ID.

  Note: this parameter is set to “-” by default if no value is not specified.

• **vaultName** *(string)* – [REQUIRED]

  The name of the vault.

Return type  
dict

Returns

Response Syntax

```python
{
  'location': 'string'
}
```

Response Structure

• *(dict)* –

  Contains the Amazon Glacier response to your request.

  – location *(string)* –

  The URI of the vault that was created.

delete_archive(**kwargs)**

This operation deletes an archive from a vault. Subsequent requests to initiate a retrieval of this archive will fail. Archive retrievals that are in progress for this archive ID may or may not succeed according to the following scenarios:

• If the archive retrieval job is actively preparing the data for download when Amazon Glacier receives the delete archive request, the archival retrieval operation might fail.

• If the archive retrieval job has successfully prepared the archive for download when Amazon Glacier receives the delete archive request, you will be able to download the output.

This operation is idempotent. Attempting to delete an already-deleted archive does not result in an error.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Deleting an Archive in Amazon Glacier and Delete Archive in the Amazon Glacier Developer Guide.

Request Syntax

```python
response = client.delete_archive(
    vaultName='string',
    archiveId='string'
)
```

Parameters

• **accountId** *(string)* – The `AccountId` value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos”-“ apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
Note: this parameter is set to “-” by default if no value is not specified.

- **vaultName (string)** – [REQUIRED]
The name of the vault.

- **archiveId (string)** – [REQUIRED]
The ID of the archive to delete.

**Returns** None

### delete_vault(**kwargs**)

This operation deletes a vault. Amazon Glacier will delete a vault only if there are no archives in the vault as of the last inventory and there have been no writes to the vault since the last inventory. If either of these conditions is not satisfied, the vault deletion fails (that is, the vault is not removed) and Amazon Glacier returns an error. You can use DescribeVault to return the number of archives in a vault, and you can use Initiate a Job (POST jobs) to initiate a new inventory retrieval for a vault. The inventory contains the archive IDs you use to delete archives using Delete Archive (DELETE archive).

This operation is idempotent.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Deleting a Vault in Amazon Glacier and Delete Vault in the Amazon Glacier Developer Guide.

**Request Syntax**

```python
response = client.delete_vault(
    vaultName='string'
)
```

**Parameters**

- **accountId (string)** – The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos’’apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.

  Note: this parameter is set to “-” by default if no value is not specified.

- **vaultName (string)** – [REQUIRED]
The name of the vault.

**Returns** None

### delete_vault_access_policy(**kwargs**)

This operation deletes the access policy associated with the specified vault. The operation is eventually consistent; that is, it might take some time for Amazon Glacier to completely remove the access policy, and you might still see the effect of the policy for a short time after you send the delete request.

This operation is idempotent. You can invoke delete multiple times, even if there is no policy associated with the vault. For more information about vault access policies, see Amazon Glacier Access Control with Vault Access Policies.

**Request Syntax**
response = client.delete_vault_access_policy(
    vaultName='string'
)

Parameters

- **accountId (string)** – The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos''-'' apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to “-” by default if no value is not specified.

- **vaultName (string)** – [REQUIRED]
  
  The name of the vault.

Returns

None

delete_vault_notifications(**kwargs)

This operation deletes the notification configuration set for a vault. The operation is eventually consistent; that is, it might take some time for Amazon Glacier to completely disable the notifications and you might still receive some notifications for a short time after you send the delete request.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Configuring Vault Notifications in Amazon Glacier and Delete Vault Notification Configuration in the Amazon Glacier Developer Guide.

Request Syntax

response = client.delete_vault_notifications(
    vaultName='string'
)

Parameters

- **accountId (string)** – The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos''-'' apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to “-” by default if no value is not specified.

- **vaultName (string)** – [REQUIRED]
  
  The name of the vault.

Returns

None

describe_job(**kwargs)

This operation returns information about a job you previously initiated, including the job initiation date, the user who initiated the job, the job status code/message and the Amazon SNS topic to notify after Amazon Glacier completes the job. For more information about initiating a job, see InitiateJob.

---

**Note:** This operation enables you to check the status of your job. However, it is strongly recommended that you set up an Amazon SNS topic and specify it in your initiate job request so that Amazon Glacier can notify the topic after it completes the job.
A job ID will not expire for at least 24 hours after Amazon Glacier completes the job.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For information about the underlying REST API, go to Working with Archives in Amazon Glacier in the Amazon Glacier Developer Guide.

**Request Syntax**

```python
response = client.describe_job(
    vaultName='string',
    jobId='string'
)
```

**Parameters**

- **accountId** *(string)* – The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos`'`apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to `"-"` by default if no value is not specified.

- **vaultName** *(string)* – [REQUIRED]

  The name of the vault.

- **jobId** *(string)* – [REQUIRED]

  The ID of the job to describe.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'JobId': 'string',
    'JobDescription': 'string',
    'Action': 'ArchiveRetrieval'|'InventoryRetrieval',
    'ArchiveId': 'string',
    'VaultARN': 'string',
    'CreationDate': 'string',
    'Completed': True|False,
    'StatusCode': 'InProgress'|'Succeeded'|'Failed',
    'StatusMessage': 'string',
    'ArchiveSizeInBytes': 123,
    'InventorySizeInBytes': 123,
    'SNSTopic': 'string',
    'CompletionDate': 'string',
    'SHA256TreeHash': 'string',
    'ArchiveSHA256TreeHash': 'string',
    'RetrievalByteRange': 'string',
    'InventoryRetrievalParameters': {
        'Format': 'string',
        'StartDate': 'string',
        'EndDate': 'string',
        'Limit': 'string',
        'Marker': 'string'
    }
}
```
Response Structure

- **(dict)**
  
  Describes an Amazon Glacier job.

  - **JobId**(string)**
    An opaque string that identifies an Amazon Glacier job.

  - **JobDescription**(string)**
    The job description you provided when you initiated the job.

  - **Action**(string)**
    The job type. It is either ArchiveRetrieval or InventoryRetrieval.

  - **ArchiveId**(string)**
    For an ArchiveRetrieval job, this is the archive ID requested for download. Otherwise, this field is null.

  - **VaultARN**(string)**
    The Amazon Resource Name (ARN) of the vault from which the archive retrieval was requested.

  - **CreationDate**(string)**
    The UTC date when the job was created. A string representation of ISO 8601 date format, for example, “2012-03-20T17:03:43.221Z”.

  - **Completed**(boolean)**
    The job status. When a job is completed, you get the job’s output.

  - **StatusCode**(string)**
    The status code can be InProgress, Succeeded, or Failed, and indicates the status of the job.

  - **StatusMessage**(string)**
    A friendly message that describes the job status.

  - **ArchiveSizeInBytes**(integer)**
    For an ArchiveRetrieval job, this is the size in bytes of the archive being requested for download. For the InventoryRetrieval job, the value is null.

  - **InventorySizeInBytes**(integer)**
    For an InventoryRetrieval job, this is the size in bytes of the inventory requested for download. For the ArchiveRetrieval job, the value is null.

  - **SNSTopic**(string)**
    An Amazon Simple Notification Service (Amazon SNS) topic that receives notification.

  - **CompletionDate**(string)**
    The UTC time that the archive retrieval request completed. While the job is in progress, the value will be null.

  - **SHA256TreeHash**(string)**
    For an ArchiveRetrieval job, it is the checksum of the archive. Otherwise, the value is null.

The SHA256 tree hash value for the requested range of an archive. If the Initiate a Job request for an archive specified a tree-hash aligned range, then this field returns a value.
For the specific case when the whole archive is retrieved, this value is the same as the ArchiveSHA256TreeHash value.

This field is null in the following situations:
* Archive retrieval jobs that specify a range that is not tree-hash aligned.
* Archival jobs that specify a range that is equal to the whole archive and the job status is InProgress.
* Inventory jobs.

- **ArchiveSHA256TreeHash** *(string)* –
  The SHA256 tree hash of the entire archive for an archive retrieval. For inventory retrieval jobs, this field is null.

- **RetrievalByteRange** *(string)* –
  The retrieved byte range for archive retrieval jobs in the form “StartByteValue -EndByteValue”. If no range was specified in the archive retrieval, then the whole archive is retrieved and StartByteValue equals 0 and EndByteValue equals the size of the archive minus 1. For inventory retrieval jobs this field is null.

- **InventoryRetrievalParameters** *(dict)* –
  Parameters used for range inventory retrieval.
  * **Format** *(string)* –
    The output format for the vault inventory list, which is set by the InitiateJob request when initiating a job to retrieve a vault inventory. Valid values are “CSV” and “JSON”.
  * **StartDate** *(string)* –
    The start of the date range in UTC for vault inventory retrieval that includes archives created on or after this date. A string representation of ISO 8601 date format, for example, 2013-03-20T17:03:43Z.
  * **EndDate** *(string)* –
    The end of the date range in UTC for vault inventory retrieval that includes archives created before this date. A string representation of ISO 8601 date format, for example, 2013-03-20T17:03:43Z.
  * **Limit** *(string)* –
    Specifies the maximum number of inventory items returned per vault inventory retrieval request. This limit is set when initiating the job with the a InitiateJob request.
  * **Marker** *(string)* –
    An opaque string that represents where to continue pagination of the vault inventory retrieval results. You use the marker in a new InitiateJob request to obtain additional inventory items. If there are no more inventory items, this value is null. For more information, see Range Inventory Retrieval.

### describe_vault(**kwargs)**

This operation returns information about a vault, including the vault’s Amazon Resource Name (ARN), the date the vault was created, the number of archives it contains, and the total size of all the archives in the vault. The number of archives and their total size are as of the last inventory generation. This means that if you add or remove an archive from a vault, and then immediately use Describe Vault, the change in contents will not be immediately reflected. If you want to retrieve the latest inventory of the vault, use InitiateJob. Amazon Glacier generates vault inventories approximately daily. For more information, see Downloading a Vault Inventory in Amazon Glacier.
An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Retrieving Vault Metadata in Amazon Glacier and Describe Vault in the Amazon Glacier Developer Guide.

**Request Syntax**

```python
response = client.describe_vault(
    vaultName='string'
)
```

**Parameters**

- **accountId (string)** – The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos”-“apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to “-” by default if no value is not specified.
- **vaultName (string)** – [REQUIRED]
  
  The name of the vault.

**Return type** dict

**Returns**

- **Response Syntax**

  ```
  
  { 
    'VaultARN': 'string',
    'VaultName': 'string',
    'CreationDate': 'string',
    'LastInventoryDate': 'string',
    'NumberOfArchives': 123,
    'SizeInBytes': 123
  }
  ```

- **Response Structure**

  - (dict) –

  Contains the Amazon Glacier response to your request.

  - **VaultARN (string)** –

    The Amazon Resource Name (ARN) of the vault.

  - **VaultName (string)** –

    The name of the vault.

  - **CreationDate (string)** –

    The UTC date when the vault was created. A string representation of ISO 8601 date format, for example, “2012-03-20T17:03:43.221Z”.

  - **LastInventoryDate (string)** –

    The UTC date when Amazon Glacier completed the last vault inventory. A string representation of ISO 8601 date format, for example, “2012-03-20T17:03:43.221Z”.
- **NumberOfArchives (integer)** –
  The number of archives in the vault as of the last inventory date. This field will return null if an inventory has not yet run on the vault, for example, if you just created the vault.

- **SizeInBytes (integer)** –
  Total size, in bytes, of the archives in the vault as of the last inventory date. This field will return null if an inventory has not yet run on the vault, for example, if you just created the vault.

**generate_presigned_url** *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*
Generate a presigned url given a client, its method, and arguments

**Parameters**

- **ClientMethod (string)** – The client method to presign for
- **Params (dict)** – The parameters normally passed to ClientMethod.
- **ExpiresIn (int)** – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod (string)** – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns**
The presigned url

**get_data_retrieval_policy** (**kwargs)**
This operation returns the current data retrieval policy for the account and region specified in the GET request. For more information about data retrieval policies, see Amazon Glacier Data Retrieval Policies.

**Request Syntax**

```python
response = client.get_data_retrieval_policy(
)
```

**Parameters**

- **accountId (string)** – The AccountId value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single apos”-“ apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens (apos-apos) in the ID.
  Note: this parameter is set to “.” by default if no value is not specified.

**Return type**
dict

**Returns**

**Response Syntax**

```json
{
    'Policy': {
        'Rules': [
        {
            'Strategy': 'string',
            'BytesPerHour': 123
        }
      ]
    }
}
```

**Response Structure**

- **(dict)** –
Contains the Amazon Glacier response to the GetDataRetrievalPolicy request.

- **Policy (dict)**

Contains the returned data retrieval policy in JSON format.

- **Rules (list)**

The policy rule. Although this is a list type, currently there must be only one rule, which contains a Strategy field and optionally a BytesPerHour field.

  - (dict)

    Data retrieval policy rule.

  - **Strategy (string)**

    The type of data retrieval policy to set.

    Valid values: BytesPerHour|FreeTier|None

  - **BytesPerHour (integer)**

    The maximum number of bytes that can be retrieved in an hour.

    This field is required only if the value of the Strategy field is BytesPerHour. Your PUT operation will be rejected if the Strategy field is not set to BytesPerHour and you set this field.

---

### get_job_output (**kwargs)

This operation downloads the output of the job you initiated using InitiateJob. Depending on the job type you specified when you initiated the job, the output will be either the content of an archive or a vault inventory.

A job ID will not expire for at least 24 hours after Amazon Glacier completes the job. That is, you can download the job output within the 24 hours period after Amazon Glacier completes the job.

If the job output is large, then you can use the Range request header to retrieve a portion of the output. This allows you to download the entire output in smaller chunks of bytes. For example, suppose you have 1 GB of job output you want to download and you decide to download 128 MB chunks of data at a time, which is a total of eight Get Job Output requests. You use the following process to download the job output:

- Download a 128 MB chunk of output by specifying the appropriate byte range using the Range header.
- Along with the data, the response includes a SHA256 tree hash of the payload. You compute the checksum of the payload on the client and compare it with the checksum you received in the response to ensure you received all the expected data.
- Repeat steps 1 and 2 for all the eight 128 MB chunks of output data, each time specifying the appropriate byte range.
- After downloading all the parts of the job output, you have a list of eight checksum values. Compute the tree hash of these values to find the checksum of the entire output. Using the DescribeJob API, obtain job information of the job that provided you the output. The response includes the checksum of the entire archive stored in Amazon Glacier. You compare this value with the checksum you computed to ensure you have downloaded the entire archive content with no errors.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).
For conceptual information and the underlying REST API, go to Downloading a Vault Inventory, Downloading an Archive, and Get Job Output

Request Syntax

```python
response = client.get_job_output(
    vaultName='string',
    jobId='string',
    range='string'
)
```

Parameters

- **accountId** (string) – The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos‘-apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to “-” by default if no value is not specified.
- **vaultName** (string) – [REQUIRED]
  
  The name of the vault.
- **jobId** (string) – [REQUIRED]
  
  The job ID whose data is downloaded.
- **range** (string) – The range of bytes to retrieve from the output. For example, if you want to download the first 1,048,576 bytes, specify “Range: bytes=0-1048575”. By default, this operation downloads the entire output.

Return type  dict

Returns

Response Syntax

```python
{
    'body': b'bytes',
    'checksum': 'string',
    'status': 123,
    'contentRange': 'string',
    'acceptRanges': 'string',
    'contentType': 'string',
    'archiveDescription': 'string'
}
```

Response Structure

- (dict) –

  Contains the Amazon Glacier response to your request.
  
  - **body** (bytes) –
    
    The job data, either archive data or inventory data.
  
  - **checksum** (string) –
    
    The checksum of the data in the response. This header is returned only when retrieving the output for an archive retrieval job. Furthermore, this header appears only under the following conditions:
    
    * You get the entire range of the archive.
    * You request a range to return of the archive that starts and ends on a multiple of 1 MB. For example, if you have an 3.1 MB archive and
you specify a range to return that starts at 1 MB and ends at 2 MB, then the x-amz-sha256-tree-hash is returned as a response header.

* You request a range of the archive to return that starts on a multiple of 1 MB and goes to the end of the archive. For example, if you have a 3.1 MB archive and you specify a range that starts at 2 MB and ends at 3.1 MB (the end of the archive), then the x-amz-sha256-tree-hash is returned as a response header.

- **status (integer)**
  The HTTP response code for a job output request. The value depends on whether a range was specified in the request.

- **contentRange (string)**
  The range of bytes returned by Amazon Glacier. If only partial output is downloaded, the response provides the range of bytes Amazon Glacier returned. For example, bytes 0-1048575/8388608 returns the first 1 MB from 8 MB.

- **acceptRanges (string)**
  Indicates the range units accepted. For more information, go to RFC2616.

- **contentType (string)**
  The Content-Type depends on whether the job output is an archive or a vault inventory. For archive data, the Content-Type is application/octet-stream. For vault inventory, if you requested CSV format when you initiated the job, the Content-Type is text/csv. Otherwise, by default, vault inventory is returned as JSON, and the Content-Type is application/json.

- **archiveDescription (string)**
  The description of an archive.

### get_paginator (operation_name)
Create a paginator for an operation.

**Parameters**

- **operation_name (string)** – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you'd normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

**Raises** OperationNotPageableError
Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

**Return type** L{botocore.paginate.Paginator}

**Returns**
A paginator object.

### get_vault_access_policy (**kwargs)
This operation retrieves the access-policy subresource set on the vault; for more information on setting this subresource, see Set Vault Access Policy (PUT access-policy). If there is no access policy set on the vault, the operation returns a 404 Not found error. For more information about vault access policies, see Amazon Glacier Access Control with Vault Access Policies.

**Request Syntax**

```python
response = client.get_vault_access_policy(
    vaultName='string'
)
```

**Parameters**
Boto3 Documentation, Release 1.1.4

- **accountId** *(string)* – The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos"-apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to "-" by default if no value is not specified.

- **vaultName** *(string)* – [REQUIRED]
  The name of the vault.

Return type  `dict`

Returns

Response Syntax

```python
{
    'policy': {
        'Policy': 'string'
    }
}
```

Response Structure

- *(dict)* –
  Output for GetVaultAccessPolicy.
  - **policy** *(dict)* –
    Contains the returned vault access policy as a JSON string.
    - **Policy** *(string)* –
      The vault access policy.

**get_vault_lock(**kwargs**)

This operation retrieves the following attributes from the lock-policy subresource set on the specified vault:

- The vault lock policy set on the vault.
- The state of the vault lock, which is either InProgress or Locked.
- When the lock ID expires. The lock ID is used to complete the vault locking process.
- When the vault lock was initiated and put into the InProgress state.

A vault lock is put into the InProgress state by calling InitiateVaultLock. A vault lock is put into the Locked state by calling CompleteVaultLock. You can abort the vault locking process by calling AbortVaultLock. For more information about the vault locking process, see Amazon Glacier Vault Lock.

If there is no vault lock policy set on the vault, the operation returns a 404 Not found error. For more information about vault lock policies, see Amazon Glacier Access Control with Vault Lock Policies.

Request Syntax

```python
response = client.get_vault_lock(
    vaultName='string'
)
```

Parameters

- **accountId** *(string)* – The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos"-apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
Note: this parameter is set to “-” by default if no value is not specified.

- **vaultName** *(string)* – [REQUIRED]

  The name of the vault.

Return type  dict

Returns

Response Syntax

```python
{
    'Policy': 'string',
    'State': 'string',
    'ExpirationDate': 'string',
    'CreationDate': 'string'
}
```

Response Structure

- *(dict)* –

  Contains the Amazon Glacier response to your request.

  - **Policy** *(string)* –

    The vault lock policy as a JSON string, which uses “\"” as an escape character.

  - **State** *(string)* –

    The state of the vault lock. *InProgress* or *Locked*.

  - **ExpirationDate** *(string)* –

    The UTC date and time at which the lock ID expires. This value can be null if the vault lock is in a *Locked* state.

  - **CreationDate** *(string)* –

    The UTC date and time at which the vault lock was put into the *InProgress* state.

get_vault_notifications(**kwargs)**

This operation retrieves the **notification-configuration** subresource of the specified vault.

For information about setting a notification configuration on a vault, see SetVaultNotifications. If a notification configuration for a vault is not set, the operation returns a 404 *Not Found* error. For more information about vault notifications, see Configuring Vault Notifications in Amazon Glacier.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Configuring Vault Notifications in Amazon Glacier and Get Vault Notification Configuration in the Amazon Glacier Developer Guide.

Request Syntax

```python
response = client.get_vault_notifications(
    vaultName='string'
)
```

Parameters
• **accountId** *(string)* – The `accountId` value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos''-'apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.

  Note: this parameter is set to “-” by default if no value is not specified.

• **vaultName** *(string)* – [REQUIRED]

  The name of the vault.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'vaultNotificationConfig': {
        'SNSTopic': 'string',
        'Events': [
            'string',
        ]
    }
}
```

**Response Structure**

• *(dict)* –

  Contains the Amazon Glacier response to your request.

  – **vaultNotificationConfig** *(dict)* –

    Returns the notification configuration set on the vault.

    • **SNSTopic** *(string)* –

      The Amazon Simple Notification Service (Amazon SNS) topic Amazon Resource Name (ARN).

    • **Events** *(list)* –

      A list of one or more events for which Amazon Glacier will send a notification to the specified Amazon SNS topic.

• *(string)* –

**get_waiter** *(waiter_name)*

**initiate_job** *(**kwargs)*

This operation initiates a job of the specified type. In this release, you can initiate a job to retrieve either an archive or a vault inventory (a list of archives in a vault).

Retrieving data from Amazon Glacier is a two-step process:

• Initiate a retrieval job. .. note::A data retrieval policy can cause your initiate retrieval job request to fail with a `PolicyEnforcedException` exception. For more information about data retrieval policies, see [Amazon Glacier Data Retrieval Policies](https://docs.aws.amazon.com/glacier/latest/dev/data-retrieval-policies.html). For more information about the `PolicyEnforcedException` exception, see [Error Responses](https://docs.aws.amazon.com/glacier/latest/dev/clouderrorcodes.html).

• After the job completes, download the bytes.

The retrieval request is executed asynchronously. When you initiate a retrieval job, Amazon Glacier creates a job and returns a job ID in the response. When Amazon Glacier completes the job, you can get the job output (archive or inventory data). For information about getting job output, see [GetJobOutput operation](https://docs.aws.amazon.com/glacier/latest/dev/how-to-get-output-data.html).

The job must complete before you can get its output. To determine when a job is complete, you have the following options:
• **Use Amazon SNS Notification** You can specify an Amazon Simple Notification Service (Amazon SNS) topic to which Amazon Glacier can post a notification after the job is completed. You can specify an SNS topic per job request. The notification is sent only after Amazon Glacier completes the job. In addition to specifying an SNS topic per job request, you can configure vault notifications for a vault so that job notifications are always sent. For more information, see SetVaultNotifications.

• **Get job details** You can make a DescribeJob request to obtain job status information while a job is in progress. However, it is more efficient to use an Amazon SNS notification to determine when a job is complete.

**Note:** The information you get via notification is same that you get by calling DescribeJob.

If for a specific event, you add both the notification configuration on the vault and also specify an SNS topic in your initiate job request, Amazon Glacier sends both notifications. For more information, see SetVaultNotifications.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

**About the Vault Inventory**

Amazon Glacier prepares an inventory for each vault periodically, every 24 hours. When you initiate a job for a vault inventory, Amazon Glacier returns the last inventory for the vault. The inventory data you get might be up to a day or two days old. Also, the initiate inventory job might take some time to complete before you can download the vault inventory. So you do not want to retrieve a vault inventory for each vault operation. However, in some scenarios, you might find the vault inventory useful. For example, when you upload an archive, you can provide an archive description but not an archive name. Amazon Glacier provides you a unique archive ID, an opaque string of characters. So, you might maintain your own database that maps archive names to their corresponding Amazon Glacier assigned archive IDs. You might find the vault inventory useful in the event you need to reconcile information in your database with the actual vault inventory.

**Range Inventory Retrieval**

You can limit the number of inventory items retrieved by filtering on the archive creation date or by setting a limit.

**Filtering by Archive Creation Date**

You can retrieve inventory items for archives created between **StartDate** and **EndDate** by specifying values for these parameters in the **InitiateJob** request. Archives created on or after the **StartDate** and before the **EndDate** will be returned. If you only provide the **StartDate** without the **EndDate**, you will retrieve the inventory for all archives created on or after the **StartDate**. If you only provide the **EndDate** without the **StartDate**, you will get back the inventory for all archives created before the **EndDate**.

**Limiting Inventory Items per Retrieval**

You can limit the number of inventory items returned by setting the **Limit** parameter in the **InitiateJob** request. The inventory job output will contain inventory items up to the specified **Limit**. If there are more inventory items available, the result is paginated. After a job is complete you can use the DescribeJob operation to get a marker that you use in a subsequent **InitiateJob** request. The marker will indicate the starting point to retrieve the next set of inventory items. You can page through your entire inventory by repeatedly making **InitiateJob** requests with the marker from the previous **DescribeJob** output, until you get a marker from **DescribeJob** that returns null, indicating that there are no more inventory items available.
You can use the `Limit` parameter together with the date range parameters.

**About Ranged Archive Retrieval**

You can initiate an archive retrieval for the whole archive or a range of the archive. In the case of ranged archive retrieval, you specify a byte range to return or the whole archive. The range specified must be megabyte (MB) aligned, that is the range start value must be divisible by 1 MB and range end value plus 1 must be divisible by 1 MB or equal the end of the archive. If the ranged archive retrieval is not megabyte aligned, this operation returns a 400 response. Furthermore, to ensure you get checksum values for data you download using Get Job Output API, the range must be tree hash aligned.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see [Access Control Using AWS Identity and Access Management (IAM)](#).

For conceptual information and the underlying REST API, go to [Initiate a Job and Downloading a Vault Inventory](#).

**Request Syntax**

```python
response = client.initiate_job(
    vaultName='string',
    jobParameters={
        'Format': 'string',
        'Type': 'string',
        'ArchiveId': 'string',
        'Description': 'string',
        'SNSTopic': 'string',
        'RetrievalByteRange': 'string',
        'InventoryRetrievalParameters': {
            'StartDate': 'string',
            'EndDate': 'string',
            'Limit': 'string',
            'Marker': 'string'
        }
    }
)
```

**Parameters**

- **accountId (string)** – The `AccountId` value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos‘-apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to “-“ by default if no value is not specified.

- **vaultName (string)** – [REQUIRED]
  
  The name of the vault.

- **jobParameters (dict)** – Provides options for specifying job information.
  
  - **Format (string)** –
    
    When initiating a job to retrieve a vault inventory, you can optionally add this parameter to your request to specify the output format. If you are initiating an inventory job and do not specify a Format field, JSON is the default format. Valid values are “CSV” and “JSON”.
  
  - **Type (string)** –

3.1. Services 2655
The job type. You can initiate a job to retrieve an archive or get an inventory of a vault. Valid values are “archive-retrieval” and “inventory-retrieval”.

- **ArchiveId** *(string)*

  The ID of the archive that you want to retrieve. This field is required only if **Type** is set to archive-retrieval. An error occurs if you specify this request parameter for an inventory retrieval job request.

- **Description** *(string)*

  The optional description for the job. The description must be less than or equal to 1,024 bytes. The allowable characters are 7-bit ASCII without control codes—specifically, ASCII values 32-126 decimal or 0x20-0x7E hexadecimal.

- **SNSTopic** *(string)*

  The Amazon SNS topic ARN to which Amazon Glacier sends a notification when the job is completed and the output is ready for you to download. The specified topic publishes the notification to its subscribers. The SNS topic must exist.

- **RetrievalByteRange** *(string)*

  The byte range to retrieve for an archive retrieval, in the form “StartByteValue -EndByteValue”. If not specified, the whole archive is retrieved. If specified, the byte range must be megabyte (1024*1024) aligned which means that **StartByteValue** must be divisible by 1 MB and **EndByteValue** plus 1 must be divisible by 1 MB or be the end of the archive specified as the archive byte size value minus 1. If RetrievalByteRange is not megabyte aligned, this operation returns a 400 response.

An error occurs if you specify this field for an inventory retrieval job request.

- **InventoryRetrievalParameters** *(dict)*

  Input parameters used for range inventory retrieval.

  * **StartDate** *(string)*

    The start of the date range in UTC for vault inventory retrieval that includes archives created on or after this date. A string representation of ISO 8601 date format, for example, 2013-03-20T17:03:43Z.

  * **EndDate** *(string)*

    The end of the date range in UTC for vault inventory retrieval that includes archives created before this date. A string representation of ISO 8601 date format, for example, 2013-03-20T17:03:43Z.

  * **Limit** *(string)*

    Specifies the maximum number of inventory items returned per vault inventory retrieval request. Valid values are greater than or equal to 1.

  * **Marker** *(string)*

    An opaque string that represents where to continue pagination of the vault inventory retrieval results. You use the marker in a new **InitiateJob** request to obtain additional inventory items. If there are no more inventory items, this value is **null**.

**Return type** dict
**Returns**
Response Syntax

```
{
    'location': 'string',
    'jobId': 'string'
}
```

Response Structure

- (dict) –
  Contains the Amazon Glacier response to your request.
  - location (string) –
    The relative URI path of the job.
  - jobId (string) –
    The ID of the job.

`initiate_multipart_upload(**kwargs)`

This operation initiates a multipart upload. Amazon Glacier creates a multipart upload resource and returns its ID in the response. The multipart upload ID is used in subsequent requests to upload parts of an archive (see `UploadMultipartPart`).

When you initiate a multipart upload, you specify the part size in number of bytes. The part size must be a megabyte (1024 KB) multiplied by a power of 2—for example, 1048576 (1 MB), 2097152 (2 MB), 4194304 (4 MB), 8388608 (8 MB), and so on. The minimum allowable part size is 1 MB, and the maximum is 4 GB.

Every part you upload to this resource (see `UploadMultipartPart`), except the last one, must have the same size. The last one can be the same size or smaller. For example, suppose you want to upload a 16.2 MB file. If you initiate the multipart upload with a part size of 4 MB, you will upload four parts of 4 MB each and one part of 0.2 MB.

**Note:** You don’t need to know the size of the archive when you start a multipart upload because Amazon Glacier does not require you to specify the overall archive size.

After you complete the multipart upload, Amazon Glacier removes the multipart upload resource referenced by the ID. Amazon Glacier also removes the multipart upload resource if you cancel the multipart upload or it may be removed if there is no activity for a period of 24 hours.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see [Access Control Using AWS Identity and Access Management (IAM)](https://docs.aws.amazon.com/IAM/latest/UserGuide/idLETTE.html).

For conceptual information and underlying REST API, go to [Uploading Large Archives in Parts (Multipart Upload)](https://docs.aws.amazon.com/AmazonGlacier/latest/dev/uploading-large-archives-in-parts.html) and [Initiate Multipart Upload](https://docs.aws.amazon.com/AmazonGlacier/latest/dev/initiate-multipart-upload.html) in the [Amazon Glacier Developer Guide](https://docs.aws.amazon.com/AmazonGlacier/latest/dev/).

**Request Syntax**

```python
response = client.initiate_multipart_upload(
    vaultName='string',
    archiveDescription='string',
    partSize='string'
)
```

**Parameters**
• **accountId** *(string)* – The `AccountId` value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single `apos''-apos` (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (`apos-apos`) in the ID.

  Note: this parameter is set to “-“ by default if no value is not specified.

• **vaultName** *(string)* – [REQUIRED]

  The name of the vault.

• **archiveDescription** *(string)* – The archive description that you are uploading in parts.

  The part size must be a megabyte (1024 KB) multiplied by a power of 2, for example 1048576 (1 MB), 2097152 (2 MB), 4194304 (4 MB), 8388608 (8 MB), and so on. The minimum allowable part size is 1 MB, and the maximum is 4 GB (4096 MB).

• **partSize** *(string)* – The size of each part except the last, in bytes. The last part can be smaller than this part size.

  **Return type**  
dict

  **Returns**

  **Response Syntax**

  ```
  {
      'location': 'string',
      'uploadId': 'string'
  }
  ```

  **Response Structure**

  • *(dict)* –

    The Amazon Glacier response to your request.

    • **location** *(string)* –

      The relative URI path of the multipart upload ID Amazon Glacier created.

    • **uploadId** *(string)* –

      The ID of the multipart upload. This value is also included as part of the location.

  **initiate_vault_lock** *(**kwargs**)*

  This operation initiates the vault locking process by doing the following:

  • Installing a vault lock policy on the specified vault.
  • Setting the lock state of vault lock to `InProgress`.
  • Returning a lock ID, which is used to complete the vault locking process.

  You can set one vault lock policy for each vault and this policy can be up to 20 KB in size. For more information about vault lock policies, see Amazon Glacier Access Control with Vault Lock Policies.

  You must complete the vault locking process within 24 hours after the vault lock enters the `InProgress` state. After the 24 hour window ends, the lock ID expires, the vault automatically exits the `InProgress` state, and the vault lock policy is removed from the vault. You call CompleteVaultLock to complete the vault locking process by setting the state of the vault lock to `Locked`.

  After a vault lock is in the `Locked` state, you cannot initiate a new vault lock for the vault.

  You can abort the vault locking process by calling AbortVaultLock. You can get the state of the vault lock by calling GetVaultLock. For more information about the vault locking process, Amazon Glacier Vault Lock.
If this operation is called when the vault lock is in the InProgress state, the operation returns an AccessDeniedException error. When the vault lock is in the InProgress state you must call AbortVaultLock before you can initiate a new vault lock policy.

**Request Syntax**

```python
response = client.initiate_vault_lock(
    vaultName='string',
    policy={
        'Policy': 'string'
    }
)
```

**Parameters**

- **accountId (string)** – The AccountId value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single apos’-apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to “-” by default if no value is not specified.

- **vaultName (string)** – [REQUIRED]
  
  The name of the vault.

- **policy (dict)** – The vault lock policy as a JSON string, which uses “” as an escape character.
  
  - **Policy (string)** –
    
    The vault lock policy.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'lockId': 'string'
}
```

**Response Structure**

- (dict) –
  
  Contains the Amazon Glacier response to your request.

  - **lockId (string)** –
    
    The lock ID, which is used to complete the vault locking process.

**list_jobs(****kwargs**)**

This operation lists jobs for a vault, including jobs that are in-progress and jobs that have recently finished.

**Note:** Amazon Glacier retains recently completed jobs for a period before deleting them; however, it eventually removes completed jobs. The output of completed jobs can be retrieved. Retaining completed jobs for a period of time after they have completed enables you to get a job output in the event you miss the job completion notification or your first attempt to download it fails. For example, suppose you start an archive retrieval job to download an archive. After the job completes, you start to download the archive but encounter a network error. In this scenario, you can retry and download the archive while the job exists.
To retrieve an archive or retrieve a vault inventory from Amazon Glacier, you first initiate a job, and after the job completes, you download the data. For an archive retrieval, the output is the archive data, and for an inventory retrieval, it is the inventory list. The List Job operation returns a list of these jobs sorted by job initiation time.

This List Jobs operation supports pagination. By default, this operation returns up to 1,000 jobs in the response. You should always check the response for a marker at which to continue the list; if there are no more items the marker is null. To return a list of jobs that begins at a specific job, set the marker request parameter to the value you obtained from a previous List Jobs request. You can also limit the number of jobs returned in the response by specifying the limit parameter in the request.

Additionally, you can filter the jobs list returned by specifying an optional statuscode (InProgress, Succeeded, or Failed) and completed (true, false) parameter. The statuscode allows you to specify that only jobs that match a specified status are returned. The completed parameter allows you to specify that only jobs in a specific completion state are returned.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For the underlying REST API, go to List Jobs

**Request Syntax**

```python
response = client.list_jobs(
    vaultName='string',
    limit='string',
    marker='string',
    statuscode='string',
    completed='string'
)
```

**Parameters**

- `accountId` *(string)* – The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single aposapos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (aposapos) in the ID.
  
  Note: this parameter is set to “” by default if no value is not specified.

- `vaultName` *(string)* – [REQUIRED]
  
  The name of the vault.

- `limit` *(string)* – Specifies that the response be limited to the specified number of items or fewer. If not specified, the List Jobs operation returns up to 1,000 jobs.

- `marker` *(string)* – An opaque string used for pagination. This value specifies the job at which the listing of jobs should begin. Get the marker value from a previous List Jobs response. You need only include the marker if you are continuing the pagination of results started in a previous List Jobs request.

- `statuscode` *(string)* – Specifies the type of job status to return. You can specify the following values: “InProgress”, “Succeeded”, or “Failed”.

- `completed` *(string)* – Specifies the state of the jobs to return. You can specify true or false.

**Return type** dict

**Response Syntax**
```json
{
'JobList': [
{
'JobId': 'string',
'JobDescription': 'string',
'Action': 'ArchiveRetrieval'|'InventoryRetrieval',
'ArchiveId': 'string',
'VaultARN': 'string',
'CreationDate': 'string',
'Completed': True|False,
'StatusCode': 'InProgress'|'Succeeded'|'Failed',
'StatusMessage': 'string',
'ArchiveSizeInBytes': 123,
'InventorySizeInBytes': 123,
'SNSTopic': 'string',
'CompletionDate': 'string',
'SHA256TreeHash': 'string',
'ArchiveSHA256TreeHash': 'string',
'RetrievalByteRange': 'string',
'InventoryRetrievalParameters': {
'Format': 'string',
'StartDate': 'string',
'EndDate': 'string',
'Limit': 'string',
'Marker': 'string'
}
},
'Marker': 'string'
}

Response Structure

- (dict) –

Contains the Amazon Glacier response to your request.

- JobList (list) –

A list of job objects. Each job object contains metadata describing the job.

* (dict) –

Describes an Amazon Glacier job.

- JobId (string) –

An opaque string that identifies an Amazon Glacier job.

- JobDescription (string) –

The job description you provided when you initiated the job.

- Action (string) –

The job type. It is either ArchiveRetrieval or InventoryRetrieval.

- ArchivalId (string) –

For an ArchiveRetrieval job, this is the archive ID requested for download. Otherwise, this field is null.

- VaultARN (string) –

The Amazon Resource Name (ARN) of the vault from which the archive retrieval was requested.

3.1. Services 2661
- **CreationDate** (string) –
  The UTC date when the job was created. A string representation of ISO 8601 date format, for example, “2012-03-20T17:03:43.221Z”.
- **Completed** (boolean) –
  The job status. When a job is completed, you get the job’s output.
- **StatusCode** (string) –
  The status code can be InProgress, Succeeded, or Failed, and indicates the status of the job.
- **StatusMessage** (string) –
  A friendly message that describes the job status.
- **ArchiveSizeInBytes** (integer) –
  For an ArchiveRetrieval job, this is the size in bytes of the archive being requested for download. For the InventoryRetrieval job, the value is null.
- **InventorySizeInBytes** (integer) –
  For an InventoryRetrieval job, this is the size in bytes of the inventory requested for download. For the ArchiveRetrieval job, the value is null.
- **SNSTopic** (string) –
  An Amazon Simple Notification Service (Amazon SNS) topic that receives notification.
- **CompletionDate** (string) –
  The UTC time that the archive retrieval request completed. While the job is in progress, the value will be null.
- **SHA256TreeHash** (string) –
  For an ArchiveRetrieval job, it is the checksum of the archive. Otherwise, the value is null.
  The SHA256 tree hash value for the requested range of an archive. If the Initiate a Job request for an archive specified a tree-hash aligned range, then this field returns a value.
  For the specific case when the whole archive is retrieved, this value is the same as the ArchiveSHA256TreeHash value.
  This field is null in the following situations:
  - Archive retrieval jobs that specify a range that is not tree-hash aligned.
  - Archival jobs that specify a range that is equal to the whole archive and the job status is InProgress.
  - Inventory jobs.
- **ArchiveSHA256TreeHash** (string) –
  The SHA256 tree hash of the entire archive for an archive retrieval. For inventory retrieval jobs, this field is null.
- **RetrievalByteRange** (string) –
  The retrieved byte range for archive retrieval jobs in the form “StartByteValue -EndByteValue”. If no range was specified in the archive retrieval, then the whole archive is retrieved and
StartByteValue equals 0 and EndByteValue equals the size of the archive minus 1. For inventory retrieval jobs this field is null.

- **InventoryRetrievalParameters** *(dict)* –

  Parameters used for range inventory retrieval.

- **Format** *(string)* –

  The output format for the vault inventory list, which is set by the InitiateJob request when initiating a job to retrieve a vault inventory. Valid values are “CSV” and “JSON”.

- **StartDate** *(string)* –

  The start of the date range in UTC for vault inventory retrieval that includes archives created on or after this date. A string representation of ISO 8601 date format, for example, 2013-03-20T17:03:43Z.

- **EndDate** *(string)* –

  The end of the date range in UTC for vault inventory retrieval that includes archives created before this date. A string representation of ISO 8601 date format, for example, 2013-03-20T17:03:43Z.

- **Limit** *(string)* –

  Specifies the maximum number of inventory items returned per vault inventory retrieval request. This limit is set when initiating the job with the a InitiateJob request.

- **Marker** *(string)* –

  An opaque string that represents where to continue pagination of the vault inventory retrieval results. You use the marker in a new InitiateJob request to obtain additional inventory items. If there are no more inventory items, this value is null. For more information, see Range Inventory Retrieval.

**list_multipart_uploads** *(**kwargs**)*

This operation lists in-progress multipart uploads for the specified vault. An in-progress multipart upload is a multipart upload that has been initiated by an InitiateMultipartUpload request, but has not yet been completed or aborted. The list returned in the List Multipart Upload response has no guaranteed order.

The List Multipart Uploads operation supports pagination. By default, this operation returns up to 1,000 multipart uploads in the response. You should always check the response for a marker at which to continue the list; if there are no more items the marker is null. To return a list of multipart uploads that begins at a specific upload, set the marker request parameter to the value you obtained from a previous List Multipart Upload request. You can also limit the number of uploads returned in the response by specifying the limit parameter in the request.

Note the difference between this operation and listing parts (ListParts). The List Multipart Uploads operation lists all multipart uploads for a vault and does not require a multipart upload ID. The List Parts operation requires a multipart upload ID since parts are associated with a single upload.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit
permission to perform specific actions. For more information, see *Access Control Using AWS Identity and Access Management (IAM)*.

For conceptual information and the underlying REST API, go to *Working with Archives in Amazon Glacier* and *List Multipart Uploads* in the *Amazon Glacier Developer Guide*.

**Request Syntax**

```python
response = client.list_multipart_uploads(
    vaultName='string',
    marker='string',
    limit='string'
)
```

**Parameters**

- **accountId** *(string)* – The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos''-''apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to "-" by default if no value is specified.

- **vaultName** *(string)* – [REQUIRED]
  
  The name of the vault.

- **marker** *(string)* – An opaque string used for pagination. This value specifies the upload at which the listing of uploads should begin. Get the marker value from a previous List Uploads response. You need only include the marker if you are continuing the pagination of results started in a previous List Uploads request.

- **limit** *(string)* – Specifies the maximum number of uploads returned in the response body. If this value is not specified, the List Uploads operation returns up to 1,000 uploads.

**Return type** dict

**Response Syntax**

```json
{
    'UploadsList': [
        {
            'MultipartUploadId': 'string',
            'VaultARN': 'string',
            'ArchiveDescription': 'string',
            'PartSizeInBytes': 123,
            'CreationDate': 'string'
        },
        {
            'MultipartUploadId': 'string',
            'VaultARN': 'string',
            'ArchiveDescription': 'string',
            'PartSizeInBytes': 123,
            'CreationDate': 'string'
        }
    ],
    'Marker': 'string'
}
```

**Response Structure**

- *(dict)* –
  
  Contains the Amazon Glacier response to your request.

  - **UploadsList** *(list)* –
    
    A list of in-progress multipart uploads.
* (dict) –

A list of in-progress multipart uploads for a vault.

- **MultipartUploadId (string)** –
  The ID of a multipart upload.

- **VaultARN (string)** –
  The Amazon Resource Name (ARN) of the vault that contains the archive.

- **ArchiveDescription (string)** –
  The description of the archive that was specified in the Initiate Multipart Upload request.

- **PartSizeInBytes (integer)** –
  The part size, in bytes, specified in the Initiate Multipart Upload request. This is the size of all the parts in the upload except the last part, which may be smaller than this size.

- **CreationDate (string)** –
  The UTC time at which the multipart upload was initiated.

- **Marker (string)** –
  An opaque string that represents where to continue pagination of the results. You use the marker in a new List Multipart Uploads request to obtain more uploads in the list. If there are no more uploads, this value is `null`.

**list_parts(**kwargs)**

This operation lists the parts of an archive that have been uploaded in a specific multipart upload. You can make this request at any time during an in-progress multipart upload before you complete the upload (see CompleteMultipartUpload). List Parts returns an error for completed uploads. The list returned in the List Parts response is sorted by part range.

The List Parts operation supports pagination. By default, this operation returns up to 1,000 uploaded parts in the response. You should always check the response for a `marker` at which to continue the list; if there are no more items the `marker` is `null`. To return a list of parts that begins at a specific part, set the `marker` request parameter to the value you obtained from a previous List Parts request. You can also limit the number of parts returned in the response by specifying the `limit` parameter in the request.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and the underlying REST API, go to Working with Archives in Amazon Glacier and List Parts in the Amazon Glacier Developer Guide.

**Request Syntax**

```python
response = client.list_parts(
    vaultName='string',
    uploadId='string',
    marker='string',
    limit='string'
)
```

**Parameters**
• **accountId (string)** – The `AccountId` value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single `'-'` (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.

  Note: this parameter is set to `'-'` by default if no value is not specified.

• **vaultName (string)** – [REQUIRED]

  The name of the vault.

• **uploadId (string)** – [REQUIRED]

  The upload ID of the multipart upload.

• **marker (string)** – An opaque string used for pagination. This value specifies the part at which the listing of parts should begin. Get the marker value from the response of a previous List Parts response. You need only include the marker if you are continuing the pagination of results started in a previous List Parts request.

• **limit (string)** – Specifies the maximum number of parts returned in the response body. If this value is not specified, the List Parts operation returns up to 1,000 uploads.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'MultipartUploadId': 'string',
    'VaultARN': 'string',
    'ArchiveDescription': 'string',
    'PartSizeInBytes': 123,
    'CreationDate': 'string',
    'Parts': [
        {
            'RangeInBytes': 'string',
            'SHA256TreeHash': 'string'
        },
    ],
    'Marker': 'string'
}
```

**Response Structure**

• **(dict)** –

  Contains the Amazon Glacier response to your request.

  - **MultipartUploadId (string)** –

    The ID of the upload to which the parts are associated.

  - **VaultARN (string)** –

    The Amazon Resource Name (ARN) of the vault to which the multipart upload was initiated.

  - **ArchiveDescription (string)** –

    The description of the archive that was specified in the Initiate Multipart Upload request.

  - **PartSizeInBytes (integer)** –

    The part size in bytes.
– **CreationDate (string)** –
  The UTC time at which the multipart upload was initiated.

– **Parts (list)** –
  A list of the part sizes of the multipart upload.
  * (dict) –
    A list of the part sizes of the multipart upload.
    · **RangeInBytes (string)** –
      The byte range of a part, inclusive of the upper value of the range.
    · **SHA256TreeHash (string)** –
      The SHA256 tree hash value that Amazon Glacier calculated for the part. This field is never null.

– **Marker (string)** –
  An opaque string that represents where to continue pagination of the results. You use the marker in a new List Parts request to obtain more jobs in the list. If there are no more parts, this value is null.

**list_tags_for_vault (**kwargs)**
This operation lists all the tags attached to a vault. The operation returns an empty map if there are no tags. For more information about tags, see Tagging Amazon Glacier Resources.

**Request Syntax**

```python
response = client.list_tags_for_vault(
    vaultName='string'
)
```

**Parameters**

- **accountId (string)** – The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos''-apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
  Note: this parameter is set to “-” by default if no value is not specified.

- **vaultName (string)** – [REQUIRED]
  The name of the vault.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'Tags': {
        'string': 'string'
    }
}
```

**Response Structure**

- (dict) –
  Contains the Amazon Glacier response to your request.
Tags (dict)

The tags attached to the vault. Each tag is composed of a key and a value.

* (string) –
  · (string) –

list_vaults(**kwargs)

This operation lists all vaults owned by the calling user’s account. The list returned in the response is ASCII-sorted by vault name.

By default, this operation returns up to 1,000 items. If there are more vaults to list, the response marker field contains the vault Amazon Resource Name (ARN) at which to continue the list with a new List Vaults request; otherwise, the marker field is null. To return a list of vaults that begins at a specific vault, set the marker request parameter to the vault ARN you obtained from a previous List Vaults request. You can also limit the number of vaults returned in the response by specifying the limit parameter in the request.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Retrieving Vault Metadata in Amazon Glacier and List Vaults in the Amazon Glacier Developer Guide.

Request Syntax

response = client.list_vaults(
    marker='string',
    limit='string'
)

Parameters

- **accountID (string)** – The AccountId value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single apos’-apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to “-” by default if no value is not specified.

- **marker (string)** – A string used for pagination. The marker specifies the vault ARN after which the listing of vaults should begin.

- **limit (string)** – The maximum number of items returned in the response. If you don’t specify a value, the List Vaults operation returns up to 1,000 items.

Return type: dict

Returns

Response Syntax

```python
{
    'VaultList': [
        {
            'VaultARN': 'string',
            'VaultName': 'string',
            'CreationDate': 'string',
            'LastInventoryDate': 'string',
            'NumberOfArchives': 123,
        }
    ]
}
```
Response Structure

- (dict) –
  Contains the Amazon Glacier response to your request.
  - VaultList (list) –
    List of vaults.
    * (dict) –
      Contains the Amazon Glacier response to your request.
      - VaultARN (string) –
        The Amazon Resource Name (ARN) of the vault.
      - VaultName (string) –
        The name of the vault.
      - CreationDate (string) –
        The UTC date when the vault was created. A string repre- sentation of ISO 8601 date format, for example, “2012-03-20T17:03:43.221Z”.
      - LastInventoryDate (string) –
        The UTC date when Amazon Glacier completed the last vault inventory. A string representation of ISO 8601 date format, for example, “2012-03-20T17:03:43.221Z”.
      - NumberOfArchives (integer) –
        The number of archives in the vault as of the last inventory date. This field will return null if an inventory has not yet run on the vault, for example, if you just created the vault.
      - SizeInBytes (integer) –
        Total size, in bytes, of the archives in the vault as of the last inventory date. This field will return null if an inventory has not yet run on the vault, for example, if you just created the vault.
    - Marker (string) –
      The vault ARN at which to continue pagination of the results. You use the marker in another List Vaults request to obtain more vaults in the list.

remove_tags_from_vault (**kwargs)

This operation removes one or more tags from the set of tags attached to a vault. For more information about tags, see Tagging Amazon Glacier Resources. This operation is idempotent. The operation will be successful, even if there are no tags attached to the vault.

Request Syntax

```python
response = client.remove_tags_from_vault(
    vaultName='string',
    TagKeys=[
        'string',
    ]
)```
Parameters

- accountId (string) – The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos-apos apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to “-” by default if no value is not specified.

- vaultName (string) – [REQUIRED]

  The name of the vault.

- TagKeys (list) – A list of tag keys. Each corresponding tag is removed from the vault.
  
  - (string) –

Returns None

set_data_retrieval_policy(**kwargs)

This operation sets and then enacts a data retrieval policy in the region specified in the PUT request. You can set one policy per region for an AWS account. The policy is enacted within a few minutes of a successful PUT operation.

The set policy operation does not affect retrieval jobs that were in progress before the policy was enacted. For more information about data retrieval policies, see Amazon Glacier Data Retrieval Policies.

Request Syntax

response = client.set_data_retrieval_policy(
    Policy={
        'Rules': [
            {'Strategy': 'string',
             'BytesPerHour': 123},
        ]
    }
)

Parameters

- accountId (string) – The AccountId value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single apos-apos apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to “-” by default if no value is not specified.

- Policy (dict) – The data retrieval policy in JSON format.
  
  - Rules (list) –
    
    The policy rule. Although this is a list type, currently there must be only one rule, which contains a Strategy field and optionally a BytesPerHour field.
    
    * (dict) –
    
    Data retrieval policy rule.
- **Strategy** *(string)* –
  The type of data retrieval policy to set.
  Valid values: BytesPerHour|FreeTier|None
- **BytesPerHour** *(integer)* –
  The maximum number of bytes that can be retrieved in an hour.
  This field is required only if the value of the Strategy field is BytesPerHour. Your PUT operation will be rejected if the Strategy field is not set to BytesPerHour and you set this field.

**Returns** None

**set_vault_access_policy(**kwargs **)**
This operation configures an access policy for a vault and will overwrite an existing policy. To configure a vault access policy, send a PUT request to the access-policy subresource of the vault. An access policy is specific to a vault and is also called a vault subresource. You can set one access policy per vault and the policy can be up to 20 KB in size. For more information about vault access policies, see Amazon Glacier Access Control with Vault Access Policies.

**Request Syntax**

```python
response = client.set_vault_access_policy(
    vaultName='string',
    policy={
        'Policy': 'string'
    }
)
```

**Parameters**
- **accountId** *(string)* – The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos '-' apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
  Note: this parameter is set to "-" by default if no value is not specified.
- **vaultName** *(string)* – [REQUIRED]
  The name of the vault.
- **policy** *(dict)* – The vault access policy as a JSON string.
  - **Policy** *(string)* –
    The vault access policy.

**Returns** None

**set_vault_notifications(**kwargs **)**
This operation configures notifications that will be sent when specific events happen to a vault. By default, you don’t get any notifications.

To configure vault notifications, send a PUT request to the notification-configuration subresource of the vault. The request should include a JSON document that provides an Amazon SNS topic and specific events for which you want Amazon Glacier to send notifications to the topic.

Amazon SNS topics must grant permission to the vault to be allowed to publish notifications to the topic.

You can configure a vault to publish a notification for the following vault events:
• ArchiveRetrievalCompleted This event occurs when a job that was initiated for an archive retrieval is completed (InitiateJob). The status of the completed job can be “Succeeded” or “Failed”. The notification sent to the SNS topic is the same output as returned from DescribeJob.

• InventoryRetrievalCompleted This event occurs when a job that was initiated for an inventory retrieval is completed (InitiateJob). The status of the completed job can be “Succeeded” or “Failed”. The notification sent to the SNS topic is the same output as returned from DescribeJob.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Configuring Vault Notifications in Amazon Glacier and Set Vault Notification Configuration in the Amazon Glacier Developer Guide.

Request Syntax

```python
response = client.set_vault_notifications(
    vaultName='string',
    vaultNotificationConfig={
        'SNSTopic': 'string',
        'Events': ['string'],
    }
)
```

Parameters

- **accountId (string)** – The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos‘-apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
  
  Note: this parameter is set to “-” by default if no value is specified.

- **vaultName (string)** – [REQUIRED]
  
  The name of the vault.

- **vaultNotificationConfig (dict)** – Provides options for specifying notification configuration.
  
  - **SNSTopic (string)** –
    
    The Amazon Simple Notification Service (Amazon SNS) topic Amazon Resource Name (ARN).
  
  - **Events (list)** –
    
    A list of one or more events for which Amazon Glacier will send a notification to the specified Amazon SNS topic.

Returns None

upload_archive(**kwargs)

This operation adds an archive to a vault. This is a synchronous operation, and for a successful upload, your data is durably persisted. Amazon Glacier returns the archive ID in the x-amz-archive-id header of the response.

You must use the archive ID to access your data in Amazon Glacier. After you upload an archive, you should save the archive ID returned so that you can retrieve or delete the archive later. Besides saving the archive ID, you can also index it and give it a friendly name to allow for better searching. You can also
use the optional archive description field to specify how the archive is referred to in an external index of archives, such as you might create in Amazon DynamoDB. You can also get the vault inventory to obtain a list of archive IDs in a vault. For more information, see InitiateJob.

You must provide a SHA256 tree hash of the data you are uploading. For information about computing a SHA256 tree hash, see Computing Checksums.

You can optionally specify an archive description of up to 1,024 printable ASCII characters. You can get the archive description when you either retrieve the archive or get the vault inventory. For more information, see InitiateJob. Amazon Glacier does not interpret the description in any way. An archive description does not need to be unique. You cannot use the description to retrieve or sort the archive list.

Archives are immutable. After you upload an archive, you cannot edit the archive or its description.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Uploading an Archive in Amazon Glacier and Upload Archive in the Amazon Glacier Developer Guide.

Request Syntax

```python
response = client.upload_archive(
    vaultName='string',
    archiveDescription='string',
    body=b'bytes'
)
```

Parameters

- **vaultName** *(string)* – [REQUIRED]
  The name of the vault.

- **accountId** *(string)* – The `AccountId` value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos”-apos” apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
  Note: this parameter is set to “-” by default if no value is not specified.

- **archiveDescription** *(string)* – The optional description of the archive you are uploading.

- **checksum** *(string)* – The SHA256 tree hash of the data being uploaded.
  Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required

- **body** *(bytes)* – The data to upload.

Return type  dict

Returns

Response Syntax

```python
{
    'location': 'string',
    'checksum': 'string',
    'archiveId': 'string'
}
```

Response Structure
• *(dict)* –
  Contains the Amazon Glacier response to your request.

  For information about the underlying REST API, go to [Upload Archive](#). For conceptual information, go to [Working with Archives in Amazon Glacier](#).

  - **location** *(string)* –
    The relative URI path of the newly added archive resource.

  - **checksum** *(string)* –
    The checksum of the archive computed by Amazon Glacier.

  - **archiveId** *(string)* –
    The ID of the archive. This value is also included as part of the location.

**upload_multipart_part** (**kwargs**)

This operation uploads a part of an archive. You can upload archive parts in any order. You can also upload them in parallel. You can upload up to 10,000 parts for a multipart upload.

Amazon Glacier rejects your upload part request if any of the following conditions is true:

  • **SHA256 tree hash does not match** To ensure that part data is not corrupted in transmission, you compute a SHA256 tree hash of the part and include it in your request. Upon receiving the part data, Amazon Glacier also computes a SHA256 tree hash. If these hash values don’t match, the operation fails. For information about computing a SHA256 tree hash, see [Computing Checksums](#).

  • **Part size does not match** The size of each part except the last must match the size specified in the corresponding InitiateMultipartUpload request. The size of the last part must be the same size as, or smaller than, the specified size. **Note:** If you upload a part whose size is smaller than the part size you specified in your initiate multipart upload request and that part is not the last part, then the upload part request will succeed. However, the subsequent Complete Multipart Upload request will fail.

  • **Range does not align** The byte range value in the request does not align with the part size specified in the corresponding initiate request. For example, if you specify a part size of 4194304 bytes (4 MB), then 0 to 4194303 bytes (4 MB - 1) and 4194304 (4 MB) to 8388607 (8 MB - 1) are valid part ranges. However, if you set a range value of 2 MB to 6 MB, the range does not align with the part size and the upload will fail.

This operation is idempotent. If you upload the same part multiple times, the data included in the most recent request overwrites the previously uploaded data.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see [Access Control Using AWS Identity and Access Management (IAM)](#).

For conceptual information and underlying REST API, go to [Uploading Large Archives in Parts (Multipart Upload)](#) and [Upload Part](#) in the [Amazon Glacier Developer Guide](#).

**Request Syntax**

```python
response = client.upload_multipart_part(
    vaultName='string',
    uploadId='string',
    range='string',
    body=b'bytes'
)
```

**Parameters**
• **accountId (string)** – The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single apos‘-apos (hyphen), in which case Amazon Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (apos-apos) in the ID.
   
   Note: this parameter is set to “-” by default if no value is not specified.

• **vaultName (string) – [REQUIRED]**
   
   The name of the vault.

• **uploadId (string) – [REQUIRED]**
   
   The upload ID of the multipart upload.

• **checksum (string)** – The SHA256 tree hash of the data being uploaded.

   Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.

• **range (string)** – Identifies the range of bytes in the assembled archive that will be uploaded in this part. Amazon Glacier uses this information to assemble the archive in the proper sequence. The format of this header follows RFC 2616. An example header is Content-Range:bytes 0-4194303/*.

• **body (bytes)** – The data to upload.

**Return type** `dict`

**Returns**

**Response Syntax**

```
{
    'checksum': 'string'
}
```

**Response Structure**

• `(dict)` –

  Contains the Amazon Glacier response to your request.

  – **checksum (string)** –

    The SHA256 tree hash that Amazon Glacier computed for the uploaded part.

**Service Resource**

```python
import boto3

glacier = boto3.resource('glacier')
```

These are the resource’s available actions:

- **create_vault()**

These are the resource’s available sub-resources:

- **Account()**
- **Archive()**
- **Job()**
- **MultipartUpload()**
- **Notification()**
Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

create_vault(**kwargs)

This operation creates a new vault with the specified name. The name of the vault must be unique within a region for an AWS account. You can create up to 1,000 vaults per account. If you need to create more vaults, contact Amazon Glacier.

You must use the following guidelines when naming a vault.

• Names can be between 1 and 255 characters long.
• Allowed characters are a-z, A-Z, 0-9, ‘-’ (underscore), ‘.’ (hyphen), and ‘.’ (period).

This operation is idempotent.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Creating a Vault in Amazon Glacier and Create Vault in the Amazon Glacier Developer Guide.

Request Syntax

```python
vault = glacier.create_vault(
    vaultName='string'
)
```

Parameters vaultName (string) – [REQUIRED]

The name of the vault.

Return type glacier.Vault

Returns Vault resource

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

Account (id)

Creates a Account resource:

```python
account = glacier.Account('id')
```

Parameters id (string) – The Account’s id identifier. This must be set.

Return type Glacier.Account

Returns A Account resource

Archive (account_id, vault_name, id)

Creates a Archive resource:

```python
archive = glacier.Archive('account_id','vault_name','id')
```

Parameters

• account_id (string) – The Archive’s account_id identifier. This must be set.
• vault_name (string) – The Archive’s vault_name identifier. This must be set.
• **id (string)** – The Archive’s id identifier. This **must** be set.

  Returns A Archive resource

**Job (account_id, vault_name, id)**

Creates a Job resource.:

```python
job = glacier.Job('account_id','vault_name','id')
```

**Parameters**

- **account_id (string)** – The Job’s account_id identifier. This **must** be set.
- **vault_name (string)** – The Job’s vault_name identifier. This **must** be set.
- **id (string)** – The Job’s id identifier. This **must** be set.

**Return type** Glacier.Job

**MultipartUpload (account_id, vault_name, id)**

Creates a MultipartUpload resource.:

```python
multipart_upload = glacier.MultipartUpload('account_id','vault_name','id')
```

**Parameters**

- **account_id (string)** – The MultipartUpload’s account_id identifier. This **must** be set.
- **vault_name (string)** – The MultipartUpload’s vault_name identifier. This **must** be set.
- **id (string)** – The MultipartUpload’s id identifier. This **must** be set.

**Return type** Glacier.MultipartUpload

**Notification (account_id, vault_name)**

Creates a Notification resource.:

```python
notification = glacier.Notification('account_id','vault_name')
```

**Parameters**

- **account_id (string)** – The Notification’s account_id identifier. This **must** be set.
- **vault_name (string)** – The Notification’s vault_name identifier. This **must** be set.

**Return type** Glacier.Notification

**Vault (account_id, name)**

Creates a Vault resource.:

```python
vault = glacier.Vault('account_id','name')
```

**Parameters**

- **account_id (string)** – The Vault’s account_id identifier. This **must** be set.
- **name (string)** – The Vault’s name identifier. This **must** be set.

**Return type** Glacier.Vault

Collections

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the *Resources Introduction Guide.*
**vaults**

**all()**
Creates an iterable of all Vault resources in the collection.

**Request Syntax**

```python
vault_iterator = glacier.vaults.all()
```

**Return type** list(glacier.Vault)

**Returns** A list of Vault resources

**filter(**kwargs)**
Creates an iterable of all Vault resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
vault_iterator = glacier.vaults.filter(
    marker='string',
    limit='string'
)
```

**Parameters**

- **marker (string)** – A string used for pagination. The marker specifies the vault ARN after which the listing of vaults should begin.
- **limit (string)** – The maximum number of items returned in the response. If you don’t specify a value, the List Vaults operation returns up to 1,000 items.

**Return type** list(glacier.Vault)

**Returns** A list of Vault resources

**limit(**kwargs)**
Creates an iterable up to a specified amount of Vault resources in the collection.

**Request Syntax**

```python
vault_iterator = glacier.vaults.limit(
    count=123
)
```

**Parameters**

- **count (integer)** – The limit to the number of resources in the iterable.

**Return type** list(glacier.Vault)

**Returns** A list of Vault resources

**page_size(**kwargs)**
Creates an iterable of all Vault resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
vault_iterator = glacier.vaults.page_size(
    count=123
)
```

**Parameters**

- **count (integer)** – The number of items returned by each service call

**Return type** list(glacier.Vault)

**Returns** A list of Vault resources
Account

class Glacier.Account(id)
   A resource representing an Amazon Glacier Account:

   import boto3

   glacier = boto3.resource('glacier')
   account = glacier.Account('id')

   Parameters id (string) – The Account’s id identifier. This must be set.

   These are the resource’s available identifiers:
   * id
   
   These are the resource’s available actions:
   * create_vault()
   
   These are the resource’s available sub-resources:
   * Vault()
   
   These are the resource’s available collections:
   * vaults

   Identifiers

   Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

   id

   (string) The Account’s id identifier. This must be set.

   Actions

   Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

   create_vault(**kwargs)

   This operation creates a new vault with the specified name. The name of the vault must be unique within a region for an AWS account. You can create up to 1,000 vaults per account. If you need to create more vaults, contact Amazon Glacier.

   You must use the following guidelines when naming a vault.
   * Names can be between 1 and 255 characters long.
   * Allowed characters are a-z, A-Z, 0-9, ‘_’ (underscore), ‘-’ (hyphen), and ‘.’ (period).

   This operation is idempotent.

   An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

   For conceptual information and underlying REST API, go to Creating a Vault in Amazon Glacier and Create Vault in the Amazon Glacier Developer Guide.

   Request Syntax

   vault = account.create_vault(
       vaultName='string'
   )

   Parameters vaultName (string) – [REQUIRED]

   The name of the vault.
Return type  glacier.Vault
Returns  Vault resource

Sub-resources
Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

Vault (name)
Creates a Vault resource:

```python
vault = account.Vault('name')
```

Parameters name (string) – The Vault’s name identifier. This must be set.

Return type  Glacier.Vault
Returns  A Vault resource

Collections
Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the Resources Introduction Guide.

vaults

all()
Creates an iterable of all Vault resources in the collection.

Request Syntax

```python
vault_iterator = account.vaults.all()
```

Return type  list(glacier.Vault)
Returns  A list of Vault resources

filter(**kwargs)
Creates an iterable of all Vault resources in the collection filtered by kwargs passed to method.

Request Syntax

```python
vault_iterator = account.vaults.filter(
    marker='string',
    limit='string'
)
```

Parameters

- marker (string) – A string used for pagination. The marker specifies the vault ARN after which the listing of vaults should begin.
- limit (string) – The maximum number of items returned in the response. If you don’t specify a value, the List Vaults operation returns up to 1,000 items.

Return type  list(glacier.Vault)
Returns  A list of Vault resources

limit(**kwargs)
Creates an iterable up to a specified amount of Vault resources in the collection.

Request Syntax
vault_iterator = account.vaults.limit(
    count=123
)

Parameters  count (integer) – The limit to the number of resources in the iterable.
Return type  list(glacier.Vault)
Returns  A list of Vault resources

count (**kwargs)

page_size (integer) – The number of items returned by each service call
Return type  list(glacier.Vault)
Returns  A list of Vault resources

class Glacier.Archive (account_id, vault_name, id)

A resource representing an Amazon Glacier Archive:

    import boto3

    glacier = boto3.resource('glacier')
    archive = glacier.Archive('account_id', 'vault_name', 'id')

Parameters
    • account_id (string) – The Archive’s account_id identifier. This must be set.
    • vault_name (string) – The Archive’s vault_name identifier. This must be set.
    • id (string) – The Archive’s id identifier. This must be set.

These are the resource’s available identifiers:
    • account_id
    • vault_name
    • id

These are the resource’s available actions:
    • delete()
    • initiate_archive_retrieval()

These are the resource’s available sub-resources:
    • Vault()

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

    account_id
        (string) The Archive’s account_id identifier. This must be set.

    vault_name
        (string) The Archive’s vault_name identifier. This must be set.
id

(string) The Archive’s id identifier. This must be set.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from
identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

delete()

This operation deletes an archive from a vault. Subsequent requests to initiate a retrieval of this archive
will fail. Archive retrievals that are in progress for this archive ID may or may not succeed according to
the following scenarios:

• If the archive retrieval job is actively preparing the data for download when Amazon Glacier re-
  ceives the delete archive request, the archival retrieval operation might fail.
• If the archive retrieval job has successfully prepared the archive for download when Amazon Glacier
  receives the delete archive request, you will be able to download the output.

This operation is idempotent. Attempting to delete an already-deleted archive does not result in an error.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and
Access Management (IAM) users don’t have any permissions by default. You must grant them explicit
permission to perform specific actions. For more information, see Access Control Using AWS Identity
and Access Management (IAM).

For conceptual information and underlying REST API, go to Deleting an Archive in Amazon Glacier and
Delete Archive in the Amazon Glacier Developer Guide.

Request Syntax

response = archive.delete()

Returns None

initiate_archive_retrieval()

This operation initiates a job of the specified type. In this release, you can initiate a job to retrieve either
an archive or a vault inventory (a list of archives in a vault).

Retrieving data from Amazon Glacier is a two-step process:

• Initiate a retrieval job. .. note:: A data retrieval policy can cause your initiate retrieval job request to
  fail with a PolicyEnforcedException exception. For more information about data retrieval policies,
  see Amazon Glacier Data Retrieval Policies. For more information about the PolicyEnforcedEx-
  ception exception, see Error Responses.
• After the job completes, download the bytes.

The retrieval request is executed asynchronously. When you initiate a retrieval job, Amazon Glacier
creates a job and returns a job ID in the response. When Amazon Glacier completes the job, you can get
the job output (archive or inventory data). For information about getting job output, see GetJobOutput
operation.

The job must complete before you can get its output. To determine when a job is complete, you have the
following options:

• Use Amazon SNS Notification You can specify an Amazon Simple Notification Service (Amazon
  SNS) topic to which Amazon Glacier can post a notification after the job is completed. You can
  specify an SNS topic per job request. The notification is sent only after Amazon Glacier completes
  the job. In addition to specifying an SNS topic per job request, you can configure vault notifications
  for a vault so that job notifications are always sent. For more information, see SetVaultNotifications
  .
• Get job details You can make a DescribeJob request to obtain job status information while a job is
  in progress. However, it is more efficient to use an Amazon SNS notification to determine when a
  job is complete.
Note: The information you get via notification is same that you get by calling DescribeJob.

If for a specific event, you add both the notification configuration on the vault and also specify an SNS topic in your initiate job request, Amazon Glacier sends both notifications. For more information, see SetVaultNotifications.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

About the Vault Inventory

Amazon Glacier prepares an inventory for each vault periodically, every 24 hours. When you initiate a job for a vault inventory, Amazon Glacier returns the last inventory for the vault. The inventory data you get might be up to a day or two days old. Also, the initiate inventory job might take some time to complete before you can download the vault inventory. So you do not want to retrieve a vault inventory for each vault operation. However, in some scenarios, you might find the vault inventory useful. For example, when you upload an archive, you can provide an archive description but not an archive name. Amazon Glacier provides you a unique archive ID, an opaque string of characters. So, you might maintain your own database that maps archive names to their corresponding Amazon Glacier assigned archive IDs. You might find the vault inventory useful in the event you need to reconcile information in your database with the actual vault inventory.

Range Inventory Retrieval

You can limit the number of inventory items retrieved by filtering on the archive creation date or by setting a limit.

Filtering by Archive Creation Date

You can retrieve inventory items for archives created between StartDate and EndDate by specifying values for these parameters in the InitiateJob request. Archives created on or after the StartDate and before the EndDate will be returned. If you only provide the StartDate without the EndDate, you will retrieve the inventory for all archives created on or after the StartDate. If you only provide the EndDate without the StartDate, you will get back the inventory for all archives created before the EndDate.

Limiting Inventory Items per Retrieval

You can limit the number of inventory items returned by setting the Limit parameter in the InitiateJob request. The inventory job output will contain inventory items up to the specified Limit. If there are more inventory items available, the result is paginated. After a job is complete you can use the DescribeJob operation to get a marker that you use in a subsequent InitiateJob request. The marker will indicate the starting point to retrieve the next set of inventory items. You can page through your entire inventory by repeatedly making InitiateJob requests with the marker from the previous DescribeJob output, until you get a marker from DescribeJob that returns null, indicating that there are no more inventory items available.

You can use the Limit parameter together with the date range parameters.

About Ranged Archive Retrieval

You can initiate an archive retrieval for the whole archive or a range of the archive. In the case of ranged archive retrieval, you specify a byte range to return or the whole archive. The range specified must be megabyte (MB) aligned, that is the range start value must be divisible by 1 MB and range end value plus 1 must be divisible by 1 MB or equal the end of the archive. If the ranged archive retrieval is not megabyte aligned, this operation returns a 400 response. Furthermore, to ensure you get checksum values for data you download using Get Job Output API, the range must be tree hash aligned.
An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and the underlying REST API, go to Initiate a Job and Downloading a Vault Inventory

**Request Syntax**

```python
job = archive.initiate_archive_retrieval()

**Return type** glacier.Job
**Returns** Job resource
```

**Sub-resources**

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

**Vault()**

Creates a Vault resource:

```python
vault = archive.Vault()

**Return type** Glacier.Vault
**Returns** A Vault resource
```

**Job**

```python
class Glacier.Job (account_id, vault_name, id)
```

A resource representing an Amazon Glacier Job:

```python
import boto3

glacier = boto3.resource('glacier')
job = glacier.Job('account_id','vault_name','id')
```

**Parameters**

- **account_id** *(string)* – The Job’s account_id identifier. This must be set.
- **vault_name** *(string)* – The Job’s vault_name identifier. This must be set.
- **id** *(string)* – The Job’s id identifier. This must be set.

These are the resource’s available identifiers:

- account_id
- vault_name
- id

These are the resource’s available attributes:

- action
- archive_id
- archive_sha256_tree_hash
- archive_size_in_bytes
- completed
- completion_date
- creation_date
- inventory_retrieval_parameters
- inventory_size_in_bytes
These are the resource’s available actions:
- get_output()
- load()
- reload()

These are the resource’s available sub-resources:
- Vault()

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

account_id
   (string) The Job’s account_id identifier. This must be set.

vault_name
   (string) The Job’s vault_name identifier. This must be set.

id
   (string) The Job’s id identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

action
   (string)
   The job type. It is either ArchiveRetrieval or InventoryRetrieval.

archive_id
   (string)
   For an ArchiveRetrieval job, this is the archive ID requested for download. Otherwise, this field is null.

archive_sha256_tree_hash
   (string)
   The SHA256 tree hash of the entire archive for an archive retrieval. For inventory retrieval jobs, this field is null.

archive_size_in_bytes
   (integer)
   For an ArchiveRetrieval job, this is the size in bytes of the archive being requested for download. For the InventoryRetrieval job, the value is null.

completed
   (boolean)
   The job status. When a job is completed, you get the job’s output.

completion_date
   (string)
The UTC time that the archive retrieval request completed. While the job is in progress, the value will be null.

**creation_date**

*(string)*

The UTC date when the job was created. A string representation of ISO 8601 date format, for example, “2012-03-20T17:03:43.221Z”.

**inventory_retrieval_parameters**

*(dict)*

Parameters used for range inventory retrieval.

**inventory_size_in_bytes**

*(integer)*

For an InventoryRetrieval job, this is the size in bytes of the inventory requested for download. For the ArchiveRetrieval job, the value is null.

**job_description**

*(string)*

The job description you provided when you initiated the job.

**job_id**

*(string)*

An opaque string that identifies an Amazon Glacier job.

**retrieval_byte_range**

*(string)*

The retrieved byte range for archive retrieval jobs in the form “StartByteValue - EndByteValue” If no range was specified in the archive retrieval, then the whole archive is retrieved and StartByteValue equals 0 and EndByteValue equals the size of the archive minus 1. For inventory retrieval jobs this field is null.

**sha256_tree_hash**

*(string)*

For an ArchiveRetrieval job, it is the checksum of the archive. Otherwise, the value is null.

The SHA256 tree hash value for the requested range of an archive. If the Initiate a Job request for an archive specified a tree-hash aligned range, then this field returns a value.

For the specific case when the whole archive is retrieved, this value is the same as the Archive-SHA256TreeHash value.

This field is null in the following situations:

- Archive retrieval jobs that specify a range that is not tree-hash aligned.
- Archival jobs that specify a range that is equal to the whole archive and the job status is InProgress.
- Inventory jobs.

**sns_topic**

*(string)*

An Amazon Simple Notification Service (Amazon SNS) topic that receives notification.

**status_code**

*(string)*

The status code can be InProgress, Succeeded, or Failed, and indicates the status of the job.
**status_message**

*(string)*

A friendly message that describes the job status.

**vault_arn**

*(string)*

The Amazon Resource Name (ARN) of the vault from which the archive retrieval was requested.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the [Resources Introduction Guide](#).

**get_output**( **kwargs)**

This operation downloads the output of the job you initiated using InitiateJob. Depending on the job type you specified when you initiated the job, the output will be either the content of an archive or a vault inventory.

A job ID will not expire for at least 24 hours after Amazon Glacier completes the job. That is, you can download the job output within the 24 hours period after Amazon Glacier completes the job.

If the job output is large, then you can use the `Range` request header to retrieve a portion of the output. This allows you to download the entire output in smaller chunks of bytes. For example, suppose you have 1 GB of job output you want to download and you decide to download 128 MB chunks of data at a time, which is a total of eight Get Job Output requests. You use the following process to download the job output:

- Download a 128 MB chunk of output by specifying the appropriate byte range using the `Range` header.
- Along with the data, the response includes a SHA256 tree hash of the payload. You compute the checksum of the payload on the client and compare it with the checksum you received in the response to ensure you received all the expected data.
- Repeat steps 1 and 2 for all the eight 128 MB chunks of output data, each time specifying the appropriate byte range.
- After downloading all the parts of the job output, you have a list of eight checksum values. Compute the tree hash of these values to find the checksum of the entire output. Using the DescribeJob API, obtain job information of the job that provided you the output. The response includes the checksum of the entire archive stored in Amazon Glacier. You compare this value with the checksum you computed to ensure you have downloaded the entire archive content with no errors.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see [Access Control Using AWS Identity and Access Management (IAM)](#).

For conceptual information and the underlying REST API, go to [Downloading a Vault Inventory](#), [Downloading an Archive](#), and [Get Job Output](#).

**Request Syntax**

```python
response = job.get_output(
    range='string'
)
```

**Parameters**

- **range** *(string)* – The range of bytes to retrieve from the output. For example, if you want to download the first 1,048,576 bytes, specify “Range: bytes=0-1048575”. By default, this operation downloads the entire output.

**Return type** *dict*
Returns

Response Syntax

```
{
    'body': b'bytes',
    'checksum': 'string',
    'status': 123,
    'contentRange': 'string',
    'acceptRanges': 'string',
    'contentType': 'string',
    'archiveDescription': 'string'
}
```

Response Structure

- **(dict)** –
  Contains the Amazon Glacier response to your request.
  - **body (bytes)** –
    The job data, either archive data or inventory data.
  - **checksum (string)** –
    The checksum of the data in the response. This header is returned only when retrieving the output for an archive retrieval job. Furthermore, this header appears only under the following conditions:
    * You get the entire range of the archive.
    * You request a range to return of the archive that starts and ends on a multiple of 1 MB. For example, if you have an 3.1 MB archive and you specify a range to return that starts at 1 MB and ends at 2 MB, then the x-amz-sha256-tree-hash is returned as a response header.
    * You request a range of the archive to return that starts on a multiple of 1 MB and goes to the end of the archive. For example, if you have a 3.1 MB archive and you specify a range that starts at 2 MB and ends at 3.1 MB (the end of the archive), then the x-amz-sha256-tree-hash is returned as a response header.
  - **status (integer)** –
    The HTTP response code for a job output request. The value depends on whether a range was specified in the request.
  - **contentRange (string)** –
    The range of bytes returned by Amazon Glacier. If only partial output is downloaded, the response provides the range of bytes Amazon Glacier returned. For example, bytes 0-1048575/8388608 returns the first 1 MB from 8 MB.
  - **acceptRanges (string)** –
    Indicates the range units accepted. For more information, go to RFC2616.
  - **contentType (string)** –
    The Content-Type depends on whether the job output is an archive or a vault inventory. For archive data, the Content-Type is application/octet-stream. For vault inventory, if you requested CSV format when you initiated the job, the Content-Type is text/csv. Otherwise, by default, vault inventory is returned as JSON, and the Content-Type is application/json.
  - **archiveDescription (string)** –
The description of an archive.

**load()**
Calls `glacier.Client.describe_job()` to update the attributes of the Job resource

**Request Syntax**

```
job.load()
```

**Returns** None

**reload()**
Calls `glacier.Client.describe_job()` to update the attributes of the Job resource

**Request Syntax**

```
job.reload()
```

**Returns** None

**Sub-resources**

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the [Resources Introduction Guide](#).

**Vault()**

Creates a Vault resource:

```
vault = job.Vault()
```

**Return type** `Glacier.Vault`

**Returns** A Vault resource

### MultipartUpload

**class** `Glacier.MultipartUpload(account_id, vault_name, id)`

A resource representing an Amazon Glacier MultipartUpload:

```
import boto3

glacier = boto3.resource('glacier')
multipart_upload = glacier.MultipartUpload(account_id='account_id', vault_name='vault_name', id='id')
```

**Parameters**

- **account_id** (*string*) – The MultipartUpload’s account_id identifier. This **must** be set.
- **vault_name** (*string*) – The MultipartUpload’s vault_name identifier. This **must** be set.
- **id** (*string*) – The MultipartUpload’s id identifier. This **must** be set.

These are the resource’s available identifiers:

- account_id
- vault_name
- id

These are the resource’s available attributes:

- archive_description
- creation_date
- multipart_upload_id
- part_size_in_bytes
- vault_arn
These are the resource’s available actions:

- `abort()`
- `complete()`
- `parts()`
- `upload_part()`

These are the resource’s available sub-resources:

- `Vault()`

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the `Resources Introduction Guide`.

- `account_id`
  
  (string) The MultipartUpload’s `account_id` identifier. This **must** be set.

- `vault_name`
  
  (string) The MultipartUpload’s `vault_name` identifier. This **must** be set.

- `id`
  
  (string) The MultipartUpload’s `id` identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the `Resources Introduction Guide`.

- `archive_description`
  
  (string) The description of the archive that was specified in the Initiate Multipart Upload request.

- `creation_date`
  
  (string) The UTC time at which the multipart upload was initiated.

- `multipart_upload_id`
  
  (string) The ID of a multipart upload.

- `part_size_in_bytes`
  
  (integer) The part size, in bytes, specified in the Initiate Multipart Upload request. This is the size of all the parts in the upload except the last part, which may be smaller than this size.

- `vault_arn`
  
  (string) The Amazon Resource Name (ARN) of the vault that contains the archive.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the `Resources Introduction Guide`.

- `abort()`

  This operation aborts a multipart upload identified by the upload ID.

  After the Abort Multipart Upload request succeeds, you cannot upload any more parts to the multipart upload or complete the multipart upload. Aborting a completed upload fails. However, aborting an already-aborted upload will succeed, for a short time. For more information about uploading a part and completing a multipart upload, see `UploadMultipartPart` and `CompleteMultipartUpload`.
This operation is idempotent.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Working with Archives in Amazon Glacier and Abort Multipart Upload in the Amazon Glacier Developer Guide.

Request Syntax

```python
response = multipart_upload.abort()
```

Returns None

complete(**kwargs)

You call this operation to inform Amazon Glacier that all the archive parts have been uploaded and that Amazon Glacier can now assemble the archive from the uploaded parts. After assembling and saving the archive to the vault, Amazon Glacier returns the URI path of the newly created archive resource. Using the URI path, you can then access the archive. After you upload an archive, you should save the archive ID returned to retrieve the archive at a later point. You can also get the vault inventory to obtain a list of archive IDs in a vault. For more information, see InitiateJob.

In the request, you must include the computed SHA256 tree hash of the entire archive you have uploaded. For information about computing a SHA256 tree hash, see Computing Checksums. On the server side, Amazon Glacier also constructs the SHA256 tree hash of the assembled archive. If the values match, Amazon Glacier saves the archive to the vault; otherwise, it returns an error, and the operation fails. The ListParts operation returns a list of parts uploaded for a specific multipart upload. It includes checksum information for each uploaded part that can be used to debug a bad checksum issue.

Additionally, Amazon Glacier also checks for any missing content ranges when assembling the archive, if missing content ranges are found, Amazon Glacier returns an error and the operation fails.

Complete Multipart Upload is an idempotent operation. After your first successful complete multipart upload, if you call the operation again within a short period, the operation will succeed and return the same archive ID. This is useful in the event you experience a network issue that causes an aborted connection or receive a 500 server error, in which case you can repeat your Complete Multipart Upload request and get the same archive ID without creating duplicate archives. Note, however, that after the multipart upload completes, you cannot call the List Parts operation and the multipart upload will not appear in List Multipart Uploads response, even if idempotent complete is possible.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Uploading Large Archives in Parts (Multipart Upload) and Complete Multipart Upload in the Amazon Glacier Developer Guide.

Request Syntax

```python
response = multipart_upload.complete(
    archiveSize='string',
)
```

Parameters
• **archiveSize** *(string)* – The total size, in bytes, of the entire archive. This value should be the sum of all the sizes of the individual parts that you uploaded.

• **checksum** *(string)* – The SHA256 tree hash of the entire archive. It is the tree hash of SHA256 tree hash of the individual parts. If the value you specify in the request does not match the SHA256 tree hash of the final assembled archive as computed by Amazon Glacier, Amazon Glacier returns an error and the request fails.

Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.

Return type: dict

Returns:

Response Syntax:

```json
{
    'location': 'string',
    'checksum': 'string',
    'archiveId': 'string'
}
```

Response Structure:

• *(dict)* –

  Contains the Amazon Glacier response to your request.

  For information about the underlying REST API, go to [Upload Archive](https://docs.aws.amazon.com/). For conceptual information, go to [Working with Archives in Amazon Glacier](https://docs.aws.amazon.com/).

  - **location** *(string)* –

    The relative URI path of the newly added archive resource.

  - **checksum** *(string)* –

    The checksum of the archive computed by Amazon Glacier.

  - **archiveId** *(string)* –

    The ID of the archive. This value is also included as part of the location.

**parts(** **kwargs**)**

This operation lists the parts of an archive that have been uploaded in a specific multipart upload. You can make this request at any time during an in-progress multipart upload before you complete the upload (see [CompleteMultipartUpload](https://docs.aws.amazon.com/)). List Parts returns an error for completed uploads. The list returned in the List Parts response is sorted by part range.

The List Parts operation supports pagination. By default, this operation returns up to 1,000 uploaded parts in the response. You should always check the response for a **marker** at which to continue the list; if there are no more items the marker is null. To return a list of parts that begins at a specific part, set the **marker** request parameter to the value you obtained from a previous List Parts request. You can also limit the number of parts returned in the response by specifying the **limit** parameter in the request.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see [Access Control Using AWS Identity and Access Management (IAM)](https://docs.aws.amazon.com/).

For conceptual information and the underlying REST API, go to [Working with Archives in Amazon Glacier](https://docs.aws.amazon.com/) and [List Parts](https://docs.aws.amazon.com/) in the [Amazon Glacier Developer Guide](https://docs.aws.amazon.com/).

Request Syntax
response = multipart_upload.parts(
    marker='string',
    limit='string'
)

Parameters

- **marker (string)** – An opaque string used for pagination. This value specifies the part at which the listing of parts should begin. Get the marker value from the response of a previous List Parts response. You need only include the marker if you are continuing the pagination of results started in a previous List Parts request.

- **limit (string)** – Specifies the maximum number of parts returned in the response body. If this value is not specified, the List Parts operation returns up to 1,000 uploads.

Return type: dict

Returns

Response Syntax

```
{
    'MultipartUploadId': 'string',
    'VaultARN': 'string',
    'ArchiveDescription': 'string',
    'PartSizeInBytes': 123,
    'CreationDate': 'string',
    'Parts': [
        {
            'RangeInBytes': 'string',
            'SHA256TreeHash': 'string'
        },
        {
            'RangeInBytes': 'string',
            'SHA256TreeHash': 'string'
        }
    ],
    'Marker': 'string'
}
```

Response Structure

- *(dict)* –

  Contains the Amazon Glacier response to your request.

  - **MultipartUploadId (string)** –
    The ID of the upload to which the parts are associated.

  - **VaultARN (string)** –
    The Amazon Resource Name (ARN) of the vault to which the multipart upload was initiated.

  - **ArchiveDescription (string)** –
    The description of the archive that was specified in the Initiate Multipart Upload request.

  - **PartSizeInBytes (integer)** –
    The part size in bytes.

  - **CreationDate (string)** –
    The UTC time at which the multipart upload was initiated.

  - **Parts (list)** –
    A list of the part sizes of the multipart upload.
upload_part(**kwargs)

This operation uploads a part of an archive. You can upload archive parts in any order. You can also upload them in parallel. You can upload up to 10,000 parts for a multipart upload.

Amazon Glacier rejects your upload part request if any of the following conditions is true:

• **SHA256 tree hash does not match** To ensure that part data is not corrupted in transmission, you compute a SHA256 tree hash of the part and include it in your request. Upon receiving the part data, Amazon Glacier also computes a SHA256 tree hash. If these hash values don’t match, the operation fails. For information about computing a SHA256 tree hash, see Computing Checksums.

• **Part size does not match** The size of each part except the last must match the size specified in the corresponding InitiateMultipartUpload request. The size of the last part must be the same size as, or smaller than, the specified size. .. note:: If you upload a part whose size is smaller than the part size you specified in your initiate multipart upload request and that part is not the last part, then the upload part request will succeed. However, the subsequent Complete Multipart Upload request will fail.

• **Range does not align** The byte range value in the request does not align with the part size specified in the corresponding initiate request. For example, if you specify a part size of 4194304 bytes (4 MB), then 0 to 4194303 bytes (4 MB - 1) and 4194304 (4 MB) to 8388607 (8 MB - 1) are valid part ranges. However, if you set a range value of 2 MB to 6 MB, the range does not align with the part size and the upload will fail.

This operation is idempotent. If you upload the same part multiple times, the data included in the most recent request overwrites the previously uploaded data.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Uploading Large Archives in Parts (Multipart Upload) and Upload Part in the Amazon Glacier Developer Guide.

Request Syntax

```python
response = multipart_upload.upload_part(
    range='string',
    body=b'bytes'
)
```

**Parameters**

• **checksum (string)** – The SHA256 tree hash of the data being uploaded.
Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.

- **range** *(string)* – Identifies the range of bytes in the assembled archive that will be uploaded in this part. Amazon Glacier uses this information to assemble the archive in the proper sequence. The format of this header follows RFC 2616. An example header is Content-Range:bytes 0-4194303/*.
- **body** *(bytes)* – The data to upload.

**Return type** *dict*

**Returns**

**Response Syntax**

```
{
   'checksum': 'string'
}
```

**Response Structure**

- *(dict)* –
  - **checksum** *(string)* –
    - The SHA256 tree hash that Amazon Glacier computed for the uploaded part.

**Sub-resources**

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the [Resources Introduction Guide](#).

**Vault()**

Creates a Vault resource:

```python
vault = multipart_upload.Vault()
```

**Return type** *Glacier.Vault*

**Returns** A Vault resource

**Notification**

```python
import boto3

glacier = boto3.resource('glacier')
notification = glacier.Notification('account_id','vault_name')
```

**Parameters**

- **account_id** *(string)* – The Notification’s account_id identifier. This must be set.
- **vault_name** *(string)* – The Notification’s vault_name identifier. This must be set.

These are the resource’s available identifiers:

- `account_id`
- `vault_name`

These are the resource’s available attributes:

- `events`
•sns_topic
These are the resource’s available actions:
•delete()
•load()
•reload()
•set()
These are the resource’s available sub-resources:
•Vault()

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

account_id
(string) The Notification’s account_id identifier. This must be set.

vault_name
(string) The Notification’s vault_name identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

events
(list)
A list of one or more events for which Amazon Glacier will send a notification to the specified Amazon SNS topic.

sns_topic
(string)
The Amazon Simple Notification Service (Amazon SNS) topic Amazon Resource Name (ARN).

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

delelte()
This operation deletes the notification configuration set for a vault. The operation is eventually consistent; that is, it might take some time for Amazon Glacier to completely disable the notifications and you might still receive some notifications for a short time after you send the delete request.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Configuring Vault Notifications in Amazon Glacier and Delete Vault Notification Configuration in the Amazon Glacier Developer Guide.

Request Syntax

response = notification.delete()

Returns None

load()
Calls glacier.Client.get_vault_notifications() to update the attributes of the Notification resource
Request Syntax

```python
notification.load()
```

Returns None

```python reload()
```

Calls `glacier.Client.get_vault_notifications()` to update the attributes of the Notification resource.

Request Syntax

```python
notification.reload()
```

Returns None

```python set(**kwargs)
```

This operation configures notifications that will be sent when specific events happen to a vault. By default, you don’t get any notifications.

To configure vault notifications, send a PUT request to the `notification-configuration` subresource of the vault. The request should include a JSON document that provides an Amazon SNS topic and specific events for which you want Amazon Glacier to send notifications to the topic.

Amazon SNS topics must grant permission to the vault to be allowed to publish notifications to the topic. You can configure a vault to publish a notification for the following vault events:

- **ArchiveRetrievalCompleted** This event occurs when a job that was initiated for an archive retrieval is completed (InitiateJob). The status of the completed job can be “Succeeded” or “Failed”. The notification sent to the SNS topic is the same output as returned from DescribeJob.
- **InventoryRetrievalCompleted** This event occurs when a job that was initiated for an inventory retrieval is completed (InitiateJob). The status of the completed job can be “Succeeded” or “Failed”. The notification sent to the SNS topic is the same output as returned from DescribeJob.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Configuring Vault Notifications in Amazon Glacier and Set Vault Notification Configuration in the Amazon Glacier Developer Guide.

Request Syntax

```python
response = notification.set(
    vaultNotificationConfig={
        'SNSTopic': 'string',
        'Events': [
            'string',
        ]
    }
)
```

Parameters vaultNotificationConfig (`dict`) – Provides options for specifying notification configuration.

- **SNSTopic (`string`)** –

  The Amazon Simple Notification Service (Amazon SNS) topic Amazon Resource Name (ARN).
• **Events** *(list)* –  
A list of one or more events for which Amazon Glacier will send a notification to the specified Amazon SNS topic.

– *(string)* –  

**Returns** None

**Sub-resources**

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the *Resources Introduction Guide.*

**Vault()**

Creates a Vault resource:

```python
vault = notification.Vault()
```

**Return type** Glacier.Vault  
**Returns** A Vault resource

**Vault**

**class** Glacier.Vault *(account_id, name)*

A resource representing an Amazon Glacier Vault:

```python
import boto3

glacier = boto3.resource('glacier')
vault = glacier.Vault('account_id','name')
```

**Parameters**

- **account_id** *(string)* – The Vault’s account_id identifier. This **must** be set.
- **name** *(string)* – The Vault’s name identifier. This **must** be set.

These are the resource’s available identifiers:

- **account_id**  
- **name**

These are the resource’s available attributes:

- **creation_date**  
- **last_inventory_date**  
- **number_of_archives**  
- **size_in_bytes**  
- **vault_arn**  
- **vault_name**

These are the resource’s available actions:

- **create()**  
- **delete()**  
- **initiate_inventory_retrieval()**  
- **initiate_multipart_upload()**  
- **load()**  
- **reload()**  
- **upload_archive()**

These are the resource’s available sub-resources:

- **Account()**  
- **Archive()**  
- **Job()**
• `MultipartUpload()`  
• `Notification()`  

These are the resource’s available collections:  
• `completed_jobs`  
• `failed_jobs`  
• `jobs`  
• `jobs_in_progress`  
• `multipart_uplaods`  
• `succeeded_jobs`

Identifiers  

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the `Resources Introduction Guide`.  

`account_id`  
`(string)` The Vault’s `account_id` identifier. This `must` be set.

`name`  
`(string)` The Vault’s `name` identifier. This `must` be set.

Attributes  

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the `Resources Introduction Guide`.  

`creation_date`  
`(string)`  
The UTC date when the vault was created. A string representation of ISO 8601 date format, for example, “2012-03-20T17:03:43.221Z”.

`last_inventory_date`  
`(string)`  
The UTC date when Amazon Glacier completed the last vault inventory. A string representation of ISO 8601 date format, for example, “2012-03-20T17:03:43.221Z”.

`number_of_archives`  
`(integer)`  
The number of archives in the vault as of the last inventory date. This field will return `null` if an inventory has not yet run on the vault, for example, if you just created the vault.

`size_in_bytes`  
`(integer)`  
The total size, in bytes, of the archives in the vault as of the last inventory date. This field will return `null` if an inventory has not yet run on the vault, for example, if you just created the vault.

`vault_arn`  
`(string)`  
The Amazon Resource Name (ARN) of the vault.

`vault_name`  
`(string)`  
The name of the vault.

Actions  

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the `Resources Introduction Guide`.  

3.1. Services
create()

This operation creates a new vault with the specified name. The name of the vault must be unique within a region for an AWS account. You can create up to 1,000 vaults per account. If you need to create more vaults, contact Amazon Glacier.

You must use the following guidelines when naming a vault.

• Names can be between 1 and 255 characters long.
• Allowed characters are a-z, A-Z, 0-9, ‘_’ (underscore), ‘-’ (hyphen), and ‘.’ (period).

This operation is idempotent.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Creating a Vault in Amazon Glacier and Create Vault in the Amazon Glacier Developer Guide.

Request Syntax

response = vault.create()

Return type  dict

Returns

Response Syntax

{  
    'location': 'string'
}

Response Structure

• (dict) –

Contains the Amazon Glacier response to your request.

– location (string) –

The URI of the vault that was created.

delete()

This operation deletes a vault. Amazon Glacier will delete a vault only if there are no archives in the vault as of the last inventory and there have been no writes to the vault since the last inventory. If either of these conditions is not satisfied, the vault deletion fails (that is, the vault is not removed) and Amazon Glacier returns an error. You can use DescribeVault to return the number of archives in a vault, and you can use Initiate a Job (POST jobs) to initiate a new inventory retrieval for a vault. The inventory contains the archive IDs you use to delete archives using Delete Archive (DELETE archive).

This operation is idempotent.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Deleting a Vault in Amazon Glacier and Delete Vault in the Amazon Glacier Developer Guide.

Request Syntax
response = vault.delete()

Returns  None

`initiate_inventory_retrieval()`

This operation initiates a job of the specified type. In this release, you can initiate a job to retrieve either an archive or a vault inventory (a list of archives in a vault).

Retrieving data from Amazon Glacier is a two-step process:

- Initiate a retrieval job. .. note:: A data retrieval policy can cause your initiate retrieval job request to fail with a PolicyEnforcedException exception. For more information about data retrieval policies, see Amazon Glacier Data Retrieval Policies . For more information about the PolicyEnforcedException exception, see Error Responses .
- After the job completes, download the bytes.

The retrieval request is executed asynchronously. When you initiate a retrieval job, Amazon Glacier creates a job and returns a job ID in the response. When Amazon Glacier completes the job, you can get the job output (archive or inventory data). For information about getting job output, see GetJobOutput operation.

The job must complete before you can get its output. To determine when a job is complete, you have the following options:

- **Use Amazon SNS Notification** You can specify an Amazon Simple Notification Service (Amazon SNS) topic to which Amazon Glacier can post a notification after the job is completed. You can specify an SNS topic per job request. The notification is sent only after Amazon Glacier completes the job. In addition to specifying an SNS topic per job request, you can configure vault notifications for a vault so that job notifications are always sent. For more information, see SetVaultNotifications .
- **Get job details** You can make a DescribeJob request to obtain job status information while a job is in progress. However, it is more efficient to use an Amazon SNS notification to determine when a job is complete.

**Note:** The information you get via notification is same that you get by calling DescribeJob .

If for a specific event, you add both the notification configuration on the vault and also specify an SNS topic in your initiate job request, Amazon Glacier sends both notifications. For more information, see SetVaultNotifications .

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM) .

**About the Vault Inventory**

Amazon Glacier prepares an inventory for each vault periodically, every 24 hours. When you initiate a job for a vault inventory, Amazon Glacier returns the last inventory for the vault. The inventory data you get might be up to a day or two days old. Also, the initiate inventory job might take some time to complete before you can download the vault inventory. So you do not want to retrieve a vault inventory for each vault operation. However, in some scenarios, you might find the vault inventory useful. For example, when you upload an archive, you can provide an archive description but not an archive name. Amazon Glacier provides you a unique archive ID, an opaque string of characters. So, you might maintain your own database that maps archive names to their corresponding Amazon Glacier assigned archive IDs. You might find the vault inventory useful in the event you need to reconcile information in your database with the actual vault inventory.

**Range Inventory Retrieval**

3.1. Services  2701
You can limit the number of inventory items retrieved by filtering on the archive creation date or by setting a limit.

**Filtering by Archive Creation Date**

You can retrieve inventory items for archives created between StartDate and EndDate by specifying values for these parameters in the InitiateJob request. Archives created on or after the StartDate and before the EndDate will be returned. If you only provide the StartDate without the EndDate, you will retrieve the inventory for all archives created on or after the StartDate. If you only provide the EndDate without the StartDate, you will get back the inventory for all archives created before the EndDate.

**Limiting Inventory Items per Retrieval**

You can limit the number of inventory items returned by setting the Limit parameter in the InitiateJob request. The inventory job output will contain inventory items up to the specified Limit. If there are more inventory items available, the result is paginated. After a job is complete you can use the DescribeJob operation to get a marker that you use in a subsequent InitiateJob request. The marker will indicate the starting point to retrieve the next set of inventory items. You can page through your entire inventory by repeatedly making InitiateJob requests with the marker from the previous DescribeJob output, until you get a marker from DescribeJob that returns null, indicating that there are no more inventory items available.

You can use the Limit parameter together with the date range parameters.

**About Ranged Archive Retrieval**

You can initiate an archive retrieval for the whole archive or a range of the archive. In the case of ranged archive retrieval, you specify a byte range to return or the whole archive. The range specified must be megabyte (MB) aligned, that is the range start value must be divisible by 1 MB and range end value plus 1 must be divisible by 1 MB or equal the end of the archive. If the ranged archive retrieval is not megabyte aligned, this operation returns a 400 response. Furthermore, to ensure you get checksum values for data you download using Get Job Output API, the range must be tree hash aligned.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and the underlying REST API, go to Initiate a Job and Downloading a Vault Inventory

**Request Syntax**

```python
job = vault.initiate_inventory_retrieval()
```

**Return type** glacier.Job

**Returns** Job resource

```python
initiate_multipart_upload(**kwargs)
```

This operation initiates a multipart upload. Amazon Glacier creates a multipart upload resource and returns its ID in the response. The multipart upload ID is used in subsequent requests to upload parts of an archive (see UploadMultipartPart).

When you initiate a multipart upload, you specify the part size in number of bytes. The part size must be a megabyte (1024 KB) multiplied by a power of 2—for example, 1048576 (1 MB), 2097152 (2 MB), 4194304 (4 MB), 8388608 (8 MB), and so on. The minimum allowable part size is 1 MB, and the maximum is 4 GB.

Every part you upload to this resource (see UploadMultipartPart), except the last one, must have the same size. The last one can be the same size or smaller. For example, suppose you want to upload a 16.2 MB
file. If you initiate the multipart upload with a part size of 4 MB, you will upload four parts of 4 MB each and one part of 0.2 MB.

**Note:** You don’t need to know the size of the archive when you start a multipart upload because Amazon Glacier does not require you to specify the overall archive size.

After you complete the multipart upload, Amazon Glacier removes the multipart upload resource referenced by the ID. Amazon Glacier also removes the multipart upload resource if you cancel the multipart upload or it may be removed if there is no activity for a period of 24 hours.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Uploading Large Archives in Parts (Multipart Upload) and Initiate Multipart Upload in the Amazon Glacier Developer Guide.

**Request Syntax**

```python
multipart_upload = vault.initiate_multipart_upload(
    archiveDescription='string',
    partSize='string'
)
```

**Parameters**

- **archiveDescription** *(string)* – The archive description that you are uploading in parts.
  
  The part size must be a megabyte (1024 KB) multiplied by a power of 2, for example 1048576 (1 MB), 2097152 (2 MB), 4194304 (4 MB), 8388608 (8 MB), and so on. The minimum allowable part size is 1 MB, and the maximum is 4 GB (4096 MB).

- **partSize** *(string)* – The size of each part except the last, in bytes. The last part can be smaller than this part size.

**Return type** *glacier.MultipartUpload*

**Returns** *MultipartUpload resource*

**load()**

Calls `glacier.Client.describe_vault()` to update the attributes of the Vault resource

**Request Syntax**

```python
vault.load()
```

**Returns** *None*

**reload()**

Calls `glacier.Client.describe_vault()` to update the attributes of the Vault resource

**Request Syntax**

```python
vault.reload()
```

**Returns** *None*

**upload_archive(**kwargs)**

This operation adds an archive to a vault. This is a synchronous operation, and for a successful upload,
your data is durably persisted. Amazon Glacier returns the archive ID in the `x-amz-archive-id` header of the response.

You must use the archive ID to access your data in Amazon Glacier. After you upload an archive, you should save the archive ID returned so that you can retrieve or delete the archive later. Besides saving the archive ID, you can also index it and give it a friendly name to allow for better searching. You can also use the optional archive description field to specify how the archive is referred to in an external index of archives, such as you might create in Amazon DynamoDB. You can also get the vault inventory to obtain a list of archive IDs in a vault. For more information, see InitiateJob.

You must provide a SHA256 tree hash of the data you are uploading. For information about computing a SHA256 tree hash, see Computing Checksums.

You can optionally specify an archive description of up to 1,024 printable ASCII characters. You can get the archive description when you either retrieve the archive or get the vault inventory. For more information, see InitiateJob. Amazon Glacier does not interpret the description in any way. An archive description does not need to be unique. You cannot use the description to retrieve or sort the archive list.

Archives are immutable. After you upload an archive, you cannot edit the archive or its description.

An AWS account has full permission to perform all operations (actions). However, AWS Identity and Access Management (IAM) users don’t have any permissions by default. You must grant them explicit permission to perform specific actions. For more information, see Access Control Using AWS Identity and Access Management (IAM).

For conceptual information and underlying REST API, go to Uploading an Archive in Amazon Glacier and Upload Archive in the Amazon Glacier Developer Guide.

Request Syntax

```python
archive = vault.upload_archive(
    archiveDescription='string',
    body=b'bytes'
)
```

**Parameters**

- `archiveDescription` *(string)* – The optional description of the archive you are uploading.
- `checksum` *(string)* – The SHA256 tree hash of the data being uploaded.
  
  Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required
- `body` *(bytes)* – The data to upload.

**Return type** glacier.Archive

**Returns** Archive resource

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

**Account** *(id)*

Creates a Account resource:

```python
account = vault.Account()
```

**Return type** Glacier.Account

**Returns** A Account resource

**Archive** *(id)*

Creates a Archive resource:
archive = vault.Archive('id')

**Parameters** `id` (string) – The Archive’s id identifier. This **must** be set.

**Return type** Glacier.Archive

**Returns** A Archive resource

```python
Job(id)
```

Creates a Job resource:

```python
job = vault.Job('id')
```

**Parameters** `id` (string) – The Job’s id identifier. This **must** be set.

**Return type** Glacier.Job

**Returns** A Job resource

```python
MultipartUpload(id)
```

Creates a MultipartUpload resource:

```python
multipart_upload = vault.MultipartUpload('id')
```

**Parameters** `id` (string) – The MultipartUpload’s id identifier. This **must** be set.

**Return type** Glacier.MultipartUpload

**Returns** A MultipartUpload resource

```python
Notification()
```

Creates a Notification resource:

```python
notification = vault.Notification()
```

**Return type** Glacier.Notification

**Returns** A Notification resource

**Collections**

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the *Resources Introduction Guide*.

```python
collections
```

### completed_jobs

```python
all()
```

Creates an iterable of all Job resources in the collection.

**Request Syntax**

```python
job_iterator = vault.completed_jobs.all()
```

**Return type** list(glacier.Job)

**Returns** A list of Job resources

```python
filter(**kwargs)
```

Creates an iterable of all Job resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
job_iterator = vault.completed_jobs.filter(
    limit='string',
    marker='string',
    statuscode='string',
)```
Parameters

- **limit (string)** – Specifies that the response be limited to the specified number of items or fewer. If not specified, the List Jobs operation returns up to 1,000 jobs.
- **marker (string)** – An opaque string used for pagination. This value specifies the job at which the listing of jobs should begin. Get the marker value from a previous List Jobs response. You need only include the marker if you are continuing the pagination of results started in a previous List Jobs request.
- **statuscode (string)** – Specifies the type of job status to return. You can specify the following values: “InProgress”, “Succeeded”, or “Failed”.

Return type

list(glacier.Job)

Returns

A list of Job resources

**limit(****kwargs**

Creates an iterable up to a specified amount of Job resources in the collection.

Request Syntax

```python
job_iterator = vault.completed_jobs.limit(
    count=123
)
```

Parameters

- **count (integer)** – The limit to the number of resources in the iterable.

Return type

list(glacier.Job)

Returns

A list of Job resources

**page_size(****kwargs**

Creates an iterable of all Job resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

```python
job_iterator = vault.completed_jobs.page_size(
    count=123
)
```

Parameters

- **count (integer)** – The number of items returned by each service call

Return type

list(glacier.Job)

Returns

A list of Job resources

**failed_jobs**

**all()**

Creates an iterable of all Job resources in the collection.

Request Syntax

```python
job_iterator = vault.failed_jobs.all()
```

Return type

list(glacier.Job)

Returns

A list of Job resources

**filter(****kwargs**

Creates an iterable of all Job resources in the collection filtered by kwargs passed to method.
Request Syntax

```python
job_iterator = vault.failed_jobs.filter(
    limit='string',
    marker='string',
    completed='string'
)
```

**Parameters**

- **limit (string)** – Specifies that the response be limited to the specified number of items or fewer. If not specified, the List Jobs operation returns up to 1,000 jobs.
- **marker (string)** – An opaque string used for pagination. This value specifies the job at which the listing of jobs should begin. Get the marker value from a previous List Jobs response. You need only include the marker if you are continuing the pagination of results started in a previous List Jobs request.
- **completed (string)** – Specifies the state of the jobs to return. You can specify `true` or `false`.

**Return type** `list(glacier.Job)`

**Returns** A list of Job resources

```python
limit(**kwargs)
```

Creates an iterable up to a specified amount of Job resources in the collection.

**Request Syntax**

```python
job_iterator = vault.failed_jobs.limit(
    count=123
)
```

**Parameters**

- **count (integer)** – The limit to the number of resources in the iterable.

**Return type** `list(glacier.Job)`

**Returns** A list of Job resources

```python
page_size(**kwargs)
```

Creates an iterable of all Job resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
job_iterator = vault.failed_jobs.page_size(
    count=123
)
```

**Parameters**

- **count (integer)** – The number of items returned by each service call

**Return type** `list(glacier.Job)`

**Returns** A list of Job resources

```python
jobs
```

**all ()**

Creates an iterable of all Job resources in the collection.

**Request Syntax**

```python
job_iterator = vault.jobs.all()
```
Return type list(glacier.Job)
Returns A list of Job resources

**filter(**kwargs)
Creates an iterable of all Job resources in the collection filtered by kwargs passed to method.

Request Syntax

```python
job_iterator = vault.jobs.filter(
    limit='string',
    marker='string',
    statuscode='string',
    completed='string'
)
```

Parameters

- **limit (string)** – Specifies that the response be limited to the specified number of items or fewer. If not specified, the List Jobs operation returns up to 1,000 jobs.
- **marker (string)** – An opaque string used for pagination. This value specifies the job at which the listing of jobs should begin. Get the marker value from a previous List Jobs response. You need only include the marker if you are continuing the pagination of results started in a previous List Jobs request.
- **statuscode (string)** – Specifies the type of job status to return. You can specify the following values: “InProgress”, “Succeeded”, or “Failed”.
- **completed (string)** – Specifies the state of the jobs to return. You can specify true or false.

Return type list(glacier.Job)
Returns A list of Job resources

**limit(**kwargs)
Creates an iterable up to a specified amount of Job resources in the collection.

Request Syntax

```python
job_iterator = vault.jobs.limit(
    count=123
)
```

Parameters

- **count (integer)** – The limit to the number of resources in the iterable.

Return type list(glacier.Job)
Returns A list of Job resources

**page_size(**kwargs)
Creates an iterable of all Job resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

```python
job_iterator = vault.jobs.page_size(
    count=123
)
```

Parameters

- **count (integer)** – The number of items returned by each service call

Return type list(glacier.Job)
Returns A list of Job resources
jobs_in_progress

all()
Creates an iterable of all Job resources in the collection.

Request Syntax

job_iterator = vault.jobs_in_progress.all()

Return type list(glacier.Job)
Returns A list of Job resources

filter(**kwargs)
Creates an iterable of all Job resources in the collection filtered by kwargs passed to method.

Request Syntax

job_iterator = vault.jobs_in_progress.filter(
    limit='string',
    marker='string',
    completed='string'
)

Parameters

• **limit** *(string)* – Specifies that the response be limited to the specified number of items or fewer. If not specified, the List Jobs operation returns up to 1,000 jobs.
• **marker** *(string)* – An opaque string used for pagination. This value specifies the job at which the listing of jobs should begin. Get the marker value from a previous List Jobs response. You need only include the marker if you are continuing the pagination of results started in a previous List Jobs request.
• **completed** *(string)* – Specifies the state of the jobs to return. You can specify true or false.

Return type list(glacier.Job)
Returns A list of Job resources

limit(**kwargs)
Creates an iterable up to a specified amount of Job resources in the collection.

Request Syntax

job_iterator = vault.jobs_in_progress.limit(
    count=123
)

Parameters count *(integer)* – The limit to the number of resources in the iterable.

Return type list(glacier.Job)
Returns A list of Job resources

page_size(**kwargs)
Creates an iterable of all Job resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax
job_iterator = vault.jobs_in_progress.page_size(
    count=123
)

Parameters  count (integer) – The number of items returned by each service call  
Return type  list(glacier.Job)  
Returns  A list of Job resources

multipart_uplaods

all()  
Creates an iterable of all MultipartUpload resources in the collection.

Request Syntax

multipart_upload_iterator = vault.multipart_uplaods.all()

Return type  list(glacier.MultipartUpload)  
Returns  A list of MultipartUpload resources

filter(**kwargs)  
Creates an iterable of all MultipartUpload resources in the collection filtered by kwargs passed to method.

Request Syntax

multipart_upload_iterator = vault.multipart_uplaods.filter(
    marker='string',
    limit='string'
)

Parameters

- marker (string) – An opaque string used for pagination. This value specifies the upload at which the listing of uploads should begin. Get the marker value from a previous List Uploads response. You need only include the marker if you are continuing the pagination of results started in a previous List Uploads request.
- limit (string) – Specifies the maximum number of uploads returned in the response body. If this value is not specified, the List Uploads operation returns up to 1,000 uploads.

Return type  list(glacier.MultipartUpload)  
Returns  A list of MultipartUpload resources

limit(**kwargs)  
Creates an iterable up to a specified amount of MultipartUpload resources in the collection.

Request Syntax

multipart_upload_iterator = vault.multipart_uplaods.limit(
    count=123
)

Parameters  count (integer) – The limit to the number of resources in the iterable.  
Return type  list(glacier.MultipartUpload)  
Returns  A list of MultipartUpload resources
**page_size(**kwargs**)

Creates an iterable of all MultipartUpload resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
multipart_upload_iterator = vault.multipart_uploads.page_size(
    count=123
)
```

**Parameters**
- `count (integer)` – The number of items returned by each service call

**Return type**
- list(glacier.MultipartUpload)

**Returns**
- A list of MultipartUpload resources

**succeeded_jobs**

**all()**

Creates an iterable of all Job resources in the collection.

**Request Syntax**

```python
job_iterator = vault.succeeded_jobs.all()
```

**Return type**
- list(glacier.Job)

**Returns**
- A list of Job resources

**filter(**kwargs**)**

Creates an iterable of all Job resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
job_iterator = vault.succeeded_jobs.filter(
    limit='string',
    marker='string',
    completed='string'
)
```

**Parameters**
- `limit (string)` – Specifies that the response be limited to the specified number of items or fewer. If not specified, the List Jobs operation returns up to 1,000 jobs.
- `marker (string)` – An opaque string used for pagination. This value specifies the job at which the listing of jobs should begin. Get the marker value from a previous List Jobs response. You need only include the marker if you are continuing the pagination of results started in a previous List Jobs request.
- `completed (string)` – Specifies the state of the jobs to return. You can specify true or false.

**Return type**
- list(glacier.Job)

**Returns**
- A list of Job resources

**limit(**kwargs**)**

Creates an iterable up to a specified amount of Job resources in the collection.

**Request Syntax**
job_iterator = vault.succeeded_jobs.limit(
    count=123
)

Parameters count (integer) – The limit to the number of resources in the iterable.
Return type list(glacier.Job)
Returns A list of Job resources

page_size(**kwargs)
Creates an iterable of all Job resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

job_iterator = vault.succeeded_jobs.page_size(
    count=123
)

Parameters count (integer) – The number of items returned by each service call
Return type list(glacier.Job)
Returns A list of Job resources

IAM
Client

class IAM.Client
    A low-level client representing AWS Identity and Access Management (IAM):

    import boto3

    client = boto3.client('iam')

    These are the available methods:
    • add_client_id_to_open_id_connect_provider()
    • add_role_to_instance_profile()
    • add_user_to_group()
    • attach_group_policy()
    • attach_role_policy()
    • attach_user_policy()
    • can_paginate()
    • change_password()
    • create_access_key()
    • create_account_alias()
    • create_group()
    • create_instance_profile()
    • create_login_profile()
    • create_open_id_connect_provider()
    • create_policy()
    • create_policy_version()
    • create_role()
    • create_saml_provider()
    • create_user()
    • create_virtual_mfa_device()
    • deactivate_mfa_device()
    • delete_access_key()
    • delete_account_alias()
    • delete_account_password_policy()
    • delete_group()
    • delete_group_policy()
    • delete_instance_profile()
    • delete_login_profile()
    • delete_open_id_connect_provider()
    • delete_policy()
    • delete_policy_version()
    • delete_role()
    • delete_role_policy()
    • delete_saml_provider()
    • delete_server_certificate()
    • delete_signing_certificate()
    • delete_ssh_public_key()
    • delete_user()
    • delete_user_policy()
    • delete_virtual_mfa_device()
    • detach_group_policy()
    • detach_role_policy()
    • detach_user_policy()
    • enable_mfa_device()
• generate_credential_report()
• generate_presigned_url()
• get_access_key_last_used()
• get_account_authorization_details()
• get_account_password_policy()
• get_account_summary()
• get_context_keys_for_custom_policy()
• get_context_keys_for_principal_policy()
• get_credential_report()
• get_group()
• get_group_policy()
• get_instance_profile()
• get_login_profile()
• get_open_id_connect_provider()
• get_paginated()
• get_policy()
• get_policy_version()
• get_role()
• get_role_policy()
• get_saml_provider()
• get_server_certificate()
• get_ssh_public_key()
• get_user()
• get_user_policy()
• get_waiter()
• list_access_keys()
• list_account_aliases()
• listAttachedGroupPolicies()
• listAttachedRolePolicies()
• listAttachedUserPolicies()
• listEntitiesForPolicy()
• list_group_policies()
• list_groups()
• listGroupsForUser()
• list_instance_profiles()
• list_instance_profiles_for_role()
• list_mfa_devices()
• list_open_id_connect_providers()
• list_policies()
• list_policy_versions()
• list_role_policies()
• list_roles()
• list_saml_providers()
• list_server_certificates()
• list_signing_certificates()
• list_ssh_public_keys()
• list_user_policies()
• list_users()
• list_virtual_mfa_devices()
• put_group_policy()
• put_role_policy()
• put_user_policy()
• remove_client_id_from_open_id_connect_provider()
• remove_role_from_instance_profile()
• remove_user_from_group()
• resync_mfa_device()
• set_default_policy_version()
• simulate_custom_policy()
• simulate_principal_policy()
• update_access_key()
• update_account_password_policy()
• update_assume_role_policy()
• update_group()
• update_login_profile()
• update_open_id_connect_provider_thumbprint()
• update_saml_provider()
• update_server_certificate()
• update_signing_certificate()
• update_ssh_public_key()
• update_user()
• upload_server_certificate()
• upload_signing_certificate()
• upload_ssh_public_key()

add_client_id_to_open_id_connect_provider(**kwargs)

Adds a new client ID (also known as audience) to the list of client IDs already registered for the specified
IAM OpenID Connect provider.

This action is idempotent; it does not fail or return an error if you add an existing client ID to the provider.

Request Syntax

response = client.add_client_id_to_open_id_connect_provider(
    OpenIDConnectProviderArn='string',
    ClientID='string'
)

Parameters

• OpenIDConnectProviderArn (string) – [REQUIRED]

    The Amazon Resource Name (ARN) of the IAM OpenID Connect (OIDC) provider to add the client ID to. You can get a list of OIDC provider ARNs by using the ListOpenIDConnectProviders action.

• ClientID (string) – [REQUIRED]

    The client ID (also known as audience) to add to the IAM OpenID Connect provider.

Returns None

add_role_to_instance_profile(**kwargs)

Adds the specified role to the specified instance profile. For more information about roles, go to Working
with Roles . For more information about instance profiles, go to About Instance Profiles .

Request Syntax

response = client.add_role_to_instance_profile(
    InstanceProfileName='string',
    RoleName='string'
)

Parameters
• InstanceProfileName (string) – [REQUIRED]
  The name of the instance profile to update.
• RoleName (string) – [REQUIRED]
  The name of the role to add.

Returns None

add_user_to_group (**kwargs)
  Adds the specified user to the specified group.

Request Syntax

response = client.add_user_to_group(
    GroupName='string',
    UserName='string'
)

Parameters
  • GroupName (string) – [REQUIRED]
    The name of the group to update.
  • UserName (string) – [REQUIRED]
    The name of the user to add.

Returns None

attach_group_policy (**kwargs)
  Attaches the specified managed policy to the specified group.

You use this API to attach a managed policy to a group. To embed an inline policy in a group, use
PutGroupPolicy .

For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide .

Request Syntax

response = client.attach_group_policy(
    GroupName='string',
    PolicyArn='string'
)

Parameters
  • GroupName (string) – [REQUIRED]
    The name (friendly name, not ARN) of the group to attach the policy to.
  • PolicyArn (string) – [REQUIRED]
    The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS re-
    sources.

For more information about ARNs, go to Amazon Resource Names (ARNs) and
AWS Service Namespaces in the AWS General Reference .

Returns None

attach_role_policy (**kwargs)
  Attaches the specified managed policy to the specified role.

When you attach a managed policy to a role, the managed policy is used as the role’s access (permissions) policy. You cannot use a managed policy as the role’s trust policy. The role’s trust policy is created at the
same time as the role, using CreateRole. You can update a role’s trust policy using UpdateAssumeRolePolicy.

Use this API to attach a managed policy to a role. To embed an inline policy in a role, use PutRolePolicy. For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

**Request Syntax**

```python
response = client.attach_role_policy(
    RoleName='string',
    PolicyArn='string'
)
```

**Parameters**
- **RoleName** (*string*) – [REQUIRED]
  
The name (friendly name, not ARN) of the role to attach the policy to.
- **PolicyArn** (*string*) – [REQUIRED]
  
The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

**Returns**  None

**attach_user_policy** (**kwargs**)

Attaches the specified managed policy to the specified user.

You use this API to attach a managed policy to a user. To embed an inline policy in a user, use PutUserPolicy.

For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

**Request Syntax**

```python
response = client.attach_user_policy(
    UserName='string',
    PolicyArn='string'
)
```

**Parameters**
- **UserName** (*string*) – [REQUIRED]
  
The name (friendly name, not ARN) of the user to attach the policy to.
- **PolicyArn** (*string*) – [REQUIRED]
  
The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

**Returns**  None

**can_paginate** (*operation_name*)

Check if an operation can be paginated.

**Parameters**  *operation_name* (*string*) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs),
if the `create_foo` operation can be paginated, you can use the call
```
client.get_paginator("create_foo")
```

**Returns**  True if the operation can be paginated, False otherwise.

### change_password(**kwargs)
Changes the password of the IAM user who is calling this action. The root account password is not
affected by this action.

To change the password for a different user, see `UpdateLoginProfile` . For more information about modifying passwords, see Managing Passwords in the IAM User Guide.

**Request Syntax**
```
response = client.change_password(
    OldPassword='string',
    NewPassword='string'
)
```

**Parameters**
- **OldPassword (string)** – [REQUIRED]
  The IAM user’s current password.
- **NewPassword (string)** – [REQUIRED]
  The new password. The new password must conform to the AWS account’s password policy, if one exists.

**Returns**  None

### create_access_key(**kwargs)
Creates a new AWS secret access key and corresponding AWS access key ID for the specified user. The
default status for new keys is Active.

If you do not specify a user name, IAM determines the user name implicitly based on the AWS access
key ID signing the request. Because this action works for access keys under the AWS account, you can
use this action to manage root credentials even if the AWS account has no associated users.

For information about limits on the number of keys you can create, see Limitations on IAM Entities in
the IAM User Guide.

**Warning:** To ensure the security of your AWS account, the secret access key is accessible only during
key and user creation. You must save the key (for example, in a text file) if you want to be able to
access it again. If a secret key is lost, you can delete the access keys for the associated user and then
create new keys.

**Request Syntax**
```
response = client.create_access_key(
    UserName='string'
)
```

**Parameters**  UserName (string) – The user name that the new key will belong to.

**Return type**  dict

**Returns**

**Response Syntax**
```
{
    'AccessKey': {
        'UserName': 'string',
```
'AccessKeyId': 'string',
'Status': 'Active'|'Inactive',
'SecretAccessKey': 'string',
'CreateDate': datetime(2015, 1, 1)
}

Response Structure

* (dict) –
  Contains the response to a successful CreateAccessKey request.
  
  – AccessKey (dict) –
    Information about the access key.
    
    * UserName (string) –
      The name of the IAM user that the access key is associated with.
    * AccessKeyId (string) –
      The ID for this access key.
    * Status (string) –
      The status of the access key. Active means the key is valid for API calls, while Inactive means it is not.
    * SecretAccessKey (string) –
      The secret key used to sign requests.
    * CreateDate (datetime) –
      The date when the access key was created.

create_account_alias(**kwargs)

Creates an alias for your AWS account. For information about using an AWS account alias, see Using an Alias for Your AWS Account ID in the IAM User Guide.

Request Syntax

response = client.create_account_alias(
    AccountAlias='string'
}

Parameters

AccountAlias (string) – [REQUIRED]

The account alias to create.

Returns

None

create_group(**kwargs)

Creates a new group.

For information about the number of groups you can create, see Limitations on IAM Entities in the IAM User Guide.

Request Syntax

response = client.create_group(
    Path='string',
    GroupName='string'
}

Parameters
• **Path** *(string)* – The path to the group. For more information about paths, see IAM Identifiers in the Using IAM guide.

This parameter is optional. If it is not included, it defaults to a slash (/).

• **GroupName** *(string)* – [REQUIRED]

The name of the group to create. Do not include the path in this value.

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'Group': {
        'Path': 'string',
        'GroupName': 'string',
        'GroupId': 'string',
        'Arn': 'string',
        'CreateDate': datetime(2015, 1, 1)
    }
}
```

**Response Structure**

- *(dict)* – 
  Contains the response to a successful CreateGroup request.
  - **Group** *(dict)* – 
    Information about the group.
    - **Path** *(string)* – 
      The path to the group. For more information about paths, see IAM Identifiers in the Using IAM guide.
    - **GroupName** *(string)* – 
      The friendly name that identifies the group.
    - **GroupId** *(string)* – 
      The stable and unique string identifying the group. For more information about IDs, see IAM Identifiers in the Using IAM guide.
    - **Arn** *(string)* – 
      The Amazon Resource Name (ARN) specifying the group. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.
    - **CreateDate** *(datetime)* – 
      The date and time, in ISO 8601 date-time format, when the group was created.

**create_instance_profile** *(**kwargs)**

Creates a new instance profile. For information about instance profiles, go to About Instance Profiles.

For information about the number of instance profiles you can create, see Limitations on IAM Entities in the IAM User Guide.

**Request Syntax**

```python
response = client.create_instance_profile(
    InstanceProfileName='string',
```
Path='string'
}

Parameters

- **InstanceProfileName** (*string*) – [REQUIRED]
  
  The name of the instance profile to create.

- **Path** (*string*) – The path to the instance profile. For more information about paths, see IAM Identifiers in the Using IAM guide.
  
  This parameter is optional. If it is not included, it defaults to a slash (/).

Return type  dict

Returns

Response Syntax

```
{
    'InstanceProfile': {
        'Path': 'string',
        'InstanceProfileName': 'string',
        'InstanceProfileId': 'string',
        'Arn': 'string',
        'CreateDate': datetime(2015, 1, 1),
        'Roles': [
            {
                'Path': 'string',
                'RoleName': 'string',
                'RoleId': 'string',
                'Arn': 'string',
                'CreateDate': datetime(2015, 1, 1),
                'AssumeRolePolicyDocument': 'string'
            },
            ...
        ]
    }
}
```

Response Structure

- *(dict)* –
  
  Contains the response to a successful CreateInstanceProfile request.

  - **InstanceProfile** *(dict)* –
    
    Information about the instance profile.

    - **Path** (*string*) –
      
      The path to the instance profile. For more information about paths, see IAM Identifiers in the Using IAM guide.

    - **InstanceProfileName** (*string*) –
      
      The name identifying the instance profile.

    - **InstanceProfileId** (*string*) –
      
      The stable and unique string identifying the instance profile. For more information about IDs, see IAM Identifiers in the Using IAM guide.

    - **Arn** (*string*) –
      
      The Amazon Resource Name (ARN) specifying the instance profile. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.
* **CreateDate** *(datetime)* –
  The date when the instance profile was created.

* **Roles** *(list)* –
  The role associated with the instance profile.
  
  · *(dict)* –
    Contains information about an IAM role.
    
    This data type is used as a response element in the following actions:
    · CreateRole
    · GetRole
    · ListRoles
  
  · **Path** *(string)* –
    The path to the role. For more information about paths, see IAM Identifiers in the *Using IAM* guide.

  · **RoleName** *(string)* –
    The friendly name that identifies the role.

  · **RoleId** *(string)* –
    The stable and unique string identifying the role. For more information about IDs, see IAM Identifiers in the *Using IAM* guide.

  · **Arn** *(string)* –
    The Amazon Resource Name (ARN) specifying the role. For more information about ARNs and how to use them in policies, see IAM Identifiers in the *Using IAM* guide.

  · **CreateDate** *(datetime)* –
    The date and time, in ISO 8601 date-time format, when the role was created.

  · **AssumeRolePolicyDocument** *(string)* –
    The policy that grants an entity permission to assume the role.

---

**create_login_profile** (**kwargs**)

Creates a password for the specified user, giving the user the ability to access AWS services through the AWS Management Console. For more information about managing passwords, see Managing Passwords in the *Using IAM* guide.

**Request Syntax**

```python
response = client.create_login_profile(
    UserName='string',
    Password='string',
    PasswordResetRequired=True|False
)
```

**Parameters**

- **UserName** *(string)* – [REQUIRED]
  The name of the user to create a password for.

- **Password** *(string)* – [REQUIRED]
  The new password for the user.
• **PasswordResetRequired** *(boolean)* – Specifies whether the user is required to set a new password on next sign-in.

Return type  dict

Returns

Response Syntax

```python
{
    'LoginProfile': {
        'UserName': 'string',
        'CreateDate': datetime(2015, 1, 1),
        'PasswordResetRequired': True|False
    }
}
```

Response Structure

• *(dict)* –

Contains the response to a successful CreateLoginProfile request.

– **LoginProfile** *(dict)* –

  The user name and password create date.

  • **UserName** *(string)* –

    The name of the user, which can be used for signing in to the AWS Management Console.

  • **CreateDate** *(datetime)* –

    The date when the password for the user was created.

  • **PasswordResetRequired** *(boolean)* –

    Specifies whether the user is required to set a new password on next sign-in.

**create_open_id_connect_provider** (**kwargs**)

Creates an IAM entity to describe an identity provider (IdP) that supports OpenID Connect (OIDD) .

The OIDC provider that you create with this operation can be used as a principal in a role’s trust policy to establish a trust relationship between AWS and the OIDC provider.

When you create the IAM OIDC provider, you specify the URL of the OIDC identity provider (IdP) to trust, a list of client IDs (also known as audiences) that identify the application or applications that are allowed to authenticate using the OIDC provider, and a list of thumbprints of the server certificate(s) that the IdP uses. You get all of this information from the OIDC IdP that you want to use for access to AWS.

**Note:** Because trust for the OIDC provider is ultimately derived from the IAM provider that this action creates, it is a best practice to limit access to the CreateOpenIDConnectProvider action to highly-privileged users.

Request Syntax

```python
response = client.create_open_id_connect_provider(
    'Url': 'string',
    'ClientIDList': [  
        'string',
    ],
    'ThumbprintList': [  
        'string',
    ]
)
```
Parameters

- **Url (string)** – [REQUIRED]

  The URL of the identity provider. The URL must begin with “https://” and should correspond to the `iss` claim in the provider's OpenID Connect ID tokens. Per the OIDC standard, path components are allowed but query parameters are not. Typically the URL consists of only a host name, like “https://server.example.org” or “https://example.com”.

  You cannot register the same provider multiple times in a single AWS account. If you try to submit a URL that has already been used for an OpenID Connect provider in the AWS account, you will get an error.

- **ClientIDList (list)** – A list of client IDs (also known as audiences). When a mobile or web app registers with an OpenID Connect provider, they establish a value that identifies the application. (This is the value that’s sent as the `client_id` parameter on OAuth requests.)

  You can register multiple client IDs with the same provider. For example, you might have multiple applications that use the same OIDC provider. You cannot register more than 100 client IDs with a single IAM OIDC provider.

  There is no defined format for a client ID. The `CreateOpenIDConnectProviderRequest` action accepts client IDs up to 255 characters long.

- **ThumbprintList (list)** – [REQUIRED]

  A list of server certificate thumbprints for the OpenID Connect (OIDC) identity provider’s server certificate(s). Typically this list includes only one entry. However, IAM lets you have up to five thumbprints for an OIDC provider. This lets you maintain multiple thumbprints if the identity provider is rotating certificates.

  The server certificate thumbprint is the hex-encoded SHA-1 hash value of the X.509 certificate used by the domain where the OpenID Connect provider makes its keys available. It is always a 40-character string.

  You must provide at least one thumbprint when creating an IAM OIDC provider. For example, if the OIDC provider is `server.example.com` and the provider stores its keys at “https://keys.server.example.com/openid-connect”, the thumbprint string would be the hex-encoded SHA-1 hash value of the certificate used by `https://keys.server.example.com`.

  For more information about obtaining the OIDC provider’s thumbprint, see Obtaining the Thumbprint for an OpenID Connect Provider in the IAM User Guide.

- **(string)** –

  Contains a thumbprint for an identity provider’s server certificate.

  The identity provider's server certificate thumbprint is the hex-encoded SHA-1 hash value of the self-signed X.509 certificate used by the domain where the OpenID Connect provider makes its keys available. It is always a 40-character string.

Return type  dict

Returns
Response Syntax

```json
{
   'OpenIDConnectProviderArn': 'string'
}
```

Response Structure

- `(dict)` –
  Contains the response to a successful CreateOpenIDConnectProvider request.
  - `OpenIDConnectProviderArn (string)` –
    The Amazon Resource Name (ARN) of the IAM OpenID Connect provider that was created. For more information, see OpenIDConnectProviderListEntry.

create_policy(**kwargs)

Creates a new managed policy for your AWS account.

This operation creates a policy version with a version identifier of v1 and sets v1 as the policy’s default version. For more information about policy versions, see Versioning for Managed Policies in the IAM User Guide.

For more information about managed policies in general, refer to Managed Policies and Inline Policies in the IAM User Guide.

Request Syntax

```python
response = client.create_policy(
    PolicyName='string',
    Path='string',
    PolicyDocument='string',
    Description='string'
)
```

Parameters

- **PolicyName (string)** – [REQUIRED]
  The name of the policy document.
- **Path (string)** – The path for the policy.
  For more information about paths, see IAM Identifiers in the IAM User Guide.
  This parameter is optional. If it is not included, it defaults to a slash (/).
- **PolicyDocument (string)** – [REQUIRED]
  The policy document.
- **Description (string)** – A friendly description of the policy.
  Typically used to store information about the permissions defined in the policy.
  For example, “Grants access to production DynamoDB tables.”
  The policy description is immutable. After a value is assigned, it cannot be changed.

Return type: dict

Returns

Response Syntax

```json
{
    'Policy': {
        'PolicyName': 'string',
        'PolicyId': 'string',
        'Arn': 'string',
        'Path': 'string',
        'DefaultVersionId': 'string',
        'AttachmentCount': 123,
        'IsAttachable': True|False,
        'Description': 'string',
        'CreateDate': datetime(2015, 1, 1),
        'UpdateDate': datetime(2015, 1, 1)
    }
}
```

**Response Structure**

- **(dict)** –
  Contains the response to a successful CreatePolicy request.

  - **Policy (dict)** –
    Information about the policy.

      - **PolicyName (string)** –
        The friendly name (not ARN) identifying the policy.

      - **PolicyId (string)** –
        The stable and unique string identifying the policy.

        For more information about IDs, see IAM Identifiers in the Using IAM guide.

      - **Arn (string)** –
        The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

        For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

      - **Path (string)** –
        The path to the policy.

        For more information about paths, see IAM Identifiers in the Using IAM guide.

      - **DefaultVersionId (string)** –
        The identifier for the version of the policy that is set as the default version.

      - **AttachmentCount (integer)** –
        The number of entities (users, groups, and roles) that the policy is attached to.

      - **IsAttachable (boolean)** –
        Specifies whether the policy can be attached to an IAM user, group, or role.

      - **Description (string)** –
        A friendly description of the policy.
This element is included in the response to the GetPolicy operation. It is not included in the response to the ListPolicies operation.

- **CreateDate** *(datetime)* –
  The date and time, in ISO 8601 date-time format, when the policy was created.

- **UpdateDate** *(datetime)* –
  The date and time, in ISO 8601 date-time format, when the policy was last updated.

When a policy has only one version, this field contains the date and time when the policy was created. When a policy has more than one version, this field contains the date and time when the most recent policy version was created.

```python
create_policy_version(**kwargs)
```

Creates a new version of the specified managed policy. To update a managed policy, you create a new policy version. A managed policy can have up to five versions. If the policy has five versions, you must delete an existing version using DeletePolicyVersion before you create a new version.

Optionally, you can set the new version as the policy’s default version. The default version is the operative version; that is, the version that is in effect for the IAM users, groups, and roles that the policy is attached to.

For more information about managed policy versions, see Versioning for Managed Policies in the IAM User Guide.

**Request Syntax**

```python
response = client.create_policy_version(
    PolicyArn='string',
    PolicyDocument='string',
    SetAsDefault=True|False
)
```

**Parameters**

- **PolicyArn** *(string)* – [REQUIRED]
  The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

  For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

- **PolicyDocument** *(string)* – [REQUIRED]
  The policy document.

- **SetAsDefault** *(boolean)* – Specifies whether to set this version as the policy’s default version.

  When this parameter is true, the new policy version becomes the operative version; that is, the version that is in effect for the IAM users, groups, and roles that the policy is attached to.

  For more information about managed policy versions, see Versioning for Managed Policies in the IAM User Guide.

**Return type** dict

**Returns**

**Response Syntax**
Response Structure

- (dict) – Contains the response to a successful CreatePolicyVersion request.
  - PolicyVersion (dict) – Information about the policy version.
    - Document (string) – The policy document.
      The policy document is returned in the response to the GetPolicyVersion and GetAccountAuthorizationDetails operations. It is not returned in the response to the CreatePolicyVersion or ListPolicyVersions operations.
    - VersionId (string) – The identifier for the policy version.
      Policy version identifiers always begin with v (always lowercase). When a policy is created, the first policy version is v1.
    - IsDefaultVersion (boolean) – Specifies whether the policy version is set as the policy’s default version.
    - CreateDate (datetime) – The date and time, in ISO 8601 date-time format, when the policy version was created.

`create_role(**kwargs)`

Creates a new role for your AWS account. For more information about roles, go to Working with Roles. For information about limitations on role names and the number of roles you can create, go to Limitations on IAM Entities in the IAM User Guide.

The policy in the following example grants permission to an EC2 instance to assume the role.

**Request Syntax**

```python
response = client.create_role(
    Path='string',
    RoleName='string',
    AssumeRolePolicyDocument='string'
)
```

**Parameters**

- **Path (string)** – The path to the role. For more information about paths, see IAM Identifiers in the Using IAM guide.
  
  This parameter is optional. If it is not included, it defaults to a slash (/).
• **RoleName** (*string*) – [REQUIRED]
  
  The name of the role to create.

• **AssumeRolePolicyDocument** (*string*) – [REQUIRED]
  
  The policy that grants an entity permission to assume the role.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Role': {
        'Path': 'string',
        'RoleName': 'string',
        'RoleId': 'string',
        'Arn': 'string',
        'CreateDate': datetime(2015, 1, 1),
        'AssumeRolePolicyDocument': 'string'
    }
}
```

**Response Structure**

• (*dict*) –
  
  Contains the response to a successful CreateRole request.

  – **Role** (*dict*) –
    
    Information about the role.

    * **Path** (*string*) –
      
      The path to the role. For more information about paths, see IAM Identifiers in the Using IAM guide.

    * **RoleName** (*string*) –
      
      The friendly name that identifies the role.

    * **RoleId** (*string*) –
      
      The stable and unique string identifying the role. For more information about IDs, see IAM Identifiers in the Using IAM guide.

    * **Arn** (*string*) –
      
      The Amazon Resource Name (ARN) specifying the role. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.

    * **CreateDate** (*datetime*) –
      
      The date and time, in ISO 8601 date-time format, when the role was created.

    * **AssumeRolePolicyDocument** (*string*) –
      
      The policy that grants an entity permission to assume the role.

**create_saml_provider(**kwargs**)**

Creates an IAM entity to describe an identity provider (IdP) that supports SAML 2.0.

The SAML provider that you create with this operation can be used as a principal in a role’s trust policy to establish a trust relationship between AWS and a SAML identity provider. You can create an IAM role that supports Web-based single sign-on (SSO) to the AWS Management Console or one that supports API access to AWS.
When you create the SAML provider, you upload an SAML metadata document that you get from your IdP and that includes the issuer’s name, expiration information, and keys that can be used to validate the SAML authentication response (assertions) that are received from the IdP. You must generate the metadata document using the identity management software that is used as your organization’s IdP.

**Note:** This operation requires Signature Version 4.

For more information, see Enabling SAML 2.0 Federated Users to Access the AWS Management Console and About SAML 2.0-based Federation in the IAM User Guide.

**Request Syntax**

```python
response = client.create_saml_provider(
    SAMLMetadataDocument='string',
    Name='string'
)
```

**Parameters**

- **SAMLMetadataDocument** *(string)* – [REQUIRED]
  
  An XML document generated by an identity provider (IdP) that supports SAML 2.0. The document includes the issuer’s name, expiration information, and keys that can be used to validate the SAML authentication response (assertions) that are received from the IdP. You must generate the metadata document using the identity management software that is used as your organization’s IdP.

  For more information, see About SAML 2.0-based Federation in the IAM User Guide.

- **Name** *(string)* – [REQUIRED]
  
  The name of the provider to create.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'SAMLProviderArn': 'string'
}
```

**Response Structure**

- *(dict)* –

  Contains the response to a successful CreateSAMLProvider request.

    - **SAMLProviderArn** *(string)*
      
      The Amazon Resource Name (ARN) of the SAML provider.

**create_user** (**kwargs**)

Creates a new user for your AWS account.

For information about limitations on the number of users you can create, see Limitations on IAM Entities in the IAM User Guide.

**Request Syntax**

```python
response = client.create_user(
    Path='string',
    UserName='string'
)
```
Parameters

• **Path** *(string)* – The path for the user name. For more information about paths, see IAM Identifiers in the *Using IAM* guide.

  This parameter is optional. If it is not included, it defaults to a slash (/).

• **UserName** *(string)* – [REQUIRED]

  The name of the user to create.

Return type  dict

Returns

  Response Syntax

```
{
  'User': {
    'Path': 'string',
    'UserName': 'string',
    'UserId': 'string',
    'Arn': 'string',
    'CreateDate': datetime(2015, 1, 1),
    'PasswordLastUsed': datetime(2015, 1, 1)
  }
}
```

  Response Structure

  • *(dict)* –

  Contains the response to a successful CreateUser request.

  – **User** *(dict)* –

    Information about the user.

      • **Path** *(string)* –

        The path to the user. For more information about paths, see IAM Identifiers in the *Using IAM* guide.

      • **UserName** *(string)* –

        The friendly name identifying the user.

      • **UserId** *(string)* –

        The stable and unique string identifying the user. For more information about IDs, see IAM Identifiers in the *Using IAM* guide.

      • **Arn** *(string)* –

        The Amazon Resource Name (ARN) that identifies the user. For more information about ARNs and how to use ARNs in policies, see IAM Identifiers in the *Using IAM* guide.

      • **CreateDate** *(datetime)* –

        The date and time, in ISO 8601 date-time format, when the user was created.

      • **PasswordLastUsed** *(datetime)* –

        The date and time, in ISO 8601 date-time format, when the user’s password was last used to sign in to an AWS website. For a list of AWS websites that capture a user’s last sign-in time, see the Credential Reports topic in the *Using IAM* guide. If a password is used more than once in a five-minute span, only the first use is returned in this field. This field is null (not present) when:
The user does not have a password
- The password exists but has never been used (at least not since
  IAM started tracking this information on October 20th, 2014
- there is no sign-in data associated with the user

This value is returned only in the GetUser and ListUsers actions.

**create_virtual_mfa_device(**kwargs)

Creates a new virtual MFA device for the AWS account. After creating the virtual MFA, use EnableMFADevice to attach the MFA device to an IAM user. For more information about creating and working with virtual MFA devices, go to Using a Virtual MFA Device in the Using IAM guide.

For information about limits on the number of MFA devices you can create, see Limitations on Entities in the Using IAM guide.

**Warning:** The seed information contained in the QR code and the Base32 string should be treated like any other secret access information, such as your AWS access keys or your passwords. After you provision your virtual device, you should ensure that the information is destroyed following secure procedures.

**Request Syntax**

```python
response = client.create_virtual_mfa_device(
    Path='string',
    VirtualMFADeviceName='string'
)
```

**Parameters**

- **Path** *(string)* – The path for the virtual MFA device. For more information about paths, see IAM Identifiers in the Using IAM guide.
  
  This parameter is optional. If it is not included, it defaults to a slash (/).

- **VirtualMFADeviceName** *(string)* – [REQUIRED]
  
  The name of the virtual MFA device. Use with path to uniquely identify a virtual MFA device.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'VirtualMFADevice': {
        'SerialNumber': 'string',
        'Base32StringSeed': b'bytes',
        'QRCodePNG': b'bytes',
        'User': {
            'Path': 'string',
            'UserName': 'string',
            'UserId': 'string',
            'Arn': 'string',
            'CreateDate': datetime(2015, 1, 1),
            'PasswordLastUsed': datetime(2015, 1, 1)
        },
        'EnableDate': datetime(2015, 1, 1)
    }
}
```

**Response Structure**
Contains the response to a successful CreateVirtualMFADevice request.

- **VirtualMFADevice (dict)** –
  A newly created virtual MFA device.
  
  * **SerialNumber (string)** –
    The serial number associated with VirtualMFADevice.
  
  * **Base32StringSeed (bytes)** –
    The Base32 seed defined as specified in RFC3548. The Base32StringSeed is Base64-encoded.
  
  * **QRCodePNG (bytes)** –
    A QR code PNG image that encodes
    `otpauth://totp/$virtualMFADeviceName@$AccountName?secret=$Base32String` where
    $virtualMFADeviceName is one of the create call arguments, AccountName is the user name if set (otherwise, the account ID otherwise), and Base32String is the seed in Base32 format. The Base32String value is Base64-encoded.

- **User (dict)** –
  Contains information about an IAM user entity.

  This data type is used as a response element in the following actions:
  - CreateUser
  - GetUser
  - ListUsers
    
  * **Path (string)** –
    The path to the user. For more information about paths, see IAM Identifiers in the Using IAM guide.
  
  * **UserName (string)** –
    The friendly name identifying the user.
  
  * **UserId (string)** –
    The stable and unique string identifying the user. For more information about IDs, see IAM Identifiers in the Using IAM guide.
  
  * **Arn (string)** –
    The Amazon Resource Name (ARN) that identifies the user. For more information about ARNs and how to use ARNs in policies, see IAM Identifiers in the Using IAM guide.
  
  * **CreateDate (datetime)** –
    The date and time, in ISO 8601 date-time format, when the user was created.
  
  * **PasswordLastUsed (datetime)** –
    The date and time, in ISO 8601 date-time format, when the user’s password was last used to sign in to an AWS website. For a list of AWS websites that capture a user’s last sign-in time, see the Credential Reports topic in the Using IAM guide. If a password is used more than once in a five-minute span, only the first use is returned in this field. This field is null (not present) when:
    
    - The user does not have a password
The password exists but has never been used (at least not since IAM started tracking this information on October 20th, 2014)

- there is no sign-in data associated with the user

This value is returned only in the GetUser and ListUsers actions.

* EnableDate (datetime) – 
  The date and time on which the virtual MFA device was enabled.

def deactivate_mfa_device(**kwargs)
  Deactivates the specified MFA device and removes it from association with the user name for which it was originally enabled.

  For more information about creating and working with virtual MFA devices, go to Using a Virtual MFA Device in the Using IAM guide.

  Request Syntax

  ```python
  response = client.deactivate_mfa_device(
      UserName='string',
      SerialNumber='string'
  )
  ```

  Parameters

  - **UserName (string) – [REQUIRED]**
    The name of the user whose MFA device you want to deactivate.

  - **SerialNumber (string) – [REQUIRED]**
    The serial number that uniquely identifies the MFA device. For virtual MFA devices, the serial number is the device ARN.

  Returns

  None

def delete_access_key(**kwargs)
  Deletes the access key associated with the specified user.

  If you do not specify a user name, IAM determines the user name implicitly based on the AWS access key ID signing the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

  Request Syntax

  ```python
  response = client.delete_access_key(
      UserName='string',
      AccessKeyId='string'
  )
  ```

  Parameters

  - **UserName (string) –** The name of the user whose key you want to delete.

  - **AccessKeyId (string) – [REQUIRED]**
    The access key ID for the access key ID and secret access key you want to delete.

  Returns

  None

def delete_account_alias(**kwargs)
  Deletes the specified AWS account alias. For information about using an AWS account alias, see Using an Alias for Your AWS Account ID in the IAM User Guide.

  Request Syntax
response = client.delete_account_alias(
    AccountAlias='string'
)

**Parameters**  
AccountAlias *(string)* – [REQUIRED]

The name of the account alias to delete.

**Returns**  
None

delete_account_password_policy()

Deletes the password policy for the AWS account.

**Request Syntax**

response = client.delete_account_password_policy()

**Returns**  
None

delete_group(**kwargs**)

Deletes the specified group. The group must not contain any users or have any attached policies.

**Request Syntax**

response = client.delete_group(
    GroupName='string'
)

**Parameters**  
GroupName *(string)* – [REQUIRED]

The name of the group to delete.

**Returns**  
None

delete_group_policy(**kwargs**)

Deletes the specified inline policy that is embedded in the specified group.

A group can also have managed policies attached to it. To detach a managed policy from a group, use DetachGroupPolicy. For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

**Request Syntax**

response = client.delete_group_policy(
    GroupName='string',
    PolicyName='string'
)

**Parameters**

- **GroupName**(string) – [REQUIRED]
  
  The name (friendly name, not ARN) identifying the group that the policy is embedded in.

- **PolicyName**(string) – [REQUIRED]
  
  The name identifying the policy document to delete.

**Returns**  
None

delete_instance_profile(**kwargs**)

Deletes the specified instance profile. The instance profile must not have an associated role.
**Warning:** Make sure you do not have any Amazon EC2 instances running with the instance profile you are about to delete. Deleting a role or instance profile that is associated with a running instance will break any applications running on the instance.

For more information about instance profiles, go to About Instance Profiles.

**Request Syntax**

```python
response = client.delete_instance_profile(
    InstanceProfileName='string'
)
```

**Parameters**

- **InstanceProfileName (string)** – [REQUIRED]
  - The name of the instance profile to delete.

**Returns**

- None

---

**delete_login_profile** (**kwargs**)

Deletes the password for the specified user, which terminates the user’s ability to access AWS services through the AWS Management Console.

**Warning:** Deleting a user’s password does not prevent a user from accessing IAM through the command line interface or the API. To prevent all user access you must also either make the access key inactive or delete it. For more information about making keys inactive or deleting them, see UpdateAccessKey and DeleteAccessKey.

**Request Syntax**

```python
response = client.delete_login_profile(
    UserName='string'
)
```

**Parameters**

- **UserName (string)** – [REQUIRED]
  - The name of the user whose password you want to delete.

**Returns**

- None

---

**delete_open_id_connect_provider** (**kwargs**)

Deletes an IAM OpenID Connect identity provider.

Deleting an OIDC provider does not update any roles that reference the provider as a principal in their trust policies. Any attempt to assume a role that references a provider that has been deleted will fail.

This action is idempotent; it does not fail or return an error if you call the action for a provider that was already deleted.

**Request Syntax**

```python
response = client.delete_open_id_connect_provider(
    OpenIDConnectProviderArn='string'
)
```

**Parameters**

- **OpenIDConnectProviderArn (string)** – [REQUIRED]
  - The Amazon Resource Name (ARN) of the IAM OpenID Connect provider to delete.
  
  You can get a list of OpenID Connect provider ARNs by using the ListOpenIDConnectProviders action.

**Returns**

- None
**delete_policy(**kwargs)**

Deletes the specified managed policy.

Before you can delete a managed policy, you must detach the policy from all users, groups, and roles that it is attached to, and you must delete all of the policy’s versions. The following steps describe the process for deleting a managed policy:

• Detach the policy from all users, groups, and roles that the policy is attached to, using the DetachUserPolicy, DetachGroupPolicy, or DetachRolePolicy APIs. To list all the users, groups, and roles that a policy is attached to, use ListEntitiesForPolicy.

• Delete all versions of the policy using DeletePolicyVersion. To list the policy’s versions, use ListPolicyVersions. You cannot use DeletePolicyVersion to delete the version that is marked as the default version. You delete the policy’s default version in the next step of the process.

• Delete the policy (this automatically deletes the policy’s default version) using this API.

For information about managed policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

**Request Syntax**

```python
response = client.delete_policy(
    PolicyArn='string'
)
```

**Parameters**

**PolicyArn** *(string)* – [REQUIRED]

The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

**Returns** None

**delete_policy_version(**kwargs)**

Deletes the specified version of the specified managed policy.

You cannot delete the default version of a policy using this API. To delete the default version of a policy, use DeletePolicy. To find out which version of a policy is marked as the default version, use ListPolicyVersions.

For information about versions for managed policies, refer to Versioning for Managed Policies in the IAM User Guide.

**Request Syntax**

```python
response = client.delete_policy_version(
    PolicyArn='string',
    VersionId='string'
)
```

**Parameters**

- **PolicyArn** *(string)* – [REQUIRED]

  The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

  For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

- **VersionId** *(string)* – [REQUIRED]

  The policy version to delete.

  For more information about managed policy versions, see Versioning for Managed Policies in the IAM User Guide.
delete_role(**kwargs)

Deletes the specified role. The role must not have any policies attached. For more information about roles, go to Working with Roles.

**Warning:** Make sure you do not have any Amazon EC2 instances running with the role you are about to delete. Deleting a role or instance profile that is associated with a running instance will break any applications running on the instance.

Request Syntax

```python
response = client.delete_role(
    RoleName='string'
)
```

**Parameters**

- **RoleName (string)** – [REQUIRED]
  
  The name of the role to delete.

**Returns**

None

delete_role_policy(**kwargs)

Deletes the specified inline policy that is embedded in the specified role.

A role can also have managed policies attached to it. To detach a managed policy from a role, use DetachRolePolicy. For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

Request Syntax

```python
response = client.delete_role_policy(
    RoleName='string',
    PolicyName='string'
)
```

**Parameters**

- **RoleName (string)** – [REQUIRED]
  
  The name (friendly name, not ARN) identifying the role that the policy is embedded in.

- **PolicyName (string)** – [REQUIRED]
  
  The name identifying the policy document to delete.

**Returns**

None

delete_saml_provider(**kwargs)

Deletes a SAML provider.

Deleting the provider does not update any roles that reference the SAML provider as a principal in their trust policies. Any attempt to assume a role that references a SAML provider that has been deleted will fail.

**Note:** This operation requires Signature Version 4.

Request Syntax

```python
response = client.delete_saml_provider(
    SAMLProviderArn='string'
)
```
Parameters **SAMLProviderArn** *(string)* – [REQUIRED]

The Amazon Resource Name (ARN) of the SAML provider to delete.

Returns None

del**te**_server_certificate(**kwargs**)

Deletes the specified server certificate.

**Warning:** If you are using a server certificate with Elastic Load Balancing, deleting the certificate could have implications for your application. If Elastic Load Balancing doesn’t detect the deletion of bound certificates, it may continue to use the certificates. This could cause Elastic Load Balancing to stop accepting traffic. We recommend that you remove the reference to the certificate from Elastic Load Balancing before using this command to delete the certificate. For more information, go to DeleteLoadBalancerListeners in the Elastic Load Balancing API Reference.

Request Syntax

```python
response = client.delete_server_certificate(
    ServerCertificateName='string'
)
```

Parameters **ServerCertificateName** *(string)* – [REQUIRED]

The name of the server certificate you want to delete.

Returns None

del**e**_signing_certificate(**kwargs**)

Deletes the specified signing certificate associated with the specified user.

If you do not specify a user name, IAM determines the user name implicitly based on the AWS access key ID signing the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

Request Syntax

```python
response = client.delete_signing_certificate(
    UserName='string',
    CertificateId='string'
)
```

Parameters

- **UserName** *(string)* – The name of the user the signing certificate belongs to.
- **CertificateId** *(string)* – [REQUIRED]

The ID of the signing certificate to delete.

Returns None

del**e**_ss**h**_public_key(**kwargs**)

Deletes the specified SSH public key.

The SSH public key deleted by this action is used only for authenticating the associated IAM user to an AWS CodeCommit repository. For more information about using SSH keys to authenticate to an AWS CodeCommit repository, see Set up AWS CodeCommit for SSH Connections in the AWS CodeCommit User Guide.

Request Syntax
response = client.delete_ssh_public_key(
    UserName='string',
    SSHPublicKeyId='string'
)

Parameters

- **UserName** *(string)* – [REQUIRED]
  
  The name of the IAM user associated with the SSH public key.

- **SSHPublicKeyId** *(string)* – [REQUIRED]
  
  The unique identifier for the SSH public key.

Returns None

delete_user(**kwargs)**

Deletes the specified user. The user must not belong to any groups, have any keys or signing certificates, or have any attached policies.

Request Syntax

response = client.delete_user(
    UserName='string'
)

Parameters **UserName** *(string)* – [REQUIRED]

- The name of the user to delete.

Returns None

delete_user_policy(**kwargs)**

Deletes the specified inline policy that is embedded in the specified user.

A user can also have managed policies attached to it. To detach a managed policy from a user, use DetachUserPolicy. For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

Request Syntax

response = client.delete_user_policy(
    UserName='string',
    PolicyName='string'
)

Parameters

- **UserName** *(string)* – [REQUIRED]
  
  The name (friendly name, not ARN) identifying the user that the policy is embedded in.

- **PolicyName** *(string)* – [REQUIRED]
  
  The name identifying the policy document to delete.

Returns None

delete_virtual_mfa_device(**kwargs)**

Deletes a virtual MFA device.

**Note:** You must deactivate a user’s virtual MFA device before you can delete it. For information about deactivating MFA devices, see DeactivateMFADevice.

Request Syntax
response = client.delete_virtual_mfa_device(
    SerialNumber='string'
)

**Parameters**

- **SerialNumber (string)** – [REQUIRED]
  
  The serial number that uniquely identifies the MFA device. For virtual MFA devices, the serial number is the same as the ARN.

**Returns**

- None

### detach_group_policy(**kwargs)**

Removes the specified managed policy from the specified group.

A group can also have inline policies embedded with it. To delete an inline policy, use the DeleteGroupPolicy API. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

**Request Syntax**

```python
response = client.detach_group_policy(
    GroupName='string',
    PolicyArn='string'
)
```

**Parameters**

- **GroupName (string)** – [REQUIRED]
  
  The name (friendly name, not ARN) of the group to detach the policy from.

- **PolicyArn (string)** – [REQUIRED]
  
  The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

**Returns**

- None

### detach_role_policy(**kwargs)**

Removes the specified managed policy from the specified role.

A role can also have inline policies embedded with it. To delete an inline policy, use the DeleteRolePolicy API. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

**Request Syntax**

```python
response = client.detach_role_policy(
    RoleName='string',
    PolicyArn='string'
)
```

**Parameters**

- **RoleName (string)** – [REQUIRED]
  
  The name (friendly name, not ARN) of the role to detach the policy from.

- **PolicyArn (string)** – [REQUIRED]
  
  The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.
For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

Returns None

detach_user_policy(**kwargs)

Removes the specified managed policy from the specified user.

A user can also have inline policies embedded with it. To delete an inline policy, use the DeleteUserPolicy API. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

Request Syntax

response = client.detach_user_policy(
    UserName='string',
    PolicyArn='string'
)

Parameters

• **UserName** *(string)* – [REQUIRED]
  
The name (friendly name, not ARN) of the user to detach the policy from.

• **PolicyArn** *(string)* – [REQUIRED]
  
The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

  For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

Returns None

enable_mfa_device(**kwargs)

Enables the specified MFA device and associates it with the specified user name. When enabled, the MFA device is required for every subsequent login by the user name associated with the device.

Request Syntax

response = client.enable_mfa_device(
    UserName='string',
    SerialNumber='string',
    AuthenticationCode1='string',
    AuthenticationCode2='string'
)

Parameters

• **UserName** *(string)* – [REQUIRED]
  
The name of the user for whom you want to enable the MFA device.

• **SerialNumber** *(string)* – [REQUIRED]
  
The serial number that uniquely identifies the MFA device. For virtual MFA devices, the serial number is the device ARN.

• **AuthenticationCode1** *(string)* – [REQUIRED]
  
  An authentication code emitted by the device.

• **AuthenticationCode2** *(string)* – [REQUIRED]
  
  A subsequent authentication code emitted by the device.

Returns None
generate_credential_report()
Generates a credential report for the AWS account. For more information about the credential report, see Getting Credential Reports in the IAM User Guide.

Request Syntax
response = client.generate_credential_report()

Returns

Response Syntax

```python
{
    'State': 'STARTED'|'INPROGRESS'|'COMPLETE',
    'Description': 'string'
}
```

Response Structure
- (dict) – Contains the response to a successful GenerateCredentialReport request.
  - State (string) – Information about the state of the credential report.
  - Description (string) – Information about the credential report.

generate_presigned_url(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)
Generate a presigned url given a client, its method, and arguments

Parameters
- ClientMethod (string) – The client method to presign for
- Params (dict) – The parameters normally passed to ClientMethod.
- ExpiresIn (int) – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- HttpMethod (string) – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns The presigned url

get_access_key_last_used(**kwargs)
Retrieves information about when the specified access key was last used. The information includes the date and time of last use, along with the AWS service and region that were specified in the last request made with that key.

Request Syntax
response = client.get_access_key_last_used(
    AccessKeyId='string'
)

Parameters  AccessKeyId (string) – [REQUIRED]

    The identifier of an access key.

Returns

Response Syntax
Response Structure

- (dict) –
  Contains the response to a successful GetAccessKeyLastUsed request. It is also returned as a member of the AccessKeyMetaData structure returned by the ListAccessKeys action.
  - UserName (string) –
    The name of the AWS IAM user that owns this access key.
  - AccessKeyLastUsed (dict) –
    Contains information about the last time the access key was used.
      * LastUsedDate (datetime) –
        The date and time, in ISO 8601 date-time format, when the access key was most recently used. This field is null when:
        - The user does not have an access key.
        - An access key exists but has never been used, at least not since IAM started tracking this information on April 22nd, 2015.
        - There is no sign-in data associated with the user
      * ServiceName (string) –
        The name of the AWS service with which this access key was most recently used. This field is null when:
        - The user does not have an access key.
        - An access key exists but has never been used, at least not since IAM started tracking this information on April 22nd, 2015.
        - There is no sign-in data associated with the user
      * Region (string) –
        The AWS region where this access key was most recently used. This field is null when:
        - The user does not have an access key.
        - An access key exists but has never been used, at least not since IAM started tracking this information on April 22nd, 2015.
        - There is no sign-in data associated with the user

For more information about AWS regions, see Regions and Endpoints in the Amazon Web Services General Reference.

get_account_authorization_details (**kwargs)
Retrieves information about all IAM users, groups, roles, and policies in your account, including their relationships to one another. Use this API to obtain a snapshot of the configuration of IAM permissions (users, groups, roles, and policies) in your account.

You can optionally filter the results using the Filter parameter. You can paginate the results using the MaxItems and Marker parameters.

Request Syntax
response = client.get_account_authorization_details(
    Filter=[
        'User'|'Role'|'Group'|'LocalManagedPolicy'|'AWSManagedPolicy',
    ],
    MaxItems=123,
    Marker='string'
)

Parameters

- **Filter** *(list)* — A list of entity types (user, group, role, local managed policy, or AWS managed policy) for filtering the results.
  - *(string)*
- **MaxItems** *(integer)* — Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the `IsTruncated` response element is `true`.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the `IsTruncated` response element returns `true` and `Marker` contains a value to include in the subsequent call that tells the service where to continue from.

- **Marker** *(string)* — Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the `Marker` element in the response you received to inform the next call about where to start.

Return type dict

Response Syntax

```python
{
    'UserDetailList': [
        {
            'Path': 'string',
            'UserName': 'string',
            'UserId': 'string',

Response Structure

- *(dict)* – 
  Contains the response to a successful GetAccountAuthorizationDetails request.

  - **UserDetailList**(list) – 
    A list containing information about IAM users.
    *
      *(dict)* – 
      Contains information about an IAM user, including all the user’s policies and all the IAM groups the user is in.

      This data type is used as a response element in the GetAccountAuthorizationDetails action.

      - **Path**(string) – 
        The path to the user. For more information about paths, see IAM Identifiers in the Using IAM guide.

      - **UserName**(string) – 
        The friendly name identifying the user.

      - **UserId**(string) – 
        The stable and unique string identifying the user. For more information about IDs, see IAM Identifiers in the Using IAM guide.

      - **Arn**(string) – 
        The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.
For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

- **CreateDate** *(datetime)* –
  The date and time, in ISO 8601 date-time format, when the user was created.

- **UserPolicyList** *(list)* –
  A list of the inline policies embedded in the user.

  - *(dict)* –
    Contains information about an IAM policy, including the policy document.

    This data type is used as a response element in the GetAccountAuthorizationDetails action.

    - **PolicyName** *(string)* –
      The name of the policy.

    - **PolicyDocument** *(string)* –
      The policy document.

- **GroupList** *(list)* –
  A list of IAM groups that the user is in.

  - *(string)* –
    - **AttachedManagedPolicies** *(list)* –
      A list of the managed policies attached to the user.

        - *(dict)* –
          Contains information about an attached policy.

          An attached policy is a managed policy that has been attached to a user, group, or role. This data type is used as a response element in the ListAttachedGroupPolicies, ListAttachedRolePolicies, ListAttachedUserPolicies, and GetAccountAuthorizationDetails actions.

          For more information about managed policies, refer to Managed Policies and Inline Policies in the Using IAM guide.

    - **PolicyName** *(string)* –
      The friendly name of the attached policy.

    - **PolicyArn** *(string)* –
      The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

      For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

- **GroupDetailList** *(list)* –
  A list containing information about IAM groups.

  - *(dict)* –
    Contains information about an IAM group, including all of the group’s policies.
This data type is used as a response element in the GetAccountAuthorizationDetails action.

- **Path (string)** –
  The path to the group. For more information about paths, see IAM Identifiers in the Using IAM guide.

- **GroupName (string)** –
  The friendly name that identifies the group.

- **GroupId (string)** –
  The stable and unique string identifying the group. For more information about IDs, see IAM Identifiers in the Using IAM guide.

- **Arn (string)** –
  The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.
  
  For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference .

- **CreateDate (datetime)** –
  The date and time, in ISO 8601 date-time format , when the group was created.

- **GroupPolicyList (list)** –
  A list of the inline policies embedded in the group.

  - **(dict)** –
    Contains information about an IAM policy, including the policy document.

This data type is used as a response element in the GetAccountAuthorizationDetails action.

- **PolicyName (string)** –
  The name of the policy.

- **PolicyDocument (string)** –
  The policy document.

- **AttachedManagedPolicies (list)** –
  A list of the managed policies attached to the group.

  - **(dict)** –
    Contains information about an attached policy.

An attached policy is a managed policy that has been attached to a user, group, or role. This data type is used as a response element in the ListAttachedGroupPolicies, ListAttachedRolePolicies, ListAttachedUserPolicies, and GetAccountAuthorizationDetails actions.

For more information about managed policies, refer to Managed Policies and Inline Policies in the Using IAM guide.

- **PolicyName (string)** –
  The friendly name of the attached policy.

- **PolicyArn (string)** –
The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

- **RoleDetailList (list)** –

  A list containing information about IAM roles.

  * (dict) –

  Contains information about an IAM role, including all of the role’s policies.

  This data type is used as a response element in the GetAccountAuthorizationDetails action.

  - **Path (string)** –

    The path to the role. For more information about paths, see IAM Identifiers in the Using IAM guide.

  - **RoleName (string)** –

    The friendly name that identifies the role.

  - **RoleId (string)** –

    The stable and unique string identifying the role. For more information about IDs, see IAM Identifiers in the Using IAM guide.

  - **Arn (string)** –

    The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

    For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

  - **CreateDate (datetime)** –

    The date and time, in ISO 8601 date-time format, when the role was created.

  - **AssumeRolePolicyDocument (string)** –

    The trust policy that grants permission to assume the role.

  - **InstanceProfileList (list)** –

    Contains a list of instance profiles.

    * (dict) –

    Contains information about an instance profile.

    This data type is used as a response element in the following actions:

    - CreateInstanceProfile
    - GetInstanceProfile
    - ListInstanceProfiles
    - ListInstanceProfilesForRole

    - **Path (string)** –

      The path to the instance profile. For more information about paths, see IAM Identifiers in the Using IAM guide.
- **InstanceProfileName** *(string)* –
  The name identifying the instance profile.
- **InstanceProfileId** *(string)* –
  The stable and unique string identifying the instance profile. For more information about IDs, see IAM Identifiers in the Using IAM guide.
- **Arn** *(string)* –
  The Amazon Resource Name (ARN) specifying the instance profile. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.
- **CreateDate** *(datetime)* –
  The date when the instance profile was created.
- **Roles** *(list)* –
  The role associated with the instance profile.
  - *(dict)* –
    Contains information about an IAM role.
  
  This data type is used as a response element in the following actions:
  - CreateRole
  - GetRole
  - ListRoles
  - **Path** *(string)* –
    The path to the role. For more information about paths, see IAM Identifiers in the Using IAM guide.
  - **RoleName** *(string)* –
    The friendly name that identifies the role.
  - **RoleId** *(string)* –
    The stable and unique string identifying the role. For more information about IDs, see IAM Identifiers in the Using IAM guide.
  - **Arn** *(string)* –
    The Amazon Resource Name (ARN) specifying the role. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.
  - **CreateDate** *(datetime)* –
    The date and time, in ISO 8601 date-time format, when the role was created.
  - **AssumeRolePolicyDocument** *(string)* –
    The policy that grants an entity permission to assume the role.
  - **RolePolicyList** *(list)* –
    A list of inline policies embedded in the role. These policies are the role’s access (permissions) policies.
  - *(dict)* –
    Contains information about an IAM policy, including the policy document.
This data type is used as a response element in the GetAccountAuthorizationDetails action.

- **PolicyName** *(string)*
  - The name of the policy.

- **PolicyDocument** *(string)*
  - The policy document.

- **AttachedManagedPolicies** *(list)*
  - A list of managed policies attached to the role. These policies are the role’s access (permissions) policies.

  - *(dict)*
    - Contains information about an attached policy.

  An attached policy is a managed policy that has been attached to a user, group, or role. This data type is used as a response element in the ListAttachedGroupPolicies, ListAttachedRolePolicies, ListAttachedUserPolicies, and GetAccountAuthorizationDetails actions.

  For more information about managed policies, refer to Managed Policies and Inline Policies in the Using IAM guide.

  - **PolicyName** *(string)*
    - The friendly name of the attached policy.

  - **PolicyArn** *(string)*
    - The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

    For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

- **Policies** *(list)*
  - A list containing information about managed policies.

    - *(dict)*
      - Contains information about a managed policy, including the policy’s ARN, versions, and the number of principal entities (users, groups, and roles) that the policy is attached to.

This data type is used as a response element in the GetAccountAuthorizationDetails action.

For more information about managed policies, see Managed Policies and Inline Policies in the Using IAM guide.

  - **PolicyName** *(string)*
    - The friendly name (not ARN) identifying the policy.

  - **PolicyId** *(string)*
    - The stable and unique string identifying the policy.

    For more information about IDs, see IAM Identifiers in the Using IAM guide.

  - **Arn** *(string)*
    - The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.
For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

- **Path** (string) –
  
  The path to the policy.

  For more information about paths, see IAM Identifiers in the Using IAM guide.

- **DefaultVersionId** (string) –
  
  The identifier for the version of the policy that is set as the default (operative) version.

  For more information about policy versions, see Versioning for Managed Policies in the Using IAM guide.

- **AttachmentCount** (integer) –
  
  The number of principal entities (users, groups, and roles) that the policy is attached to.

- **IsAttachable** (boolean) –
  
  Specifies whether the policy can be attached to an IAM user, group, or role.

- **Description** (string) –
  
  A friendly description of the policy.

- **CreateDate** (datetime) –
  
  The date and time, in ISO 8601 date-time format, when the policy was created.

- **UpdateDate** (datetime) –
  
  The date and time, in ISO 8601 date-time format, when the policy was last updated.

  When a policy has only one version, this field contains the date and time when the policy was created. When a policy has more than one version, this field contains the date and time when the most recent policy version was created.

- **PolicyVersionList** (list) –
  
  A list containing information about the versions of the policy.

  - (dict) –
    
    Contains information about a version of a managed policy.

    This data type is used as a response element in the CreatePolicyVersion, GetPolicyVersion, ListPolicyVersions, and GetAccountAuthorizationDetails actions.

    For more information about managed policies, refer to Managed Policies and Inline Policies in the Using IAM guide.

- **Document** (string) –
  
  The policy document.

  The policy document is returned in the response to the GetPolicyVersion and GetAccountAuthorizationDetails operations. It is not returned in the response to the CreatePolicyVersion or ListPolicyVersions operations.
- **VersionId (string)** –
  The identifier for the policy version.
  Policy version identifiers always begin with v (always lowercase). When a policy is created, the first policy version is v1.

- **IsDefaultVersion (boolean)** –
  Specifies whether the policy version is set as the policy’s default version.

- **CreateDate (datetime)** –
  The date and time, in ISO 8601 date-time format, when the policy version was created.

- **IsTruncated (boolean)** –
  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **Marker (string)** –
  When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

get_account_password_policy()

Retrieves the password policy for the AWS account. For more information about using a password policy, go to Managing an IAM Password Policy.

Request Syntax

```python
response = client.get_account_password_policy()
```

Return type  dict

Returns

Response Syntax

```python
{
    'PasswordPolicy': {
        'MinimumPasswordLength': 123,
        'RequireSymbols': True|False,
        'RequireNumbers': True|False,
        'RequireUppercaseCharacters': True|False,
        'RequireLowercaseCharacters': True|False,
        'AllowUsersToChangePassword': True|False,
        'ExpirePasswords': True|False,
        'MaxPasswordAge': 123,
        'PasswordReusePrevention': 123,
        'HardExpiry': True|False
    }
}
```

Response Structure

- (dict) –
  Contains the response to a successful GetAccountPasswordPolicy request.
-- PasswordPolicy (dict) --

Contains information about the account password policy.

This data type is used as a response element in the GetAccountPasswordPolicy action.

* MinimumPasswordLength (integer) --
  Minimum length to require for IAM user passwords.
* RequireSymbols (boolean) --
  Specifies whether to require symbols for IAM user passwords.
* RequireNumbers (boolean) --
  Specifies whether to require numbers for IAM user passwords.
* RequireUppercaseCharacters (boolean) --
  Specifies whether to require uppercase characters for IAM user passwords.
* RequireLowercaseCharacters (boolean) --
  Specifies whether to require lowercase characters for IAM user passwords.
* AllowUsersToChangePassword (boolean) --
  Specifies whether IAM users are allowed to change their own password.
* ExpirePasswords (boolean) --
  Specifies whether IAM users are required to change their password after a specified number of days.
* MaxPasswordAge (integer) --
  The number of days that an IAM user password is valid.
* PasswordReusePrevention (integer) --
  Specifies the number of previous passwords that IAM users are prevented from reusing.
* HardExpiry (boolean) --
  Specifies whether IAM users are prevented from setting a new password after their password has expired.

get_account_summary()
Retrieves information about IAM entity usage and IAM quotas in the AWS account.

For information about limitations on IAM entities, see Limitations on IAM Entities in the IAM User Guide.

Request Syntax

response = client.get_account_summary()

Return type  dict

Returns

Response Syntax

{
  'SummaryMap': {
    'string': 123
  }
}
Response Structure

- **(dict)** –

  Contains the response to a successful GetAccountSummary request.

  - **SummaryMap (dict)** –

    A set of key value pairs containing information about IAM entity usage and IAM quotas.

    SummaryMap contains the following keys:

    - **AccessKeysPerUserQuota** The maximum number of active access keys allowed for each IAM user.
    - **AccountAccessKeysPresent** This value is 1 if the AWS account (root) has an access key, otherwise it is 0.
    - **AccountMFAEnabled** This value is 1 if the AWS account (root) has an MFA device assigned, otherwise it is 0.
    - **AccountSigningCertificatesPresent** This value is 1 if the AWS account (root) has a signing certificate, otherwise it is 0.
    - **AssumeRolePolicySizeQuota** The maximum allowed size for assume role policy documents (trust policies), in non-whitespace characters.
    - **AttachedPoliciesPerGroupQuota** The maximum number of managed policies that can be attached to an IAM group.
    - **AttachedPoliciesPerRoleQuota** The maximum number of managed policies that can be attached to an IAM role.
    - **AttachedPoliciesPerUserQuota** The maximum number of managed policies that can be attached to an IAM user.
    - **GroupPolicySizeQuota** The maximum allowed size for the aggregate of all inline policies embedded in an IAM group, in non-whitespace characters.
    - **Groups** The number of IAM groups in the AWS account.
    - **GroupsPerUserQuota** The maximum number of IAM groups each IAM user can belong to.
    - **GroupsQuota** The maximum number of IAM groups allowed in the AWS account.
    - **InstanceProfiles** The number of instance profiles in the AWS account.
    - **InstanceProfilesQuota** The maximum number of instance profiles allowed in the AWS account.
    - **MFADevices** The number of MFA devices in the AWS account, including those assigned and unassigned.
    - **MFADevicesInUse** The number of MFA devices that have been assigned to an IAM user or to the AWS account (root).
    - **Policies** The number of customer managed policies in the AWS account.
    - **PoliciesQuota** The maximum number of customer managed policies allowed in the AWS account.
    - **PolicySizeQuota** The maximum allowed size of a customer managed policy, in non-whitespace characters.
    - **PolicyVersionsInUse** The number of managed policies that are attached to IAM users, groups, or roles in the AWS account.
    - **PolicyVersionsInUseQuota** The maximum number of managed policies.
policies that can be attached to IAM users, groups, or roles in the AWS account.

* Providers The number of identity providers in the AWS account.
* RolePolicySizeQuota The maximum allowed size for the aggregate of all inline policies (access policies, not the trust policy) embedded in an IAM role, in non-whitespace characters.
* Roles The number of IAM roles in the AWS account.
* RolesQuota The maximum number of IAM roles allowed in the AWS account.
* ServerCertificates The number of server certificates in the AWS account.
* ServerCertificatesQuota The maximum number of server certificates allowed in the AWS account.
* SigningCertificatesPerUserQuota The maximum number of X.509 signing certificates allowed for each IAM user.
* UserPolicySizeQuota The maximum allowed size for the aggregate of all inline policies embedded in an IAM user, in non-whitespace characters.
* Users The number of IAM users in the AWS account.
* UsersQuota The maximum number of IAM users allowed in the AWS account.
* VersionsPerPolicyQuota The maximum number of policy versions allowed for each managed policy.

* (string) –
  * (integer) –

get_context_keys_for_custom_policy(**kwargs)

Gets a list of all of the context keys referenced in Condition elements in the input policies. The policies are supplied as a list of one or more strings. To get the context keys from policies associated with an IAM user, group, or role, use GetContextKeysForPrincipalPolicy.

Context keys are variables maintained by AWS and its services that provide details about the context of an API query request, and can be evaluated by using the Condition element of an IAM policy. Use GetContextKeysForCustomPolicy to understand what key names and values you must supply when you call SimulateCustomPolicy. Note that all parameters are shown in unencoded form here for clarity, but must be URL encoded to be included as a part of a real HTML request.

Request Syntax

```python
response = client.get_context_keys_for_custom_policy(
    PolicyInputList=[
        'string',
    ]
)
```

Parameters

PolicyInputList (list) – [REQUIRED]

A list of policies for which you want list of context keys used in Condition elements.

* (string) –

Return type

dict

Returns

Response Syntax

```python
{
    'ContextKeyNames': [ 
```
get_context_keys_for_principal_policy(**kwargs)

Gets a list of all of the context keys referenced in Condition elements in all of the IAM policies attached to the specified IAM entity. The entity can be an IAM user, group, or role. If you specify a user, then the request also includes all of the policies attached to groups that the user is a member of.

You can optionally include a list of one or more additional policies, specified as strings. If you want to include only a list of policies by string, use GetContextKeysForCustomPolicy instead.

**Note:** This API discloses information about the permissions granted to other users. If you do not want users to see other user’s permissions, then consider allowing them to use GetContextKeysForCustomPolicy instead.

Context keys are variables maintained by AWS and its services that provide details about the context of an API query request, and can be evaluated by using the Condition element of an IAM policy. Use GetContextKeysForPrincipalPolicy to understand what key names and values you must supply when you call SimulatePrincipalPolicy.

**Request Syntax**

```python
response = client.get_context_keys_for_principal_policy(
    PolicySourceArn='string',
    PolicyInputList=[
        'string',
    ]
)
```

**Parameters**

- **PolicySourceArn (string)** – [REQUIRED]
  
  The ARN of a user, group, or role whose policies contain the context keys that you want listed. If you specify a user, the list includes context keys that are found in all policies attached to the user as well as to all groups that the user is a member of. If you pick a group or a role, then it includes only those context keys that are found in policies attached to that entity. Note that all parameters are shown in unencoded form here for clarity, but must be URL encoded to be included as a part of a real HTML request.

- **PolicyInputList (list)** – A optional list of additional policies for which you want list of context keys used in Condition elements.

  - (string) –

**Return type** dict

**Response Syntax**
Response Structure

- *(dict)* —
  Contains the response to a successful GetContextKeysForPrincipalPolicy or GetContextKeysForCustomPolicy request.
  - **ContextKeyNames** *(list)* —
    The list of context keys that are used in the *Condition* elements of the input policies.
    
    * *(string)* —

**get_credential_report()**
Retrieves a credential report for the AWS account. For more information about the credential report, see Getting Credential Reports in the IAM User Guide.

Request Syntax

```python
response = client.get_credential_report()
```

Return type **dict**

Returns

Response Syntax

```python
{
    'Content': b'bytes',
    'ReportFormat': 'text/csv',
    'GeneratedTime': datetime(2015, 1, 1)
}
```

Response Structure

- *(dict)* —
  Contains the response to a successful GetCredentialReport request.
  - **Content** *(bytes)* —
    Contains the credential report. The report is Base64-encoded.
  - **ReportFormat** *(string)* —
    The format (MIME type) of the credential report.
  - **GeneratedTime** *(datetime)* —
    The date and time when the credential report was created, in ISO 8601 date-time format.

**get_group(**kwargs**)**
Returns a list of users that are in the specified group. You can paginate the results using the *MaxItems* and *Marker* parameters.

Request Syntax

```python
response = client.get_group(
    GroupName='string',
    Marker='string',
)
```
MaxItems=123

Parameters

- **GroupName** *(string)* - [REQUIRED]
  
The name of the group.

- **Marker** *(string)* - Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

- **MaxItems** *(integer)* - Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.

  This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

Return type  *dict*

Returns

Response Syntax

```python
{
    'Group': {
        'Path': 'string',
        'GroupName': 'string',
        'GroupId': 'string',
        'Arn': 'string',
        'CreateDate': datetime(2015, 1, 1)
    },
    'Users': [
        {
            'Path': 'string',
            'UserName': 'string',
            'UserId': 'string',
            'Arn': 'string',
            'CreateDate': datetime(2015, 1, 1),
            'PasswordLastUsed': datetime(2015, 1, 1)
        },
    ],
    'IsTruncated': True|False,
    'Marker': 'string'
}
```

Response Structure

- *(dict)* - Contains the response to a successful GetGroup request.
  
  - **Group** *(dict)* - Information about the group.
    - **Path** *(string)* - The path to the group. For more information about paths, see IAM Identifiers in the Using IAM guide.
* **GroupName** *(string)* –
  
The friendly name that identifies the group.

* **GroupId** *(string)* –
  
The stable and unique string identifying the group. For more information about IDs, see IAM Identifiers in the *Using IAM* guide.

* **Arn** *(string)* –
  
The Amazon Resource Name (ARN) specifying the group. For more information about ARNs and how to use them in policies, see IAM Identifiers in the *Using IAM* guide.

* **CreateDate** *(datetime)* –
  
The date and time, in ISO 8601 date-time format, when the group was created.

  - **Users** *(list)* –
    
    A list of users in the group.

    * *(dict)* –
      
      Contains information about an IAM user entity.

      This data type is used as a response element in the following actions:
      - CreateUser
      - GetUser
      - ListUsers

      * **Path** *(string)* –
        
        The path to the user. For more information about paths, see IAM Identifiers in the *Using IAM* guide.

      * **UserName** *(string)* –
        
        The friendly name identifying the user.

      * **UserId** *(string)* –
        
        The stable and unique string identifying the user. For more information about IDs, see IAM Identifiers in the *Using IAM* guide.

      * **Arn** *(string)* –
        
        The Amazon Resource Name (ARN) that identifies the user. For more information about ARNs and how to use ARNs in policies, see IAM Identifiers in the *Using IAM* guide.

      * **CreateDate** *(datetime)* –
        
        The date and time, in ISO 8601 date-time format, when the user was created.

      * **PasswordLastUsed** *(datetime)* –
        
        The date and time, in ISO 8601 date-time format, when the user’s password was last used to sign in to an AWS website. For a list of AWS websites that capture a user’s last sign-in time, see the Credential Reports topic in the *Using IAM* guide. If a password is used more than once in a five-minute span, only the first use is returned in this field. This field is null (not present) when:
        - The user does not have a password
        - The password exists but has never been used (at least not since IAM started tracking this information on October 20th, 2014
· there is no sign-in data associated with the user

This value is returned only in the GetUser and ListUsers actions.

– IsTruncated (boolean) –

A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

– Marker (string) –

When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

group_policy(**kwargs)

Retrieves the specified inline policy document that is embedded in the specified group.

A group can also have managed policies attached to it. To retrieve a managed policy document that is attached to a group, use GetPolicy to determine the policy’s default version, then use GetPolicyVersion to retrieve the policy document.

For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

Request Syntax

def response = client.get_group_policy(
    GroupName='string',
    PolicyName='string'
)

Parameters

• **GroupName (string)** – [REQUIRED]

  The name of the group the policy is associated with.

• **PolicyName (string)** – [REQUIRED]

  The name of the policy document to get.

Return type dict

Returns

Response Syntax

{
    'GroupName': 'string',
    'PolicyName': 'string',
    'PolicyDocument': 'string'
}

Response Structure

• (dict) –

  Contains the response to a successful GetGroupPolicy request.

  – **GroupName (string)** –

    The group the policy is associated with.
– **PolicyName** *(string)* –

The name of the policy.

– **PolicyDocument** *(string)* –

The policy document.

**get_instance_profile** (**kwargs**)

Retrieves information about the specified instance profile, including the instance profile’s path, GUID, ARN, and role. For more information about instance profiles, go to About Instance Profiles. For more information about ARNs, go to ARNs.

**Request Syntax**

```python
response = client.get_instance_profile(
    InstanceProfileName='string'
)
```

**Parameters**

- **InstanceProfileName** *(string)* – [REQUIRED]

  The name of the instance profile to get information about.

**Return type**

- dict

**Returns**

**Response Syntax**

```python
{
    'InstanceProfile': {
        'Path': 'string',
        'InstanceProfileName': 'string',
        'InstanceProfileId': 'string',
        'Arn': 'string',
        'CreateDate': datetime(2015, 1, 1),
        'Roles': [
            {
                'Path': 'string',
                'RoleName': 'string',
                'RoleId': 'string',
                'Arn': 'string',
                'CreateDate': datetime(2015, 1, 1),
                'AssumeRolePolicyDocument': 'string'
            },
            ...
        ]
    }
}
```

**Response Structure**

- *(dict)* – Contains the response to a successful GetInstanceProfile request.

  – **InstanceProfile** *(dict)* – Information about the instance profile.

    - **Path** *(string)* – The path to the instance profile. For more information about paths, see IAM Identifiers in the Using IAM guide.

    - **InstanceProfileName** *(string)* – The name identifying the instance profile.
* **InstanceProfileId (string)** –
  The stable and unique string identifying the instance profile. For more information about IDs, see IAM Identifiers in the Using IAM guide.

* **Arn (string)** –
  The Amazon Resource Name (ARN) specifying the instance profile. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.

* **CreateDate (datetime)** –
  The date when the instance profile was created.

* **Roles (list)** –
  The role associated with the instance profile.
    · **(dict)** –
      Contains information about an IAM role.
      This data type is used as a response element in the following actions:
      · CreateRole
      · GetRole
      · ListRoles
    · **Path (string)** –
      The path to the role. For more information about paths, see IAM Identifiers in the Using IAM guide.
    · **RoleName (string)** –
      The friendly name that identifies the role.
    · **RoleId (string)** –
      The stable and unique string identifying the role. For more information about IDs, see IAM Identifiers in the Using IAM guide.
    · **Arn (string)** –
      The Amazon Resource Name (ARN) specifying the role. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.
    · **CreateDate (datetime)** –
      The date and time, in ISO 8601 date-time format, when the role was created.
    · **AssumeRolePolicyDocument (string)** –
      The policy that grants an entity permission to assume the role.

**get_login_profile(**kwargs**)**

Retrieves the user name and password-creation date for the specified user. If the user has not been assigned a password, the action returns a 404 (NoSuchEntity) error.

**Request Syntax**

```python
response = client.get_login_profile(
    UserName='string'
)
```
Parameters  **UserName (string)** – **[REQUIRED]**

   The name of the user whose login profile you want to retrieve.

Return type  dict

Returns

Response Syntax

{  
    'LoginProfile': {  
        'UserName': 'string',  
        'CreateDate': datetime(2015, 1, 1),  
        'PasswordResetRequired': True|False  
    }  
}

Response Structure

- (dict) –
  
  Contains the response to a successful GetLoginProfile request.
  
  - **LoginProfile (dict)** –
    
    The user name and password create date for the user.
    
    - **UserName (string)** –
      
      The name of the user, which can be used for signing in to the AWS Management Console.

    - **CreateDate (datetime)** –
      
      The date when the password for the user was created.

    - **PasswordResetRequired (boolean)** –
      
      Specifies whether the user is required to set a new password on next sign-in.

get_open_id_connect_provider (**kwargs)**

Returns information about the specified OpenID Connect provider.

Request Syntax

response = client.get_open_id_connect_provider(  
    OpenIDConnectProviderArn='string'  
)

Parameters  **OpenIDConnectProviderArn (string)** – **[REQUIRED]**

   The Amazon Resource Name (ARN) of the IAM OpenID Connect (OIDC) provider to get information for. You can get a list of OIDC provider ARNs by using the ListOpenIDConnectProviders action.

Return type  dict

Returns

Response Syntax

{  
    'Url': 'string',  
    'ClientIDList': [  
        'string',  
    ],  
    'ThumbprintList': [  
        'string',  
    ]  
}
Response Structure

- **(dict)** –
  Contains the response to a successful GetOpenIDConnectProvider request.

  - **Url** *(string)* –
    The URL that the IAM OpenID Connect provider is associated with. For more information, see CreateOpenIDConnectProvider.

  - **ClientIDList** *(list)* –
    A list of client IDs (also known as audiences) that are associated with the specified IAM OpenID Connect provider. For more information, see CreateOpenIDConnectProvider.

  - **ThumbprintList** *(list)* –
    A list of certificate thumbprints that are associated with the specified IAM OpenID Connect provider. For more information, see CreateOpenIDConnectProvider.

  - **CreateDate** *(datetime)* –
    The date and time when the IAM OpenID Connect provider entity was created in the AWS account.

get_paginator *(operation_name)*

Create a paginator for an operation.

Parameters

- **operation_name** *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

Raises

- **OperationNotPageableError** Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

Return type

- L{botocore.paginate.Paginator}

Returns

- A paginator object.

get_policy(**kwargs)**

Retrieves information about the specified managed policy, including the policy’s default version and the total number of users, groups, and roles that the policy is attached to. For a list of the specific users, groups, and roles that the policy is attached to, use the ListEntitiesForPolicy API. This API returns metadata about the policy. To retrieve the policy document for a specific version of the policy, use GetPolicyVersion.

This API retrieves information about managed policies. To retrieve information about an inline policy that is embedded with a user, group, or role, use the GetUserPolicy, GetGroupPolicy, or GetRolePolicy API.
For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

Request Syntax

```python
response = client.get_policy(
    PolicyArn='string'
)
```

**Parameters**  
**PolicyArn (string)** – [REQUIRED]

The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources. For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

**Return type**  
dict

**Response Syntax**

```python
{
    'Policy': {
        'PolicyName': 'string',
        'PolicyId': 'string',
        'Arn': 'string',
        'Path': 'string',
        'DefaultVersionId': 'string',
        'AttachmentCount': 123,
        'IsAttachable': True|False,
        'Description': 'string',
        'CreateDate': datetime(2015, 1, 1),
        'UpdateDate': datetime(2015, 1, 1)
    }
}
```

**Response Structure**

• (dict) –

Contains the response to a successful GetPolicy request.

  • Policy (dict) –

  Information about the policy.

  • PolicyName (string) –

  The friendly name (not ARN) identifying the policy.

  • PolicyId (string) –

  The stable and unique string identifying the policy.

  For more information about IDs, see IAM Identifiers in the Using IAM guide.

  • Arn (string) –

  The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

  For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.
Path (string) –
The path to the policy. For more information about paths, see IAM Identifiers in the Using IAM guide.

DefaultVersionId (string) –
The identifier for the version of the policy that is set as the default version.

AttachmentCount (integer) –
The number of entities (users, groups, and roles) that the policy is attached to.

IsAttachable (boolean) –
Specifies whether the policy can be attached to an IAM user, group, or role.

Description (string) –
A friendly description of the policy. This element is included in the response to the GetPolicy operation. It is not included in the response to the ListPolicies operation.

CreateDate (datetime) –
The date and time, in ISO 8601 date-time format, when the policy was created.

UpdateDate (datetime) –
The date and time, in ISO 8601 date-time format, when the policy was last updated.

When a policy has only one version, this field contains the date and time when the policy was created. When a policy has more than one version, this field contains the date and time when the most recent policy version was created.

```
get_policy_version(**kwargs)
```
Retrieves information about the specified version of the specified managed policy, including the policy document.

To list the available versions for a policy, use ListPolicyVersions.

This API retrieves information about managed policies. To retrieve information about an inline policy that is embedded in a user, group, or role, use the GetUserPolicy, GetGroupPolicy, or GetRolePolicy API.

For more information about the types of policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

Request Syntax

```
response = client.get_policy_version(
    PolicyArn='string',
    VersionId='string'
)
```

Parameters

- **PolicyArn (string)** – [REQUIRED]

  The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.
For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

**VersionId** *(string)* – [REQUIRED]

Identifies the policy version to retrieve.

**Return type**  dict

**Returns**

**Response Syntax**

```
{
    'PolicyVersion': {
        'Document': 'string',
        'VersionId': 'string',
        'IsDefaultVersion': True|False,
        'CreateDate': datetime(2015, 1, 1)
    }
}
```

**Response Structure**

- *(dict)* –

  Contains the response to a successful GetPolicyVersion request.

  - **PolicyVersion** *(dict)* –

    Information about the policy version.

    For more information about managed policy versions, see Versioning for Managed Policies in the IAM User Guide.

    - **Document** *(string)* –

      The policy document.

      The policy document is returned in the response to the GetPolicyVersion and GetAccountAuthorizationDetails operations. It is not returned in the response to the CreatePolicyVersion or ListPolicyVersions operations.

    - **VersionId** *(string)* –

      The identifier for the policy version.

      Policy version identifiers always begin with `v` (always lowercase). When a policy is created, the first policy version is `v1`.

    - **IsDefaultVersion** *(boolean)* –

      Specifies whether the policy version is set as the policy’s default version.

    - **CreateDate** *(datetime)* –

      The date and time, in ISO 8601 date-time format, when the policy version was created.

**get_role(**kwargs**)

Retrieves information about the specified role, including the role’s path, GUID, ARN, and the policy granting permission to assume the role. For more information about ARNs, go to ARNs. For more information about roles, go to Working with Roles.

**Request Syntax**
response = client.get_role(
    RoleName='string'
)

Parameters  RoleName (string) – [REQUIRED]
The name of the role to get information about.

Return type  dict

Returns

Response Syntax

{  
    'Role': {
        'Path': 'string',
        'RoleName': 'string',
        'RoleId': 'string',
        'Arn': 'string',
        'CreateDate': datetime(2015, 1, 1),
        'AssumeRolePolicyDocument': 'string'
    }
}

Response Structure

• (dict) –
  Contains the response to a successful GetRole request.
  – Role (dict) –
    Information about the role.
    • Path (string) –
      The path to the role. For more information about paths, see IAM Identities in the Using IAM guide.
    • RoleName (string) –
      The friendly name that identifies the role.
    • RoleId (string) –
      The stable and unique string identifying the role. For more information about IDs, see IAM Identities in the Using IAM guide.
    • Arn (string) –
      The Amazon Resource Name (ARN) specifying the role. For more information about ARNs and how to use them in policies, see IAM Identities in the Using IAM guide.
    • CreateDate (datetime) –
      The date and time, in ISO 8601 date-time format , when the role was created.
    • AssumeRolePolicyDocument (string) –
      The policy that grants an entity permission to assume the role.

get_role_policy (**kwargs)
Retrieves the specified inline policy document that is embedded with the specified role.

A role can also have managed policies attached to it. To retrieve a managed policy document that is attached to a role, use GetPolicy to determine the policy’s default version, then use GetPolicyVersion to retrieve the policy document.
For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

For more information about roles, go to Using Roles to Delegate Permissions and Federate Identities.

Request Syntax

response = client.get_role_policy(
    RoleName='string',
    PolicyName='string'
)

Parameters

- **RoleName** *(string)* – [REQUIRED]
  The name of the role associated with the policy.

- **PolicyName** *(string)* – [REQUIRED]
  The name of the policy document to get.

Return type  dict

Returns

Response Syntax

{
    'RoleName': 'string',
    'PolicyName': 'string',
    'PolicyDocument': 'string'
}

Response Structure

- *(dict)* –
  Contains the response to a successful GetRolePolicy request.
  - **RoleName** *(string)* –
    The role the policy is associated with.
  - **PolicyName** *(string)* –
    The name of the policy.
  - **PolicyDocument** *(string)* –
    The policy document.

get_saml_provider(**kwargs)

Returns the SAML provider metadocument that was uploaded when the provider was created or updated.

**Note:** This operation requires Signature Version 4.

Request Syntax

response = client.get_saml_provider(
    SAMLProviderArn='string'
)

Parameters  **SAMLProviderArn** *(string)* – [REQUIRED]

  The Amazon Resource Name (ARN) of the SAML provider to get information about.

Return type  dict
Returns

Response Syntax

{'SAMLMetadataDocument': 'string',
'CreateDate': datetime(2015, 1, 1),
'ValidUntil': datetime(2015, 1, 1)
}

Response Structure
• (dict) –

Contains the response to a successful GetSAMLProvider request.

– SAMLMetadataDocument (string) –

The XML metadata document that includes information about an identity provider.

– CreateDate (datetime) –

The date and time when the SAML provider was created.

– ValidUntil (datetime) –

The expiration date and time for the SAML provider.

get_server_certificate(**kwargs)

Retrieves information about the specified server certificate.

Request Syntax

response = client.get_server_certificate(
    ServerCertificateName='string'
)

Parameters  ServerCertificateName (string) – [REQUIRED]

The name of the server certificate you want to retrieve information about.

Return type  dict

Returns

Response Syntax

{'ServerCertificate': {
    'ServerCertificateMetadata': {
        'Path': 'string',
        'ServerCertificateName': 'string',
        'ServerCertificateId': 'string',
        'Arn': 'string',
        'UploadDate': datetime(2015, 1, 1),
        'Expiration': datetime(2015, 1, 1)
    },
    'CertificateBody': 'string',
    'CertificateChain': 'string'
}}

Response Structure
• (dict) –

Contains the response to a successful GetServerCertificate request.
– **ServerCertificate** *(dict)* –
  Information about the server certificate.
  * **ServerCertificateMetadata** *(dict)* –
    The meta information of the server certificate, such as its name, path, ID, and ARN.
    * **Path** *(string)* –
      The path to the server certificate. For more information about paths, see IAM Identifiers in the *Using IAM* guide.
    * **ServerCertificateName** *(string)* –
      The name that identifies the server certificate.
    * **ServerCertificateId** *(string)* –
      The stable and unique string identifying the server certificate. For more information about IDs, see IAM Identifiers in the *Using IAM* guide.
    * **Arn** *(string)* –
      The Amazon Resource Name (ARN) specifying the server certificate. For more information about ARNs and how to use them in policies, see IAM Identifiers in the *Using IAM* guide.
    * **UploadDate** *(datetime)* –
      The date when the server certificate was uploaded.
    * **Expiration** *(datetime)* –
      The date on which the certificate is set to expire.
  * **CertificateBody** *(string)* –
    The contents of the public key certificate.
  * **CertificateChain** *(string)* –
    The contents of the public key certificate chain.

**get_ssh_public_key(**kwargs**)**
Retrieves the specified SSH public key, including metadata about the key.

The SSH public key retrieved by this action is used only for authenticating the associated IAM user to an AWS CodeCommit repository. For more information about using SSH keys to authenticate to an AWS CodeCommit repository, see Set up AWS CodeCommit for SSH Connections in the *AWS CodeCommit User Guide*.

**Request Syntax**

```python
def get_ssh_public_key(**kwargs):
    response = client.get_ssh_public_key(
        UserName='string',
        SSHPublicKeyId='string',
        Encoding='SSH'|'PEM'
    )
```

**Parameters**

- **UserName** *(string)* – [REQUIRED]
  The name of the IAM user associated with the SSH public key.
- **SSHPublicKeyId** *(string)* – [REQUIRED]
  The unique identifier for the SSH public key.
• **Encoding** *(string)* – [REQUIRED]

Specifies the public key encoding format to use in the response. To retrieve the public key in ssh-rsa format, use `SSH`. To retrieve the public key in PEM format, use `PEM`.

**Return type** `dict`

**Returns**

**Response Syntax**

```
{
  'SSHPublicKey': {
    'UserName': 'string',
    'SSHPublicKeyId': 'string',
    'Fingerprint': 'string',
    'SSHPublicKeyBody': 'string',
    'Status': 'Active'|'Inactive',
    'UploadDate': datetime(2015, 1, 1)
  }
}
```

**Response Structure**

• *(dict)* –

Contains the response to a successful GetSSHPublicKey request.

– **SSHPublicKey** *(dict)* –

Information about the SSH public key.

* **UserName** *(string)* –

  The name of the IAM user associated with the SSH public key.

* **SSHPublicKeyId** *(string)* –

  The unique identifier for the SSH public key.

* **Fingerprint** *(string)* –

  The MD5 message digest of the SSH public key.

* **SSHPublicKeyBody** *(string)* –

  The SSH public key.

* **Status** *(string)* –

  The status of the SSH public key. `Active` means the key can be used for authentication with an AWS CodeCommit repository. `Inactive` means the key cannot be used.

* **UploadDate** *(datetime)* –

  The date and time, in ISO 8601 date-time format, when the SSH public key was uploaded.

```python
def get_user(**kwargs)
    Retrieves information about the specified user, including the user’s creation date, path, unique ID, and ARN.

    If you do not specify a user name, IAM determines the user name implicitly based on the AWS access key ID used to sign the request.

    **Request Syntax**
    ```python
    ```
response = client.get_user(
    UserName='string'
)

Parameters  UserName (string) – The name of the user to get information about.

This parameter is optional. If it is not included, it defaults to the user making the request.

Return type  dict

Returns

Response Syntax

```
{
    'User': {
        'Path': 'string',
        'UserName': 'string',
        'UserId': 'string',
        'Arn': 'string',
        'CreateDate': datetime(2015, 1, 1),
        'PasswordLastUsed': datetime(2015, 1, 1)
    }
}
```

Response Structure

- (dict) –

Contains the response to a successful GetUser request.

  - User (dict) –

Information about the user.

- Path (string) –

  The path to the user. For more information about paths, see IAM Identifiers in the Using IAM guide.

- UserName (string) –

  The friendly name identifying the user.

- UserId (string) –

  The stable and unique string identifying the user. For more information about IDs, see IAM Identifiers in the Using IAM guide.

- Arn (string) –

  The Amazon Resource Name (ARN) that identifies the user. For more information about ARNs and how to use ARNs in policies, see IAM Identifiers in the Using IAM guide.

- CreateDate (datetime) –

  The date and time, in ISO 8601 date-time format, when the user was created.

- PasswordLastUsed (datetime) –

  The date and time, in ISO 8601 date-time format, when the user’s password was last used to sign in to an AWS website. For a list of AWS websites that capture a user’s last sign-in time, see the Credential Reports topic in the Using IAM guide. If a password is used more than once in a five-minute span, only the first use is returned in this field. This field is null (not present) when:
  - The user does not have a password
The password exists but has never been used (at least not since
IAM started tracking this information on October 20th, 2014
· there is no sign-in data associated with the user
This value is returned only in the GetUser and ListUsers actions.

**getUserPolicy(**kwargs**)

Retrieves the specified inline policy document that is embedded in the specified user.

A user can also have managed policies attached to it. To retrieve a managed policy document that is
attached to a user, use GetPolicy to determine the policy’s default version, then use GetPolicyVersion to
retrieve the policy document.

For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide
.

Request Syntax

```python
response = client.get_user_policy(
    UserName='string',
    PolicyName='string'
)
```

Parameters

- **UserName** *(string)* – [REQUIRED]
  The name of the user who the policy is associated with.
- **PolicyName** *(string)* – [REQUIRED]
  The name of the policy document to get.

Returns

- **Response Syntax**

```python
{
    'UserName': 'string',
    'PolicyName': 'string',
    'PolicyDocument': 'string'
}
```

- **Response Structure**

  - *(dict)* –
    Contains the response to a successful GetUserPolicy request.
    - **UserName** *(string)* –
        The user the policy is associated with.
    - **PolicyName** *(string)* –
        The name of the policy.
    - **PolicyDocument** *(string)* –
        The policy document.

**get_waiter**(waiter_name)

**list_access_keys**(**kwargs**)

Returns information about the access key IDs associated with the specified user. If there are none, the
action returns an empty list.

Although each user is limited to a small number of keys, you can still paginate the results using the
MaxItems and Marker parameters.
If the `UserName` field is not specified, the `UserName` is determined implicitly based on the AWS access key ID used to sign the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

**Note:** To ensure the security of your AWS account, the secret access key is accessible only during key and user creation.

### Request Syntax

```python
response = client.list_access_keys(
    UserName='string',
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- `UserName (string)` – The name of the user.
- `Marker (string)` – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the `Marker` element in the response you received to inform the next call about where to start.
- `MaxItems (integer)` – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the `IsTruncated` response element is `true`.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the `IsTruncated` response element returns `true` and `Marker` contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'AccessKeyMetadata': [
        {
            'UserName': 'string',
            'AccessKeyId': 'string',
            'Status': 'Active'|'Inactive',
            'CreateDate': datetime(2015, 1, 1)
        },
    ],
    'IsTruncated': True|False,
    'Marker': 'string'
}
```

**Response Structure**

- `(dict)` –

  Contains the response to a successful `ListAccessKeys` request.

  - `AccessKeyMetadata (list)` –

    A list of access key metadata.
** (dict) –
Contains information about an AWS access key, without its secret key.

This data type is used as a response element in the ListAccessKeys action.

- **UserName** *(string)* –
The name of the IAM user that the key is associated with.

- **AccessKeyId** *(string)* –
The ID for this access key.

- **Status** *(string)* –
The status of the access key. **Active** means the key is valid for API calls; **Inactive** means it is not.

- **CreateDate** *(datetime)* –
The date when the access key was created.

- **IsTruncated** *(boolean)* –
A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **Marker** *(string)* –
When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

**list_account_aliases** (**kwargs)**
Lists the account aliases associated with the account. For information about using an AWS account alias, see **Using an Alias for Your AWS Account ID** in the **IAM User Guide**.

You can paginate the results using the **MaxItems** and **Marker** parameters.

**Request Syntax**

```python
response = client.list_account_aliases(
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

- **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and
Marker contains a value to include in the subsequent call that tells the service where to continue from.

Return type: dict
Returns:

Response Syntax

```python
{
    'AccountAliases': [  
        'string',
    ],
    'IsTruncated': True|False,
    'Marker': 'string'
}
```

Response Structure

* (dict) –

Contains the response to a successful ListAccountAliases request.

- AccountAliases (list) –

A list of aliases associated with the account.

* (string) –

- IsTruncated (boolean) –

A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- Marker (string) –

When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

list_attached_group_policies(**kwargs)

Lists all managed policies that are attached to the specified group.

A group can also have inline policies embedded with it. To list the inline policies for a group, use the ListGroupPolicies API. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

You can paginate the results using the MaxItems and Marker parameters. You can use the PathPrefix parameter to limit the list of policies to only those matching the specified path prefix. If there are no policies attached to the specified group (or none that match the specified path prefix), the action returns an empty list.

Request Syntax

```python
response = client.list_attached_group_policies(
    GroupName='string',
    PathPrefix='string',
    Marker='string',
    MaxItems=123
)
```

Parameters
• **GroupName (string)** – [REQUIRED]

  The name (friendly name, not ARN) of the group to list attached policies for.

• **PathPrefix (string)** – The path prefix for filtering the results. This parameter is optional. If it is not included, it defaults to a slash (/), listing all policies.

• **Marker (string)** – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

• **MaxItems (integer)** – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is `true`.

  This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns `true` and Marker contains a value to include in the subsequent call that tells the service where to continue from.

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'AttachedPolicies': [
        {
            'PolicyName': 'string',
            'PolicyArn': 'string'
        },
    ],
    'IsTruncated': True|False,
    'Marker': 'string'
}
```

**Response Structure**

• *(dict)* –

  Contains the response to a successful ListAttachedGroupPolicies request.

  – **AttachedPolicies (list)** –

    A list of the attached policies.

    • *(dict)* –

      Contains information about an attached policy.

      An attached policy is a managed policy that has been attached to a user, group, or role. This data type is used as a response element in the ListAttachedGroupPolicies, ListAttachedRolePolicies, ListAttachedUserPolicies, and GetAccountAuthorizationDetails actions.

      For more information about managed policies, refer to Managed Policies and Inline Policies in the Using IAM guide.

      • **PolicyName (string)** –

        The friendly name of the attached policy.

      • **PolicyArn (string)** –

        The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.
For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

- **IsTruncated** (boolean) –
  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **Marker** (string) –
  When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

### list_attached_role_policies(**kwargs)**

Lists all managed policies that are attached to the specified role.

A role can also have inline policies embedded with it. To list the inline policies for a role, use the ListRolePolicies API. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

You can paginate the results using the MaxItems and Marker parameters. You can use the PathPrefix parameter to limit the list of policies to only those matching the specified path prefix. If there are no policies attached to the specified role (or none that match the specified path prefix), the action returns an empty list.

#### Request Syntax

```python
response = client.list_attached_role_policies(
    RoleName='string',
    PathPrefix='string',
    Marker='string',
    MaxItems=123
)
```

#### Parameters

- **RoleName** (string) – [REQUIRED]
  The name (friendly name, not ARN) of the role to list attached policies for.

- **PathPrefix** (string) – The path prefix for filtering the results. This parameter is optional. If it is not included, it defaults to a slash (/), listing all policies.

- **Marker** (string) – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

- **MaxItems** (integer) – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.

  This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

#### Return type
dict
Returns

Response Syntax

{
    'AttachedPolicies': [
        {
            'PolicyName': 'string',
            'PolicyArn': 'string'
        },
    ],
    'IsTruncated': True|False,
    'Marker': 'string'
}

Response Structure

• (dict) –
  Contains the response to a successful ListAttachedRolePolicies request.
  
  – AttachedPolicies (list) –
    A list of the attached policies.
    * (dict) –
      Contains information about an attached policy.
      An attached policy is a managed policy that has been attached to a
      user, group, or role. This data type is used as a response element in
      the ListAttachedGroupPolicies , ListAttachedRolePolicies , ListAt-
      tachedUserPolicies , and GetAccountAuthorizationDetails actions.
      For more information about managed policies, refer to Managed
      Policies and Inline Policies in the Using IAM guide.
      
      • PolicyName (string) –
        The friendly name of the attached policy.
      • PolicyArn (string) –
        The Amazon Resource Name (ARN). ARNs are unique identi-
        fiers for AWS resources.
        
        For more information about ARNs, go to Amazon Resource
        Names (ARNs) and AWS Service Namespaces in the AWS
        General Reference.

  – IsTruncated (boolean) –
    A flag that indicates whether there are more items to return. If your results
    were truncated, you can make a subsequent pagination request using the
    Marker request parameter to retrieve more items. Note that IAM might
    return fewer than the MaxItems number of results even when there are
    more results available. We recommend that you check IsTruncated
    after every call to ensure that you receive all of your results.

  – Marker (string) –
    When IsTruncated is true , this element is present and contains the
    value to use for the Marker parameter in a subsequent pagination request.

list_attached_user_policies(**kwargs)
Lists all managed policies that are attached to the specified user.
A user can also have inline policies embedded with it. To list the inline policies for a user, use the ListUserPolicies API. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

You can paginate the results using the MaxItems and Marker parameters. You can use the PathPrefix parameter to limit the list of policies to only those matching the specified path prefix. If there are no policies attached to the specified group (or none that match the specified path prefix), the action returns an empty list.

**Request Syntax**

```python
response = client.list_attached_user_policies(
    UserName='string',
    PathPrefix='string',
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **UserName** (*string*) – [REQUIRED]
  
  The name (friendly name, not ARN) of the user to list attached policies for.

- **PathPrefix** (*string*) – The path prefix for filtering the results. This parameter is optional. If it is not included, it defaults to a slash (/), listing all policies.

- **Marker** (*string*) – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

- **MaxItems** (*integer*) – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.

  This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

**Return type**  dict

**Response Syntax**

```python
{  
    'AttachedPolicies': [
        {  
            'PolicyName': 'string',
            'PolicyArn': 'string'
        },
    ],
    'IsTruncated': True|False,
    'Marker': 'string'
}
```

**Response Structure**

- *(dict)* –
  
  Contains the response to a successful ListAttachedUserPolicies request.
– **AttachedPolicies** *(list)* –

A list of the attached policies.

* *(dict)* –

Contains information about an attached policy.

An attached policy is a managed policy that has been attached to a user, group, or role. This data type is used as a response element in the ListAttachedGroupPolicies, ListAttachedRolePolicies, ListAttachedUserPolicies, and GetAccountAuthorizationDetails actions.

For more information about managed policies, refer to Managed Policies and Inline Policies in the *Using IAM* guide.

• **PolicyName** *(string)* –

The friendly name of the attached policy.

• **PolicyArn** *(string)* –

The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the *AWS General Reference*.

– **IsTruncated** *(boolean)* –

A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

– **Marker** *(string)* –

When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

**list_entities_for_policy** 

Lists all users, groups, and roles that the specified managed policy is attached to.

You can use the optional EntityFilter parameter to limit the results to a particular type of entity (users, groups, or roles). For example, to list only the roles that are attached to the specified policy, set EntityFilter to Role.

You can paginate the results using the MaxItems and Marker parameters.

**Request Syntax**

```python
response = client.list_entities_for_policy(
    PolicyArn='string',
    EntityFilter='User'|'Role'|'Group'|'LocalManagedPolicy'|'AWSManagedPolicy',
    PathPrefix='string',
    Marker='string',
    MaxItems=123
)
```

**Parameters**

• **PolicyArn** *(string)* – [REQUIRED]

The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.
For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

- **EntityFilter** *(string)* – The entity type to use for filtering the results.

For example, when `EntityFilter` is `Role`, only the roles that are attached to the specified policy are returned. This parameter is optional. If it is not included, all attached entities (users, groups, and roles) are returned.

- **PathPrefix** *(string)* – The path prefix for filtering the results. This parameter is optional. If it is not included, it defaults to a slash (/), listing all entities.

- **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the `Marker` element in the response you received to inform the next call about where to start.

- **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the `IsTruncated` response element is `true`.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the `IsTruncated` response element returns `true` and `Marker` contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'PolicyGroups': [
        {
            'GroupName': 'string'
        },
    ],
    'PolicyUsers': [
        {
            'UserName': 'string'
        },
    ],
    'PolicyRoles': [
        {
            'RoleName': 'string'
        },
    ],
    'IsTruncated': True|False,
    'Marker': 'string'
}
```

**Response Structure**

- *(dict)* –

  Contains the response to a successful ListEntitiesForPolicy request.

    - **PolicyGroups** *(list)* –

      A list of groups that the policy is attached to.

    - *(dict)* –

      Contains information about a group that a managed policy is attached to.
This data type is used as a response element in the ListEntitiesForPolicy action.

For more information about managed policies, refer to Managed Policies and Inline Policies in the Using IAM guide.

· **GroupName** *(string)* – The name (friendly name, not ARN) identifying the group.

- **PolicyUsers** *(list)* – A list of users that the policy is attached to.
  * *(dict)* – Contains information about a user that a managed policy is attached to.

  This data type is used as a response element in the ListEntitiesForPolicy action.

  For more information about managed policies, refer to Managed Policies and Inline Policies in the Using IAM guide.

  · **UserName** *(string)* – The name (friendly name, not ARN) identifying the user.

- **PolicyRoles** *(list)* – A list of roles that the policy is attached to.
  * *(dict)* – Contains information about a role that a managed policy is attached to.

  This data type is used as a response element in the ListEntitiesForPolicy action.

  For more information about managed policies, refer to Managed Policies and Inline Policies in the Using IAM guide.

  · **RoleName** *(string)* – The name (friendly name, not ARN) identifying the role.

- **IsTruncated** *(boolean)* – A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **Marker** *(string)* – When IsTruncated is True, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

### list_group_policies(**kwargs**)

Lists the names of the inline policies that are embedded in the specified group.

A group can also have managed policies attached to it. To list the managed policies that are attached to a group, use ListAttachedGroupPolicies. For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

You can paginate the results using the MaxItems and Marker parameters. If there are no inline policies embedded with the specified group, the action returns an empty list.
Request Syntax

```python
response = client.list_group_policies(
    GroupName='string',
    Marker='string',
    MaxItems=123
)
```

Parameters

- **GroupName** *(string)* – [REQUIRED]
  The name of the group to list policies for.

- **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the `Marker` element in the response you received to inform the next call about where to start.

- **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the `IsTruncated` response element is `true`.

  This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the `IsTruncated` response element returns `true` and Marker contains a value to include in the subsequent call that tells the service where to continue from.

Return type  `dict`

Returns

Response Syntax

```json
{
    'PolicyNames': [
        'string',
    ],
    'IsTruncated': True|False,
    'Marker': 'string'
}
```

Response Structure

- *(dict)* –
  Contains the response to a successful `ListGroupPolicies` request.
  - **PolicyNames** *(list)* –
    A list of policy names.
    - *(string)* –
  - **IsTruncated** *(boolean)* –
    A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the `Marker` request parameter to retrieve more items. Note that IAM might return fewer than the `MaxItems` number of results even when there are more results available. We recommend that you check `IsTruncated` after every call to ensure that you receive all of your results.

  - **Marker** *(string)* –
    When `IsTruncated` is `true`, this element is present and contains the value to use for the `Marker` parameter in a subsequent pagination request.
list_groups(**kwargs)

Lists the groups that have the specified path prefix.

You can paginate the results using the MaxItems and Marker parameters.

Request Syntax

```python
response = client.list_groups(
    PathPrefix='string',
    Marker='string',
    MaxItems=123
)
```

Parameters

- **PathPrefix (string)** – The path prefix for filtering the results. For example, the prefix `/division_abc/subdivision_xyz/` gets all groups whose path starts with `/division_abc/subdivision_xyz/`.

  This parameter is optional. If it is not included, it defaults to a slash (/), listing all groups.

- **Marker (string)** – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

- **MaxItems (integer)** – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is True.

  This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns True and Marker contains a value to include in the subsequent call that tells the service where to continue from.

Return type dict

Returns

**Response Syntax**

```python
{
    'Groups': [
        {
            'Path': 'string',
            'GroupName': 'string',
            'GroupId': 'string',
            'Arn': 'string',
            'CreateDate': datetime(2015, 1, 1)
        },
        ...
    ],
    'IsTruncated': True|False,
    'Marker': 'string'
}
```

**Response Structure**

- **(dict)** –

  Contains the response to a successful ListGroups request.
– **Groups** *(list)* –

A list of groups.

* *(dict)* –

Contains information about an IAM group entity.

This data type is used as a response element in the following actions:

- CreateGroup
- GetGroup
- ListGroups

- **Path** *(string)* –

The path to the group. For more information about paths, see IAM Identifiers in the Using IAM guide.

- **GroupName** *(string)* –

The friendly name that identifies the group.

- **GroupId** *(string)* –

The stable and unique string identifying the group. For more information about IDs, see IAM Identifiers in the Using IAM guide.

- **Arn** *(string)* –

The Amazon Resource Name (ARN) specifying the group. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.

- **CreateDate** *(datetime)* –

The date and time, in ISO 8601 date-time format, when the group was created.

– **IsTruncated** *(boolean)* –

A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

– **Marker** *(string)* –

When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

**list_groups_for_user** *(**kwargs]*)

Lists the groups the specified user belongs to.

You can paginate the results using the MaxItems and Marker parameters.

**Request Syntax**

```python
response = client.list_groups_for_user(
    UserName='string',
    Marker='string',
    MaxItems=123
)
```

**Parameters**
• **UserName** *(string)* – [REQUIRED]
  The name of the user to list groups for.

• **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

• **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.

  This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

**Return type**  dict

**Returns**

**Response Syntax**

```json
{
  'Groups': [
    {
      'Path': 'string',
      'GroupName': 'string',
      'GroupId': 'string',
      'Arn': 'string',
      'CreateDate': datetime(2015, 1, 1)
    },
  ],
  'IsTruncated': True|False,
  'Marker': 'string'
}
```

**Response Structure**

• *(dict)* –
  Contains the response to a successful ListGroupsForUser request.
  
  – **Groups** *(list)* –
    A list of groups.
    
    • *(dict)* –
      Contains information about an IAM group entity.
      
      This data type is used as a response element in the following actions:
      
      · CreateGroup
      · GetGroup
      · ListGroups

      • **Path** *(string)* –
        The path to the group. For more information about paths, see IAM Identifiers in the Using IAM guide.

      • **GroupName** *(string)* –
        The friendly name that identifies the group.
- **GroupId (string)** –
  The stable and unique string identifying the group. For more information about IDs, see IAM Identifiers in the Using IAM guide.

- **Arn (string)** –
  The Amazon Resource Name (ARN) specifying the group. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.

- **CreateDate (datetime)** –
  The date and time, in ISO 8601 date-time format, when the group was created.

- **IsTruncated (boolean)** –
  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **Marker (string)** –
  When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

### list_instance_profiles(**kwargs)**

Lists the instance profiles that have the specified path prefix. If there are none, the action returns an empty list. For more information about instance profiles, go to About Instance Profiles.

You can paginate the results using the MaxItems and Marker parameters.

**Request Syntax**

```python
response = client.list_instance_profiles(
    PathPrefix='string',
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **PathPrefix (string)** – The path prefix for filtering the results. For example, the prefix `/application_abcd/component_xyz/` gets all instance profiles whose path starts with `/application_abcd/component_xyz/`. This parameter is optional. If it is not included, it defaults to a slash (/), listing all instance profiles.

- **Marker (string)** – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

- **MaxItems (integer)** – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true. This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results avail-
able. If this is the case, the `IsTruncated` response element returns `true` and `Marker` contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
   'InstanceProfiles': [
      {
         'Path': 'string',
         'InstanceProfileName': 'string',
         'InstanceProfileId': 'string',
         'Arn': 'string',
         'CreateDate': datetime(2015, 1, 1),
         'Roles': [
            {
               'Path': 'string',
               'RoleName': 'string',
               'RoleId': 'string',
               'Arn': 'string',
               'CreateDate': datetime(2015, 1, 1),
               'AssumeRolePolicyDocument': 'string'
            }
         ]
      },
      
   ],
   'IsTruncated': True|False,
   'Marker': 'string'
}
```

**Response Structure**

- *(dict)* –
  
  Contains the response to a successful `ListInstanceProfiles` request.

  - **InstanceProfiles** *(list)* –
    
    A list of instance profiles.

    - *(dict)* –
      
      Contains information about an instance profile.

      This data type is used as a response element in the following actions:

      - CreateInstanceProfile
      - GetInstanceProfile
      - ListInstanceProfiles
      - ListInstanceProfilesForRole

    - **Path** *(string)* –
      
      The path to the instance profile. For more information about paths, see `IAM Identifiers` in the *Using IAM* guide.

    - **InstanceProfileName** *(string)* –
      
      The name identifying the instance profile.

    - **InstanceProfileId** *(string)* –
      
      The stable and unique string identifying the instance profile. For more information about IDs, see `IAM Identifiers` in the **Using IAM** guide.
Using IAM guide.

- **Arn (string)** –
  The Amazon Resource Name (ARN) specifying the instance profile. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.

- **CreateDate (datetime)** –
  The date when the instance profile was created.

- **Roles (list)** –
  The role associated with the instance profile.

  - **(dict)** –
    Contains information about an IAM role.

    This data type is used as a response element in the following actions:
    - CreateRole
    - GetRole
    - ListRoles

  - **Path (string)** –
    The path to the role. For more information about paths, see IAM Identifiers in the Using IAM guide.

  - **RoleName (string)** –
    The friendly name that identifies the role.

  - **RoleId (string)** –
    The stable and unique string identifying the role. For more information about IDs, see IAM Identifiers in the Using IAM guide.

  - **Arn (string)** –
    The Amazon Resource Name (ARN) specifying the role. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.

  - **CreateDate (datetime)** –
    The date and time, in ISO 8601 date-time format, when the role was created.

  - **AssumeRolePolicyDocument (string)** –
    The policy that grants an entity permission to assume the role.

- **IsTruncated (boolean)** –
  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **Marker (string)** –
  When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

**list_instance_profiles_for_role (****kwargs)**

Lists the instance profiles that have the specified associated role. If there are none, the action returns an empty list. For more information about instance profiles, go to About Instance Profiles.
You can paginate the results using the `MaxItems` and `Marker` parameters.

**Request Syntax**

```python
def response = client.list_instance_profiles_for_role(  
    RoleName='string',  
    Marker='string',  
    MaxItems=123  
)
```

**Parameters**

- **RoleName** *(string)* – [REQUIRED]
  The name of the role to list instance profiles for.

- **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the `Marker` element in the response you received to inform the next call about where to start.

- **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the `IsTruncated` response element is `true`.
  
  This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the `IsTruncated` response element returns `true` and `Marker` contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
  'InstanceProfiles': [
    {
      'Path': 'string',
      'InstanceProfileName': 'string',
      'InstanceProfileId': 'string',
      'Arn': 'string',
      'CreateDate': datetime(2015, 1, 1),
      'Roles': [
        {
          'Path': 'string',
          'RoleName': 'string',
          'RoleId': 'string',
          'Arn': 'string',
          'CreateDate': datetime(2015, 1, 1),
          'AssumeRolePolicyDocument': 'string'
        }
      ]
    },
  ],
  'IsTruncated': True|False,
  'Marker': 'string'
}
```

**Response Structure**
• (dict) –
  Contains the response to a successful ListInstanceProfilesForRole request.
  • InstanceProfiles (list) –
    A list of instance profiles.
      • (dict) –
        Contains information about an instance profile.
        This data type is used as a response element in the following actions:
        • CreateInstanceProfile
        • GetInstanceProfile
        • ListInstanceProfiles
        • ListInstanceProfilesForRole
          • Path (string) –
            The path to the instance profile. For more information about paths, see IAM Identifiers in the Using IAM guide.
          • InstanceProfileName (string) –
            The name identifying the instance profile.
          • InstanceProfileId (string) –
            The stable and unique string identifying the instance profile. For more information about IDs, see IAM Identifiers in the Using IAM guide.
          • Arn (string) –
            The Amazon Resource Name (ARN) specifying the instance profile. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.
          • CreateDate (datetime) –
            The date when the instance profile was created.
          • Roles (list) –
            The role associated with the instance profile.
            • (dict) –
              Contains information about an IAM role.
              This data type is used as a response element in the following actions:
              • CreateRole
              • GetRole
              • ListRoles
              • Path (string) –
                The path to the role. For more information about paths, see IAM Identifiers in the Using IAM guide.
              • RoleName (string) –
                The friendly name that identifies the role.
              • RoleId (string) –
                The stable and unique string identifying the role. For more information about IDs, see IAM Identifiers in the Using IAM guide.
              • Arn (string) –
The Amazon Resource Name (ARN) specifying the role. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.

- **CreateDate** *(datetime)* – The date and time, in ISO 8601 date-time format, when the role was created.
- **AssumeRolePolicyDocument** *(string)* – The policy that grants an entity permission to assume the role.

- **IsTruncated** *(boolean)* – A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **Marker** *(string)* – When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

### list_mfa_devices(**kwargs)**

Lists the MFA devices. If the request includes the user name, then this action lists all the MFA devices associated with the specified user name. If you do not specify a user name, IAM determines the user name implicitly based on the AWS access key ID signing the request.

You can paginate the results using the MaxItems and Marker parameters.

#### Request Syntax

```python
response = client.list_mfa_devices(
    UserName='string',
    Marker='string',
    MaxItems=123
)
```

#### Parameters

- **UserName** *(string)* – The name of the user whose MFA devices you want to list.
- **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.
- **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

#### Return type
dict

#### Returns

#### Response Syntax
{  
  'MFADevices': [  
    {  
      'UserName': 'string',  
      'SerialNumber': 'string',  
      'EnableDate': datetime(2015, 1, 1)  
    },  
    {  
      'UserName': 'string',  
      'SerialNumber': 'string',  
      'EnableDate': datetime(2015, 1, 1)  
    },  
  ],  
  'IsTruncated': True|False,  
  'Marker': 'string'  
}

Response Structure

• (dict) –
  Contains the response to a successful ListMFADevices request.
  – MFADevices (list) –
    A list of MFA devices.
    * (dict) –
      Contains information about an MFA device.
      This data type is used as a response element in the ListMFADevices action.
      · UserName (string) –
        The user with whom the MFA device is associated.
      · SerialNumber (string) –
        The serial number that uniquely identifies the MFA device.
        For virtual MFA devices, the serial number is the device ARN.
      · EnableDate (datetime) –
        The date when the MFA device was enabled for the user.
  – IsTruncated (boolean) –
    A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.
  – Marker (string) –
    When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

list_open_id_connect_providers()

Lists information about the OpenID Connect providers in the AWS account.

Request Syntax

response = client.list_open_id_connect_providers()

Return type dict
Returns

Response Syntax
{  'OpenIDConnectProviderList': [  {  'Arn': 'string'  }  ]}

Response Structure
• (dict) –
  Contains the response to a successful ListOpenIDConnectProviders request.
  – OpenIDConnectProviderList (list) –
    The list of IAM OpenID Connect providers in the AWS account.
    • (dict) –
      Contains the Amazon Resource Name (ARN) for an IAM OpenID Connect provider.
      • Arn (string) –
        The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.
        For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

list_policies(**kwargs)
Lists all the managed policies that are available to your account, including your own customer managed policies and all AWS managed policies.

You can filter the list of policies that is returned using the optional OnlyAttached, Scope, and PathPrefix parameters. For example, to list only the customer managed policies in your AWS account, set Scope to Local. To list only AWS managed policies, set Scope to AWS.

You can paginate the results using the MaxItems and Marker parameters.

For more information about managed policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

Request Syntax
response = client.list_policies(
  Scope='All'|'AWS'|'Local',
  OnlyAttached=True|False,
  PathPrefix='string',
  Marker='string',
  MaxItems=123
)

Parameters
• Scope (string) – The scope to use for filtering the results.

  To list only AWS managed policies, set Scope to AWS. To list only the customer managed policies in your AWS account, set Scope to Local.

  This parameter is optional. If it is not included, or if it is set to All, all policies are returned.
• **OnlyAttached** (*boolean*) – A flag to filter the results to only the attached policies.

When `OnlyAttached` is `true`, the returned list contains only the policies that are attached to a user, group, or role. When `OnlyAttached` is `false`, or when the parameter is not included, all policies are returned.

• **PathPrefix** (*string*) – The path prefix for filtering the results. This parameter is optional. If it is not included, it defaults to a slash `/`, listing all policies.

• **Marker** (*string*) – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the `Marker` element in the response you received to inform the next call about where to start.

• **MaxItems** (*integer*) – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the `IsTruncated` response element is `true`.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the `IsTruncated` response element returns `true` and `Marker` contains a value to include in the subsequent call that tells the service where to continue from.

**Return type**  `dict`

**Returns**

**Response Syntax**

```python
{
    'Policies': [
        {
            'PolicyName': 'string',
            'PolicyId': 'string',
            'Arn': 'string',
            'Path': 'string',
            'DefaultVersionId': 'string',
            'AttachmentCount': 123,
            'IsAttachable': True|False,
            'Description': 'string',
            'CreateDate': datetime(2015, 1, 1),
            'UpdateDate': datetime(2015, 1, 1)
        },
    ],
    'IsTruncated': True|False,
    'Marker': 'string'
}
```

**Response Structure**

• *(dict)* –

Contains the response to a successful ListPolicies request.

  – **Policies** *(list)* –

A list of policies.

    • *(dict)* –

Contains information about a managed policy.

This data type is used as a response element in the CreatePolicy, GetPolicy, and ListPolicies actions.
For more information about managed policies, refer to Managed Policies and Inline Policies in the Using IAM guide.

- **PolicyName** *(string)*
  
The friendly name (not ARN) identifying the policy.

- **PolicyId** *(string)*
  
The stable and unique string identifying the policy.

  For more information about IDs, see IAM Identifiers in the Using IAM guide.

- **Arn** *(string)*
  
The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

  For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

- **Path** *(string)*
  
The path to the policy.

  For more information about paths, see IAM Identifiers in the Using IAM guide.

- **DefaultVersionId** *(string)*
  
The identifier for the version of the policy that is set as the default version.

- **AttachmentCount** *(integer)*
  
The number of entities (users, groups, and roles) that the policy is attached to.

- **IsAttachable** *(boolean)*
  
  Specifies whether the policy can be attached to an IAM user, group, or role.

- **Description** *(string)*
  
  A friendly description of the policy.

  This element is included in the response to the GetPolicy operation. It is not included in the response to the ListPolicies operation.

- **CreateDate** *(datetime)*
  
The date and time, in ISO 8601 date-time format, when the policy was created.

- **UpdateDate** *(datetime)*
  
The date and time, in ISO 8601 date-time format, when the policy was last updated.

  When a policy has only one version, this field contains the date and time when the policy was created. When a policy has more than one version, this field contains the date and time when the most recent policy version was created.

- **IsTruncated** *(boolean)*
  
  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might
return fewer than the `MaxItems` number of results even when there are more results available. We recommend that you check `IsTruncated` after every call to ensure that you receive all of your results.

- **Marker (string)** –

  When `IsTruncated` is `true`, this element is present and contains the value to use for the `Marker` parameter in a subsequent pagination request.

`list_policy_versions (**kwargs)`

Lists information about the versions of the specified managed policy, including the version that is set as the policy’s default version.

For more information about managed policies, refer to Managed Policies and Inline Policies in the *IAM User Guide*.

**Request Syntax**

```python
response = client.list_policy_versions(
    PolicyArn='string',
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **PolicyArn (string)** – [REQUIRED]

  The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

  For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the *AWS General Reference*.

- **Marker (string)** – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the `Marker` element in the response you received to inform the next call about where to start.

- **MaxItems (integer)** – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the `IsTruncated` response element is `true`.

  This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the `IsTruncated` response element returns `true` and `Marker` contains a value to include in the subsequent call that tells the service where to continue from.

**Return type**: dict

**Returns**

**Response Syntax**

```python
{
    'Versions': [
        {
            'Document': 'string',
            'VersionId': 'string',
            'IsDefaultVersion': True|False,
            'CreateDate': datetime(2015, 1, 1)
        },
    ],
}
```
'IsTruncated': True|False,
'Marker': 'string'
}

**Response Structure**

- **(dict)**

  Contains the response to a successful ListPolicyVersions request.

  - **Versions (list)**

    A list of policy versions.

    For more information about managed policy versions, see Versioning for Managed Policies in the *IAM User Guide*.

    - **(dict)**

      Contains information about a version of a managed policy.

      This data type is used as a response element in the CreatePolicyVersion, GetPolicyVersion, ListPolicyVersions, and GetAccountAuthorizationDetails actions.

      For more information about managed policies, refer to Managed Policies and Inline Policies in the *Using IAM* guide.

      - **Document (string)**

        The policy document.

        The policy document is returned in the response to the GetPolicyVersion and GetAccountAuthorizationDetails operations. It is not returned in the response to the CreatePolicyVersion or ListPolicyVersions operations.

      - **VersionId (string)**

        The identifier for the policy version.

        Policy version identifiers always begin with `v` (always lowercase). When a policy is created, the first policy version is `v1`.

      - **IsDefaultVersion (boolean)**

        Specifies whether the policy version is set as the policy’s default version.

      - **CreateDate (datetime)**

        The date and time, in ISO 8601 date-time format, when the policy version was created.

  - **IsTruncated (boolean)**

    A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

  - **Marker (string)**

    When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.
list_role_policies(**kwargs)

Lists the names of the inline policies that are embedded in the specified role.

A role can also have managed policies attached to it. To list the managed policies that are attached to a role, use ListAttachedRolePolicies. For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

You can paginate the results using the MaxItems and Marker parameters. If there are no inline policies embedded with the specified role, the action returns an empty list.

Request Syntax

response = client.list_role_policies(
    RoleName='string',
    Marker='string',
    MaxItems=123
)

Parameters

- **RoleName (string)** – [REQUIRED]
  
The name of the role to list policies for.

- **Marker (string)** – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

- **MaxItems (integer)** – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is True.

  This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns True and Marker contains a value to include in the subsequent call that tells the service where to continue from.

Return type  dict

Returns

Response Syntax

{
    'PolicyNames': [ 'string',
    ],
    'IsTruncated': True|False,
    'Marker': 'string'
}

Response Structure

- (dict) –
  
  Contains the response to a successful ListRolePolicies request.

  - **PolicyNames (list)** –
    
    A list of policy names.

    - (string) –
- **IsTruncated (boolean)**  
  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **Marker (string)**  
  When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

list_roles(**kwargs)

Lists the roles that have the specified path prefix. If there are none, the action returns an empty list. For more information about roles, go to Working with Roles.

You can paginate the results using the MaxItems and Marker parameters.

**Request Syntax**

```python
response = client.list_roles(
    PathPrefix='string',
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **PathPrefix (string)** – The path prefix for filtering the results. For example, the prefix /application_abcd/component_xyz/ gets all roles whose path starts with /application_abcd/component_xyz/.  
  This parameter is optional. If it is not included, it defaults to a slash (/), listing all roles.

- **Marker (string)** – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

- **MaxItems (integer)** – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.
  This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Roles': [
        {
            'Path': 'string',
            'RoleName': 'string',
        },
    ],
}
```
Response Structure

- (dict) –
  Contains the response to a successful ListRoles request.

  - Roles (list) –
    A list of roles.
    * (dict) –
      Contains information about an IAM role.
      This data type is used as a response element in the following actions:
      - CreateRole
      - GetRole
      - ListRoles
      - Path (string) –
        The path to the role. For more information about paths, see IAM Identifiers in the Using IAM guide.
      - RoleName (string) –
        The friendly name that identifies the role.
      - RoleId (string) –
        The stable and unique string identifying the role. For more information about IDs, see IAM Identifiers in the Using IAM guide.
      - Arn (string) –
        The Amazon Resource Name (ARN) specifying the role. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.
      - CreateDate (datetime) –
        The date and time, in ISO 8601 date-time format, when the role was created.
      - AssumeRolePolicyDocument (string) –
        The policy that grants an entity permission to assume the role.
  - IsTruncated (boolean) –
    A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.
  - Marker (string) –
When `IsTruncated` is `true`, this element is present and contains the value to use for the `Marker` parameter in a subsequent pagination request.

`list_saml_providers()`
Lists the SAML providers in the account.

**Note:** This operation requires Signature Version 4.

**Request Syntax**

```python
response = client.list_saml_providers()
```

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'SAMLProviderList': [
        {
            'Arn': 'string',
            'ValidUntil': datetime(2015, 1, 1),
            'CreateDate': datetime(2015, 1, 1)
        },
    ]
}
```

**Response Structure**

- `(dict)` –
  - Contains the response to a successful ListSAMLProviders request.
  - **SAMLProviderList** (list) –
    - The list of SAML providers for this account.
      - `(dict)` –
        - Contains the list of SAML providers for this account.
          - **Arn** (string) –
            - The Amazon Resource Name (ARN) of the SAML provider.
          - **ValidUntil** (datetime) –
            - The expiration date and time for the SAML provider.
          - **CreateDate** (datetime) –
            - The date and time when the SAML provider was created.

`list_server_certificates(**kwargs)`

Lists the server certificates that have the specified path prefix. If none exist, the action returns an empty list.

You can paginate the results using the `MaxItems` and `Marker` parameters.

**Request Syntax**

```python
response = client.list_server_certificates(
    PathPrefix='string',
    Marker='string',
    MaxItems=123
)
```
Parameters

- **PathPrefix** *(string)* – The path prefix for filtering the results. For example: /company/servercerts would get all server certificates for which the path starts with /company/servercerts.

  This parameter is optional. If it is not included, it defaults to a slash (/), listing all server certificates.

- **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

- **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.

  This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

Return type  **dict**

Returns

**Response Syntax**

```python
{
    'ServerCertificateMetadataList': [
        {
            'Path': 'string',
            'ServerCertificateName': 'string',
            'ServerCertificateId': 'string',
            'Arn': 'string',
            'UploadDate': datetime(2015, 1, 1),
            'Expiration': datetime(2015, 1, 1)
        },
    ],
    'IsTruncated': True|False,
    'Marker': 'string'
}
```

**Response Structure**

- *(dict)* –

  Contains the response to a successful ListServerCertificates request.

- **ServerCertificateMetadataList** *(list)* –

  A list of server certificates.

- *(dict)* –

  Contains information about a server certificate without its certificate body, certificate chain, and private key.

  This data type is used as a response element in the UploadServerCertificate and ListServerCertificates actions.

- **Path** *(string)* –

  The path to the server certificate. For more information about paths, see IAM Identifiers in the Using IAM guide.
- **ServerCertificateName** *(string)* –
  The name that identifies the server certificate.

- **ServerCertificateId** *(string)* –
  The stable and unique string identifying the server certificate.
  For more information about IDs, see IAM Identifiers in the Using IAM guide.

- **Arn** *(string)* –
  The Amazon Resource Name (ARN) specifying the server certificate. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.

- **UploadDate** *(datetime)* –
  The date when the server certificate was uploaded.

- **Expiration** *(datetime)* –
  The date on which the certificate is set to expire.

- **IsTruncated** *(boolean)* –
  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **Marker** *(string)* –
  When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

### list_signing_certificates(**kwargs)**

Returns information about the signing certificates associated with the specified user. If there are none, the action returns an empty list.

Although each user is limited to a small number of signing certificates, you can still paginate the results using the MaxItems and Marker parameters.

If the UserName field is not specified, the user name is determined implicitly based on the AWS access key ID used to sign the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

**Request Syntax**

```python
response = client.list_signing_certificates(
    UserName='string',
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **UserName** *(string)* – The name of the user.
- **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.
- **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items be-
yond the maximum you specify, the IsTruncated response element is true.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

Return type  dict

Returns

Response Syntax

```
{
  'Certificates': [  
    {
      'UserName': 'string',
      'CertificateId': 'string',
      'CertificateBody': 'string',
      'Status': 'Active'|'Inactive',
      'UploadDate': datetime(2015, 1, 1)
    },
  ],
  'IsTruncated': True|False,
  'Marker': 'string'
}
```

Response Structure

• (dict) –
  Contains the response to a successful ListSigningCertificates request.

  – Certificates (list) –
    A list of the user’s signing certificate information.
    • (dict) –
      Contains information about an X.509 signing certificate.
      This data type is used as a response element in the UploadSigningCertificate and ListSigningCertificates actions.
      • UserName (string) –
        The name of the user the signing certificate is associated with.
      • CertificateId (string) –
        The ID for the signing certificate.
      • CertificateBody (string) –
        The contents of the signing certificate.
      • Status (string) –
        The status of the signing certificate. Active means the key is valid for API calls, while Inactive means it is not.
      • UploadDate (datetime) –
        The date when the signing certificate was uploaded.

  – IsTruncated (boolean) –
    A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might
return fewer than the `MaxItems` number of results even when there are more results available. We recommend that you check `IsTruncated` after every call to ensure that you receive all of your results.

### Marker (string)

When `IsTruncated` is `true`, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

**list_ssh_public_keys(**kwargs)**

Returns information about the SSH public keys associated with the specified IAM user. If there are none, the action returns an empty list.

The SSH public keys returned by this action are used only for authenticating the IAM user to an AWS CodeCommit repository. For more information about using SSH keys to authenticate to an AWS CodeCommit repository, see Set up AWS CodeCommit for SSH Connections in the *AWS CodeCommit User Guide*.

Although each user is limited to a small number of keys, you can still paginate the results using the `MaxItems` and `Marker` parameters.

**Request Syntax**

```python
response = client.list_ssh_public_keys(
    UserName='string',
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- `UserName (string)` – The name of the IAM user to list SSH public keys for. If none is specified, the `UserName` field is determined implicitly based on the AWS access key used to sign the request.

- `Marker (string)` – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the `Marker` element in the response you received to inform the next call about where to start.

- `MaxItems (integer)` – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the `IsTruncated` response element is `true`.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the `IsTruncated` response element returns `true` and `Marker` contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'SSHPublicKeys': [
        {
            'UserName': 'string',
            'SSHPublicKeyId': 'string',
            'Status': 'Active'|'Inactive',
            'UploadDate': datetime(2015, 1, 1)
        }
    ]
}
```
Response Structure

- (dict) –
  Contains the response to a successful ListSSHPublicKeys request.
  - SSHPublicKeys (list) –
    A list of SSH public keys.
    * (dict) –
      Contains information about an SSH public key, without the key's body or fingerprint.

      This data type is used as a response element in the ListSSHPublicKeys action.
      - UserName (string) –
        The name of the IAM user associated with the SSH public key.
      - SSHPublicKeyId (string) –
        The unique identifier for the SSH public key.
      - Status (string) –
        The status of the SSH public key. Active means the key can be used for authentication with an AWS CodeCommit repository. Inactive means the key cannot be used.
      - UploadDate (datetime) –
        The date and time, in ISO 8601 date-time format, when the SSH public key was uploaded.
  - IsTruncated (boolean) –
    A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.
  - Marker (string) –
    When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

list_user_policies(**kwargs)

Lists the names of the inline policies embedded in the specified user.

A user can also have managed policies attached to it. To list the managed policies that are attached to a user, use ListAttachedUserPolicies. For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

You can paginate the results using the MaxItems and Marker parameters. If there are no inline policies embedded with the specified user, the action returns an empty list.

Request Syntax

3.1. Services 2811
response = client.list_user_policies(
    UserName='string',
    Marker='string',
    MaxItems=123
)

Parameters

- **UserName** *(string)* – [REQUIRED]
  The name of the user to list policies for.

- **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

- **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is `true`.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns `true` and Marker contains a value to include in the subsequent call that tells the service where to continue from.

Return type  `dict`

Returns

Response Syntax

```
{
    'PolicyNames': [ 'string',
    'string',
    ],
    'IsTruncated': True|False,
    'Marker': 'string'
}
```

Response Structure

- *(dict)* –

  Contains the response to a successful ListUserPolicies request.

  - **PolicyNames** *(list)* –

    A list of policy names.

    - *(string)* –

  - **IsTruncated** *(boolean)* –

    A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

  - **Marker** *(string)* –

    When IsTruncated is `true`, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.
**list_users(**kwargs)**

Lists the IAM users that have the specified path prefix. If no path prefix is specified, the action returns all users in the AWS account. If there are none, the action returns an empty list.

You can paginate the results using the **MaxItems** and **Marker** parameters.

**Request Syntax**

```python
response = client.list_users(
    PathPrefix='string',
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **PathPrefix** *(string)* – The path prefix for filtering the results. For example: `/division_abc/subdivision_xyz/`, which would get all user names whose path starts with `/division_abc/subdivision_xyz/`.  
  
  This parameter is optional. If it is not included, it defaults to a slash (/), listing all user names.

- **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the **Marker** element in the response you received to inform the next call about where to start.

- **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the **IsTruncated** response element is `true`
  
  This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the **IsTruncated** response element returns `true` and **Marker** contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'Users': [
        {
            'Path': 'string',
            'UserName': 'string',
            'UserId': 'string',
            'Arn': 'string',
            'CreateDate': datetime(2015, 1, 1),
            'PasswordLastUsed': datetime(2015, 1, 1)
        },
    ],
    'IsTruncated': True|False,
    'Marker': 'string'
}
```

**Response Structure**

- *(dict)* –
  
  Contains the response to a successful ListUsers request.
– **Users** *(list)* –

A list of users.

* *(dict)* –

Contains information about an IAM user entity.

This data type is used as a response element in the following actions:

- CreateUser
- GetUser
- ListUsers

- **Path** *(string)* –

  The path to the user. For more information about paths, see IAM Identifiers in the Using IAM guide.

- **UserName** *(string)* –

  The friendly name identifying the user.

- **UserId** *(string)* –

  The stable and unique string identifying the user. For more information about IDs, see IAM Identifiers in the Using IAM guide.

- **Arn** *(string)* –

  The Amazon Resource Name (ARN) that identifies the user. For more information about ARNs and how to use ARNs in policies, see IAM Identifiers in the Using IAM guide.

- **CreateDate** *(datetime)* –

  The date and time, in ISO 8601 date-time format, when the user was created.

- **PasswordLastUsed** *(datetime)* –

  The date and time, in ISO 8601 date-time format, when the user’s password was last used to sign in to an AWS website. For a list of AWS websites that capture a user’s last sign-in time, see the Credential Reports topic in the Using IAM guide.

  If a password is used more than once in a five-minute span, only the first use is returned in this field. This field is null (not present) when:

  - The user does not have a password
  - The password exists but has never been used (at least not since IAM started tracking this information on October 20th, 2014)
  - there is no sign-in data associated with the user

  This value is returned only in the GetUser and ListUsers actions.

- **IsTruncated** *(boolean)* –

  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **Marker** *(string)* –

When `IsTruncated` is `true`, this element is present and contains the value to use for the `Marker` parameter in a subsequent pagination request.

`list_virtual_mfa_devices(**kwargs)`

Lists the virtual MFA devices under the AWS account by assignment status. If you do not specify an assignment status, the action returns a list of all virtual MFA devices. Assignment status can be `Assigned`, `Unassigned`, or `Any`.

You can paginate the results using the `MaxItems` and `Marker` parameters.

**Request Syntax**

```python
response = client.list_virtual_mfa_devices(
    AssignmentStatus='Assigned'|'Unassigned'|'Any',
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **AssignmentStatus** *(string)* – The status (unassigned or assigned) of the devices to list. If you do not specify an `AssignmentStatus`, the action defaults to `Any` which lists both assigned and unassigned virtual MFA devices.
- **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the `Marker` element in the response you received to inform the next call about where to start.
- **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the `IsTruncated` response element is `true`.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the `IsTruncated` response element returns `true` and `Marker` contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'VirtualMFADevices': [ {
        'SerialNumber': 'string',
        'Base32StringSeed': b'bytes',
        'QRCodePNG': b'bytes',
        'User': { 
            'Path': 'string',
            'UserName': 'string',
            'UserId': 'string',
            'Arn': 'string',
            'CreateDate': datetime(2015, 1, 1),
            'PasswordLastUsed': datetime(2015, 1, 1)
        },
        'EnableDate': datetime(2015, 1, 1)
    },
    ...
}
```

3.1. Services
'IsTruncated': True|False,
'Marker': 'string'
}

**Response Structure**

- *(dict)*

  Contains the response to a successful ListVirtualMFADevices request.

  - **VirtualMFADevices** *(list)*

    The list of virtual MFA devices in the current account that match the 
    AssignmentStatus value that was passed in the request.

    - *(dict)*

      Contains information about a virtual MFA device.

      - **SerialNumber** *(string)*

        The serial number associated with VirtualMFADevice.

      - **Base32StringSeed** *(bytes)*

        The Base32 seed defined as specified in RFC3548. The 
        Base32StringSeed is Base64-encoded.

      - **QRCodePNG** *(bytes)*

        A QR code PNG image that encodes 
        otpauth://totp/$virtualMFADeviceName@$AccountName?secret=$Base32String 
        where $virtualMFADeviceName is one of the create call arguments, 
        AccountName is the user name if set (otherwise, the account ID otherwise), 
        and Base32String is the seed in Base32 format. The Base32String value is 
        Base64-encoded.

      - **User** *(dict)*

        Contains information about an IAM user entity.

        This data type is used as a response element in the following actions:

        - Create User
        - Get User
        - List Users

        - **Path** *(string)*

          The path to the user. For more information about paths, see 
          IAM Identifiers in the Using IAM guide.

        - **UserName** *(string)*

          The friendly name identifying the user.

        - **UserId** *(string)*

          The stable and unique string identifying the user. For more 
          information about IDs, see IAM Identifiers in the Using IAM guide.

        - **Arn** *(string)*

          The Amazon Resource Name (ARN) that identifies the user. For more information about ARNs and how to use ARNs in 
          policies, see IAM Identifiers in the Using IAM guide.

        - **CreateDate** *(datetime)*

          The date and time that the user was created.
The date and time, in ISO 8601 date-time format, when the user was created.

- **PasswordLastUsed (datetime)** –
  The date and time, in ISO 8601 date-time format, when the user’s password was last used to sign in to an AWS website. For a list of AWS websites that capture a user’s last sign-in time, see the Credential Reports topic in the Using IAM guide. If a password is used more than once in a five-minute span, only the first use is returned in this field. This field is null (not present) when:
  - The user does not have a password
  - The password exists but has never been used (at least not since IAM started tracking this information on October 20th, 2014)
  - there is no sign-in data associated with the user

  This value is returned only in the GetUser and ListUsers actions.

- **EnableDate (datetime)** –
  The date and time on which the virtual MFA device was enabled.

- **IsTruncated (boolean)** –
  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **Marker (string)** –
  When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

**put_group_policy(****kwargs**)
Adds (or updates) an inline policy document that is embedded in the specified group.

A user can also have managed policies attached to it. To attach a managed policy to a group, use AttachGroupPolicy. To create a new managed policy, use CreatePolicy. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

For information about limits on the number of inline policies that you can embed in a group, see Limitations on IAM Entities in the IAM User Guide.

**Note:** Because policy documents can be large, you should use POST rather than GET when calling PutGroupPolicy. For general information about using the Query API with IAM, go to Making Query Requests in the Using IAM guide.

**Request Syntax**

```python
response = client.put_group_policy(
    GroupName='string',
    PolicyName='string',
    PolicyDocument='string'
)
```

**Parameters**

---

3.1. Services 2817
• **GroupName** *(string)* – [REQUIRED]
  The name of the group to associate the policy with.
• **PolicyName** *(string)* – [REQUIRED]
  The name of the policy document.
• **PolicyDocument** *(string)* – [REQUIRED]
  The policy document.

**Returns** None

### put_role_policy(**kwargs**)
Adds (or updates) an inline policy document that is embedded in the specified role.

When you embed an inline policy in a role, the inline policy is used as the role’s access (permissions) policy. The role’s trust policy is created at the same time as the role, using CreateRole. You can update a role’s trust policy using UpdateAssumeRolePolicy. For more information about roles, go to Using Roles to Delegate Permissions and Federate Identities.

A role can also have a managed policy attached to it. To attach a managed policy to a role, use AttachRolePolicy. To create a new managed policy, use CreatePolicy. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

For information about limits on the number of inline policies that you can embed with a role, see Limitations on IAM Entities in the IAM User Guide.

**Note:** Because policy documents can be large, you should use POST rather than GET when calling PutRolePolicy. For general information about using the Query API with IAM, go to Making Query Requests in the Using IAM guide.

**Request Syntax**

```python
response = client.put_role_policy(
    RoleName='string',
    PolicyName='string',
    PolicyDocument='string'
)
```

**Parameters**

- **RoleName** *(string)* – [REQUIRED]
  The name of the role to associate the policy with.
- **PolicyName** *(string)* – [REQUIRED]
  The name of the policy document.
- **PolicyDocument** *(string)* – [REQUIRED]
  The policy document.

**Returns** None

### put_user_policy(**kwargs**)
Adds (or updates) an inline policy document that is embedded in the specified user.

A user can also have a managed policy attached to it. To attach a managed policy to a user, use AttachUserPolicy. To create a new managed policy, use CreatePolicy. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

For information about limits on the number of inline policies that you can embed in a user, see Limitations on IAM Entities in the IAM User Guide.

**Note:** Because policy documents can be large, you should use POST rather than GET when calling
PutUserPolicy. For general information about using the Query API with IAM, go to Making Query Requests in the Using IAM guide.

Request Syntax

```python
response = client.put_user_policy(
    UserName='string',
    PolicyName='string',
    PolicyDocument='string'
)
```

Parameters

- **UserName (string)** – [REQUIRED]
  The name of the user to associate the policy with.
- **PolicyName (string)** – [REQUIRED]
  The name of the policy document.
- **PolicyDocument (string)** – [REQUIRED]
  The policy document.

Returns None

`remove_client_id_from_open_id_connect_provider(**kwargs)`

Removes the specified client ID (also known as audience) from the list of client IDs registered for the specified IAM OpenID Connect provider.

This action is idempotent; it does not fail or return an error if you try to remove a client ID that was removed previously.

Request Syntax

```python
response = client.remove_client_id_from_open_id_connect_provider(
    OpenIDConnectProviderArn='string',
    ClientID='string'
)
```

Parameters

- **OpenIDConnectProviderArn (string)** – [REQUIRED]
  The Amazon Resource Name (ARN) of the IAM OpenID Connect (OIDC) provider to remove the client ID from. You can get a list of OIDC provider ARNs by using the ListOpenIDConnectProviders action.
- **ClientID (string)** – [REQUIRED]
  The client ID (also known as audience) to remove from the IAM OpenID Connect provider. For more information about client IDs, see CreateOpenIDConnectProvider.

Returns None

`remove_role_from_instance_profile(**kwargs)`

Removes the specified role from the specified instance profile.

**Warning:** Make sure you do not have any Amazon EC2 instances running with the role you are about to remove from the instance profile. Removing a role from an instance profile that is associated with a running instance will break any applications running on the instance.

For more information about roles, go to Working with Roles. For more information about instance profiles, go to About Instance Profiles.
Request Syntax

```python
response = client.remove_role_from_instance_profile(
    InstanceProfileName='string',
    RoleName='string'
)
```

**Parameters**

- **InstanceProfileName** *(string)* – [REQUIRED]
  The name of the instance profile to update.

- **RoleName** *(string)* – [REQUIRED]
  The name of the role to remove.

**Returns** None

```python
remove_user_from_group(**kwargs)
```

Removes the specified user from the specified group.

Request Syntax

```python
response = client.remove_user_from_group(
    GroupName='string',
    UserName='string'
)
```

**Parameters**

- **GroupName** *(string)* – [REQUIRED]
  The name of the group to update.

- **UserName** *(string)* – [REQUIRED]
  The name of the user to remove.

**Returns** None

```python
resync_mfa_device(**kwargs)
```

Synchronizes the specified MFA device with AWS servers.

For more information about creating and working with virtual MFA devices, go to Using a Virtual MFA Device in the Using IAM guide.

Request Syntax

```python
response = client.resync_mfa_device(
    UserName='string',
    SerialNumber='string',
    AuthenticationCode1='string',
    AuthenticationCode2='string'
)
```

**Parameters**

- **UserName** *(string)* – [REQUIRED]
  The name of the user whose MFA device you want to resynchronize.

- **SerialNumber** *(string)* – [REQUIRED]
  Serial number that uniquely identifies the MFA device.

- **AuthenticationCode1** *(string)* – [REQUIRED]
  An authentication code emitted by the device.
• **AuthenticationCode2** *(string)* – [REQUIRED]

A subsequent authentication code emitted by the device.

**Returns** None

### set_default_policy_version(**kwargs)

Sets the specified version of the specified policy as the policy’s default (operative) version.

This action affects all users, groups, and roles that the policy is attached to. To list the users, groups, and roles that the policy is attached to, use the ListEntitiesForPolicy API.

For information about managed policies, refer to Managed Policies and Inline Policies in the *IAM User Guide*.

**Request Syntax**

```python
response = client.set_default_policy_version(
    PolicyArn='string',
    VersionId='string'
)
```

**Parameters**

- **PolicyArn** *(string)* – [REQUIRED]

  The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

  For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the *AWS General Reference*.

- **VersionId** *(string)* – [REQUIRED]

  The version of the policy to set as the default (operative) version.

  For more information about managed policy versions, see Versioning for Managed Policies in the *IAM User Guide*.

**Returns** None

### simulate_custom_policy(**kwargs)

Simulate a set of IAM policies against a list of API actions and AWS resources to determine the policies’ effective permissions. The policies are provided as a list of strings.

The simulation does not perform the API actions, it only checks the authorization to determine if the simulated policies allow or deny the actions.

If you want to simulate existing policies attached to an IAM user, group, or role, use SimulatePrincipalPolicy instead.

Context keys are variables maintained by AWS and its services that provide details about the context of an API query request, and can be evaluated by using the Condition element of an IAM policy. To get the list of context keys required by the policies to simulate them correctly, use GetContextKeysForCustomPolicy.

If the output is long, you can paginate the results using the MaxItems and Marker parameters.

**Request Syntax**

```python
response = client.simulate_custom_policy(
    PolicyInputList=[
        'string',
    ],
    ActionNames=[
        'string',
    ]
)
```
Parameters

- **PolicyInputList** *(list)* – [REQUIRED]
  
  A list of policy documents to include in the simulation. Each document is specified as a string containing the complete, valid JSON text of an IAM policy.

  - *(string)* –

- **ActionNames** *(list)* – [REQUIRED]
  
  A list of names of API actions to evaluate in the simulation. Each action is evaluated for each resource. Each action must include the service identifier, such as `iam:CreateUser`.

  - *(string)* –

- **ResourceArns** *(list)* – A list of ARNs of AWS resources to include in the simulation. If this parameter is not provided then the value defaults to `*` (all resources). Each API in the `ActionNames` parameter is evaluated for each resource in this list. The simulation determines the access result (allowed or denied) of each combination and reports it in the response.

  - *(string)* –

- **ContextEntries** *(list)* – A list of context keys and corresponding values that are used by the simulation. Whenever a context key is evaluated by a `Condition` element in one of the simulated IAM permission policies, the corresponding value is supplied.

  - *(dict)* –

  Contains information about a condition context key. It includes the name of the key and specifies the value (or values, if the context key supports multiple values) to use in the simulation. This information is used when evaluating the `Condition` elements of the input policies.

  This data type is used as an input parameter to `SimulatePolicy`.

  - **ContextKeyName** *(string)* –
    
    The full name of a condition context key, including the service prefix. For example, `aws:SourceIp` or `s3:VersionId`.

  - **ContextKeyValues** *(list)* –
    
    The value (or values, if the condition context key supports multiple values) to provide to the simulation for use when the key is referenced by a `Condition` element in an input policy.

    - *(string)* –

  - **ContextKeyType** *(string)* –
The data type of the value (or values) specified in the ContextKeyValues parameter.

- **MaxItems (integer)** – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.

  This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

- **Marker (string)** – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

**Return type**  
**dict**

**Returns**

**Response Syntax**

```json
{
'EvaluationResults': [
    {
      'EvalActionName': 'string',
      'EvalResourceName': 'string',
      'EvalDecision': 'allowed'|'explicitDeny'|'implicitDeny',
      'MatchedStatements': [
        {
          'SourcePolicyId': 'string',
          'SourcePolicyType': 'user'|'group'|'role'|'aws-managed'|'user-managed'|'none',
          'StartPosition': {
            'Line': 123,
            'Column': 123
          },
          'EndPosition': {
            'Line': 123,
            'Column': 123
          }
        },
      ],
      'MissingContextValues': [ 'string',
      ],
      'IsTruncated': True|False,
      'Marker': 'string'
    }
},
```

**Response Structure**

- (dict) –

  Contains the response to a successful SimulatePrincipalPolicy or SimulateCustomPolicy request.

  - **EvaluationResults (list)** –

    The results of the simulation.
* (dict) –

Contains the results of a simulation.

This data type is used by the return parameter of `SimulatePolicy`.

- **EvalActionName** (string) –
  The name of the API action tested on the indicated resource.

- **EvalResourceName** (string) –
  The ARN of the resource that the indicated API action was tested on.

- **EvalDecision** (string) –
  The result of the simulation.

- **MatchedStatements** (list) –
  A list of the statements in the input policies that determine the result for this scenario. Remember that even if multiple statements allow the action on the resource, if only one statement denies that action, then the explicit deny overrides any allow, and the deny statement is the only entry included in the result.

- (dict) –
  Contains a reference to a `Statement` element in a policy document that determines the result of the simulation.

This data type is used by the `MatchedStatements` member of the `EvaluationResult` type.

- **SourcePolicyId** (string) –
  The identifier of the policy that was provided as an input.

- **SourcePolicyType** (string) –
  The type of the policy.

- **StartPosition** (dict) –
  The row and column of the beginning of the `Statement` in an IAM policy.

- **Line** (integer) –
  The line containing the specified position in the document.

- **Column** (integer) –
  The column in the line containing the specified position in the document.

- **EndPosition** (dict) –
  The row and column of the end of a `Statement` in an IAM policy.

- **Line** (integer) –
  The line containing the specified position in the document.

- **Column** (integer) –
  The column in the line containing the specified position in the document.

- **MissingContextValues** (list) –
  A list of context keys that are required by the included input policies but that were not provided by one of the input param-
eters. To discover the context keys used by a set of policies, you can call GetContextKeysForCustomPolicy or GetContextKeysForPrincipalPolicy.

If the response includes any keys in this list, then the reported results might be untrustworthy because the simulation could not completely evaluate all of the conditions specified in the policies that would occur in a real world request.

- `IsTruncated (boolean) –`

A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- `Marker (string) –`

When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

**simulate_principal_policy(** **kwargs)**

Simulate the set of IAM policies attached to an IAM entity against a list of API actions and AWS resources to determine the policies’ effective permissions. The entity can be an IAM user, group, or role. If you specify a user, then the simulation also includes all of the policies attached to groups that the user is a member of.

You can optionally include a list of one or more additional policies specified as strings to include in the simulation. If you want to simulate only policies specified as strings, use SimulateCustomPolicy instead.

The simulation does not perform the API actions, it only checks the authorization to determine if the simulated policies allow or deny the actions.

**Note:** This API discloses information about the permissions granted to other users. If you do not want users to see other user’s permissions, then consider allowing them to use SimulateCustomPolicy instead.

Context keys are variables maintained by AWS and its services that provide details about the context of an API query request, and can be evaluated by using the Condition element of an IAM policy. To get the list of context keys required by the policies to simulate them correctly, use GetContextKeysForPrincipalPolicy.

If the output is long, you can paginate the results using the MaxItems and Marker parameters.

**Request Syntax**

```python
response = client.simulate_principal_policy(
    PolicySourceArn='string',
    PolicyInputList=[
        'string',
    ],
    ActionNames=[
        'string',
    ],
    ResourceArns=[
        'string',
    ],
    ContextEntries=[
        {'ContextKeyName': 'string',
    }
```

3.1. Services 2825
Parameters

- **PolicySourceArn (string)** – [REQUIRED]
  
The Amazon Resource Name (ARN) of a user, group, or role whose policies you want to include in the simulation. If you specify a user, group, or role, the simulation includes all policies associated with that entity. If you specify a user, the simulation also includes all policies attached to any groups the user is a member of.

- **PolicyInputList (list)** – An optional list of additional policy documents to include in the simulation. Each document is specified as a string containing the complete, valid JSON text of an IAM policy.

- **ActionNames (list)** – [REQUIRED]
  
  A list of names of API actions to evaluate in the simulation. Each action is evaluated for each resource. Each action must include the service identifier, such as `iam:CreateUser`.

- **ResourceArns (list)** – A list of ARNs of AWS resources to include in the simulation. If this parameter is not provided then the value defaults to `*` (all resources). Each API in the `ActionNames` parameter is evaluated for each resource in this list. The simulation determines the access result (allowed or denied) of each combination and reports it in the response.

- **ContextEntries (list)** – A list of context keys and corresponding values that are used by the simulation. Whenever a context key is evaluated by a `Condition` element in one of the simulated IAM permission policies, the corresponding value is supplied.

  Contains information about a condition context key. It includes the name of the key and specifies the value (or values, if the context key supports multiple values) to use in the simulation. This information is used when evaluating the `Condition` elements of the input policies.

  This data type is used as an input parameter to `SimulatePolicy`.

  - **ContextKeyName (string)** –
    
    The full name of a condition context key, including the service prefix. For example, `aws:SourceIp` or `s3:VersionId`.

  - **ContextKeyValues (list)** –
    
    The value (or values, if the context key supports multiple values) to provide to the simulation for use when the key is referenced by a `Condition` element in an input policy.

  - **ContextKeyType (string)** –
The data type of the value (or values) specified in the ContextKeyValues parameter.

- **MaxItems** (*integer*) – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.

  This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

- **Marker** (*string*) – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

**Return type** dict

**Returns**

**Response Syntax**

```
{
  'EvaluationResults': [
    {
      'EvalActionName': 'string',
      'EvalResourceName': 'string',
      'EvalDecision': 'allowed'|'explicitDeny'|'implicitDeny',
      'MatchedStatements': [
        {
          'SourcePolicyId': 'string',
          'SourcePolicyType': 'user'|'group'|'role'|'aws-managed'|'user-managed'|'none',
          'StartPosition': {
            'Line': 123,
            'Column': 123
          },
          'EndPosition': {
            'Line': 123,
            'Column': 123
          }
        },
        {
          'SourcePolicyId': 'string',
          'SourcePolicyType': 'user'|'group'|'role'|'aws-managed'|'user-managed'|'none',
          'StartPosition': {
            'Line': 123,
            'Column': 123
          },
          'EndPosition': {
            'Line': 123,
            'Column': 123
          }
        }
      ],
      'MissingContextValues': ['string'],
      'IsTruncated': True|False,
      'Marker': 'string'
    }
  ],
  'IsTruncated': True|False,
  'Marker': 'string'
}
```

**Response Structure**

- **(dict) –**

  Contains the response to a successful SimulatePrincipalPolicy or SimulateCustomPolicy request.

  - **EvaluationResults** (*list*) –

    The results of the simulation.
* (dict) –

Contains the results of a simulation.

This data type is used by the return parameter of `SimulatePolicy`.

- **EvalActionName (string)** –
  The name of the API action tested on the indicated resource.
- **EvalResourceName (string)** –
  The ARN of the resource that the indicated API action was tested on.
- **EvalDecision (string)** –
  The result of the simulation.
- **MatchedStatements (list)** –
  A list of the statements in the input policies that determine the result for this scenario. Remember that even if multiple statements allow the action on the resource, if only one statement denies that action, then the explicit deny overrides any allow, and the deny statement is the only entry included in the result.
- (dict) –
  Contains a reference to a `Statement` element in a policy document that determines the result of the simulation.

This data type is used by the `MatchedStatements` member of the `EvaluationResult` type.
- **SourcePolicyId (string)** –
  The identifier of the policy that was provided as an input.
- **SourcePolicyType (string)** –
  The type of the policy.
- **StartPosition (dict)** –
  The row and column of the beginning of the `Statement` in an IAM policy.
- **Line (integer)** –
  The line containing the specified position in the document.
- **Column (integer)** –
  The column in the line containing the specified position in the document.
- **EndPosition (dict)** –
  The row and column of the end of a `Statement` in an IAM policy.
- **Line (integer)** –
  The line containing the specified position in the document.
- **Column (integer)** –
  The column in the line containing the specified position in the document.
- **MissingContextValues (list)** –
  A list of context keys that are required by the included input policies but that were not provided by one of the input param-
eters. To discover the context keys used by a set of policies, you can call GetContextKeysForCustomPolicy or GetContextKeysForPrincipalPolicy.

If the response includes any keys in this list, then the reported results might be untrustworthy because the simulation could not completely evaluate all of the conditions specified in the policies that would occur in a real world request.

- **IsTruncated (boolean)**
  
  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **Marker (string)**
  
  When IsTruncated is true, this element is present and contains the value to use for the Marker parameter in a subsequent pagination request.

update_access_key(**kwargs)**

Changes the status of the specified access key from Active to Inactive, or vice versa. This action can be used to disable a user’s key as part of a key rotation work flow.

If the **UserName** field is not specified, the **UserName** is determined implicitly based on the AWS access key ID used to sign the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

For information about rotating keys, see Managing Keys and Certificates in the IAM User Guide.

Request Syntax

```python
response = client.update_access_key(
    UserName='string',
    AccessKeyId='string',
    Status='Active'|'Inactive'
)
```

**Parameters**

- **UserName (string)** – The name of the user whose key you want to update.
- **AccessKeyId (string)** – [REQUIRED]
  
  The access key ID of the secret access key you want to update.
- **Status (string)** – [REQUIRED]
  
  The status you want to assign to the secret access key. Active means the key can be used for API calls to AWS, while Inactive means the key cannot be used.

**Returns** None

update_account_password_policy(**kwargs)**

Updates the password policy settings for the AWS account.

**Note:** This action does not support partial updates. No parameters are required, but if you do not specify a parameter, that parameter’s value reverts to its default value. See the **Request Parameters** section for each parameter’s default value.
For more information about using a password policy, see Managing an IAM Password Policy in the IAM User Guide.

Request Syntax

```python
response = client.update_account_password_policy(
    MinimumPasswordLength=123,
    RequireSymbols=True|False,
    RequireNumbers=True|False,
    RequireUppercaseCharacters=True|False,
    RequireLowercaseCharacters=True|False,
    AllowUsersToChangePassword=True|False,
    MaxPasswordAge=123,
    PasswordReusePrevention=123,
    HardExpire=True|False
)
```

Parameters

- **MinimumPasswordLength** (*integer*) – The minimum number of characters allowed in an IAM user password.
  
  Default value: 6

- **RequireSymbols** (*boolean*) – Specifies whether IAM user passwords must contain at least one of the following non-alphanumeric characters:
  
  ```
  ! @ # $ % ^ amp; * ( ) _ + - = [ ] { } | '
  ```
  
  Default value: false

- **RequireNumbers** (*boolean*) – Specifies whether IAM user passwords must contain at least one numeric character (0 to 9).
  
  Default value: false

- **RequireUppercaseCharacters** (*boolean*) – Specifies whether IAM user passwords must contain at least one uppercase character from the ISO basic Latin alphabet (A to Z).
  
  Default value: false

- **RequireLowercaseCharacters** (*boolean*) – Specifies whether IAM user passwords must contain at least one lowercase character from the ISO basic Latin alphabet (a to z).
  
  Default value: false

- **AllowUsersToChangePassword** (*boolean*) – Allows all IAM users in your account to use the AWS Management Console to change their own passwords. For more information, see Letting IAM Users Change Their Own Passwords in the IAM User Guide.
  
  Default value: false

- **MaxPasswordAge** (*integer*) – The number of days that an IAM user password is valid. The default value of 0 means IAM user passwords never expire.
  
  Default value: 0

- **PasswordReusePrevention** (*integer*) – Specifies the number of previous passwords that IAM users are prevented from reusing. The default value of 0 means IAM users are not prevented from reusing previous passwords.
  
  Default value: 0

- **HardExpire** (*boolean*) – Prevents IAM users from setting a new password after their password has expired.
Default value: false

Returns None

**update_assume_role_policy(**kwargs**)

Updates the policy that grants an entity permission to assume a role. For more information about roles, go to Using Roles to Delegate Permissions and Federate Identities.

**Request Syntax**

```python
response = client.update_assume_role_policy(
    RoleName='string',
    PolicyDocument='string'
)
```

**Parameters**

- **RoleName** *(string)* – [REQUIRED]
  The name of the role to update.
- **PolicyDocument** *(string)* – [REQUIRED]
  The policy that grants an entity permission to assume the role.

Returns None

**update_group(**kwargs**)

Updates the name and/or the path of the specified group.

**Warning:** You should understand the implications of changing a group’s path or name. For more information, see Renaming Users and Groups in the IAM User Guide.

**Note:** To change a group name the requester must have appropriate permissions on both the source object and the target object. For example, to change Managers to MGRs, the entity making the request must have permission on Managers and MGRs, or must have permission on all (*). For more information about permissions, see Permissions and Policies.

**Request Syntax**

```python
response = client.update_group(
    GroupName='string',
    NewPath='string',
    NewGroupName='string'
)
```

**Parameters**

- **GroupName** *(string)* – [REQUIRED]
  Name of the group to update. If you’re changing the name of the group, this is the original name.
- **NewPath** *(string)* – New path for the group. Only include this if changing the group’s path.
- **NewGroupName** *(string)* – New name for the group. Only include this if changing the group’s name.

Returns None

**update_login_profile(**kwargs**)

Changes the password for the specified user.

Users can change their own passwords by calling ChangePassword. For more information about modifying passwords, see Managing Passwords in the IAM User Guide.
Request Syntax

```python
response = client.update_login_profile(
    UserName='string',
    Password='string',
    PasswordResetRequired=True|False
)
```

Parameters

- **UserName** *(string) – [REQUIRED]*
  The name of the user whose password you want to update.
- **Password** *(string)* – The new password for the specified user.
- **PasswordResetRequired** *(boolean)* – Require the specified user to set a new password on next sign-in.

Returns

None

**update_open_id_connect_provider_thumbprint(**kwargs**)**

Replaces the existing list of server certificate thumbprints with a new list.

The list that you pass with this action completely replaces the existing list of thumbprints. (The lists are not merged.)

Typically, you need to update a thumbprint only when the identity provider’s certificate changes, which occurs rarely. However, if the provider’s certificate does change, any attempt to assume an IAM role that specifies the OIDC provider as a principal will fail until the certificate thumbprint is updated.

**Note:** Because trust for the OpenID Connect provider is ultimately derived from the provider’s certificate and is validated by the thumbprint, it is a best practice to limit access to the `UpdateOpenIDConnectProviderThumbprint` action to highly-privileged users.

Request Syntax

```python
response = client.update_open_id_connect_provider_thumbprint(
    OpenIDConnectProviderArn='string',
    ThumbprintList=[
        'string',
    ]
)
```

Parameters

- **OpenIDConnectProviderArn** *(string) – [REQUIRED]*
  The Amazon Resource Name (ARN) of the IAM OpenID Connect (OIDC) provider to update the thumbprint for. You can get a list of OIDC provider ARNs by using the `ListOpenIDConnectProviders` action.
- **ThumbprintList** *(list) – [REQUIRED]*
  A list of certificate thumbprints that are associated with the specified IAM OpenID Connect provider. For more information, see `CreateOpenIDConnectProvider`.

  - *(string)* –
    Contains a thumbprint for an identity provider’s server certificate.

    The identity provider’s server certificate thumbprint is the hex-encoded SHA-1 hash value of the self-signed X.509 certificate used by the domain where the OpenID Connect provider makes its keys available. It is always a 40-character string.
Returns None

**update_saml_provider**(**kwargs**)
Updates the metadata document for an existing SAML provider.

**Note:** This operation requires Signature Version 4.

Request Syntax

```python
response = client.update_saml_provider(
    SAMLMetadataDocument='string',
    SAMLProviderArn='string'
)
```

Parameters

- **SAMLMetadataDocument** *(string)* – [REQUIRED]
  
  An XML document generated by an identity provider (IdP) that supports SAML 2.0. The document includes the issuer’s name, expiration information, and keys that can be used to validate the SAML authentication response (assertions) that are received from the IdP. You must generate the metadata document using the identity management software that is used as your organization’s IdP.

- **SAMLProviderArn** *(string)* – [REQUIRED]
  
  The Amazon Resource Name (ARN) of the SAML provider to update.

Return type: dict

Returns None

**Response Syntax**

```python
{
    'SAMLProviderArn': 'string'
}
```

**Response Structure**

- *(dict)* –
  
  Contains the response to a successful UpdateSAMLProvider request.

  - **SAMLProviderArn** *(string)* –
    
    The Amazon Resource Name (ARN) of the SAML provider that was updated.

**update_server_certificate**(**kwargs**)

Updates the name and/or the path of the specified server certificate.

**Warning:** You should understand the implications of changing a server certificate’s path or name. For more information, see Managing Server Certificates in the IAM User Guide.

**Note:** To change a server certificate name the requester must have appropriate permissions on both the source object and the target object. For example, to change the name from ProductionCert to ProdCert, the entity making the request must have permission on ProductionCert and ProdCert, or must have permission on all (*). For more information about permissions, see Permissions and Policies.

Request Syntax
```python
response = client.update_server_certificate(
    ServerCertificateName='string',
    NewPath='string',
    NewServerCertificateName='string'
)

Parameters

- **ServerCertificateName** (string) – [REQUIRED]
  The name of the server certificate that you want to update.
- **NewPath** (string) – The new path for the server certificate. Include this only if you are updating the server certificate's path.
- **NewServerCertificateName** (string) – The new name for the server certificate. Include this only if you are updating the server certificate's name. The name of the certificate cannot contain any spaces.

Returns None
```

```python
update_signing_certificate(**kwargs)
Changes the status of the specified signing certificate from active to disabled, or vice versa. This action can be used to disable a user's signing certificate as part of a certificate rotation work flow.

If the **UserName** field is not specified, the UserName is determined implicitly based on the AWS access key ID used to sign the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

Request Syntax

```python
response = client.update_signing_certificate(
    UserName='string',
    CertificateId='string',
    Status='Active'|'Inactive'
)

Parameters

- **UserName** (string) – The name of the user the signing certificate belongs to.
- **CertificateId** (string) – [REQUIRED]
  The ID of the signing certificate you want to update.
- **Status** (string) – [REQUIRED]
  The status you want to assign to the certificate. **Active** means the certificate can be used for API calls to AWS, while **Inactive** means the certificate cannot be used.

Returns None
```

```python
update_ssh_public_key(**kwargs)
Sets the status of the specified SSH public key to active or inactive. SSH public keys that are inactive cannot be used for authentication. This action can be used to disable a user's SSH public key as part of a key rotation work flow.

The SSH public key affected by this action is used only for authenticating the associated IAM user to an AWS CodeCommit repository. For more information about using SSH keys to authenticate to an AWS CodeCommit repository, see Set up AWS CodeCommit for SSH Connections in the AWS CodeCommit User Guide.

Request Syntax
```
response = client.update_ssh_public_key(
    UserName='string',
    SSHPublicKeyId='string',
    Status='Active'|'Inactive'
)

**Parameters**

- **UserName** *(string)* – [REQUIRED]
  
  The name of the IAM user associated with the SSH public key.

- **SSHPublicKeyId** *(string)* – [REQUIRED]
  
  The unique identifier for the SSH public key.

- **Status** *(string)* – [REQUIRED]
  
  The status to assign to the SSH public key. `Active` means the key can be used for authentication with an AWS CodeCommit repository. `Inactive` means the key cannot be used.

**Returns** None

#### update_user(**kwargs**)

Updates the name and/or the path of the specified user.

**Warning:** You should understand the implications of changing a user’s path or name. For more information, see Renaming Users and Groups in the IAM User Guide.

**Note:** To change a user name the requester must have appropriate permissions on both the source object and the target object. For example, to change Bob to Robert, the entity making the request must have permission on Bob and Robert, or must have permission on all (*). For more information about permissions, see Permissions and Policies.

**Request Syntax**

response = client.update_user(
    UserName='string',
    NewPath='string',
    NewUserName='string'
)

**Parameters**

- **UserName** *(string)* – [REQUIRED]
  
  Name of the user to update. If you’re changing the name of the user, this is the original user name.

- **NewPath** *(string)* – New path for the user. Include this parameter only if you’re changing the user’s path.

- **NewUserName** *(string)* – New name for the user. Include this parameter only if you’re changing the user’s name.

**Returns** None

#### upload_server_certificate(**kwargs**)

Uploads a server certificate entity for the AWS account. The server certificate entity includes a public key certificate, a private key, and an optional certificate chain, which should all be PEM-encoded.

For information about the number of server certificates you can upload, see Limitations on IAM Entities in the IAM User Guide.
**Note:** Because the body of the public key certificate, private key, and the certificate chain can be large, you should use POST rather than GET when calling `UploadServerCertificate`. For information about setting up signatures and authorization through the API, go to Signing AWS API Requests in the AWS General Reference. For general information about using the Query API with IAM, go to Making Query Requests in the IAM User Guide.

### Request Syntax

```python
response = client.upload_server_certificate(
    Path='string',
    ServerCertificateName='string',
    CertificateBody='string',
    PrivateKey='string',
    CertificateChain='string'
)
```

**Parameters**

- **Path** *(string)* – The path for the server certificate. For more information about paths, see IAM Identifiers in the Using IAM guide.
  
  This parameter is optional. If it is not included, it defaults to a slash (/).

  **Note:** If you are uploading a server certificate specifically for use with Amazon CloudFront distributions, you must specify a path using the `--path` option. The path must begin with `/cloudfront` and must include a trailing slash (for example, `/cloudfront/test/`).

- **ServerCertificateName** *(string)* – [REQUIRED]
  
  The name for the server certificate. Do not include the path in this value. The name of the certificate cannot contain any spaces.

- **CertificateBody** *(string)* – [REQUIRED]
  
  The contents of the public key certificate in PEM-encoded format.

- **PrivateKey** *(string)* – [REQUIRED]
  
  The contents of the private key in PEM-encoded format.

- **CertificateChain** *(string)* – The contents of the certificate chain. This is typically a concatenation of the PEM-encoded public key certificates of the chain.

### Return type

`dict`

### Returns

**Response Syntax**

```python
{
    'ServerCertificateMetadata': {
        'Path': 'string',
        'ServerCertificateName': 'string',
        'ServerCertificateId': 'string',
        'Arn': 'string',
        'UploadDate': datetime(2015, 1, 1),
        'Expiration': datetime(2015, 1, 1)
    }
}
```

**Response Structure**

- *(dict)* –
  
  Contains the response to a successful UploadServerCertificate request.
- **ServerCertificateMetadata (dict)** –
  
The meta information of the uploaded server certificate without its certificate body, certificate chain, and private key.
  
  * **Path (string)** –
    
The path to the server certificate. For more information about paths, see IAM Identifiers in the *Using IAM* guide.
  
  * **ServerCertificateName (string)** –
    
The name that identifies the server certificate.
  
  * **ServerCertificateId (string)** –
    
The stable and unique string identifying the server certificate. For more information about IDs, see IAM Identifiers in the *Using IAM* guide.
  
  * **Arn (string)** –
    
The Amazon Resource Name (ARN) specifying the server certificate. For more information about ARNs and how to use them in policies, see IAM Identifiers in the *Using IAM* guide.
  
  * **UploadDate (datetime)** –
    
The date when the server certificate was uploaded.
  
  * **Expiration (datetime)** –
    
The date on which the certificate is set to expire.

**upload_signing_certificate(**kwargs**)**

Uploads an X.509 signing certificate and associates it with the specified user. Some AWS services use X.509 signing certificates to validate requests that are signed with a corresponding private key. When you upload the certificate, its default status is Active.

If the **UserName** field is not specified, the user name is determined implicitly based on the AWS access key ID used to sign the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

**Note:** Because the body of a X.509 certificate can be large, you should use POST rather than GET when calling **UploadSigningCertificate**. For information about setting up signatures and authorization through the API, go to Signing AWS API Requests in the *AWS General Reference*. For general information about using the Query API with IAM, go to Making Query Requests in the *Using IAM* guide.

**Request Syntax**

```python
response = client.upload_signing_certificate(
    UserName='string',
    CertificateBody='string'
)
```

**Parameters**

- **UserName (string)** – The name of the user the signing certificate is for.

- **CertificateBody (string)** – [REQUIRED]

  The contents of the signing certificate.

**Return type**

dict

**Returns**

dict

**Response Syntax**

---

3.1. Services 2837
{  
  'Certificate': {  
    'UserName': 'string',  
    'CertificateId': 'string',  
    'CertificateBody': 'string',  
    'Status': 'Active'|'Inactive',  
    'UploadDate': datetime(2015, 1, 1)  
  }  
}

**Response Structure**

- *(dict)* –  
  Contains the response to a successful UploadSigningCertificate request.
  - **Certificate** *(dict)* –  
    Information about the certificate.
    - **UserName** *(string)* –  
      The name of the user the signing certificate is associated with.
    - **CertificateId** *(string)* –  
      The ID for the signing certificate.
    - **CertificateBody** *(string)* –  
      The contents of the signing certificate.
    - **Status** *(string)* –  
      The status of the signing certificate. *Active* means the key is valid for API calls, while *Inactive* means it is not.
    - **UploadDate** *(datetime)* –  
      The date when the signing certificate was uploaded.

**upload_ssh_public_key(**kwargs**)**

Uploads an SSH public key and associates it with the specified IAM user.

The SSH public key uploaded by this action can be used only for authenticating the associated IAM user to an AWS CodeCommit repository. For more information about using SSH keys to authenticate to an AWS CodeCommit repository, see Set up AWS CodeCommit for SSH Connections in the [AWS CodeCommit User Guide](https://docs.aws.amazon.com/codecommit/latest/userguide/codecommit-sshtools.html).

**Request Syntax**

```
response = client.upload_ssh_public_key(  
    UserName='string',  
    SSHPublicKeyBody='string'  
)
```

**Parameters**

- **UserName** *(string)* – `[REQUIRED]`
  The name of the IAM user to associate the SSH public key with.
- **SSHPublicKeyBody** *(string)* – `[REQUIRED]`
  The SSH public key. The public key must be encoded in ssh-rsa format or PEM format.

**Return type** *dict*

**Returns**

**Response Syntax**
Response Structure

- *(dict)* –
  Contains the response to a successful UploadSSHPublicKey request.

  - **SSHPublicKey**(dict)** –
    Contains information about the SSH public key.
    - **UserName**(string)** –
      The name of the IAM user associated with the SSH public key.
    - **SSHPublicKeyId**(string)** –
      The unique identifier for the SSH public key.
    - **Fingerprint**(string)** –
      The MD5 message digest of the SSH public key.
    - **SSHPublicKeyBody**(string)** –
      The SSH public key.
    - **Status**(string)** –
      The status of the SSH public key. **Active** means the key can be used for authentication with an AWS CodeCommit repository. **Inactive** means the key cannot be used.
    - **UploadDate**(datetime)** –
      The date and time, in ISO 8601 date-time format, when the SSH public key was uploaded.

**Paginators**

The available paginators are:

- **IAM.Paginator.GetGroup**
- **IAM.Paginator.ListAccessKeys**
- **IAM.Paginator.ListAccountAliases**
- **IAM.Paginator.ListGroupPolicies**
- **IAM.Paginator.ListGroups**
- **IAM.Paginator.ListGroupsForUser**
- **IAM.Paginator.ListInstanceProfiles**
- **IAM.Paginator.ListInstanceProfilesForRole**
- **IAM.Paginator.ListMFADevices**
class IAM.Paginator.GetGroup

paginator = client.get_paginator('get_group')

paginate(**kwargs)

Creates an iterator that will paginate through responses from IAM.Client.get_group().

Request Syntax

response_iterator = paginator.paginate(
    GroupName='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **GroupName (string)** – [REQUIRED]
  The name of the group.
- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize (integer)** –
    The size of each page.
  - **StartingToken (string)** –
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type dict

Returns

Response Syntax

```xml
{
    'Group': {
        'Path': 'string',
        'GroupName': 'string',
```
'GroupId': 'string',
'Arn': 'string',
'CreateDate': datetime(2015, 1, 1)
]
'Users': [
{
'Path': 'string',
'UserName': 'string',
'UserId': 'string',
'Arn': 'string',
'CreateDate': datetime(2015, 1, 1),
'PasswordLastUsed': datetime(2015, 1, 1)
},

'

'IsTruncated': True|False,
'NextToken': 'string'
}

Response Structure

- (dict) –
  Contains the response to a successful GetGroup request.
  - Group (dict) –
    Information about the group.
    * Path (string) –
      The path to the group. For more information about paths, see IAM Identifiers in the Using IAM guide.
    * GroupName (string) –
      The friendly name that identifies the group.
    * GroupId (string) –
      The stable and unique string identifying the group. For more information about IDs, see IAM Identifiers in the Using IAM guide.
    * Arn (string) –
      The Amazon Resource Name (ARN) specifying the group. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.
    * CreateDate (datetime) –
      The date and time, in ISO 8601 date-time format, when the group was created.
  - Users (list) –
    A list of users in the group.
    * (dict) –
      Contains information about an IAM user entity.
      This data type is used as a response element in the following actions:
      - CreateUser
      - GetUser
      - ListUsers
      - Path (string) –
        The path to the user. For more information about paths, see IAM Identifiers in the Using IAM guide.
- **UserName** *(string)* –
  The friendly name identifying the user.
- **UserId** *(string)* –
  The stable and unique string identifying the user. For more information about IDs, see IAM Identifiers in the Using IAM guide.
- **Arn** *(string)* –
  The Amazon Resource Name (ARN) that identifies the user. For more information about ARNs and how to use ARNs in policies, see IAM Identifiers in the Using IAM guide.
- **CreateDate** *(datetime)* –
  The date and time, in ISO 8601 date-time format, when the user was created.
- **PasswordLastUsed** *(datetime)* –
  The date and time, in ISO 8601 date-time format, when the user’s password was last used to sign in to an AWS website. For a list of AWS websites that capture a user’s last sign-in time, see the Credential Reports topic in the Using IAM guide. If a password is used more than once in a five-minute span, only the first use is returned in this field. This field is null (not present) when:
  - The user does not have a password
  - The password exists but has never been used (at least not since IAM started tracking this information on October 20th, 2014
  - there is no sign-in data associated with the user
  This value is returned only in the GetUser and ListUsers actions.
- **IsTruncated** *(boolean)* –
  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.
- **NextToken** *(string)* –
  A token to resume pagination.

```python
class IAM.Paginator.ListAccessKeys

paginator = client.get_paginator('list_access_keys')

paginate(**kwargs)

Creates an iterator that will paginate through responses from IAM.Client.list_access_keys().

Request Syntax

response_iterator = paginator.paginate(
    UserName='string',
    PaginationConfig={
        'MaxItems': 123,
```
Parameters

- **UserName** *(string)* – The name of the user.
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* – The total number of items to return. If the total number of items available is more than the value specified in max-items then a **NextToken** will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* – The size of each page.
  - **StartingToken** *(string)* – A token to specify where to start paginating. This is the **NextToken** from a previous response.

Return type  dict

Returns

Response Syntax

```
{
    'AccessKeyMetadata': [
        {
            'UserName': 'string',
            'AccessKeyId': 'string',
            'Status': 'Active'|'Inactive',
            'CreateDate': datetime(2015, 1, 1)
        },
    ],
    'IsTruncated': True|False,
    'NextToken': 'string'
}
```

Response Structure

- *(dict)* – Contains the response to a successful ListAccessKeys request.
  - **AccessKeyMetadata** *(list)* – A list of access key metadata.
    - *(dict)* – Contains information about an AWS access key, without its secret key.
      This data type is used as a response element in the ListAccessKeys action.
        - **UserName** *(string)* – The name of the IAM user that the key is associated with.
        - **AccessKeyId** *(string)* – The ID for this access key.
- **Status** *(string)* –
  The status of the access key. *Active* means the key is valid for API calls; *Inactive* means it is not.
- **CreateDate** *(datetime)* –
  The date when the access key was created.
- **IsTruncated** *(boolean)* –
  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.
- **NextToken** *(string)* –
  A token to resume pagination.

```python
class IAM.Paginator.ListAccountAliases

    paginator = client.get_paginator('list_account_aliases')

    paginate(**kwargs)
    # Creates an iterator that will paginate through responses from IAM.Client.list_account_aliases().

    Parameters
    ----------
    PaginationConfig *(dict)* – A dictionary that provides parameters to control pagination.

    **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

    **PageSize** *(integer)* –
    The size of each page.

    **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the NextToken from a previous response.

    Returns
    -------
    dict

    Response Syntax

    {
        'AccountAliases': [
```
Response Structure

* (dict) –

Contains the response to a successful ListAccountAliases request.

- AccountAliases (list) –

  A list of aliases associated with the account.
  *
  - IsTruncated (boolean) –

    A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- NextToken (string) –

  A token to resume pagination.

```
class IAM.Paginator.ListGroupPolicies

paginator = client.get_paginator('list_group_policies')

paginate(**kwargs)

Creates an iterator that will paginate through responses from IAM.Client.list_group_policies().

Request Syntax

response_iterator = paginator.paginate(
    GroupName='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

* GroupName (string) – [REQUIRED]

  The name of the group to list policies for.

* PaginationConfig (dict) – A dictionary that provides parameters to control pagination.

  - MaxItems (integer) –

    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
- **PageSize** *(integer)* –
  The size of each page.
- **StartingToken** *(string)* –
  A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** dict

**Returns**

**Response Syntax**

```
{
    'PolicyNames': [  
        'string',  
    ],
    'IsTruncated': True|False,
    'NextToken': 'string'
}
```

**Response Structure**

- *(dict)*

  Contains the response to a successful ListGroupPolicies request.

  - **PolicyNames** *(list)* –
    A list of policy names.
    - *(string)* –
  - **IsTruncated** *(boolean)* –
    A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check `IsTruncated` after every call to ensure that you receive all of your results.

  - **NextToken** *(string)* –
    A token to resume pagination.

**class IAM.Paginator.ListGroups**

```
paginator = client.get_paginator('list_groups')
```

**paginate(** *kwargs*

Creates an iterator that will paginate through responses from `IAM.Client.list_groups()`.

**Request Syntax**

```
response_iterator = paginator.paginate(
    PathPrefix='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**
• **PathPrefix** *(string)* – The path prefix for filtering the results. For example, the prefix `/division_abc/subdivision_xyz/` gets all groups whose path starts with `/division_abc/subdivision_xyz/`.

This parameter is optional. If it is not included, it defaults to a slash (/), listing all groups.

• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  – **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  
  – **PageSize** *(integer)* –
    
    The size of each page.
  
  – **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Groups': [
        {
            'Path': 'string',
            'GroupName': 'string',
            'GroupId': 'string',
            'Arn': 'string',
            'CreateDate': datetime(2015, 1, 1)
        },
    ],
    'IsTruncated': True|False,
    'NextToken': 'string'
}
```

**Response Structure**

• *(dict)* –
  
  Contains the response to a successful ListGroups request.

  – **Groups** *(list)* –
    
    A list of groups.

    * *(dict)* –
      
      Contains information about an IAM group entity.

      This data type is used as a response element in the following actions:

      - CreateGroup
      - GetGroup
      - ListGroups

    – **Path** *(string)* –
      
      The path to the group. For more information about paths, see IAM Identifiers in the *Using IAM* guide.
- **GroupName** *(string)* –  
The friendly name that identifies the group.

- **GroupId** *(string)* –  
The stable and unique string identifying the group. For more information about IDs, see IAM Identifiers in the Using IAM guide.

- **Arn** *(string)* –  
The Amazon Resource Name (ARN) specifying the group. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.

- **CreateDate** *(datetime)* –  
The date and time, in ISO 8601 date-time format, when the group was created.

- **IsTruncated** *(boolean)* –  
A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **NextToken** *(string)* –  
A token to resume pagination.

class IAM.Paginator.ListGroupsForUser

    paginator = client.get_paginator('list_groups_for_user')

    pagin()(**kwargs)  
    Creates an iterator that will paginate through responses from IAM.Client.list_groups_for_user().

    Request Syntax

    response_iterator = paginator.paginate(  
        UserName='string',  
        PaginationConfig={  
            'MaxItems': 123,  
            'PageSize': 123,  
            'StartingToken': 'string'  
        }
    )

    Parameters

    - **UserName** *(string)* – [REQUIRED]  
The name of the user to list groups for.

    - **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

        - **MaxItems** *(integer)* –  
The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
- **PageSize** *(integer)*
  The size of each page.

- **StartingToken** *(string)*
  A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
  'Groups': [
    {
      'Path': 'string',
      'GroupName': 'string',
      'GroupId': 'string',
      'Arn': 'string',
      'CreateDate': datetime(2015, 1, 1)
    },
  ],
  'IsTruncated': True|False,
  'NextToken': 'string'
}
```

**Response Structure**

- *(dict)*
  Contains the response to a successful ListGroupsForUser request.

  - **Groups** *(list)*
    A list of groups.

    - *(dict)*
      Contains information about an IAM group entity.

      This data type is used as a response element in the following actions:

      - CreateGroup
      - GetGroup
      - ListGroups

      - **Path** *(string)*
        The path to the group. For more information about paths, see IAM Identifiers in the *Using IAM* guide.

      - **GroupName** *(string)*
        The friendly name that identifies the group.

      - **GroupId** *(string)*
        The stable and unique string identifying the group. For more information about IDs, see IAM Identifiers in the *Using IAM* guide.

      - **Arn** *(string)*
        The Amazon Resource Name (ARN) specifying the group. For more information about ARNs and how to use them in policies, see IAM Identifiers in the *Using IAM* guide.

      - **CreateDate** *(datetime)*

The date and time, in ISO 8601 date-time format, when the group was created.

- **IsTruncated (boolean)** –
  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **NextToken (string)** –
  A token to resume pagination.

class IAMaginator.ListInstanceProfiles

paginator = client.get_paginator('list_instance_profiles')

paginate(**kwargs)

Creates an iterator that will paginate through responses from IAM.Client.list_instance_profiles().

Request Syntax

response_iterator = paginator.paginate(
    PathPrefix='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **PathPrefix (string)** – The path prefix for filtering the results. For example, the prefix /application_abc/component_xyz/ gets all instance profiles whose path starts with /application_abc/component_xyz/.
  This parameter is optional. If it is not included, it defaults to a slash (/), listing all instance profiles.
- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  
  - **MaxItems (integer)** –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  
  - **PageSize (integer)** –
    The size of each page.
  
  - **StartingToken (string)** –
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type dict

Returns

Response Syntax
Response Structure

- (dict) –
  Contains the response to a successful ListInstanceProfiles request.
  - InstanceProfiles (list) –
    A list of instance profiles.
    * (dict) –
      Contains information about an instance profile.
      This data type is used as a response element in the following actions:
      - CreateInstanceProfile
      - GetInstanceProfile
      - ListInstanceProfiles
      - ListInstanceProfilesForRole
      - Path (string) –
        The path to the instance profile. For more information about paths, see IAM Identifiers in the Using IAM guide.
      - InstanceProfileName (string) –
        The name identifying the instance profile.
      - InstanceProfileId (string) –
        The stable and unique string identifying the instance profile. For more information about IDs, see IAM Identifiers in the Using IAM guide.
      - Arn (string) –
        The Amazon Resource Name (ARN) specifying the instance profile. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.
      - CreateDate (datetime) –
The date when the instance profile was created.

- Roles (list) –
  The role associated with the instance profile.
  - (dict) –
    Contains information about an IAM role.
    This data type is used as a response element in the following actions:
    - CreateRole
    - GetRole
    - ListRoles
    - Path (string) –
      The path to the role. For more information about paths, see IAM Identifiers in the Using IAM guide.
    - RoleName (string) –
      The friendly name that identifies the role.
    - RoleId (string) –
      The stable and unique string identifying the role. For more information about IDs, see IAM Identifiers in the Using IAM guide.
    - Arn (string) –
      The Amazon Resource Name (ARN) specifying the role. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.
    - CreateDate (datetime) –
      The date and time, in ISO 8601 date-time format, when the role was created.
    - AssumeRolePolicyDocument (string) –
      The policy that grants an entity permission to assume the role.

- IsTruncated (boolean) –
  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- NextToken (string) –
  A token to resume pagination.

```
class IAM.Paginator.ListInstanceProfilesForRole

    paginator = client.get_paginator('list_instance_profiles_for_role')

    paginate(**kwargs)
        Creates an iterator that will paginate through responses from
        IAM.Client.list_instance_profiles_for_role().

    Request Syntax
```
```python
response_iterator = paginator.paginate(
    RoleName='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **RoleName** *(string)* – [REQUIRED]
  
  The name of the role to list instance profiles for.

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  - **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.

  - **PageSize** *(integer)* –
    
    The size of each page.

  - **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

Return type: dict

Response Syntax

```json
{
    'InstanceProfiles': [
        {
            'Path': 'string',
            'InstanceProfileName': 'string',
            'InstanceProfileId': 'string',
            'Arn': 'string',
            'CreateDate': datetime(2015, 1, 1),
            'Roles': [
                {
                    'Path': 'string',
                    'RoleName': 'string',
                    'RoleId': 'string',
                    'Arn': 'string',
                    'CreateDate': datetime(2015, 1, 1),
                    'AssumeRolePolicyDocument': 'string'
                },
            ],
        },
    ],
    'IsTruncated': True|False,
    'NextToken': 'string'
}
```

Response Structure

- *(dict)* –
Contains the response to a successful ListInstanceProfilesForRole request.

- **InstanceProfiles (list)** –
  A list of instance profiles.
  *
  - **(dict)** –

  Contains information about an instance profile.

  This data type is used as a response element in the following actions:
  · CreateInstanceProfile
  · GetInstanceProfile
  · ListInstanceProfiles
  · ListInstanceProfilesForRole

- **Path (string)** –

  The path to the instance profile. For more information about paths, see IAM Identifiers in the Using IAM guide.

- **InstanceProfileName (string)** –

  The name identifying the instance profile.

- **InstanceProfileId (string)** –

  The stable and unique string identifying the instance profile. For more information about IDs, see IAM Identifiers in the Using IAM guide.

- **Arn (string)** –

  The Amazon Resource Name (ARN) specifying the instance profile. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.

- **CreateDate (datetime)** –

  The date when the instance profile was created.

- **Roles (list)** –

  The role associated with the instance profile.

  *
  - **(dict)** –

  Contains information about an IAM role.

  This data type is used as a response element in the following actions:
  · CreateRole
  · GetRole
  · ListRoles

- **Path (string)** –

  The path to the role. For more information about paths, see IAM Identifiers in the Using IAM guide.

- **RoleName (string)** –

  The friendly name that identifies the role.

- **RoleId (string)** –

  The stable and unique string identifying the role. For more information about IDs, see IAM Identifiers in the Using IAM guide.

- **Arn (string)** –
The Amazon Resource Name (ARN) specifying the role. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.

- **CreateDate** *(datetime)* –
  
  The date and time, in ISO 8601 date-time format, when the role was created.

- **AssumeRolePolicyDocument** *(string)* –
  
  The policy that grants an entity permission to assume the role.

- **IsTruncated** *(boolean)* –
  
  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **NextToken** *(string)* –
  
  A token to resume pagination.

```python
class IAM.Paginator.ListMFADevices

paginator = client.get_paginator('list_mfa_devices')

paginate(**kwargs)

Creates an iterator that will paginate through responses from IAM.Client.list_mfa_devices().

Parameters

- **UserName** *(string)* – The name of the user whose MFA devices you want to list.
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  - **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  
  - **PageSize** *(integer)* –
    
    The size of each page.
  
  - **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict
Returns

Response Syntax

```json
{
    'MFADevices': [
        {
            'UserName': 'string',
            'SerialNumber': 'string',
            'EnableDate': datetime(2015, 1, 1)
        },
        {
            'UserName': 'string',
            'SerialNumber': 'string',
            'EnableDate': datetime(2015, 1, 1)
        }
    ],
    'IsTruncated': True|False,
    'NextToken': 'string'
}
```

Response Structure

- **(dict)** – Contains the response to a successful ListMFADevices request.
  - **MFADevices (list)** – A list of MFA devices.
    - *(dict)* – Contains information about an MFA device.
      - **UserName (string)** – The user with whom the MFA device is associated.
      - **SerialNumber (string)** – The serial number that uniquely identifies the MFA device. For virtual MFA devices, the serial number is the device ARN.
      - **EnableDate (datetime)** – The date when the MFA device was enabled for the user.
  - **IsTruncated (boolean)** – A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.
  - **NextToken (string)** – A token to resume pagination.

```python
class IAM.Paginator.ListPolicies

paginator = client.get_paginator('list_policies')
paginate(**kwargs)
```

Request Syntax
response_iterator = paginator.paginate(
    Scope='All'|'AWS'|'Local',
    OnlyAttached=True|False,
    PathPrefix='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **Scope** *(string)* – The scope to use for filtering the results.
  
  To list only AWS managed policies, set `Scope` to `AWS`. To list only the customer managed policies in your AWS account, set `Scope` to `Local`.
  
  This parameter is optional. If it is not included, or if it is set to `All`, all policies are returned.

- **OnlyAttached** *(boolean)* – A flag to filter the results to only the attached policies.
  
  When `OnlyAttached` is `true`, the returned list contains only the policies that are attached to a user, group, or role. When `OnlyAttached` is `false`, or when the parameter is not included, all policies are returned.

- **PathPrefix** *(string)* – The path prefix for filtering the results. This parameter is optional. If it is not included, it defaults to a slash (/), listing all policies.

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  - **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  
  - **PageSize** *(integer)* –
    
    The size of each page.
  
  - **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

Return type  *dict*

Returns

Response Syntax

```
{
    'Policies': [
        {
            'PolicyName': 'string',
            'PolicyId': 'string',
            'Arn': 'string',
            'Path': 'string',
            'DefaultVersionId': 'string',
            'AttachmentCount': 123,
            'IsAttachable': True|False,
            'Description': 'string',
            'CreateDate': datetime(2015, 1, 1),
        },
    ]
}
```
Response Structure

- (dict) –
  Contains the response to a successful ListPolicies request.
  
  - Policies (list) –
    A list of policies.
    
    * (dict) –
      Contains information about a managed policy.
      
      This data type is used as a response element in the CreatePolicy, GetPolicy, and ListPolicies actions.
      
      For more information about managed policies, refer to Managed Policies and Inline Policies in the Using IAM guide.
      
      - PolicyName (string) –
        The friendly name (not ARN) identifying the policy.
      
      - PolicyId (string) –
        The stable and unique string identifying the policy.
        
        For more information about IDs, see IAM Identifiers in the Using IAM guide.
      
      - Arn (string) –
        The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.
        
        For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.
      
      - Path (string) –
        The path to the policy.
        
        For more information about paths, see IAM Identifiers in the Using IAM guide.
      
      - DefaultVersionId (string) –
        The identifier for the version of the policy that is set as the default version.
      
      - AttachmentCount (integer) –
        The number of entities (users, groups, and roles) that the policy is attached to.
      
      - IsAttachable (boolean) –
        Specifies whether the policy can be attached to an IAM user, group, or role.
      
      - Description (string) –
        A friendly description of the policy.
This element is included in the response to the GetPolicy operation. It is not included in the response to the ListPolicies operation.

- **CreateDate (datetime)** –
  The date and time, in ISO 8601 date-time format, when the policy was created.

- **UpdateDate (datetime)** –
  The date and time, in ISO 8601 date-time format, when the policy was last updated.

When a policy has only one version, this field contains the date and time when the policy was created. When a policy has more than one version, this field contains the date and time when the most recent policy version was created.

- **IsTruncated (boolean)** –
  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **NextToken (string)** –
  A token to resume pagination.

```python
class IAM.Paginator.ListRolePolicies
```

```python
paginator = client.get_paginator('list_role_policies')
paginate(**kwargs)
```

Creates an iterator that will paginate through responses from IAM.Client.list_role_policies().

**Request Syntax**

```python
response_iterator = paginator.paginate(
    RoleName='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **RoleName (string)** – [REQUIRED]
  The name of the role to list policies for.

- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
– **PageSize** *(integer)* –
  The size of each page.

– **StartingToken** *(string)* –
  A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type**: `dict`

**Returns**

**Response Syntax**

```python
{
    'PolicyNames': [  
        'string',
    ],
    'IsTruncated': True|False,
    'NextToken': 'string'
}
```

**Response Structure**

- *(dict)* –
  Contains the response to a successful `ListRolePolicies` request.

  - **PolicyNames** *(list)* –
    A list of policy names.

  - **IsTruncated** *(boolean)* –
    A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the `Marker` request parameter to retrieve more items. Note that IAM might return fewer than the `MaxItems` number of results even when there are more results available. We recommend that you check `IsTruncated` after every call to ensure that you receive all of your results.

  - **NextToken** *(string)* –
    A token to resume pagination.

**class IAM.Paginator.ListRoles**

```python
paginator = client.get_paginator('list_roles')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `IAM.Client.list_roles()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    PathPrefix='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**
• **PathPrefix** *(string)* – The path prefix for filtering the results. For example, the prefix `/application_abc/component_xyz/` gets all roles whose path starts with `/application_abc/component_xyz/`. This parameter is optional. If it is not included, it defaults to a slash (/), listing all roles.

• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  - **MaxItems** *(integer)* – The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  
  - **PageSize** *(integer)* – The size of each page.
  
  - **StartingToken** *(string)* – A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Roles': [
        {
            'Path': 'string',
            'RoleName': 'string',
            'RoleId': 'string',
            'Arn': 'string',
            'CreateDate': datetime(2015, 1, 1),
            'AssumeRolePolicyDocument': 'string'
        },
    ],
    'IsTruncated': True|False,
    'NextToken': 'string'
}
```

**Response Structure**

- *(dict)* – Contains the response to a successful ListRoles request.

  - **Roles** *(list)* – A list of roles.

    - *(dict)* – Contains information about an IAM role.

      This data type is used as a response element in the following actions:

      - CreateRole
      - GetRole
      - ListRoles

    - **Path** *(string)* – The path to the role. For more information about paths, see IAM Identifiers in the *Using IAM* guide.
- **RoleName** *(string)* –
  The friendly name that identifies the role.
- **RoleId** *(string)* –
  The stable and unique string identifying the role. For more information about IDs, see IAM Identifiers in the Using IAM guide.
- **Arn** *(string)* –
  The Amazon Resource Name (ARN) specifying the role. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.
- **CreateDate** *(datetime)* –
  The date and time, in ISO 8601 date-time format, when the role was created.
- **AssumeRolePolicyDocument** *(string)* –
  The policy that grants an entity permission to assume the role.
- **IsTruncated** *(boolean)* –
  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.
- **NextToken** *(string)* –
  A token to resume pagination.

```python
class IAM.Paginator.ListServerCertificates

paginator = client.get_paginator('list_server_certificates')
paginate(**kwargs)

Creates an iterator that will paginate through responses from IAM.Client.list_server_certificates().

Request Syntax

```python
response_iterator = paginator.paginate(
    PathPrefix='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **PathPrefix** *(string)* – The path prefix for filtering the results. For example: /company/servercerts would get all server certificates for which the path starts with /company/servercerts.

  This parameter is optional. If it is not included, it defaults to a slash (/), listing all server certificates.
• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  – **MaxItems** *(integer)* –
  
  The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

  – **PageSize** *(integer)* –
  
  The size of each page.

  – **StartingToken** *(string)* –
  
  A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict

Returns

Response Syntax

```
{
  'ServerCertificateMetadataList': [
    {
      'Path': 'string',
      'ServerCertificateName': 'string',
      'ServerCertificateId': 'string',
      'Arn': 'string',
      'UploadDate': datetime(2015, 1, 1),
      'Expiration': datetime(2015, 1, 1)
    },
  ],
  'IsTruncated': True|False,
  'NextToken': 'string'
}
```

Response Structure

• *(dict)* –

  Contains the response to a successful ListServerCertificates request.

  – **ServerCertificateMetadataList** *(list)* –

    A list of server certificates.

    • *(dict)* –

      Contains information about a server certificate without its certificate body, certificate chain, and private key.

      This data type is used as a response element in the UploadServerCertificate and ListServerCertificates actions.

      – **Path** *(string)* –

      The path to the server certificate. For more information about paths, see IAM Identifiers in the Using IAM guide.

      – **ServerCertificateName** *(string)* –

      The name that identifies the server certificate.

      – **ServerCertificateId** *(string)* –

      The stable and unique string identifying the server certificate. For more information about IDs, see IAM Identifiers in the Using IAM guide.
- **Arn** *(string)* –
  The Amazon Resource Name (ARN) specifying the server certificate. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.

- **UploadDate** *(datetime)* –
  The date when the server certificate was uploaded.

- **Expiration** *(datetime)* –
  The date on which the certificate is set to expire.

- **IsTruncated** *(boolean)* –
  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **NextToken** *(string)* –
  A token to resume pagination.

```python
class IAM.Paginator.ListSigningCertificates

paginator = client.get_paginator('list_signing_certificates')

paginate(**kwargs)

Creates an iterator that will paginate through responses from IAM.Client.list_signing_certificates().

Request Syntax

response_iterator = paginator.paginate(
    UserName='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **UserName** *(string)* – The name of the user.

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –
    The size of each page.
  - **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  *dict*
Returns

Response Syntax

```
{
    'Certificates': [
        {
            'UserName': 'string',
            'CertificateId': 'string',
            'CertificateBody': 'string',
            'Status': 'Active'|'Inactive',
            'UploadDate': datetime(2015, 1, 1)
        },
    ],
    'IsTruncated': True|False,
    'NextToken': 'string'
}
```

Response Structure

- **(dict)** –
  Contains the response to a successful ListSigningCertificates request.
  - **Certificates (list)** –
    A list of the user’s signing certificate information.
    * **(dict)** –
      Contains information about an X.509 signing certificate.
      This data type is used as a response element in the UploadSign-
      ingCertificate and ListSigningCertificates actions.
      - **UserName (string)** –
        The name of the user the signing certificate is associated with.
      - **CertificateId (string)** –
        The ID for the signing certificate.
      - **CertificateBody (string)** –
        The contents of the signing certificate.
      - **Status (string)** –
        The status of the signing certificate. **Active** means the key
        is valid for API calls, while **Inactive** means it is not.
      - **UploadDate (datetime)** –
        The date when the signing certificate was uploaded.
  - **IsTruncated (boolean)** –
    A flag that indicates whether there are more items to return. If your results
    were truncated, you can make a subsequent pagination request using the
    Marker request parameter to retrieve more items. Note that IAM might
    return fewer than the MaxItems number of results even when there are
    more results available. We recommend that you check IsTruncated
    after every call to ensure that you receive all of your results.
  - **NextToken (string)** –
    A token to resume pagination.

```
paginator = client.get_paginator('list_user_policies')

paginate(**kwargs)

Creates an iterator that will paginate through responses from IAM.Client.list_user_policies().

Request Syntax

response_iterator = paginator.paginate(
    UserName='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

• **UserName (string)** – [REQUIRED]
  The name of the user to list policies for.

• **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize (integer)** –
    The size of each page.
  - **StartingToken (string)** –
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict

Returns

Response Syntax

{  'PolicyNames': [
    'string',
  ],
  'IsTruncated': True|False,
  'NextToken': 'string'
}

Response Structure

• (dict) –
  Contains the response to a successful ListUserPolicies request.
  - **PolicyNames (list)** –
    A list of policy names.
      • (string) –
  - **IsTruncated (boolean)** –
A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **NextToken (string)** –
  A token to resume pagination.

```python
class IAM.Paginator.ListUsers

paginator = client.get_paginator('list_users')

paginate(**kwargs)

Creates an iterator that will paginate through responses from IAM.Client.list_users().

Request Syntax

response_iterator = paginator.paginate(
    PathPrefix='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **PathPrefix (string)** – The path prefix for filtering the results. For example: /division_abc/subdivision_xyz/, which would get all user names whose path starts with /division_abc/subdivision_xyz/.

This parameter is optional. If it is not included, it defaults to a slash (/), listing all user names.

- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.

  - **MaxItems (integer)** –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

  - **PageSize (integer)** –
    The size of each page.

  - **StartingToken (string)** –
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  *dict*

Returns

**Response Syntax**

```python
{
    'Users': [
        {'Path': 'string'},
    ],

```
Response Structure

- *(dict)* —
  
  Contains the response to a successful ListUsers request.
  
  - **Users** *(list)* —
    
    A list of users.
    
    - *(dict)* —
      
      Contains information about an IAM user entity.
      
      This data type is used as a response element in the following actions:
      
      - CreateUser
      - GetUser
      - ListUsers
      
      - **Path** *(string)* —
        
        The path to the user. For more information about paths, see IAM Identifiers in the Using IAM guide.
      
      - **UserName** *(string)* —
        
        The friendly name identifying the user.
      
      - **UserId** *(string)* —
        
        The stable and unique string identifying the user. For more information about IDs, see IAM Identifiers in the Using IAM guide.
      
      - **Arn** *(string)* —
        
        The Amazon Resource Name (ARN) that identifies the user. For more information about ARNs and how to use ARNs in policies, see IAM Identifiers in the Using IAM guide.
      
      - **CreateDate** *(datetime)* —
        
        The date and time, in ISO 8601 date-time format, when the user was created.
      
      - **PasswordLastUsed** *(datetime)* —
        
        The date and time, in ISO 8601 date-time format, when the user’s password was last used to sign in to an AWS website. For a list of AWS websites that capture a user’s last sign-in time, see the Credential Reports topic in the Using IAM guide.
      
        If a password is used more than once in a five-minute span, only the first use is returned in this field. This field is null (not present) when:
      
      - The user does not have a password
      - The password exists but has never been used (at least not since IAM started tracking this information on October 20th, 2014
- there is no sign-in data associated with the user
  This value is returned only in the GetUser and ListUsers actions.
  - **IsTruncated** *(boolean)* –
    A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the **Marker** request parameter to retrieve more items. Note that IAM might return fewer than the **MaxItems** number of results even when there are more results available. We recommend that you check **IsTruncated** after every call to ensure that you receive all of your results.

  - **NextToken** *(string)* –
    A token to resume pagination.

class IAM.Paginator.ListVirtualMFADevices

    paginator = client.get_paginator('list_virtual_mfa_devices')

    paginate(**kwargs)
    Creates an iterator that will paginate through responses from IAM.Client.list_virtual_mfa_devices().

    Request Syntax

    response_iterator = paginator.paginate(
        AssignmentStatus='Assigned'|'Unassigned'|'Any',
        PaginationConfig={
            'MaxItems': 123,
            'PageSize': 123,
            'StartingToken': 'string'
        }
    )

    Parameters
    - **AssignmentStatus** *(string)* – The status (unassigned or assigned) of the devices to list. If you do not specify an **AssignmentStatus**, the action defaults to **Any** which lists both assigned and unassigned virtual MFA devices.

    - **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
      - **MaxItems** *(integer)* –
        The total number of items to return. If the total number of items available is more than the value specified in max-items then a **NextToken** will be provided in the output that you can use to resume pagination.

      - **PageSize** *(integer)* –
        The size of each page.

      - **StartingToken** *(string)* –
        A token to specify where to start paginating. This is the **NextToken** from a previous response.

    Return type  **dict**
    Returns

    Response Syntax
Response Structure

- (dict) –
  Contains the response to a successful ListVirtualMFADevices request.

  - VirtualMFADevices (list) –
    The list of virtual MFA devices in the current account that match the AssignmentStatus value that was passed in the request.
    * (dict) –
      Contains information about a virtual MFA device.
      - SerialNumber (string) –
        The serial number associated with VirtualMFADevice.
      - Base32StringSeed (bytes) –
        The Base32 seed defined as specified in RFC3548. The Base32StringSeed is Base64-encoded.
      - QRCodePNG (bytes) –
        A QR code PNG image that encodes
        `otpauth://totp/$virtualMFADeviceName@$AccountName?secret=$Base32String` where
        $virtualMFADeviceName is one of the create call arguments, AccountName is the user name if set
        (otherwise, the account ID otherwise), and Base32String is the seed in Base32 format. The Base32String value is
        Base64-encoded.
      - User (dict) –
        Contains information about an IAM user entity.
        This data type is used as a response element in the following actions:
        - CreateUser
        - GetUser
        - ListUsers
        - Path (string) –
The path to the user. For more information about paths, see IAM Identifiers in the Using IAM guide.

- **UserName** *(string)* –

  The friendly name identifying the user.

- **UserId** *(string)* –

  The stable and unique string identifying the user. For more information about IDs, see IAM Identifiers in the Using IAM guide.

- **Arn** *(string)* –

  The Amazon Resource Name (ARN) that identifies the user. For more information about ARNs and how to use ARNs in policies, see IAM Identifiers in the Using IAM guide.

- **CreateDate** *(datetime)* –

  The date and time, in ISO 8601 date-time format, when the user was created.

- **PasswordLastUsed** *(datetime)* –

  The date and time, in ISO 8601 date-time format, when the user’s password was last used to sign in to an AWS website. For a list of AWS websites that capture a user’s last sign-in time, see the Credential Reports topic in the Using IAM guide. If a password is used more than once in a five-minute span, only the first use is returned in this field. This field is null (not present) when:
  - The user does not have a password
  - The password exists but has never been used (at least not since IAM started tracking this information on October 20th, 2014
  - there is no sign-in data associated with the user
  This value is returned only in the GetUser and ListUsers actions.

- **EnableDate** *(datetime)* –

  The date and time on which the virtual MFA device was enabled.

- **IsTruncated** *(boolean)* –

  A flag that indicates whether there are more items to return. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more items. Note that IAM might return fewer than the MaxItems number of results even when there are more results available. We recommend that you check IsTruncated after every call to ensure that you receive all of your results.

- **NextToken** *(string)* –

  A token to resume pagination.

**Waiters**

The available waiters are:

- IAM.Waiter.InstanceProfileExists
- IAM.Waiter.UserExists
class IAM.Waiter.InstanceProfileExists

waiter = client.get_waiter('instance_profile_exists')

wait(**kwargs)

Polls IAM.Client.get_instance_profile() every 1 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

waiter.wait(
    InstanceProfileName='string'
)

Parameters InstanceProfileName (string) – [REQUIRED]

The name of the instance profile to get information about.

Returns None

class IAM.Waiter.UserExists

waiter = client.get_waiter('user_exists')

wait(**kwargs)

Polls IAM.Client.get_user() every 1 seconds until a successful state is reached. An error is returned after 20 failed checks.

Request Syntax

waiter.wait(
    UserName='string'
)

Parameters UserName (string) – The name of the user to get information about.

This parameter is optional. If it is not included, it defaults to the user making the request.

Returns None

Service Resource

class IAM.ServiceResource

A resource representing AWS Identity and Access Management (IAM):

```
import boto3

iam = boto3.resource('iam')
```

These are the resource’s available actions:

- change_password()
- create_account_alias()
- create_account_password_policy()
- create_group()
- create_instance_profile()
- create_policy()
These are the resource’s available sub-resources:

- AccessKey()
- AccessKeyPair()
- AccountPasswordPolicy()
- AccountSummary()
- AssumeRolePolicy()
- CurrentUser()
- Group()
- GroupPolicy()
- InstanceProfile()
- LoginProfile()
- MfaDevice()
- Policy()
- PolicyVersion()
- Role()
- RolePolicy()
- SamlProvider()
- ServerCertificate()
- SigningCertificate()
- User()
- UserPolicy()
- VirtualMfaDevice()

These are the resource’s available collections:

- groups
- instance_profiles
- policies
- roles
- saml_providers
- server_certificates
- users
- virtual_mfa_devices

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

change_password(**kwargs)

Changes the password of the IAM user who is calling this action. The root account password is not affected by this action.

To change the password for a different user, see UpdateLoginProfile. For more information about modifying passwords, see Managing Passwords in the IAM User Guide.

Request Syntax

```python
response = iam.change_password(
    OldPassword='string',
    NewPassword='string'
)
```
Parameters

- **OldPassword** *(string)* – [REQUIRED]
  
  The IAM user’s current password.

- **NewPassword** *(string)* – [REQUIRED]
  
  The new password. The new password must conform to the AWS account’s password policy, if one exists.

Returns None

create_account_alias(**kwargs)**

 Creates an alias for your AWS account. For information about using an AWS account alias, see Using an Alias for Your AWS Account ID in the IAM User Guide.

Request Syntax

```python
response = iam.create_account_alias(
    AccountAlias='string'
)
```

Parameters **AccountAlias** *(string)* – [REQUIRED]

  The account alias to create.

Returns None

create_account_password_policy(**kwargs)**

 Updates the password policy settings for the AWS account.

**Note:** This action does not support partial updates. No parameters are required, but if you do not specify a parameter, that parameter’s value reverts to its default value. See the Request Parameters section for each parameter’s default value.

For more information about using a password policy, see Managing an IAM Password Policy in the IAM User Guide.

Request Syntax

```python
account_password_policy = iam.create_account_password_policy(
    MinimumPasswordLength=123,
    RequireSymbols=True|False,
    RequireNumbers=True|False,
    RequireUppercaseCharacters=True|False,
    RequireLowercaseCharacters=True|False,
    AllowUsersToChangePassword=True|False,
    MaxPasswordAge=123,
    PasswordReusePrevention=123,
    HardExpiry=True|False
)
```

Parameters

- **MinimumPasswordLength** *(integer)* – The minimum number of characters allowed in an IAM user password.

  Default value: 6

- **RequireSymbols** *(boolean)* – Specifies whether IAM user passwords must contain at least one of the following non-alphanumeric characters:

  `! @ # $ % ^ & * ( ) _ + - = [ ] { } | '``

  Default value: false
• **RequireNumbers (boolean)** – Specifies whether IAM user passwords must contain at least one numeric character (0 to 9).
  Default value: false

• **RequireUppercaseCharacters (boolean)** – Specifies whether IAM user passwords must contain at least one uppercase character from the ISO basic Latin alphabet (A to Z).
  Default value: false

• **RequireLowercaseCharacters (boolean)** – Specifies whether IAM user passwords must contain at least one lowercase character from the ISO basic Latin alphabet (a to z).
  Default value: false

• **AllowUsersToChangePassword (boolean)** – Allows all IAM users in your account to use the AWS Management Console to change their own passwords. For more information, see Letting IAM Users Change Their Own Passwords in the *IAM User Guide*.
  Default value: false

• **MaxPasswordAge (integer)** – The number of days that an IAM user password is valid. The default value of 0 means IAM user passwords never expire.
  Default value: 0

• **PasswordReusePrevention (integer)** – Specifies the number of previous passwords that IAM users are prevented from reusing. The default value of 0 means IAM users are not prevented from reusing previous passwords.
  Default value: 0

• **HardExpiry (boolean)** – Prevents IAM users from setting a new password after their password has expired.
  Default value: false

**Return type**  
`iam.AccountPasswordPolicy`  
**Returns**  
AccountPasswordPolicy resource

```python
create_group(**kwargs)
```

Creates a new group.

For information about the number of groups you can create, see Limitations on IAM Entities in the *IAM User Guide*.

**Request Syntax**

```python
group = iam.create_group(
    Path='string',
    GroupName='string'
)
```

**Parameters**

- **Path (string)** – The path to the group. For more information about paths, see IAM Identifiers in the *Using IAM* guide.
  This parameter is optional. If it is not included, it defaults to a slash (/).

- **GroupName (string)** – [REQUIRED]
  The name of the group to create. Do not include the path in this value.

**Return type**  
`iam.Group`  
**Returns**  
Group resource
create_instance_profile(**kwargs)

Creates a new instance profile. For information about instance profiles, go to About Instance Profiles.

For information about the number of instance profiles you can create, see Limitations on IAM Entities in the IAM User Guide.

Request Syntax

```python
instance_profile = iam.create_instance_profile(
    InstanceProfileName='string',
    Path='string'
)
```

Parameters

- **InstanceProfileName**: REQUIRED
  
  The name of the instance profile to create.

- **Path**: string
  
  The path to the instance profile. For more information about paths, see IAM Identifiers in the Using IAM guide.

  This parameter is optional. If it is not included, it defaults to a slash (/).

Return type: iam.InstanceProfile

Create Policy

create_policy(**kwargs)

Creates a new managed policy for your AWS account.

This operation creates a policy version with a version identifier of v1 and sets v1 as the policy's default version. For more information about policy versions, see Versioning for Managed Policies in the IAM User Guide.

For more information about managed policies in general, refer to Managed Policies and Inline Policies in the IAM User Guide.

Request Syntax

```python
policy = iam.create_policy(
    PolicyName='string',
    Path='string',
    PolicyDocument='string',
    Description='string'
)
```

Parameters

- **PolicyName**: REQUIRED
  
  The name of the policy document.

- **Path**: string
  
  The path for the policy.

  For more information about paths, see IAM Identifiers in the IAM User Guide.

  This parameter is optional. If it is not included, it defaults to a slash (/).

- **PolicyDocument**: REQUIRED
  
  The policy document.

- **Description**: string
  
  A friendly description of the policy.

  Typically used to store information about the permissions defined in the policy.
  For example, “Grants access to production DynamoDB tables.”

  The policy description is immutable. After a value is assigned, it cannot be changed.
Return type  iam.Policy
Returns  Policy resource

**create_role(**\*\*kwargs\*)**

Creates a new role for your AWS account. For more information about roles, go to Working with Roles. For information about limitations on role names and the number of roles you can create, go to Limitations on IAM Entities in the IAM User Guide.

The policy in the following example grants permission to an EC2 instance to assume the role.

**Request Syntax**

code:
```python
role = iam.create_role(
    Path='string',
    RoleName='string',
    AssumeRolePolicyDocument='string'
)
```

**Parameters**

- **Path** *(string)* – The path to the role. For more information about paths, see IAM Identifiers in the Using IAM guide.
  
  This parameter is optional. If it is not included, it defaults to a slash (/).
- **RoleName** *(string)* – [REQUIRED]
  
  The name of the role to create.
- **AssumeRolePolicyDocument** *(string)* – [REQUIRED]
  
  The policy that grants an entity permission to assume the role.

Return type  iam.Role
Returns  Role resource

**create_saml_provider(**\*\*kwargs\*)**

Creates an IAM entity to describe an identity provider (IdP) that supports SAML 2.0.

The SAML provider that you create with this operation can be used as a principal in a role’s trust policy to establish a trust relationship between AWS and a SAML identity provider. You can create an IAM role that supports Web-based single sign-on (SSO) to the AWS Management Console or one that supports API access to AWS.

When you create the SAML provider, you upload an a SAML metadata document that you get from your IdP and that includes the issuer’s name, expiration information, and keys that can be used to validate the SAML authentication response (assertions) that are received from the IdP. You must generate the metadata document using the identity management software that is used as your organization’s IdP.

**Note:** This operation requires Signature Version 4.

For more information, see Enabling SAML 2.0 Federated Users to Access the AWS Management Console and About SAML 2.0-based Federation in the IAM User Guide.

**Request Syntax**

code:
```python
saml_provider = iam.create_saml_provider(
    SAMLMetadataDocument='string',
    Name='string'
)
```

**Parameters**
• **SAMLMetadataDocument** *(string)* – [REQUIRED]

An XML document generated by an identity provider (IdP) that supports SAML 2.0. The document includes the issuer’s name, expiration information, and keys that can be used to validate the SAML authentication response (assertions) that are received from the IdP. You must generate the metadata document using the identity management software that is used as your organization’s IdP.

For more information, see About SAML 2.0-based Federation in the *IAM User Guide*.

• **Name** *(string)* – [REQUIRED]

The name of the provider to create.

*Return type* `iam.SamlProvider`

*Returns* `SamlProvider` resource

**create_server_certificate**(**kwargs**)

Uploads a server certificate entity for the AWS account. The server certificate entity includes a public key certificate, a private key, and an optional certificate chain, which should all be PEM-encoded.

For information about the number of server certificates you can upload, see Limitations on IAM Entities in the *IAM User Guide*.

**Note:** Because the body of the public key certificate, private key, and the certificate chain can be large, you should use POST rather than GET when calling `UploadServerCertificate`. For information about setting up signatures and authorization through the API, go to Signing AWS API Requests in the *AWS General Reference*. For general information about using the Query API with IAM, go to Making Query Requests in the *IAM User Guide*.

**Request Syntax**

```python
server_certificate = iam.create_server_certificate(
    Path='string',
    ServerCertificateName='string',
    CertificateBody='string',
    PrivateKey='string',
    CertificateChain='string'
)
```

**Parameters**

• **Path** *(string)* – The path for the server certificate. For more information about paths, see IAM Identifiers in the *Using IAM* guide.

  This parameter is optional. If it is not included, it defaults to a slash (/).

**Note:** If you are uploading a server certificate specifically for use with Amazon CloudFront distributions, you must specify a path using the `--path` option. The path must begin with `/cloudfront` and must include a trailing slash (for example, `/cloudfront/test/`).

• **ServerCertificateName** *(string)* – [REQUIRED]

  The name for the server certificate. Do not include the path in this value. The name of the certificate cannot contain any spaces.

• **CertificateBody** *(string)* – [REQUIRED]

  The contents of the public key certificate in PEM-encoded format.

• **PrivateKey** *(string)* – [REQUIRED]
The contents of the private key in PEM-encoded format.

- **CertificateChain** *(string)* – The contents of the certificate chain. This is typically a concatenation of the PEM-encoded public key certificates of the chain.

### create_signing_certificate(**kwargs)**

Uploads an X.509 signing certificate and associates it with the specified user. Some AWS services use X.509 signing certificates to validate requests that are signed with a corresponding private key. When you upload the certificate, its default status is **Active**.

If the **UserName** field is not specified, the user name is determined implicitly based on the AWS access key ID used to sign the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

**Note:** Because the body of a X.509 certificate can be large, you should use POST rather than GET when calling **UploadSigningCertificate**. For information about setting up signatures and authorization through the API, go to Signing AWS API Requests in the AWS General Reference. For general information about using the Query API with IAM, go to Making Query Requests in the Using IAM guide.

**Request Syntax**

```python
signing_certificate = iam.create_signing_certificate(
    UserName='string',
    CertificateBody='string'
)
```

**Parameters**

- **UserName** *(string)* – The name of the user the signing certificate is for.
- **CertificateBody** *(string)* – [REQUIRED]

  The contents of the signing certificate.

**Return type** `iam.SigningCertificate`

**Returns** SigningCertificate resource

### create_user(**kwargs)**

Creates a new user for your AWS account.

For information about limitations on the number of users you can create, see Limitations on IAM Entities in the IAM User Guide.

**Request Syntax**

```python
user = iam.create_user(
    Path='string',
    UserName='string'
)
```

**Parameters**

- **Path** *(string)* – The path for the user name. For more information about paths, see IAM Identifiers in the Using IAM guide.

  This parameter is optional. If it is not included, it defaults to a slash (/).
- **UserName** *(string)* – [REQUIRED]

  The name of the user to create.

**Return type** `iam.User`

**Returns** User resource
create_virtual_mfa_device(**kwargs)

Creates a new virtual MFA device for the AWS account. After creating the virtual MFA, use EnableMFADevice to attach the MFA device to an IAM user. For more information about creating and working with virtual MFA devices, go to Using a Virtual MFA Device in the Using IAM guide.

For information about limits on the number of MFA devices you can create, see Limitations on Entities in the Using IAM guide.

Warning: The seed information contained in the QR code and the Base32 string should be treated like any other secret access information, such as your AWS access keys or your passwords. After you provision your virtual device, you should ensure that the information is destroyed following secure procedures.

Request Syntax

```python
virtual_mfa_device = iam.create_virtual_mfa_device(
    Path='string',
    VirtualMFADeviceName='string'
)
```

Parameters

- **Path (string)** – The path for the virtual MFA device. For more information about paths, see IAM Identifiers in the Using IAM guide.
  
  This parameter is optional. If it is not included, it defaults to a slash (/).
- **VirtualMFADeviceName (string)** – [REQUIRED]
  
  The name of the virtual MFA device. Use with path to uniquely identify a virtual MFA device.

Return type: `iam.VirtualMfaDevice`

Returns: VirtualMfaDevice resource

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

**AccessKey (user_name, id)**

Creates a AccessKey resource:

```python
access_key = iam.AccessKey('user_name','id')
```

Parameters

- **user_name (string)** – The AccessKey’s user_name identifier. This must be set.
- **id (string)** – The AccessKey’s id identifier. This must be set.

Return type: `IAM.AccessKey`

Returns: A AccessKey resource

**AccessKeyPair (user_name, id, secret)**

Creates a AccessKeyPair resource:

```python
access_key_pair = iam.AccessKeyPair('user_name','id','secret')
```

Parameters

- **user_name (string)** – The AccessKeyPair’s user_name identifier. This must be set.
- **id (string)** – The AccessKeyPair’s id identifier. This must be set.
- **secret (string)** – The AccessKeyPair’s secret identifier. This must be set.
Return type IAM.AccessKeyPair
Returns A AccessKeyPair resource

AccountPasswordPolicy()
Creates a AccountPasswordPolicy resource:

account_password_policy = iam.AccountPasswordPolicy()

Return type IAM.AccountPasswordPolicy
Returns A AccountPasswordPolicy resource

AccountSummary()
Creates a AccountSummary resource:

account_summary = iam.AccountSummary()

Return type IAM.AccountSummary
Returns A AccountSummary resource

AssumeRolePolicy(role_name)
Creates a AssumeRolePolicy resource:

assume_role_policy = iam.AssumeRolePolicy('role_name')

Parameters role_name (string) – The AssumeRolePolicy’s role_name identifier. This must be set.
Return type IAM.AssumeRolePolicy
Returns A AssumeRolePolicy resource

CurrentUser()
Creates a CurrentUser resource:

current_user = iam.CurrentUser()

Return type IAM.CurrentUser
Returns A CurrentUser resource

Group(name)
Creates a Group resource:

group = iam.Group('name')

Parameters name (string) – The Group’s name identifier. This must be set.
Return type IAM.Group
Returns A Group resource

GroupPolicy(group_name, name)
Creates a GroupPolicy resource:

group_policy = iam.GroupPolicy('group_name','name')

Parameters
• group_name (string) – The GroupPolicy’s group_name identifier. This must be set.
• name (string) – The GroupPolicy’s name identifier. This must be set.
Return type IAM.GroupPolicy
Returns A GroupPolicy resource
**InstanceProfile** *(name)*
Creates a InstanceProfile resource:

```python
ing_instance_profile = iam.InstanceProfile('name')
```

**Parameters** *name* *(string)* – The InstanceProfile’s name identifier. This **must** be set.

**Return type** IAM.InstanceProfile

**Returns** A InstanceProfile resource

**LoginProfile** *(user_name)*
Creates a LoginProfile resource:

```python
ing_login_profile = iam.LoginProfile('user_name')
```

**Parameters** *user_name* *(string)* – The LoginProfile’s user_name identifier. This **must** be set.

**Return type** IAM.LoginProfile

**Returns** A LoginProfile resource

**MfaDevice** *(user_name, serial_number)*
Creates a MfaDevice resource:

```python
ing_mfa_device = iam.MfaDevice('user_name','serial_number')
```

**Parameters**
- *user_name* *(string)* – The MfaDevice’s user_name identifier. This **must** be set.
- *serial_number* *(string)* – The MfaDevice’s serial_number identifier. This **must** be set.

**Return type** IAM.MfaDevice

**Returns** A MfaDevice resource

**Policy** *(policy_arn)*
Creates a Policy resource:

```python
ing_policy = iam.Policy('policy_arn')
```

**Parameters** *policy_arn* *(string)* – The Policy’s policy_arn identifier. This **must** be set.

**Return type** IAM.Policy

**Returns** A Policy resource

**PolicyVersion** *(arn, version_id)*
Creates a PolicyVersion resource:

```python
ing_policy_version = iam.PolicyVersion('arn','version_id')
```

**Parameters**
- *arn* *(string)* – The PolicyVersion’s arn identifier. This **must** be set.
- *version_id* *(string)* – The PolicyVersion’s version_id identifier. This **must** be set.

**Return type** IAM.PolicyVersion

**Returns** A PolicyVersion resource

**Role** *(name)*
Creates a Role resource:

```python
ing_role = iam.Role('name')
```
Parameters name (string) – The Role’s name identifier. This must be set.
Return type IAM.Role
Returns A Role resource

RolePolicy (role_name, name)
Creates a RolePolicy resource:

role_policy = iam.RolePolicy('role_name','name')

Parameters
• role_name (string) – The RolePolicy’s role_name identifier. This must be set.
• name (string) – The RolePolicy’s name identifier. This must be set.
Return type IAM.RolePolicy
Returns A RolePolicy resource

Sam1Provider (arn)
Creates a Sam1Provider resource:

saml_provider = iam.SamlProvider('arn')

Parameters arn (string) – The Sam1Provider’s arn identifier. This must be set.
Return type IAM.SamlProvider
Returns A Sam1Provider resource

ServerCertificate (name)
Creates a ServerCertificate resource:

server_certificate = iam.ServerCertificate('name')

Parameters name (string) – The ServerCertificate’s name identifier. This must be set.
Return type IAM.ServerCertificate
Returns A ServerCertificate resource

SigningCertificate (user_name, id)
Creates a SigningCertificate resource:

signing_certificate = iam.SigningCertificate('user_name','id')

Parameters
• user_name (string) – The SigningCertificate’s user_name identifier. This must be set.
• id (string) – The SigningCertificate’s id identifier. This must be set.
Return type IAM.SigningCertificate
Returns A SigningCertificate resource

User (name)
Creates a User resource:

user = iam.User('name')

Parameters name (string) – The User’s name identifier. This must be set.
Return type IAM.User
Returns A User resource

UserPolicy (user_name, name)
Creates a UserPolicy resource:
user_policy = iam.UserPolicy('user_name', 'name')

Parameters
  • **user_name** *(string)* – The UserPolicy’s user_name identifier. This **must** be set.
  • **name** *(string)* – The UserPolicy’s name identifier. This **must** be set.

Return type IAM.UserPolicy
Returns A UserPolicy resource

VirtualMfaDevice *(serial_number)*
Creates a VirtualMfaDevice resource:

virtual_mfa_device = iam.VirtualMfaDevice('serial_number')

Parameters **serial_number** *(string)* – The VirtualMfaDevice’s serial_number identifier. This **must** be set.

Return type IAM.VirtualMfaDevice
Returns A VirtualMfaDevice resource

Collections
Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the *Resources Introduction Guide*.

**groups**

all()
Creates an iterable of all Group resources in the collection.

Request Syntax

group_iterator = iam.groups.all()

  Return type list(iam.Group)
  Returns A list of Group resources

filter(**kwargs)
Creates an iterable of all Group resources in the collection filtered by kwargs passed to method.

Request Syntax

group_iterator = iam.groups.filter(
  PathPrefix='string',
  Marker='string',
  MaxItems=123
)

Parameters
  • **PathPrefix** *(string)* – The path prefix for filtering the results. For example, the prefix /division_abc/subdivision_xyz/ gets all groups whose path starts with /division_abc/subdivision_xyz/. This parameter is optional. If it is not included, it defaults to a slash (/), listing all groups.
  • **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.
• **MaxItems (integer)** – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the `IsTruncated` response element is `true`.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the `IsTruncated` response element returns `true` and `Marker` contains a value to include in the subsequent call that tells the service where to continue from.

**Return type**  `list(iam.Group)`  
**Returns**  A list of Group resources

**limit(**`**kwargs**`)**

Creates an iterable up to a specified amount of Group resources in the collection.

**Request Syntax**

```python
 IAM = boto3.client('iam')
group_iterator = IAM.groups.limit(
    count=123
)
```

**Parameters**  `count (integer)` – The limit to the number of resources in the iterable.  
**Return type**  `list(iam.Group)`  
**Returns**  A list of Group resources

**page_size(**`**kwargs**`)**

Creates an iterable of all Group resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
 IAM = boto3.client('iam')
group_iterator = IAM.groups.page_size(
    count=123
)
```

**Parameters**  `count (integer)` – The number of items returned by each service call  
**Return type**  `list(iam.Group)`  
**Returns**  A list of Group resources

**instance_profiles**

**all()**

Creates an iterable of all InstanceProfile resources in the collection.

**Request Syntax**

```python
 IAM = boto3.client('iam')
instance_profile_iterator = IAM.instance_profiles.all()
```

**Return type**  `list(iam.InstanceProfile)`  
**Returns**  A list of InstanceProfile resources

**filter(**`**kwargs**`)**

Creates an iterable of all InstanceProfile resources in the collection filtered by `kwargs` passed to method.

**Request Syntax**

```python
 IAM = boto3.client('iam')
instance_profile_iterator = IAM.instance_profiles.filter(
    **kwargs
)
```

**Return type**  `list(iam.InstanceProfile)`  
**Returns**  A list of InstanceProfile resources

---

**3.1. Services**
instance_profile_iterator = iam.instance_profiles.filter(
    PathPrefix='string',
    Marker='string',
    MaxItems=123
)

Parameters

- **PathPrefix** (string) – The path prefix for filtering the results. For example, the prefix `/application_abc/component_xyz/` gets all instance profiles whose path starts with `/application_abc/component_xyz/`.

  This parameter is optional. If it is not included, it defaults to a slash (`/`), listing all instance profiles.

- **Marker** (string) – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the `Marker` element in the response you received to inform the next call about where to start.

- **MaxItems** (integer) – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the `IsTruncated` response element is `true`.

  This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the `IsTruncated` response element returns `true` and `Marker` contains a value to include in the subsequent call that tells the service where to continue from.

Return type list(iam.InstanceProfile)

Returns A list of InstanceProfile resources

**limit(****kwargs**)**

Creates an iterable up to a specified amount of InstanceProfile resources in the collection.

Request Syntax

```
instance_profile_iterator = iam.instance_profiles.limit(
    count=123
)
```

Parameters **count** (integer) – The limit to the number of resources in the iterable.

Return type list(iam.InstanceProfile)

Returns A list of InstanceProfile resources

**page_size(****kwargs**)**

Creates an iterable of all InstanceProfile resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

```
instance_profile_iterator = iam.instance_profiles.page_size(
    count=123
)
```

Parameters **count** (integer) – The number of items returned by each service call

Return type list(iam.InstanceProfile)

Returns A list of InstanceProfile resources
policies

all()
   Creates an iterable of all Policy resources in the collection.

   Request Syntax

   policy_iterator = iam.policies.all()

   Return type list(iam.Policy)
   Returns A list of Policy resources

filter(**kwargs)
   Creates an iterable of all Policy resources in the collection filtered by kwargs passed to method.

   Request Syntax

   policy_iterator = iam.policies.filter(
       Scope='All'|'AWS'|'Local',
       OnlyAttached=True|False,
       PathPrefix='string',
       Marker='string',
       MaxItems=123
   )

   Parameters

   • **Scope** (string) – The scope to use for filtering the results.
     To list only AWS managed policies, set Scope to AWS. To list only the
     customer managed policies in your AWS account, set Scope to Local.
     This parameter is optional. If it is not included, or if it is set to All, all
     policies are returned.
     • **OnlyAttached** (boolean) – A flag to filter the results to only the attached
       policies.
       When OnlyAttached is true, the returned list contains only the poli-
       cies that are attached to a user, group, or role. When OnlyAttached is
       false, or when the parameter is not included, all policies are returned.
     • **PathPrefix** (string) – The path prefix for filtering the results. This param-
       eter is optional. If it is not included, it defaults to a slash (/), listing all
       policies.
     • **Marker** (string) – Use this parameter only when paginating results and
       only after you receive a response indicating that the results are truncated.
       Set it to the value of the Marker element in the response you received to
       inform the next call about where to start.
     • **MaxItems** (integer) – Use this only when paginating results to indicate the
       maximum number of items you want in the response. If there are
       additional items beyond the maximum you specify, the IsTruncated
       response element is true.
     This parameter is optional. If you do not include it, it defaults to 100. Note
     that IAM might return fewer results, even when there are more results
     available. If this is the case, the IsTruncated response element returns
     true and Marker contains a value to include in the subsequent call that
     tells the service where to continue from.

   Return type list(iam.Policy)
   Returns A list of Policy resources
**limit**(**kwargs**)  
Creates an iterable up to a specified amount of Policy resources in the collection.

**Request Syntax**

```
policy_iterator = iam.policies.limit(
    count=123
)
```

- **Parameters**  
  - **count** (*integer*) – The limit to the number of resources in the iterable.  
  - **Return type**  
    - list(iam.Policy)  
  - **Returns**  
    - A list of Policy resources

**page_size**(**kwargs**)  
Creates an iterable of all Policy resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```
policy_iterator = iam.policies.page_size(
    count=123
)
```

- **Parameters**  
  - **count** (*integer*) – The number of items returned by each service call  
  - **Return type**  
    - list(iam.Policy)  
  - **Returns**  
    - A list of Policy resources

**roles**

**all()**  
Creates an iterable of all Role resources in the collection.

**Request Syntax**

```
role_iterator = iam.roles.all()
```

- **Return type**  
  - list(iam.Role)  
- **Returns**  
  - A list of Role resources

**filter**(**kwargs**)  
Creates an iterable of all Role resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```
role_iterator = iam.roles.filter(
    PathPrefix='string',
    Marker='string',
    MaxItems=123
)
```

- **Parameters**  
  - **PathPrefix** (*string*) – The path prefix for filtering the results. For example, the prefix `/application_abc/component_xyz/` gets all roles whose path starts with `/application_abc/component_xyz/`.  
    - This parameter is optional. If it is not included, it defaults to a slash (`/`), listing all roles.
• **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

• **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the **IsTruncated** response element is **true**.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the **IsTruncated** response element returns **true** and Marker contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** `list(iam.Role)`

**Returns** A list of Role resources

### `limit(**kwargs)`

Creates an iterable up to a specified amount of Role resources in the collection.

**Request Syntax**

```python
role_iterator = iam.roles.limit(
    count=123
)
```

**Parameters** `count (integer)` – The limit to the number of resources in the iterable.

**Return type** `list(iam.Role)`

**Returns** A list of Role resources

### `page_size(**kwargs)`

Creates an iterable of all Role resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
role_iterator = iam.roles.page_size(
    count=123
)
```

**Parameters** `count (integer)` – The number of items returned by each service call

**Return type** `list(iam.Role)`

**Returns** A list of Role resources

### `saml_providers`

**all()**

Creates an iterable of all SamlProvider resources in the collection.

**Request Syntax**

```python
saml_provider_iterator = iam.saml_providers.all()
```

**Return type** `list(iam.SamlProvider)`

**Returns** A list of SamlProvider resources
filter()
Creates an iterable of all SamlProvider resources in the collection filtered by kwargs passed to
method.

Request Syntax

saml_provider_iterator = iam.saml_providers.filter()

Return type  list(iam.SamlProvider)
Returns  A list of SamlProvider resources

limit(**kwargs)
Creates an iterable up to a specified amount of SamlProvider resources in the collection.

Request Syntax

saml_provider_iterator = iam.saml_providers.limit(
  count=123
)

Parameters  count (integer) – The limit to the number of resources in the iterable.
Return type  list(iam.SamlProvider)
Returns  A list of SamlProvider resources

page_size(**kwargs)
Creates an iterable of all SamlProvider resources in the collection, but limits the number of items
returned by each service call by the specified amount.

Request Syntax

saml_provider_iterator = iam.saml_providers.page_size(
  count=123
)

Parameters  count (integer) – The number of items returned by each service call
Return type  list(iam.SamlProvider)
Returns  A list of SamlProvider resources

server_certificates

all()
Creates an iterable of all ServerCertificate resources in the collection.

Request Syntax

server_certificate_iterator = iam.server_certificates.all()

Return type  list(iam.ServerCertificate)
Returns  A list of ServerCertificate resources

filter(**kwargs)
Creates an iterable of all ServerCertificate resources in the collection filtered by kwargs passed to
method.

Request Syntax
server_certificate_iterator = iam.server_certificates.filter(  
PathPrefix='string',  
Marker='string',  
MaxItems=123  
)

Parameters

- **PathPrefix** *(string)* – The path prefix for filtering the results. For example: `/company/servercerts` would get all server certificates for which the path starts with `/company/servercerts`.

  This parameter is optional. If it is not included, it defaults to a slash (/), listing all server certificates.

- **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

- **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is `true`.

  This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns `true` and Marker contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** `list(iam.ServerCertificate)`

**Returns** A list of ServerCertificate resources

**limit(** **kwargs **)**

Creates an iterable up to a specified amount of ServerCertificate resources in the collection.

**Request Syntax**

```python
server_certificate_iterator = iam.server_certificates.limit(  
            count=123  
)
```

**Parameters**

- **count** *(integer)* – The limit to the number of resources in the iterable.

**Return type** `list(iam.ServerCertificate)`

**Returns** A list of ServerCertificate resources

**page_size(** **kwargs **)**

Creates an iterable of all ServerCertificate resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
server_certificate_iterator = iam.server_certificates.page_size(  
            count=123  
)
```

**Parameters**

- **count** *(integer)* – The number of items returned by each service call

**Return type** `list(iam.ServerCertificate)`

**Returns** A list of ServerCertificate resources
users

all()
Creates an iterable of all User resources in the collection.

Request Syntax

user_iterator = iam.users.all()

Return type  list(iam.User)
Returns  A list of User resources

filter(**kwargs)
Creates an iterable of all User resources in the collection filtered by kwargs passed to method.

Request Syntax

user_iterator = iam.users.filter(
    PathPrefix='string',
    Marker='string',
    MaxItems=123
)

Parameters

- **PathPrefix (string)** – The path prefix for filtering the results. For example: /division_abcd/subdivision_xyz/, which would get all user names whose path starts with /division_abcd/subdivision_xyz/. This parameter is optional. If it is not included, it defaults to a slash (/), listing all user names.
- **Marker (string)** – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.
- **MaxItems (integer)** – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

Return type  list(iam.User)
Returns  A list of User resources

limit(**kwargs)
Creates an iterable up to a specified amount of User resources in the collection.

Request Syntax

user_iterator = iam.users.limit(
    count=123
)

Parameters  count (integer) – The limit to the number of resources in the iterable.
Return type  list(iam.User)
Returns  A list of User resources

**page_size**(**kwargs)
Createss an iterable of all User resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

```python
user_iterator = iam.users.page_size(count=123)
```

Parameters  count (integer) – The number of items returned by each service call

Return type  list(iam.User)
Returns  A list of User resources

**virtual_mfa_devices**

**all**()
Createss an iterable of all VirtualMfaDevice resources in the collection.

Request Syntax

```python
virtual_mfa_device_iterator = iam.virtual_mfa_devices.all()
```

Return type  list(iam.VirtualMfaDevice)
Returns  A list of VirtualMfaDevice resources

**filter**(**kwargs**)
Createss an iterable of all VirtualMfaDevice resources in the collection filtered by kwargs passed to method.

Request Syntax

```python
virtual_mfa_device_iterator = iam.virtual_mfa_devices.filter(
    AssignmentStatus='Assigned'|'Unassigned'|'Any',
    Marker='string',
    MaxItems=123
)
```

Parameters

- **AssignmentStatus** (string) – The status (unassigned or assigned) of the devices to list. If you do not specify an AssignmentStatus, the action defaults to Any which lists both assigned and unassigned virtual MFA devices.
- **Marker** (string) – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.
- **MaxItems** (integer) – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns
true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** list(iam.VirtualMfaDevice)

**Returns** A list of VirtualMfaDevice resources

**limit(****kwargs**)

Creates an iterable up to a specified amount of VirtualMfaDevice resources in the collection.

**Request Syntax**

```python
virtual_mfa_device_iterator = iam.virtual_mfa_devices.limit(
    count=123
)
```

**Parameters**

- **count (integer)** – The limit to the number of resources in the iterable.

**Return type** list(iam.VirtualMfaDevice)

**Returns** A list of VirtualMfaDevice resources

**page_size(****kwargs**)

Creates an iterable of all VirtualMfaDevice resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
virtual_mfa_device_iterator = iam.virtual_mfa_devices.page_size(
    count=123
)
```

**Parameters**

- **count (integer)** – The number of items returned by each service call

**Return type** list(iam.VirtualMfaDevice)

**Returns** A list of VirtualMfaDevice resources

### AccessKey

**class** `IAM.AccessKey(user_name, id)`

A resource representing an AWS Identity and Access Management (IAM) AccessKey:

```python
import boto3

iam = boto3.resource('iam')
access_key = iam.AccessKey('user_name', 'id')
```

**Parameters**

- **user_name (string)** – The AccessKey’s user_name identifier. This **must** be set.
- **id (string)** – The AccessKey’s id identifier. This **must** be set.

These are the resource’s available identifiers:

- `user_name`
- `id`

These are the resource’s available attributes:

- `access_key_id`
- `create_date`
- `status`

These are the resource’s available actions:

- `activate()`
- `deactivate()`
Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide.*

**user_name**

*(string)* The AccessKey’s user_name identifier. This **must** be set.

**id**

*(string)* The AccessKey’s id identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the *Resources Introduction Guide.*

**access_key_id**

*(string)*

The ID for this access key.

**create_date**

*(datetime)*

The date when the access key was created.

**status**

*(string)*

The status of the access key. **Active** means the key is valid for API calls; **Inactive** means it is not.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide.*

**activate()**

Changes the status of the specified access key from Active to Inactive, or vice versa. This action can be used to disable a user’s key as part of a key rotation work flow.

If the **UserName** field is not specified, the **UserName** is determined implicitly based on the AWS access key ID used to sign the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

For information about rotating keys, see Managing Keys and Certificates in the *IAM User Guide.*

**Request Syntax**

```
response = access_key.activate()
```

**Returns**  None

**deactivate()**

Changes the status of the specified access key from Active to Inactive, or vice versa. This action can be used to disable a user’s key as part of a key rotation work flow.

If the **UserName** field is not specified, the **UserName** is determined implicitly based on the AWS access key ID used to sign the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

For information about rotating keys, see Managing Keys and Certificates in the *IAM User Guide.*
Request Syntax

```python
response = access_key.deactivate()
```

**Returns** None

delete()

Deletes the access key associated with the specified user.

If you do not specify a user name, IAM determines the user name implicitly based on the AWS access key ID signing the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

Request Syntax

```python
response = access_key.delete()
```

**Returns** None

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

User()

Creates a User resource:

```python
user = access_key.User()
```

**Return type** IAM.User

**Returns** A User resource

AccessKeyPair

```python
class IAM.AccessKeyPair (user_name, id, secret)
```

A resource representing an AWS Identity and Access Management (IAM) AccessKeyPair:

```python
import boto3

iam = boto3.resource('iam')
access_key_pair = iam.AccessKeyPair('user_name','id','secret')
```

**Parameters**

- **user_name (string)** – The AccessKeyPair’s user_name identifier. This **must** be set.
- **id (string)** – The AccessKeyPair’s id identifier. This **must** be set.
- **secret (string)** – The AccessKeyPair’s secret identifier. This **must** be set.

These are the resource’s available identifiers:

- user_name
- id
- secret

These are the resource’s available attributes:

- access_key_id
- create_date
- secret_access_key
- status

These are the resource’s available actions:
• activate()
  • deactivate()
  • delete()

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

user_name
  (string) The AccessKeyPair’s user_name identifier. This must be set.

id
  (string) The AccessKeyPair’s id identifier. This must be set.

secret
  (string) The AccessKeyPair’s secret identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

access_key_id
  (string)

  The ID for this access key.

create_date
  (datetime)

  The date when the access key was created.

secret_access_key
  (string)

  The secret key used to sign requests.

status
  (string)

  The status of the access key. Active means the key is valid for API calls, while Inactive means it is not.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

activate()

Changes the status of the specified access key from Active to Inactive, or vice versa. This action can be used to disable a user’s key as part of a key rotation work flow.

If the UserName field is not specified, the UserName is determined implicitly based on the AWS access key ID used to sign the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

For information about rotating keys, see Managing Keys and Certificates in the IAM User Guide.

Request Syntax

response = access_key_pair.activate()

Returns None
deactivate()
Changes the status of the specified access key from Active to Inactive, or vice versa. This action can be used to disable a user’s key as part of a key rotation work flow.

If the **UserName** field is not specified, the **UserName** is determined implicitly based on the AWS access key ID used to sign the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

For information about rotating keys, see Managing Keys and Certificates in the *IAM User Guide*.

**Request Syntax**

```python
response = access_key_pair.deactivate()
```

**Returns** None

delete()
Deletes the access key associated with the specified user.

If you do not specify a user name, IAM determines the user name implicitly based on the AWS access key ID signing the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

**Request Syntax**

```python
response = access_key_pair.delete()
```

**Returns** None

AccountPasswordPolicy

class IAM.AccountPasswordPolicy
A resource representing an AWS Identity and Access Management (IAM) AccountPasswordPolicy:

```python
import boto3

iam = boto3.resource('iam')
account_password_policy = iam.AccountPasswordPolicy()
```

These are the resource’s available attributes:
- `allow_users_to_change_password`
- `expire_passwords`
- `hard_expiry`
- `max_password_age`
- `minimum_password_length`
- `password_reuse_prevention`
- `require_lowercase_characters`
- `require_numbers`
- `require_symbols`
- `require_uppercase_characters`

These are the resource’s available actions:
- `delete()`
- `load()`
- `reload()`
- `update()`
Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the Resources Introduction Guide.

`allow_users_to_change_password`

(boolean)

Specifies whether IAM users are allowed to change their own password.

`expire_passwords`

(boolean)

Specifies whether IAM users are required to change their password after a specified number of days.

`hard_expiry`

(boolean)

Specifies whether IAM users are prevented from setting a new password after their password has expired.

`max_password_age`

(integer)

The number of days that an IAM user password is valid.

`minimum_password_length`

(integer)

Minimum length to require for IAM user passwords.

`passwordReusePrevention`

(integer)

Specifies the number of previous passwords that IAM users are prevented from reusing.

`require_lowercase_characters`

(boolean)

Specifies whether to require lowercase characters for IAM user passwords.

`require_numbers`

(boolean)

Specifies whether to require numbers for IAM user passwords.

`require_symbols`

(boolean)

Specifies whether to require symbols for IAM user passwords.

`require_uppercase_characters`

(boolean)

Specifies whether to require uppercase characters for IAM user passwords.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

`delete()`

Deletes the password policy for the AWS account.

Request Syntax
response = account_password_policy.delete()

Returns None

load()
Calls iam.Client.get_account_password_policy() to update the attributes of the AccountPasswordPolicy resource

Request Syntax

account_password_policy.load()

Returns None

reload()
Calls iam.Client.get_account_password_policy() to update the attributes of the AccountPasswordPolicy resource

Request Syntax

account_password_policy.reload()

Returns None

update(**kwargs)
Updates the password policy settings for the AWS account.

Note: This action does not support partial updates. No parameters are required, but if you do not specify a parameter, that parameter’s value reverts to its default value. See the Request Parameters section for each parameter’s default value.

For more information about using a password policy, see Managing an IAM Password Policy in the IAM User Guide.

Request Syntax

response = account_password_policy.update(
    MinimumPasswordLength=123,
    RequireSymbols=True|False,
    RequireNumbers=True|False,
    RequireUppercaseCharacters=True|False,
    RequireLowercaseCharacters=True|False,
    AllowUsersToChangePassword=True|False,
    MaxPasswordAge=123,
    PasswordReusePrevention=123,
    HardExpiry=True|False
)

Parameters

- MinimumPasswordLength (integer) – The minimum number of characters allowed in an IAM user password.
  Default value: 6
- RequireSymbols (boolean) – Specifies whether IAM user passwords must contain at least one of the following non-alphanumeric characters:
  ! @ $ % ^ & * ( ) _ + - = [ ] { } | '
  Default value: false
• **RequireNumbers** *(boolean)* – Specifies whether IAM user passwords must contain at least one numeric character (0 to 9).
  Default value: false

• **RequireUppercaseCharacters** *(boolean)* – Specifies whether IAM user passwords must contain at least one uppercase character from the ISO basic Latin alphabet (A to Z).
  Default value: false

• **RequireLowercaseCharacters** *(boolean)* – Specifies whether IAM user passwords must contain at least one lowercase character from the ISO basic Latin alphabet (a to z).
  Default value: false

• **AllowUsersToChangePassword** *(boolean)* – Allows all IAM users in your account to use the AWS Management Console to change their own passwords. For more information, see Letting IAM Users Change Their Own Passwords in the IAM User Guide.
  Default value: false

• **MaxPasswordAge** *(integer)* – The number of days that an IAM user password is valid. The default value of 0 means IAM user passwords never expire.
  Default value: 0

• **PasswordReusePrevention** *(integer)* – Specifies the number of previous passwords that IAM users are prevented from reusing. The default value of 0 means IAM users are not prevented from reusing previous passwords.
  Default value: 0

• **HardExpire** *(boolean)* – Prevents IAM users from setting a new password after their password has expired.
  Default value: false

**Returns** None

### AccountSummary

**class IAM.AccountSummary**

A resource representing an AWS Identity and Access Management (IAM) AccountSummary:

```python
import boto3

iam = boto3.resource('iam')
account_summary = iam.AccountSummary()
```

These are the resource’s available attributes:

- `summary_map`

**Attributes**

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the Resources Introduction Guide.

`summary_map` *(dict)*

A set of key value pairs containing information about IAM entity usage and IAM quotas.

SummaryMap contains the following keys:
• **AccessKeysPerUserQuota** The maximum number of active access keys allowed for each IAM user.
• **AccountAccessKeysPresent** This value is 1 if the AWS account (root) has an access key, otherwise it is 0.
• **AccountMFAEnabled** This value is 1 if the AWS account (root) has an MFA device assigned, otherwise it is 0.
• **AccountSigningCertificatesPresent** This value is 1 if the AWS account (root) has a signing certificate, otherwise it is 0.
• **AssumeRolePolicySizeQuota** The maximum allowed size for assume role policy documents (trust policies), in non-whitespace characters.
• **AttachedPoliciesPerGroupQuota** The maximum number of managed policies that can be attached to an IAM group.
• **AttachedPoliciesPerRoleQuota** The maximum number of managed policies that can be attached to an IAM role.
• **AttachedPoliciesPerUserQuota** The maximum number of managed policies that can be attached to an IAM user.
• **GroupPolicySizeQuota** The maximum allowed size for the aggregate of all inline policies embedded in an IAM group, in non-whitespace characters.
• **Groups** The number of IAM groups in the AWS account.
• **GroupsPerUserQuota** The maximum number of IAM groups each IAM user can belong to.
• **GroupsQuota** The maximum number of IAM groups allowed in the AWS account.
• **InstanceProfiles** The number of instance profiles in the AWS account.
• **InstanceProfilesQuota** The maximum number of instance profiles allowed in the AWS account.
• **MFADevices** The number of MFA devices in the AWS account, including those assigned and unassigned.
• **MFADevicesInUse** The number of MFA devices that have been assigned to an IAM user or to the AWS account (root).
• **Policies** The number of customer managed policies in the AWS account.
• **PoliciesQuota** The maximum number of customer managed policies allowed in the AWS account.
• **PolicySizeQuota** The maximum allowed size of a customer managed policy, in non-whitespace characters.
• **PolicyVersionsInUse** The number of managed policies that are attached to IAM users, groups, or roles in the AWS account.
• **PolicyVersionsInUseQuota** The maximum number of managed policies that can be attached to IAM users, groups, or roles in the AWS account.
• **Providers** The number of identity providers in the AWS account.
• **RolePolicySizeQuota** The maximum allowed size for the aggregate of all inline policies (access policies, not the trust policy) embedded in an IAM role, in non-whitespace characters.
• **Roles** The number of IAM roles in the AWS account.
• **RolesQuota** The maximum number of IAM roles allowed in the AWS account.
• **ServerCertificates** The number of server certificates in the AWS account.
• **ServerCertificatesQuota** The maximum number of server certificates allowed in the AWS account.
• **SigningCertificatesPerUserQuota** The maximum number of X.509 signing certificates allowed for each IAM user.
• **UserPolicySizeQuota** The maximum allowed size for the aggregate of all inline policies embedded in an IAM user, in non-whitespace characters.
• **Users** The number of IAM users in the AWS account.
• **UsersQuota** The maximum number of IAM users allowed in the AWS account.
• **VersionsPerPolicyQuota** The maximum number of policy versions allowed for each managed policy.
AssumeRolePolicy

class `IAM.AssumeRolePolicy`(*role_name*)

A resource representing an AWS Identity and Access Management (IAM) AssumeRolePolicy:

```python
import boto3

iam = boto3.resource('iam')
assume_role_policy = iam.AssumeRolePolicy('role_name')
```

**Parameters** `role_name` *(string)* – The AssumeRolePolicy’s role_name identifier. This **must** be set.

These are the resource’s available identifiers:

- `role_name`

These are the resource’s available actions:

- `update()`

These are the resource’s available sub-resources:

- `Role()`

**Identifiers**

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide*.

- `role_name` *(string)* The AssumeRolePolicy’s role_name identifier. This **must** be set.

**Actions**

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide*.

- `update(**kwargs)`

  Updates the policy that grants an entity permission to assume a role. For more information about roles, go to Using Roles to Delegate Permissions and Federate Identities.

**Request Syntax**

```python
response = assume_role_policy.update(
    PolicyDocument='string'
)
```

**Parameters** `PolicyDocument` *(string)* – [REQUIRED]

- The policy that grants an entity permission to assume the role.

**Returns** None

**Sub-resources**

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the *Resources Introduction Guide*.

- `Role()`

  Creates a Role resource.

  ```python
  role = assume_role_policy.Role()
  ```

  **Return type** `IAM.Role`

  **Returns** A Role resource
CurrentUser

class IAM.CurrentUser
   A resource representing an AWS Identity and Access Management (IAM) CurrentUser:

   import boto3

   iam = boto3.resource('iam')
   current_user = iam.CurrentUser()

   These are the resource’s available attributes:
   • arn
   • create_date
   • password_last_used
   • path
   • user_id
   • user_name

   These are the resource’s available references:
   • user

   These are the resource’s available collections:
   • access_keys
   • mfa_devices
   • signing_certificates

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

arn
   (string)

   The Amazon Resource Name (ARN) that identifies the user. For more information about ARNs and how to use ARNs in policies, see IAM Identifiers in the Using IAM guide.

create_date
   (datetime)

   The date and time, in ISO 8601 date-time format, when the user was created.

password_last_used
   (datetime)

   The date and time, in ISO 8601 date-time format, when the user’s password was last used to sign in to an AWS website. For a list of AWS websites that capture a user’s last sign-in time, see the Credential Reports topic in the Using IAM guide. If a password is used more than once in a five-minute span, only the first use is returned in this field. This field is null (not present) when:
   • The user does not have a password
   • The password exists but has never been used (at least not since IAM started tracking this information on October 20th, 2014
   • there is no sign-in data associated with the user

   This value is returned only in the GetUser and ListUsers actions.

path
   (string)

   The path to the user. For more information about paths, see IAM Identifiers in the Using IAM guide.

user_id
   (string)
The stable and unique string identifying the user. For more information about IDs, see IAM Identifiers in the *Using IAM* guide.

**user_name**

*(string)*

The friendly name identifying the user.

**References**

References are related resource instances that have a belongs-to relationship. For more information about references refer to the *Resources Introduction Guide*.

**user**

*(User)* The related user if set, otherwise `None`.

**Collections**

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the *Resources Introduction Guide*.

**access_keys**

*all()*

Creates an iterable of all AccessKey resources in the collection.

**Request Syntax**

```python
access_key_iterator = current_user.access_keys.all()
```

**Return type** list(iam.AccessKey)

**Returns** A list of AccessKey resources

*filter(**kwargs)**

Creates an iterable of all AccessKey resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
access_key_iterator = current_user.access_keys.filter(
    UserName='string',
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **UserName (string)** – The name of the user.
- **Marker (string)** – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.
- **MaxItems (integer)** – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is `true`.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns `true` and Marker contains a value to include in the subsequent call that tells the service where to continue from.
Return type  list(iam.AccessKey)
Returns  A list of AccessKey resources

**limit(**kwargs)**

Creates an iterable up to a specified amount of AccessKey resources in the collection.

Request Syntax

```python
access_key_iterator = current_user.access_keys.limit(
    count=123
)
```

*Parameters*

- **count** (integer) – The limit to the number of resources in the iterable.

*Return type*  list(iam.AccessKey)
*Returns*  A list of AccessKey resources

**page_size(**kwargs)**

Creates an iterable of all AccessKey resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

```python
access_key_iterator = current_user.access_keys.page_size(
    count=123
)
```

*Parameters*

- **count** (integer) – The number of items returned by each service call

*Return type*  list(iam.AccessKey)
*Returns*  A list of AccessKey resources

**mfa_devices**

**all()**

Creates an iterable of all MfaDevice resources in the collection.

Request Syntax

```python
mfa_device_iterator = current_user.mfa_devices.all()
```

*Return type*  list(iam.MfaDevice)
*Returns*  A list of MfaDevice resources

**filter(**kwargs)**

Creates an iterable of all MfaDevice resources in the collection filtered by kwargs passed to method.

Request Syntax

```python
mfa_device_iterator = current_user.mfa_devices.filter(
    UserName='string',
    Marker='string',
    MaxItems=123
)
```

*Parameters*

- **UserName** (string) – The name of the user whose MFA devices you want to list.
• **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

• **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is `true`.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns `true` and Marker contains a value to include in the subsequent call that tells the service where to continue from.

**Return type**  `list(iam.MfaDevice)`

**Returns**  A list of MfaDevice resources

**limit(** **kwargs)**

Creates an iterable up to a specified amount of MfaDevice resources in the collection.

**Request Syntax**

```python
mfa_device_iterator = current_user.mfa_devices.limit(count=123)
```

**Parameters**  `count` *(integer)* – The limit to the number of resources in the iterable.

**Return type**  `list(iam.MfaDevice)`

**Returns**  A list of MfaDevice resources

**page_size(** **kwargs)**

Creates an iterable of all MfaDevice resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
mfa_device_iterator = current_user.mfa_devices.page_size(count=123)
```

**Parameters**  `count` *(integer)* – The number of items returned by each service call

**Return type**  `list(iam.MfaDevice)`

**Returns**  A list of MfaDevice resources

**signing_certificates**

**all()**

Creates an iterable of all SigningCertificate resources in the collection.

**Request Syntax**

```python
signing_certificate_iterator = current_user.signing_certificates.all()
```

**Return type**  `list(iam.SigningCertificate)`

**Returns**  A list of SigningCertificate resources
**filter(**kwargs\)**

Creates an iterable of all SigningCertificate resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
signing_certificate_iterator = current_user.signing_certificates.filter(
    UserName='string',
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **UserName (string)** – The name of the user.
- **Marker (string)** – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.
- **MaxItems (integer)** – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is `true`.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns `true` and Marker contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** list(iam.SigningCertificate)

**Returns** A list of SigningCertificate resources

**limit(**kwargs\)**

Creates an iterable up to a specified amount of SigningCertificate resources in the collection.

**Request Syntax**

```python
signing_certificate_iterator = current_user.signing_certificates.limit(
    count=123
)
```

**Parameters**  
**count (integer)** – The limit to the number of resources in the iterable.

**Return type** list(iam.SigningCertificate)

**Returns** A list of SigningCertificate resources

**page_size(**kwargs\)**

Creates an iterable of all SigningCertificate resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
signing_certificate_iterator = current_user.signing_certificates.page_size(
    count=123
)
```

**Parameters**  
**count (integer)** – The number of items returned by each service call

**Return type** list(iam.SigningCertificate)

**Returns** A list of SigningCertificate resources
Group

class IAM.Group(name)

A resource representing an AWS Identity and Access Management (IAM) Group:

```python
import boto3

iam = boto3.resource('iam')
group = iam.Group('name')
```

Parameters name (string) – The Group’s name identifier. This **must** be set.

These are the resource’s available identifiers:

- name

These are the resource’s available attributes:

- arn
- create_date
- group_id
- group_name
- path

These are the resource’s available actions:

- add_user()
- attach_policy()
- create()
- create_policy()
- delete()
- detach_policy()
- load()
- reload()
- remove_user()
- update()

These are the resource’s available sub-resources:

- Policy()

These are the resource’s available collections:

- attached_policies
- policies
- users

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide.*

name

*(string)* The Group’s name identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the *Resources Introduction Guide.*

arn

*(string)*

The Amazon Resource Name (ARN) specifying the group. For more information about ARNs and how to use them in policies, see IAM Identifiers in the *Using IAM* guide.

create_date

*(datetime)*
The date and time, in ISO 8601 date-time format, when the group was created.

**group_id**

(string)

The stable and unique string identifying the group. For more information about IDs, see IAM Identifiers in the *Using IAM* guide.

**group_name**

(string)

The friendly name that identifies the group.

**path**

(string)

The path to the group. For more information about paths, see IAM Identifiers in the *Using IAM* guide.

### Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide*.

- **add_user** (**kwargs**)
  
  Adds the specified user to the specified group.

  **Request Syntax**

  ```python
  response = group.add_user(
      UserName='string'
  )
  ```

  **Parameters**  
  
  **UserName** *(string)* – [REQUIRED]

  The name of the user to add.

  **Returns**  
  None

- **attach_policy** (**kwargs**)
  
  Attaches the specified managed policy to the specified group.

  You use this API to attach a managed policy to a group. To embed an inline policy in a group, use PutGroupPolicy.

  For more information about policies, refer to Managed Policies and Inline Policies in the *IAM User Guide*.

  **Request Syntax**

  ```python
  response = group.attach_policy(
      PolicyArn='string'
  )
  ```

  **Parameters**  
  
  **PolicyArn** *(string)* – [REQUIRED]

  The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

  For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the *AWS General Reference*.

  **Returns**  
  None

- **create** (**kwargs**)
  
  Creates a new group.
For information about the number of groups you can create, see Limitations on IAM Entities in the IAM User Guide.

**Request Syntax**

```python
group = group.create(
    Path='string',
)
```

**Parameters**

- **Path (string)** – The path to the group. For more information about paths, see IAM Identifiers in the Using IAM guide.
  
  This parameter is optional. If it is not included, it defaults to a slash (/).

**Return type** iam.Group

**Returns** Group resource

**create_policy(**kwargs)**

Adds (or updates) an inline policy document that is embedded in the specified group.

A user can also have managed policies attached to it. To attach a managed policy to a group, use AttachGroupPolicy. To create a new managed policy, use CreatePolicy. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

For information about limits on the number of inline policies that you can embed in a group, see Limitations on IAM Entities in the IAM User Guide.

**Note:** Because policy documents can be large, you should use POST rather than GET when calling PutGroupPolicy. For general information about using the Query API with IAM, go to Making Query Requests in the Using IAM guide.

**Request Syntax**

```python
group_policy = group.create_policy(
    PolicyName='string',
    PolicyDocument='string'
)
```

**Parameters**

- **PolicyName (string)** – [REQUIRED]
  
  The name of the policy document.

- **PolicyDocument (string)** – [REQUIRED]
  
  The policy document.

**Return type** iam.GroupPolicy

**Returns** GroupPolicy resource

**delete()**

Deletes the specified group. The group must not contain any users or have any attached policies.

**Request Syntax**

```python
response = group.delete()
```

**Returns** None

**detach_policy(**kwargs)**

Removes the specified managed policy from the specified group.
A group can also have inline policies embedded with it. To delete an inline policy, use the `DeleteGroupPolicy` API. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

**Request Syntax**

```python
response = group.detach_policy(
    PolicyArn='string'
)
```

**Parameters**

- **PolicyArn** *(string)* – **[REQUIRED]**
  
  The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.
  
  For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

**Returns**

None

**load()**

Calls `iam.Client.get_group()` to update the attributes of the Group resource

**Request Syntax**

```python
group.load()
```

**Returns**

None

**reload()**

Calls `iam.Client.get_group()` to update the attributes of the Group resource

**Request Syntax**

```python
group.reload()
```

**Returns**

None

**remove_user(**kwargs**)**

Removes the specified user from the specified group.

**Request Syntax**

```python
response = group.remove_user(
    UserName='string'
)
```

**Parameters**

- **UserName** *(string)* – **[REQUIRED]**
  
  The name of the user to remove.

**Returns**

None

**update(**kwargs**)**

Updates the name and/or the path of the specified group.

**Warning:** You should understand the implications of changing a group’s path or name. For more information, see Renaming Users and Groups in the IAM User Guide.

**Note:** To change a group name the requester must have appropriate permissions on both the source object and the target object. For example, to change Managers to MGRs, the entity making the request must have permission on Managers and MGRs, or must have permission on all (*). For more information about permissions, see Permissions and Policies.
Request Syntax

```python
group = group.update(
    NewPath='string',
    NewGroupName='string'
)
```

**Parameters**

- **NewPath** *(string)* – New path for the group. Only include this if changing the group’s path.
- **NewGroupName** *(string)* – New name for the group. Only include this if changing the group’s name.

**Return type** `iam.Group`

**Returns** Group resource

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the `Resources Introduction Guide`.

**Policy** *(name)*

Creates a GroupPolicy resource:

```python
group_policy = group.Policy('name')
```

**Parameters** **name** *(string)* – The Policy’s name identifier. This **must** be set.

**Return type** `IAM.GroupPolicy`

**Returns** A GroupPolicy resource

Collections

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the `Resources Introduction Guide`.

**attached_policies**

**all()**

Creates an iterable of all Policy resources in the collection.

**Request Syntax**

```python
policy_iterator = group.attached_policies.all()
```

**Return type** `list(iam.Policy)`

**Returns** A list of Policy resources

**filter(****kwargs***)

Creates an iterable of all Policy resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
policy_iterator = group.attached_policies.filter(
    PathPrefix='string',
    Marker='string',
    MaxItems=123
)
```

**Parameters**
• **PathPrefix** *(string)* – The path prefix for filtering the results. This parameter is optional. If it is not included, it defaults to a slash (/), listing all policies.

• **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

• **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is `true`.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns `true` and Marker contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** `list(iam.Policy)`

**Returns** A list of Policy resources

### limit(**kwargs)**

Creates an iterable up to a specified amount of Policy resources in the collection.

**Request Syntax**

```python
policy_iterator = group.attached_policies.limit(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The limit to the number of resources in the iterable.

**Return type** `list(iam.Policy)`

**Returns** A list of Policy resources

### page_size(**kwargs)**

Creates an iterable of all Policy resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
policy_iterator = group.attached_policies.page_size(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The number of items returned by each service call

**Return type** `list(iam.Policy)`

**Returns** A list of Policy resources

### policies

**all()**

Creates an iterable of all GroupPolicy resources in the collection.

**Request Syntax**

```python
group_policy_iterator = group.policies.all()
```

**Return type** `list(iam.GroupPolicy)`

**Returns** A list of GroupPolicy resources
**filter(**kwargs)**

Creates an iterable of all GroupPolicy resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
group_policy_iterator = group.policies.filter(
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **Marker (string)** – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.
- **MaxItems (integer)** – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** list(iam.GroupPolicy)

**Returns** A list of GroupPolicy resources

**limit(**kwargs)**

Creates an iterable up to a specified amount of GroupPolicy resources in the collection.

**Request Syntax**

```python
group_policy_iterator = group.policies.limit(  
    count=123
)
```

**Parameters** count (integer) – The limit to the number of resources in the iterable.

**Return type** list(iam.GroupPolicy)

**Returns** A list of GroupPolicy resources

**page_size(**kwargs)**

Creates an iterable of all GroupPolicy resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
group_policy_iterator = group.policies.page_size(  
    count=123
)
```

**Parameters** count (integer) – The number of items returned by each service call

**Return type** list(iam.GroupPolicy)

**Returns** A list of GroupPolicy resources
all()

Creates an iterable of all User resources in the collection.

Request Syntax

```python
user_iterator = group.users.all()
```

Return type list(iam.User)

Returns A list of User resources

filter(**kwargs)

Creates an iterable of all User resources in the collection filtered by kwargs passed to method.

Request Syntax

```python
user_iterator = group.users.filter(
    Marker='string',
    MaxItems=123
)
```

Parameters

- **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.
- **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is `true`.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns `true` and Marker contains a value to include in the subsequent call that tells the service where to continue from.

Return type list(iam.User)

Returns A list of User resources

limit(**kwargs)

Creates an iterable up to a specified amount of User resources in the collection.

Request Syntax

```python
user_iterator = group.users.limit(
    count=123
)
```

Parameters **count** *(integer)* – The limit to the number of resources in the iterable.

Return type list(iam.User)

Returns A list of User resources

page_size(**kwargs)

Creates an iterable of all User resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax
user_iterator = group.users.page_size(
    count=123
)

Parameters

- `count (integer)` – The number of items returned by each service call

Return type

- `list(iam.User)`

Returns

A list of User resources

**GroupPolicy**

class IAM.GroupPolicy (group_name, name)

A resource representing an AWS Identity and Access Management (IAM) GroupPolicy:

```python
import boto3

iam = boto3.resource('iam')
group_policy = iam.GroupPolicy('group_name','name')
```

Parameters

- `group_name (string)` – The GroupPolicy’s group_name identifier. This **must** be set.
- `name (string)` – The GroupPolicy’s name identifier. This **must** be set.

These are the resource’s available identifiers:

- `group_name`
- `name`

These are the resource’s available attributes:

- `policy_document`
- `policy_name`

These are the resource’s available actions:

- `delete()`
- `load()`
- `put()`
- `reload()`

These are the resource’s available sub-resources:

- `Group()`

Identities

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

- `group_name`
  - `(string)` The GroupPolicy’s group_name identifier. This **must** be set.

- `name`
  - `(string)` The GroupPolicy’s name identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the Resources Introduction Guide.

- `policy_document`
  - `(string)` The policy document.

- `policy_name`
  - `(string)`
The name of the policy.

Actions
Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

delete()
Deletes the specified inline policy that is embedded in the specified group.

A group can also have managed policies attached to it. To detach a managed policy from a group, use DetachGroupPolicy. For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

Request Syntax

response = group_policy.delete()

Returns None

load()
Calls iam.Client.get_group_policy() to update the attributes of the GroupPolicy resource

Request Syntax

group_policy.load()

Returns None

put(**kwargs)
Adds (or updates) an inline policy document that is embedded in the specified group.

A user can also have managed policies attached to it. To attach a managed policy to a group, use AttachGroupPolicy. To create a new managed policy, use CreatePolicy. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

For information about limits on the number of inline policies that you can embed in a group, see Limitations on IAM Entities in the IAM User Guide.

Note: Because policy documents can be large, you should use POST rather than GET when calling PutGroupPolicy. For general information about using the Query API with IAM, go to Making Query Requests in the Using IAM guide.

Request Syntax

response = group_policy.put(
    PolicyDocument='string'
)

Parameters PolicyDocument (string) – [REQUIRED]

The policy document.

Returns None

reload()
Calls iam.Client.get_group_policy() to update the attributes of the GroupPolicy resource

Request Syntax

group_policy.reload()
Returns None

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

Group()

Creates a Group resource:

```
group = group_policy.Group()
```

Return type IAM.Group
Returns A Group resource

InstanceProfile

class IAM.InstanceProfile(name)

A resource representing an AWS Identity and Access Management (IAM) InstanceProfile:

```
import boto3

iam = boto3.resource('iam')
instance_profile = iam.InstanceProfile('name')
```

Parameters name (string) – The InstanceProfile’s name identifier. This must be set.

These are the resource’s available identifiers:

• name

These are the resource’s available attributes:

• arn
• create_date
• instance_profile_id
• instance_profile_name
• path
• roles_attribute

These are the resource’s available references:

• roles

These are the resource’s available actions:

• add_role()
• delete()
• load()
• reload()
• remove_role()

Identifiers

Identifiers are properties of a resource that are set upon instantation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

name

(string) The InstanceProfile’s name identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.
arn
(string)
The Amazon Resource Name (ARN) specifying the instance profile. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.

create_date
(datetime)
The date when the instance profile was created.

instance_profile_id
(string)
The stable and unique string identifying the instance profile. For more information about IDs, see IAM Identifiers in the Using IAM guide.

instance_profile_name
(string)
The name identifying the instance profile.

path
(string)
The path to the instance profile. For more information about paths, see IAM Identifiers in the Using IAM guide.

roles_attribute
(list)
The role associated with the instance profile.

References
References are related resource instances that have a belongs-to relationship. For more information about references refer to the Resources Introduction Guide.

roles
(Role) The related roles if set, otherwise None.

Actions
Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

add_role(**kwargs)
Adds the specified role to the specified instance profile. For more information about roles, go to Working with Roles. For more information about instance profiles, go to About Instance Profiles.

Request Syntax

```python
response = instance_profile.add_role(
    RoleName='string'
)
```

Parameters RoleName (string) – [REQUIRED]
The name of the role to add.

Returns None

delete()
Deletes the specified instance profile. The instance profile must not have an associated role.
Warning: Make sure you do not have any Amazon EC2 instances running with the instance profile you are about to delete. Deleting a role or instance profile that is associated with a running instance will break any applications running on the instance.

For more information about instance profiles, go to About Instance Profiles.

**Request Syntax**

```python
response = instance_profile.delete()
```

**Returns** None

### load()

Calls `iam.Client.get_instance_profile()` to update the attributes of the InstanceProfile resource.

**Request Syntax**

```python
instance_profile.load()
```

**Returns** None

### reload()

Calls `iam.Client.get_instance_profile()` to update the attributes of the InstanceProfile resource.

**Request Syntax**

```python
instance_profile.reload()
```

**Returns** None

### remove_role(**kwargs)**

Removes the specified role from the specified instance profile.

Warning: Make sure you do not have any Amazon EC2 instances running with the role you are about to remove from the instance profile. Removing a role from an instance profile that is associated with a running instance will break any applications running on the instance.

For more information about roles, go to Working with Roles. For more information about instance profiles, go to About Instance Profiles.

**Request Syntax**

```python
response = instance_profile.remove_role(
    RoleName='string'
)
```

**Parameters**

- **RoleName** *(string)* – [REQUIRED]
  
  The name of the role to remove.

**Returns** None
LoginProfile

class IAM.LoginProfile(user_name)
   A resource representing an AWS Identity and Access Management (IAM) LoginProfile:

   import boto3

   iam = boto3.resource('iam')
   login_profile = iam.LoginProfile('user_name')

   Parameters user_name (string) – The LoginProfile’s user_name identifier. This must be set.

   These are the resource’s available identifiers:
      • user_name

   These are the resource’s available attributes:
      • create_date
      • password_reset_required

   These are the resource’s available actions:
      • create()
      • delete()
      • load()
      • reload()
      • update()

   These are the resource’s available sub-resources:
      • User()

   Identifiers

   Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

   user_name
      (string) The LoginProfile’s user_name identifier. This must be set.

   Attributes

   Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

   create_date
      (datetime) The date when the password for the user was created.

   password_reset_required
      (boolean) Specifies whether the user is required to set a new password on next sign-in.

   Actions

   Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

   create (**kwargs)
      Creates a password for the specified user, giving the user the ability to access AWS services through the AWS Management Console. For more information about managing passwords, see Managing Passwords in the Using IAM guide.

   Request Syntax
```python
code
login_profile = login_profile.create(
    Password='string',
    PasswordResetRequired=True|False
)
```

### Parameters

- **Password** *(string)* – [REQUIRED]
  
  The new password for the user.

- **PasswordResetRequired** *(boolean)* – Specifies whether the user is required to set a new password on next sign-in.

### Return type

`iam.LoginProfile`

### Returns

LoginProfile resource

#### delete()

Deletes the password for the specified user, which terminates the user’s ability to access AWS services through the AWS Management Console.

**Warning:** Deleting a user’s password does not prevent a user from accessing IAM through the command line interface or the API. To prevent all user access you must also either make the access key inactive or delete it. For more information about making keys inactive or deleting them, see `UpdateAccessKey` and `DeleteAccessKey`.

#### Request Syntax

```python
code
response = login_profile.delete()
```

### Returns

None

#### load()

Calls `iam.Client.get_login_profile()` to update the attributes of the LoginProfile resource

#### Request Syntax

```python
code
login_profile.load()
```

### Returns

None

#### reload()

Calls `iam.Client.get_login_profile()` to update the attributes of the LoginProfile resource

#### Request Syntax

```python
code
login_profile.reload()
```

### Returns

None

#### update(**kwargs)

Changes the password for the specified user.

Users can change their own passwords by calling `ChangePassword`. For more information about modifying passwords, see `Managing Passwords` in the IAM User Guide.

#### Request Syntax

3.1. Services  2923
response = login_profile.update(
    Password='string',
    PasswordResetRequired=True|False
)

Parameters

- **Password** *(string)* – The new password for the specified user.
- **PasswordResetRequired** *(boolean)* – Require the specified user to set a new password on next sign-in.

Returns None

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the *Resources Introduction Guide*.

**User()**

Creates a User resource:

```python
user = login_profile.User()
```

Return type **IAM.User**

Returns A User resource

**MfaDevice**

class IAM.MfaDevice *(user_name, serial_number)*

A resource representing an AWS Identity and Access Management (IAM) MfaDevice:

```python
import boto3

iam = boto3.resource('iam')
mfa_device = iam.MfaDevice('user_name','serial_number')
```

Parameters

- **user_name** *(string)* – The MfaDevice’s user_name identifier. This **must** be set.
- **serial_number** *(string)* – The MfaDevice’s serial_number identifier. This **must** be set.

These are the resource’s available identifiers:

- **user_name**
- **serial_number**

These are the resource’s available attributes:

- **enable_date**

These are the resource’s available actions:

- **associate()**
- **disassociate()**
- **resync()**

These are the resource’s available sub-resources:

- **User()**

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide*.

**user_name** *(string)* The MfaDevice’s user_name identifier. This **must** be set.
**serial_number**

*(string)* The MfaDevice's serial_number identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the *Resources Introduction Guide*.

**enable_date**

*(datetime)*

The date when the MFA device was enabled for the user.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide*.

**associate** (**kwargs**)

Enables the specified MFA device and associates it with the specified user name. When enabled, the MFA device is required for every subsequent login by the user name associated with the device.

Request Syntax

```python
response = mfa_device.associate(
    AuthenticationCode1='string',
    AuthenticationCode2='string'
)
```

**Parameters**

- **AuthenticationCode1** *(string)* – [REQUIRED]
  - An authentication code emitted by the device.
- **AuthenticationCode2** *(string)* – [REQUIRED]
  - A subsequent authentication code emitted by the device.

**Returns** None

**disassociate()**

Deactivates the specified MFA device and removes it from association with the user name for which it was originally enabled.

For more information about creating and working with virtual MFA devices, go to Using a Virtual MFA Device in the *Using IAM* guide.

Request Syntax

```python
response = mfa_device.disassociate()
```

**Returns** None

**resync(**kwargs**)**

Synchronizes the specified MFA device with AWS servers.

For more information about creating and working with virtual MFA devices, go to Using a Virtual MFA Device in the *Using IAM* guide.

Request Syntax

```python
response = mfa_device.resync(
    AuthenticationCode1='string',
```
AuthenticationCode2='string'
)

Parameters

- **AuthenticationCode1 (string)** – [REQUIRED]
  
  An authentication code emitted by the device.

- **AuthenticationCode2 (string)** – [REQUIRED]
  
  A subsequent authentication code emitted by the device.

Returns  None

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

**User()**

Creates a User resource:

    user = mfa_device.User()

**Return type** IAM.User

**Returns**  A User resource

**Policy**

class IAM.Policy(arn)

A resource representing an AWS Identity and Access Management (IAM) Policy:

    import boto3

    iam = boto3.resource('iam')
    policy = iam.Policy('arn')

**Parameters**  arn (string) – The Policy’s arn identifier. This must be set.

These are the resource’s available identifiers:

- **arn**

These are the resource’s available attributes:

- **attachment_count**
- **create_date**
- **default_version_id**
- **description**
- **is_attachable**
- **path**
- **policy_id**
- **policy_name**
- **update_date**

These are the resource’s available references:

- **default_version**

These are the resource’s available actions:

- **attach_group()**
- **attach_role()**
- **attach_user()**
- **create_version()**
- delete()
- detach_group()
- detach_role()
- detach_user()
- load()
- reload()

These are the resource’s available collections:
- attached_groups
- attached_roles
- attached_users
- versions

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

**arn**

*(string)* The Policy’s arn identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the Resources Introduction Guide.

**attachment_count**

*(integer)*

The number of entities (users, groups, and roles) that the policy is attached to.

**create_date**

*(datetime)*

The date and time, in ISO 8601 date-time format, when the policy was created.

**default_version_id**

*(string)*

The identifier for the version of the policy that is set as the default version.

**description**

*(string)*

A friendly description of the policy.

This element is included in the response to the GetPolicy operation. It is not included in the response to the ListPolicies operation.

**is_attachable**

*(boolean)*

Specifies whether the policy can be attached to an IAM user, group, or role.

**path**

*(string)*

The path to the policy.

For more information about paths, see IAM Identifiers in the Using IAM guide.

**policy_id**

*(string)*

The stable and unique string identifying the policy.
For more information about IDs, see IAM Identifiers in the Using IAM guide.

**policy_name**
(string)

The friendly name (not ARN) identifying the policy.

**update_date**
(datetime)

The date and time, in ISO 8601 date-time format, when the policy was last updated.

When a policy has only one version, this field contains the date and time when the policy was created. When a policy has more than one version, this field contains the date and time when the most recent policy version was created.

References

References are related resource instances that have a belongs-to relationship. For more information about references refer to the Resources Introduction Guide.

**default_version**
(PolicyVersion) The related default_version if set, otherwise None.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

**attach_group**(**kwargs**)

Attaches the specified managed policy to the specified group.

You use this API to attach a managed policy to a group. To embed an inline policy in a group, use PutGroupPolicy.

For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

Request Syntax

```python
response = policy.attach_group(
    GroupName='string',
)
```

**Parameters**

GroupName (string) – [REQUIRED]

The name (friendly name, not ARN) of the group to attach the policy to.

**Returns** None

**attach_role**(**kwargs**)

Attaches the specified managed policy to the specified role.

When you attach a managed policy to a role, the managed policy is used as the role’s access (permissions) policy. You cannot use a managed policy as the role’s trust policy. The role’s trust policy is created at the same time as the role, using CreateRole. You can update a role’s trust policy using UpdateAssumeRolePolicy.

Use this API to attach a managed policy to a role. To embed an inline policy in a role, use PutRolePolicy.

For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

Request Syntax
response = policy.attach_role(
    RoleName='string',
)

Parameters  **RoleName** *(string)*  –  [REQUIRED]

The name (friendly name, not ARN) of the role to attach the policy to.

Returns  None

attach_user(**kwargs)

Attaches the specified managed policy to the specified user.

You use this API to attach a managed policy to a user. To embed an inline policy in a user, use PutUserPolicy.

For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

Request Syntax

response = policy.attach_user(
    UserName='string',
)

Parameters  **UserName** *(string)*  –  [REQUIRED]

The name (friendly name, not ARN) of the user to attach the policy to.

Returns  None

create_version(**kwargs)

Creates a new version of the specified managed policy. To update a managed policy, you create a new policy version. A managed policy can have up to five versions. If the policy has five versions, you must delete an existing version using DeletePolicyVersion before you create a new version.

Optionally, you can set the new version as the policy’s default version. The default version is the operative version; that is, the version that is in effect for the IAM users, groups, and roles that the policy is attached to.

For more information about managed policy versions, see Versioning for Managed Policies in the IAM User Guide.

Request Syntax

policy_version = policy.create_version(
    PolicyDocument='string',
    SetAsDefault=True|False
)

Parameters

-  **PolicyDocument** *(string)*  –  [REQUIRED]

  The policy document.

-  **SetAsDefault** *(boolean)*  –  Specifies whether to set this version as the policy’s default version.

  When this parameter is true, the new policy version becomes the operative version; that is, the version that is in effect for the IAM users, groups, and roles that the policy is attached to.
For more information about managed policy versions, see Versioning for Managed Policies in the IAM User Guide.

**Return type** iam.PolicyVersion

**Returns** PolicyVersion resource

`delete()`

Deletes the specified managed policy.

Before you can delete a managed policy, you must detach the policy from all users, groups, and roles that it is attached to, and you must delete all of the policy’s versions. The following steps describe the process for deleting a managed policy:

- Detach the policy from all users, groups, and roles that the policy is attached to, using the DetachUserPolicy, DetachGroupPolicy, or DetachRolePolicy APIs. To list all the users, groups, and roles that a policy is attached to, use ListEntitiesForPolicy.
- Delete all versions of the policy using DeletePolicyVersion. To list the policy’s versions, use ListPolicyVersions. You cannot use DeletePolicyVersion to delete the version that is marked as the default version. You delete the policy’s default version in the next step of the process.
- Delete the policy (this automatically deletes the policy’s default version) using this API.

For information about managed policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

**Request Syntax**

```python
response = policy.delete()
```

**Returns** None

`detach_group(**kwargs)`

Removes the specified managed policy from the specified group.

A group can also have inline policies embedded with it. To delete an inline policy, use the DeleteGroupPolicy API. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

**Request Syntax**

```python
response = policy.detach_group(
    GroupName='string',
)
```

**Parameters**

- **GroupName (string)** – [REQUIRED]
  
  The name (friendly name, not ARN) of the group to detach the policy from.

**Returns** None

`detach_role(**kwargs)`

Removes the specified managed policy from the specified role.

A role can also have inline policies embedded with it. To delete an inline policy, use the DeleteRolePolicy API. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

**Request Syntax**

```python
response = policy.detach_role(
    RoleName='string',
)
```
Parameters  RoleName (string) – [REQUIRED]

The name (friendly name, not ARN) of the role to detach the policy from.

Returns  None
detach_user(**kwargs)
Removes the specified managed policy from the specified user.

A user can also have inline policies embedded with it. To delete an inline policy, use the DeleteUserPolicy API. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

Request Syntax

response = policy.detach_user(
    UserName='string',
)

Parameters  UserName (string) – [REQUIRED]

The name (friendly name, not ARN) of the user to detach the policy from.

Returns  None
load()
Calls iam.Client.get_policy() to update the attributes of the Policy resource

Request Syntax

policy.load()

Returns  None
reload()
Calls iam.Client.get_policy() to update the attributes of the Policy resource

Request Syntax

policy.reload()

Returns  None

Collections
Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the Resources Introduction Guide.

attached_groups

all()
Creates an iterable of all Group resources in the collection.

Request Syntax

group_iterator = policy.attached_groups.all()

Return type  list(iam.Group)

Returns  A list of Group resources
filter(**kwargs)
    Creates an iterable of all Group resources in the collection filtered by kwargs passed to method.

    Request Syntax
    ```python
    group_iterator = policy.attached_groups.filter(
        PathPrefix='string',
        Marker='string',
        MaxItems=123
    )
    ```

    Parameters
    - **PathPrefix** *(string)* – The path prefix for filtering the results. This parameter is optional. If it is not included, it defaults to a slash (/), listing all entities.
    - **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.
    - **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.

    This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

    Return type  list(iam.Group)
    Returns  A list of Group resources

limit(**kwargs)
    Creates an iterable up to a specified amount of Group resources in the collection.

    Request Syntax
    ```python
    group_iterator = policy.attached_groups.limit(
        count=123
    )
    ```

    Parameters  **count** *(integer)* – The limit to the number of resources in the iterable.
    Return type  list(iam.Group)
    Returns  A list of Group resources

page_size(**kwargs)
    Creates an iterable of all Group resources in the collection, but limits the number of items returned by each service call by the specified amount.

    Request Syntax
    ```python
    group_iterator = policy.attached_groups.page_size(
        count=123
    )
    ```

    Parameters  **count** *(integer)* – The number of items returned by each service call
    Return type  list(iam.Group)
    Returns  A list of Group resources
attached_roles

all()
Creates an iterable of all Role resources in the collection.

Request Syntax

role_iterator = policy.attached_roles.all()

Return type  list(iam.Role)
Returns  A list of Role resources

filter(**kwargs)
Creates an iterable of all Role resources in the collection filtered by kwargs passed to method.

Request Syntax

role_iterator = policy.attached_roles.filter(
    PathPrefix='string',
    Marker='string',
    MaxItems=123
)

Parameters

• PathPrefix (string) – The path prefix for filtering the results. This parameter is optional. If it is not included, it defaults to a slash (/), listing all entities.

• Marker (string) – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

• MaxItems (integer) – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

Return type  list(iam.Role)
Returns  A list of Role resources

limit(**kwargs)
Creates an iterable up to a specified amount of Role resources in the collection.

Request Syntax

role_iterator = policy.attached_roles.limit(
    count=123
)

Parameters  count (integer) – The limit to the number of resources in the iterable.

Return type  list(iam.Role)
Returns  A list of Role resources
**page_size(**kwargs)**

Creates an iterable of all Role resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
role_iterator = policy.attached_roles.page_size(
    count=123
)
```

**Parameters**

- `count (integer)` – The number of items returned by each service call

**Return type**

`list(iam.Role)`

**Returns**

A list of Role resources

---

**attached_users**

**all()**

Creates an iterable of all User resources in the collection.

**Request Syntax**

```python
user_iterator = policy.attached_users.all()
```

**Return type**

`list(iam.User)`

**Returns**

A list of User resources

---

**filter(**kwargs)**

Creates an iterable of all User resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
user_iterator = policy.attached_users.filter(
    PathPrefix='string',
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- `PathPrefix (string)` – The path prefix for filtering the results. This parameter is optional. If it is not included, it defaults to a slash (/), listing all entities.
- `Marker (string)` – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the `Marker` element in the response you received to inform the next call about where to start.
- `MaxItems (integer)` – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the `IsTruncated` response element is `true`.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the `IsTruncated` response element returns `true` and `Marker` contains a value to include in the subsequent call that tells the service where to continue from.

**Return type**

`list(iam.User)`

**Returns**

A list of User resources
**limit(** ***kwargs)**

Creates an iterable up to a specified amount of User resources in the collection.

**Request Syntax**

```python
user_iterator = policy.attached_users.limit(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The limit to the number of resources in the iterable.
- **Returns**
  - **list(iam.User)**

**page_size(** ***kwargs)**

Creates an iterable of all User resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
user_iterator = policy.attached_users.page_size(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The number of items returned by each service call
- **Returns**
  - **list(iam.User)**

**versions**

**all()**

Creates an iterable of all PolicyVersion resources in the collection.

**Request Syntax**

```python
policy_version_iterator = policy.versions.all()
```

**Returns**

- **list(iam.PolicyVersion)**

**filter(** ***kwargs)**

Creates an iterable of all PolicyVersion resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
policy_version_iterator = policy.versions.filter(
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.
• **MaxItems** (*integer*) – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the `IsTruncated` response element is `true`.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the `IsTruncated` response element returns `true` and `Marker` contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** `list(iam.PolicyVersion)`
**Returns** A list of `PolicyVersion` resources

**limit** (**kwargs**)
Creates an iterable up to a specified amount of `PolicyVersion` resources in the collection.

**Request Syntax**

```python
policy_version_iterator = policy.versions.limit(
    count=123
)
```

**Parameters**
- **count** (*integer*) – The limit to the number of resources in the iterable.

**Return type** `list(iam.PolicyVersion)`
**Returns** A list of `PolicyVersion` resources

**page_size** (**kwargs**)
Creates an iterable of all `PolicyVersion` resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
policy_version_iterator = policy.versions.page_size(
    count=123
)
```

**Parameters**
- **count** (*integer*) – The number of items returned by each service call

**Return type** `list(iam.PolicyVersion)`
**Returns** A list of `PolicyVersion` resources

**PolicyVersion**

**class** `IAM.PolicyVersion(arn, version_id)`
A resource representing an AWS Identity and Access Management (IAM) `PolicyVersion`:

```python
import boto3

iam = boto3.resource('iam')
policy_version = iam.PolicyVersion('arn','version_id')
```

**Parameters**
- **arn** (*string*) – The `PolicyVersion`’s `arn` identifier. This **must** be set.
- **version_id** (*string*) – The `PolicyVersion`’s `version_id` identifier. This **must** be set.

These are the resource’s available identifiers:
- **arn**
- **version_id**
These are the resource’s available attributes:

- `create_date`
- `document`
- `is_default_version`

These are the resource’s available actions:

- `delete()`
- `load()`
- `reload()`
- `set_as_default()`

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

- `arn`  
  
  *string* The PolicyVersion’s arn identifier. This *must* be set.

- `version_id`
  
  *string* The PolicyVersion’s version_id identifier. This *must* be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the Resources Introduction Guide.

- `create_date`
  
  *datetime*  
  
  The date and time, in ISO 8601 date-time format, when the policy version was created.

- `document`
  
  *string*  
  
  The policy document.

  The policy document is returned in the response to the GetPolicyVersion and GetAccountAuthorizationDetails operations. It is not returned in the response to the CreatePolicyVersion or ListPolicyVersions operations.

- `is_default_version`
  
  *boolean*  
  
  Specifies whether the policy version is set as the policy’s default version.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

- `delete()`  
  
  Deletes the specified version of the specified managed policy.

  You cannot delete the default version of a policy using this API. To delete the default version of a policy, use DeletePolicy. To find out which version of a policy is marked as the default version, use ListPolicyVersions.

  For information about versions for managed policies, refer to Versioning for Managed Policies in the IAM User Guide.

  Request Syntax

  ```python
  response = policy_version.delete()
  ```

3.1. Services
Returns None

load()
Calls `iam.Client.get_policy_version()` to update the attributes of the PolicyVersion resource

Request Syntax

```
policy_version.load()
```

Returns None

reload()
Calls `iam.Client.get_policy_version()` to update the attributes of the PolicyVersion resource

Request Syntax

```
policy_version.reload()
```

Returns None

set_as_default()
Sets the specified version of the specified policy as the policy’s default (operative) version.
This action affects all users, groups, and roles that the policy is attached to. To list the users, groups, and
roles that the policy is attached to, use the ListEntitiesForPolicy API.
For information about managed policies, refer to Managed Policies and Inline Policies in the IAM User
Guide.

Request Syntax

```
response = policy_version.set_as_default()
```

Returns None

Role

```
class IAM.Role(name)
```

A resource representing an AWS Identity and Access Management (IAM) Role:

```
import boto3

iam = boto3.resource('iam')
role = iam.Role('name')
```

Parameters name (string) – The Role’s name identifier. This must be set.

These are the resource’s available identifiers:
* name

These are the resource’s available attributes:
* arn
* assume_role_policy_document
* create_date
* path
* role_id
* role_name

These are the resource’s available actions:
* attach_policy()
These are the resource’s available sub-resources:

• AssumeRolePolicy()
• Policy()

These are the resource’s available collections:

• attached_policies
• instance_profiles
• policies

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

name

(string) The Role’s name identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

arn

(string)

The Amazon Resource Name (ARN) specifying the role. For more information about ARNs and how to use them in policies, see IAM Identifiers in the Using IAM guide.

assume_role_policy_document

(string)

The policy that grants an entity permission to assume the role.

create_date

(datetime)

The date and time, in ISO 8601 date-time format, when the role was created.

path

(string)

The path to the role. For more information about paths, see IAM Identifiers in the Using IAM guide.

role_id

(string)

The stable and unique string identifying the role. For more information about IDs, see IAM Identifiers in the Using IAM guide.

role_name

(string)

The friendly name that identifies the role.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

attach_policy(**kwargs)

Attaches the specified managed policy to the specified role.
When you attach a managed policy to a role, the managed policy is used as the role’s access (permissions) policy. You cannot use a managed policy as the role’s trust policy. The role’s trust policy is created at the same time as the role, using CreateRole. You can update a role’s trust policy using UpdateAssumeRolePolicy.

Use this API to attach a managed policy to a role. To embed an inline policy in a role, use PutRolePolicy. For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

Request Syntax

```python
response = role.attach_policy(
    PolicyArn='string'
)
```

**Parameters**  
**PolicyArn** (*string*) -- [REQUIRED]  
The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.  
For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

**Returns**  
None

`delete()`  
Deletes the specified role. The role must not have any policies attached. For more information about roles, go to Working with Roles.

**Warning:** Make sure you do not have any Amazon EC2 instances running with the role you are about to delete. Deleting a role or instance profile that is associated with a running instance will break any applications running on the instance.

Request Syntax

```python
response = role.delete()
```

**Returns**  
None

`detach_policy(**kwargs)`  
Removes the specified managed policy from the specified role.

A role can also have inline policies embedded with it. To delete an inline policy, use the DeleteRolePolicy API. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

Request Syntax

```python
response = role.detach_policy(
    PolicyArn='string'
)
```

**Parameters**  
**PolicyArn** (*string*) -- [REQUIRED]  
The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.  
For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

**Returns**  
None
load()
   Calls iam.Client.get_role() to update the attributes of the Role resource

Request Syntax

role.load()

Returns None

reload()
   Calls iam.Client.get_role() to update the attributes of the Role resource

Request Syntax

role.reload()

Returns None

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

AssumeRolePolicy()
   Creates a AssumeRolePolicy resource.

   assume_role_policy = role.AssumeRolePolicy()

   Return type IAM.AssumeRolePolicy
   Returns A AssumeRolePolicy resource

Policy(name)
   Creates a RolePolicy resource.

   role_policy = role.Policy('name')

   Parameters name (string) – The Policy’s name identifier. This must be set.
   Return type IAM.RolePolicy
   Returns A RolePolicy resource

Collections

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the Resources Introduction Guide.

attached_policies

all()
   Creates an iterable of all Policy resources in the collection.

Request Syntax

policy_iterator = role.attached_policies.all()

Return type list(iam.Policy)
Returns A list of Policy resources
**filter(**kwargs)**

Creates an iterable of all Policy resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
policy_iterator = role.attached_policies.filter(
    PathPrefix='string',
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **PathPrefix** *(string)* – The path prefix for filtering the results. This parameter is optional. If it is not included, it defaults to a slash (/), listing all policies.
- **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.
- **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is `true`.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns `true` and Marker contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** list(iam.Policy)

**Returns** A list of Policy resources

**limit(**kwargs)**

Creates an iterable up to a specified amount of Policy resources in the collection.

**Request Syntax**

```python
policy_iterator = role.attached_policies.limit(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The limit to the number of resources in the iterable.

**Return type** list(iam.Policy)

**Returns** A list of Policy resources

**page_size(**kwargs)**

Creates an iterable of all Policy resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
policy_iterator = role.attached_policies.page_size(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The number of items returned by each service call

**Return type** list(iam.Policy)

**Returns** A list of Policy resources
instance_profiles

all()
Creates an iterable of all InstanceProfile resources in the collection.

Request Syntax

```
instance_profile_iterator = role.instance_profiles.all()
```

Return type  list(iam.InstanceProfile)
Returns  A list of InstanceProfile resources

filter(**kwargs)
Creates an iterable of all InstanceProfile resources in the collection filtered by kwargs passed to method.

Request Syntax

```
instance_profile_iterator = role.instance_profiles.filter(
    Marker='string',
    MaxItems=123
)
```

Parameters

- **Marker (string)** – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.
- **MaxItems (integer)** – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true. This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

Return type  list(iam.InstanceProfile)
Returns  A list of InstanceProfile resources

limit(**kwargs)
Creates an iterable up to a specified amount of InstanceProfile resources in the collection.

Request Syntax

```
instance_profile_iterator = role.instance_profiles.limit(
    count=123
)
```

Parameters  count (integer) – The limit to the number of resources in the iterable.
Return type  list(iam.InstanceProfile)
Returns  A list of InstanceProfile resources

page_size(**kwargs)
Creates an iterable of all InstanceProfile resources in the collection, but limits the number of items returned by each service call by the specified amount.
Request Syntax

```
instance_profile_iterator = role.instance_profiles.page_size(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The number of items returned by each service call

**Return type** *(list(iam.InstanceProfile))*

**Returns**

A list of InstanceProfile resources

---

### policies

**all()**

Creates an iterable of all RolePolicy resources in the collection.

**Request Syntax**

```
role_policy_iterator = role.policies.all()
```

**Return type** *(list(iam.RolePolicy))*

**Returns**

A list of RolePolicy resources

**filter(****kwargs**)**

Creates an iterable of all RolePolicy resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```
role_policy_iterator = role.policies.filter(
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.
- **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** *(list(iam.RolePolicy))*

**Returns**

A list of RolePolicy resources

**limit(****kwargs**)**

Creates an iterable up to a specified amount of RolePolicy resources in the collection.

**Request Syntax**

```
role_policy_iterator = role.policies.limit(
    count=123
)
```
Parameters  **count** *(integer)* – The limit to the number of resources in the iterable.

Return type  list(iam.RolePolicy)

Returns  A list of RolePolicy resources

page_size(**kwargs)**

Creates an iterable of all RolePolicy resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

```python
role_policy_iterator = role.policies.page_size(
    count=123
)
```

Parameters  **count** *(integer)* – The number of items returned by each service call

Return type  list(iam.RolePolicy)

Returns  A list of RolePolicy resources

---

**RolePolicy**

class IAM.RolePolicy *(role_name, name)*

A resource representing an AWS Identity and Access Management (IAM) RolePolicy:

```python
import boto3

iam = boto3.resource('iam')
role_policy = iam.RolePolicy('role_name', 'name')
```

Parameters

- **role_name** *(string)* – The RolePolicy’s role_name identifier. This must be set.
- **name** *(string)* – The RolePolicy’s name identifier. This must be set.

These are the resource’s available identifiers:

- role_name
- name

These are the resource’s available attributes:

- policy_document
- policy_name

These are the resource’s available actions:

- delete()
- load()
- put()
- reload()

These are the resource’s available sub-resources:

- Role()

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

**role_name** *(string)* The RolePolicy’s role_name identifier. This must be set.

**name** *(string)* The RolePolicy’s name identifier. This must be set.
Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the `Resources Introduction Guide`.

**policy_document**

(string)

The policy document.

**policy_name**

(string)

The name of the policy.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the `Resources Introduction Guide`.

**delete()**

Deletes the specified inline policy that is embedded in the specified role.

A role can also have managed policies attached to it. To detach a managed policy from a role, use `DetachRolePolicy`. For more information about policies, refer to `Managed Policies and Inline Policies` in the `IAM User Guide`.

Request Syntax

```python
response = role_policy.delete()
```

Returns: None

**load()**

Calls `iam.Client.get_role_policy()` to update the attributes of the RolePolicy resource.

Request Syntax

```python
role_policy.load()
```

Returns: None

**put(**kwargs)**

Adds (or updates) an inline policy document that is embedded in the specified role.

When you embed an inline policy in a role, the inline policy is used as the role’s access (permissions) policy. The role’s trust policy is created at the same time as the role, using CreateRole. You can update a role’s trust policy using UpdateAssumeRolePolicy. For more information about roles, go to `Using Roles to Delegate Permissions and Federate Identities`.

A role can also have a managed policy attached to it. To attach a managed policy to a role, use `AttachRolePolicy`. To create a new managed policy, use CreatePolicy. For information about policies, refer to `Managed Policies and Inline Policies` in the `IAM User Guide`.

For information about limits on the number of inline policies that you can embed with a role, see `Limitations on IAM Entities` in the `IAM User Guide`.

**Note:** Because policy documents can be large, you should use POST rather than GET when calling `PutRolePolicy`. For general information about using the Query API with IAM, go to `Making Query Requests` in the `Using IAM` guide.

Request Syntax
response = role_policy.put(  
    PolicyDocument='string'  
)

**Parameters**  
**PolicyDocument** *(string)* – [REQUIRED] 
The policy document. 

**Returns**  
None 

**reload()**  
Calls `iam.Client.get_role_policy()` to update the attributes of the RolePolicy resource 

**Request Syntax**

```
role_policy.reload()
```

**Returns**  
None 

**Sub-resources**

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the *Resources Introduction Guide.*

**Role()**

Creates a Role resource:

```
role = role_policy.Role()
```

**Return type**  
IAM.Role 

**Returns**  
A Role resource 

**SamlProvider**

```
class IAM.SamlProvider(arn) 
A resource representing an AWS Identity and Access Management (IAM) SamlProvider:
```

```
import boto3

iam = boto3.resource('iam')
saml_provider = iam.SamlProvider('arn')
```

**Parameters**  
**arn** *(string)* – The SamlProvider’s arn identifier. This **must** be set. 

These are the resource’s available identifiers:

• *arn* 

These are the resource’s available attributes:

• *create_date*  
• *saml_metadata_document*  
• *valid_until* 

These are the resource’s available actions:

• *delete()*  
• *load()*  
• *reload()*  
• *update()*
Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide.*

**arn**

*(string)* The SamlProvider’s arn identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the **load()** method. For more information about attributes refer to the *Resources Introduction Guide.*

**create_date**

*(datetime)*

The date and time when the SAML provider was created.

**saml_metadata_document**

*(string)*

The XML metadata document that includes information about an identity provider.

**valid_until**

*(datetime)*

The expiration date and time for the SAML provider.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide.*

**delete()**

Deletes a SAML provider.

Deleting the provider does not update any roles that reference the SAML provider as a principal in their trust policies. Any attempt to assume a role that references a SAML provider that has been deleted will fail.

---

**Note:** This operation requires **Signature Version 4**.

**Request Syntax**

```python
response = saml_provider.delete()
```

**Returns** None

**load()**

Calls **iam.Client.get_saml_provider()** to update the attributes of the SamlProvider resource.

**Request Syntax**

```python
saml_provider.load()
```

**Returns** None

**reload()**

Calls **iam.Client.get_saml_provider()** to update the attributes of the SamlProvider resource.

**Request Syntax**
saml_provider.reload()

Returns None

update(**kwargs)
Updates the metadata document for an existing SAML provider.

Note: This operation requires Signature Version 4.

Request Syntax

response = saml_provider.update(
    SAMLMetadataDocument='string',
}

Parameters SAMLMetadataDocument (string) – [REQUIRED]

An XML document generated by an identity provider (IdP) that supports SAML 2.0. The document includes the issuer’s name, expiration information, and keys that can be used to validate the SAML authentication response (assertions) that are received from the IdP. You must generate the metadata document using the identity management software that is used as your organization’s IdP.

Return type dict

Returns

Response Syntax

{
    'SAMLProviderArn': 'string'
}

Response Structure

• (dict) –

Contains the response to a successful UpdateSAMLProvider request.

– SAMLProviderArn (string) –

The Amazon Resource Name (ARN) of the SAML provider that was updated.

ServerCertificate

class IAM.ServerCertificate (name)

A resource representing an AWS Identity and Access Management (IAM) ServerCertificate:

import boto3

iam = boto3.resource('iam')
server_certificate = iam(ServerCertificate('name'))

Parameters name (string) – The ServerCertificate’s name identifier. This must be set.

These are the resource’s available identifiers:

• *name

These are the resource’s available attributes:
Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

name

(string) The ServerCertificate's name identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

certificate_body

(string)

The contents of the public key certificate.

certificate_chain

(string)

The contents of the public key certificate chain.

server_certificate_metadata

(dict)

The meta information of the server certificate, such as its name, path, ID, and ARN.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

delete()

Deletes the specified server certificate.

Warning: If you are using a server certificate with Elastic Load Balancing, deleting the certificate could have implications for your application. If Elastic Load Balancing doesn’t detect the deletion of bound certificates, it may continue to use the certificates. This could cause Elastic Load Balancing to stop accepting traffic. We recommend that you remove the reference to the certificate from Elastic Load Balancing before using this command to delete the certificate. For more information, go to DeleteLoadBalancerListeners in the Elastic Load Balancing API Reference.

Request Syntax

response = server_certificate.delete()

Returns None

load()

Calls iam.Client.get_server_certificate() to update the attributes of the ServerCertificate resource.
Request Syntax

```
server_certificate.load()
```

Returns None

```
reload()
```
Calls `iam.Client.get_server_certificate()` to update the attributes of the ServerCertificate resource.

Request Syntax

```
server_certificate.reload()
```

Returns None

```
update(**kwargs)
```
Updates the name and/or the path of the specified server certificate.

**Warning:** You should understand the implications of changing a server certificate’s path or name. For more information, see Managing Server Certificates in the IAM User Guide.

**Note:** To change a server certificate name the requester must have appropriate permissions on both the source object and the target object. For example, to change the name from ProductionCert to ProdCert, the entity making the request must have permission on ProductionCert and ProdCert, or must have permission on all (*). For more information about permissions, see Permissions and Policies.

Request Syntax

```
server_certificate = server_certificate.update(
    NewPath='string',
    NewServerCertificateName='string'
)
```

**Parameters**

- **NewPath** *(string)* – The new path for the server certificate. Include this only if you are updating the server certificate’s path.
- **NewServerCertificateName** *(string)* – The new name for the server certificate. Include this only if you are updating the server certificate’s name. The name of the certificate cannot contain any spaces.

**Return type** `iam.ServerCertificate`

**Returns** ServerCertificate resource

---

**SigningCertificate**

```
import boto3

iam = boto3.resource('iam')

signing_certificate = iam.SigningCertificate('user_name','id')
```

**Parameters**

- **user_name** *(string)* – The SigningCertificate’s user_name identifier. This must be set.
• **id** *(string)* – The SigningCertificate’s id identifier. This **must** be set.

These are the resource’s available identifiers:
- `user_name`
- `id`

These are the resource’s available attributes:
- `certificate_body`
- `certificate_id`
- `status`
- `upload_date`

These are the resource’s available actions:
- `activate()`
- `deactivate()`
- `delete()`

These are the resource’s available sub-resources:
- `User()`

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide*.

**user_name** *(string)*

The SigningCertificate’s user_name identifier. This **must** be set.

**id** *(string)*

The SigningCertificate’s id identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the *Resources Introduction Guide*.

**certificate_body** *(string)*

The contents of the signing certificate.

**certificate_id** *(string)*

The ID for the signing certificate.

**status** *(string)*

The status of the signing certificate. **Active** means the key is valid for API calls, while **Inactive** means it is not.

**upload_date** *(datetime)*

The date when the signing certificate was uploaded.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide*.

**activate()**

Changes the status of the specified signing certificate from active to disabled, or vice versa. This action can be used to disable a user’s signing certificate as part of a certificate rotation work flow.
If the `UserName` field is not specified, the `UserName` is determined implicitly based on the AWS access key ID used to sign the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

**Request Syntax**

```python
response = signing_certificate.activate()
```

**Returns** None

**deactivate()**

Changes the status of the specified signing certificate from active to disabled, or vice versa. This action can be used to disable a user’s signing certificate as part of a certificate rotation work flow.

If the `UserName` field is not specified, the `UserName` is determined implicitly based on the AWS access key ID used to sign the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

**Request Syntax**

```python
response = signing_certificate.deactivate()
```

**Returns** None

**delete()**

Deletes the specified signing certificate associated with the specified user.

If you do not specify a user name, IAM determines the user name implicitly based on the AWS access key ID signing the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

**Request Syntax**

```python
response = signing_certificate.delete()
```

**Returns** None

**Sub-resources**

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the [Resources Introduction Guide](#).

**User()**

Creates a User resource:

```python
user = signing_certificate.User()
```

**Return type** `IAM.User`

**Returns** A User resource

**User**

**class** `IAM.User(name)`

A resource representing an AWS Identity and Access Management (IAM) User:

```python
import boto3

iam = boto3.resource('iam')
user = iam.User('name')
```
Parameters name (string) – The User’s name identifier. This must be set.

These are the resource’s available identifiers:
• name

These are the resource’s available attributes:
• arn
  • create_date
  • password_last_used
  • path
  • user_id
  • user_name

These are the resource’s available actions:
• add_group()
• attach_policy()
• create()
• create_access_key_pair()
• create_login_profile()
• create_policy()
• delete()
• detach_policy()
• enable_mfa()
• load()
• reload()
• remove_group()
• update()

These are the resource’s available sub-resources:
• AccessKey()
• LoginProfile()
• MfaDevice()
• Policy()
• SigningCertificate()

These are the resource’s available collections:
• access_keys
• attached_policies
• groups
• mfa_devices
• policies
• signing_certificates

Identifiers
Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

name
(string) The User’s name identifier. This must be set.

Attributes
Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

arn
(string)

The Amazon Resource Name (ARN) that identifies the user. For more information about ARNs and how to use ARNs in policies, see IAM Identifiers in the Using IAM guide.
create_date
    (datetime)
    The date and time, in ISO 8601 date-time format, when the user was created.

password_last_used
    (datetime)
    The date and time, in ISO 8601 date-time format, when the user’s password was last used to sign in to an AWS website. For a list of AWS websites that capture a user's last sign-in time, see the Credential Reports topic in the Using IAM guide. If a password is used more than once in a five-minute span, only the first use is returned in this field. This field is null (not present) when:
    • The user does not have a password
    • The password exists but has never been used (at least not since IAM started tracking this information on October 20th, 2014
    • there is no sign-in data associated with the user
    This value is returned only in the GetUser and ListUsers actions.

path
    (string)
    The path to the user. For more information about paths, see IAM Identifiers in the Using IAM guide.

user_id
    (string)
    The stable and unique string identifying the user. For more information about IDs, see IAM Identifiers in the Using IAM guide.

user_name
    (string)
    The friendly name identifying the user.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

add_group (**kwargs)
    Adds the specified user to the specified group.

    Request Syntax

    response = user.add_group(
        GroupName='string',
    )

    Parameters  GroupName (string) – [REQUIRED]
        The name of the group to update.

    Returns  None

attach_policy (**kwargs)
    Attaches the specified managed policy to the specified user.

    You use this API to attach a managed policy to a user. To embed an inline policy in a user, use PutUserPolicy.

    For more information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.
**Response Syntax**

```python
response = user.attach_policy(
    PolicyArn='string'
)
```

**Parameters**  
**PolicyArn** *(string)* – [REQUIRED]

The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

**Returns**  
None

---

**create(** **kwargs**)**

Creates a new user for your AWS account.

For information about limitations on the number of users you can create, see Limitations on IAM Entities in the IAM User Guide.

**Request Syntax**

```python
user = user.create(
    Path='string',
)
```

**Parameters**  
**Path** *(string)* – The path for the user name. For more information about paths, see IAM Identifiers in the Using IAM guide.

This parameter is optional. If it is not included, it defaults to a slash (/).

**Return type**  
iam.User

**Returns**  
User resource

---

**create_access_key_pair()**

Creates a new AWS secret access key and corresponding AWS access key ID for the specified user. The default status for new keys is Active.

If you do not specify a user name, IAM determines the user name implicitly based on the AWS access key ID signing the request. Because this action works for access keys under the AWS account, you can use this action to manage root credentials even if the AWS account has no associated users.

For information about limits on the number of keys you can create, see Limitations on IAM Entities in the IAM User Guide.

**Warning:** To ensure the security of your AWS account, the secret access key is accessible only during key and user creation. You must save the key (for example, in a text file) if you want to be able to access it again. If a secret key is lost, you can delete the access keys for the associated user and then create new keys.

**Request Syntax**

```python
access_key_pair = user.create_access_key_pair()
```

**Return type**  
iam.AccessKeyPair

**Returns**  
AccessKeyPair resource

---

**create_login_profile(** **kwargs**)**

Creates a password for the specified user, giving the user the ability to access AWS services through the
AWS Management Console. For more information about managing passwords, see Managing Passwords in the Using IAM guide.

**Request Syntax**

```python
login_profile = user.create_login_profile(
  Password='string',
  PasswordResetRequired=True|False
)
```

**Parameters**

- **Password** *(string)* – [REQUIRED]
  The new password for the user.
- **PasswordResetRequired** *(boolean)* – Specifies whether the user is required to set a new password on next sign-in.

**Return type** `iam.LoginProfile`

**Returns** LoginProfile resource

**create_policy(**kwargs)**

Adds (or updates) an inline policy document that is embedded in the specified user.

A user can also have a managed policy attached to it. To attach a managed policy to a user, use AttachUserPolicy. To create a new managed policy, use CreatePolicy. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

For information about limits on the number of inline policies that you can embed in a user, see Limitations on IAM Entities in the IAM User Guide.

**Note:** Because policy documents can be large, you should use POST rather than GET when calling PutUserPolicy. For general information about using the Query API with IAM, go to Making Query Requests in the Using IAM guide.

**Request Syntax**

```python
user_policy = user.create_policy(
  PolicyName='string',
  PolicyDocument='string'
)
```

**Parameters**

- **PolicyName** *(string)* – [REQUIRED]
  The name of the policy document.
- **PolicyDocument** *(string)* – [REQUIRED]
  The policy document.

**Return type** `iam.UserPolicy`

**Returns** UserPolicy resource

**delete()**

Deletes the specified user. The user must not belong to any groups, have any keys or signing certificates, or have any attached policies.

**Request Syntax**

```python
response = user.delete()
```

**Returns** None
**detach_policy(**kwargs)**

Removes the specified managed policy from the specified user.

A user can also have inline policies embedded with it. To delete an inline policy, use the DeleteUserPolicy API. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

**Request Syntax**

```python
response = user.detach_policy(
    PolicyArn='string'
)
```

**Parameters**

- **PolicyArn** *(string)* – [REQUIRED]
  
  The Amazon Resource Name (ARN). ARNs are unique identifiers for AWS resources.

- For more information about ARNs, go to Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS General Reference.

**Returns**

None

**enable_mfa(**kwargs)**

Enables the specified MFA device and associates it with the specified user name. When enabled, the MFA device is required for every subsequent login by the user name associated with the device.

**Request Syntax**

```python
mfa_device = user.enable_mfa(
    SerialNumber='string',
    AuthenticationCode1='string',
    AuthenticationCode2='string'
)
```

**Parameters**

- **SerialNumber** *(string)* – [REQUIRED]
  
  The serial number that uniquely identifies the MFA device. For virtual MFA devices, the serial number is the device ARN.

- **AuthenticationCode1** *(string)* – [REQUIRED]
  
  An authentication code emitted by the device.

- **AuthenticationCode2** *(string)* – [REQUIRED]
  
  A subsequent authentication code emitted by the device.

**Return type**

iam.MfaDevice

**Returns**

MfaDevice resource

**load()**

Calls iam.Client.get_user() to update the attributes of the User resource

**Request Syntax**

```python
user.load()
```

**Returns**

None

**reload()**

Calls iam.Client.get_user() to update the attributes of the User resource

**Request Syntax**
user.reload()

Returns None

**remove_group(**kwargs)
Removes the specified user from the specified group.

Request Syntax

```
response = user.remove_group(
    GroupName='string',
)
```

Parameters GroupName (string) – [REQUIRED]
The name of the group to update.

Returns None

**update(**kwargs)
Updates the name and/or the path of the specified user.

**Warning:** You should understand the implications of changing a user’s path or name. For more information, see Renaming Users and Groups in the IAM User Guide.

**Note:** To change a user name the requester must have appropriate permissions on both the source object and the target object. For example, to change Bob to Robert, the entity making the request must have permission on Bob and Robert, or must have permission on all (*). For more information about permissions, see Permissions and Policies.

Request Syntax

```
user = user.update(
    NewPath='string',
    NewUserName='string'
)
```

Parameters

- **NewPath** (string) – New path for the user. Include this parameter only if you’re changing the user’s path.
- **NewUserName** (string) – New name for the user. Include this parameter only if you’re changing the user’s name.

Return type `iam.User`

Returns User resource

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

**AccessKey** (**id**)
Creates a AccessKey resource:

```
access_key = user.AccessKey('id')
```

Parameters id (string) – The AccessKey’s id identifier. This must be set.

Return type `IAM.AccessKey`

---

3.1. Services 2959
Returns A AccessKey resource

LoginProfile()
Creates a LoginProfile resource.

    login_profile = user.LoginProfile()

    Return type IAM.LoginProfile
    Returns A LoginProfile resource

MfaDevice(serial_number)
Creates a MfaDevice resource.

    mfa_device = user.MfaDevice('serial_number')

    Parameters serial_number (string) – The MfaDevice’s serial_number identifier. This must be set.
    Return type IAM.MfaDevice
    Returns A MfaDevice resource

Policy(name)
Creates a UserPolicy resource.

    user_policy = user.Policy('name')

    Parameters name (string) – The Policy’s name identifier. This must be set.
    Return type IAM.UserPolicy
    Returns A UserPolicy resource

SigningCertificate(id)
Creates a SigningCertificate resource.

    signing_certificate = user.SigningCertificate('id')

    Parameters id (string) – The SigningCertificate’s id identifier. This must be set.
    Return type IAM.SigningCertificate
    Returns A SigningCertificate resource

Collections
Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the Resources Introduction Guide.

access_keys

all()
Creates an iterable of all AccessKey resources in the collection.

    Request Syntax

    access_key_iterator = user.access_keys.all()

    Return type list(iam.AccessKey)
    Returns A list of AccessKey resources

filter(**kwargs)
Creates an iterable of all AccessKey resources in the collection filtered by kwargs passed to method.

    Request Syntax
access_key_iterator = user.access_keys.filter(
    Marker='string',
    MaxItems=123
)

Parameters

- **Marker (string)** – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

- **MaxItems (integer)** – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

Return type list(iam.AccessKey)

Returns A list of AccessKey resources

**limit(**kwargs**)

Creates an iterable up to a specified amount of AccessKey resources in the collection.

Request Syntax

```python
access_key_iterator = user.access_keys.limit(
    count=123
)
```

Parameters **count (integer)** – The limit to the number of resources in the iterable.

Return type list(iam.AccessKey)

Returns A list of AccessKey resources

**page_size(**kwargs**)

Creates an iterable of all AccessKey resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

```python
access_key_iterator = user.access_keys.page_size(
    count=123
)
```

Parameters **count (integer)** – The number of items returned by each service call

Return type list(iam.AccessKey)

Returns A list of AccessKey resources

**attached_policies**

all()

Creates an iterable of all Policy resources in the collection.

Request Syntax
policy_iterator = user.attached_policies.all()

**Return type**  list(iam.Policy)
**Returns**  A list of Policy resources

**filter(**kwargs)**

Creates an iterable of all Policy resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
policy_iterator = user.attached_policies.filter(
    PathPrefix='string',
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **PathPrefix** *(string)* – The path prefix for filtering the results. This parameter is optional. If it is not included, it defaults to a slash (/), listing all policies.
- **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.
- **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is **true**.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns **true** and Marker contains a value to include in the subsequent call that tells the service where to continue from.

**Return type**  list(iam.Policy)
**Returns**  A list of Policy resources

**limit(**kwargs)**

Creates an iterable up to a specified amount of Policy resources in the collection.

**Request Syntax**

```python
policy_iterator = user.attached_policies.limit(
    count=123
)
```

**Parameters**  **count** *(integer)* – The limit to the number of resources in the iterable.
**Return type**  list(iam.Policy)
**Returns**  A list of Policy resources

**page_size(**kwargs)**

Creates an iterable of all Policy resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**
policy_iterator = user.attached_policies.page_size(
    count=123
)

Parameters **count** (**integer**) – The number of items returned by each service call
Return type **list**(iam.Policy)
Returns A list of Policy resources

**groups**

**all()**
Creates an iterable of all Group resources in the collection.

Request Syntax

```python
group_iterator = user.groups.all()
```

Return type **list**(iam.Group)
Returns A list of Group resources

**filter(****kwargs**))
Creates an iterable of all Group resources in the collection filtered by kwargs passed to method.

Request Syntax

```python
group_iterator = user.groups.filter(
    Marker='string',
    MaxItems=123
)
```

Parameters

- **Marker** (**string**) – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the **Marker** element in the response you received to inform the next call about where to start.
- **MaxItems** (**integer**) – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the **IsTruncated** response element is **true**.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the **IsTruncated** response element returns **true** and **Marker** contains a value to include in the subsequent call that tells the service where to continue from.

Return type **list**(iam.Group)
Returns A list of Group resources

**limit(****kwargs**))
Creates an iterable up to a specified amount of Group resources in the collection.

Request Syntax

```python
group_iterator = user.groups.limit(
    count=123
)
```

Parameters **count** (**integer**) – The limit to the number of resources in the iterable.
Return type  list(iam.Group)
Returns  A list of Group resources

page_size(**kwargs)
Creates an iterable of all Group resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

```python
group_iterator = user.groups.page_size(count=123)
```

Parameters  count (integer) – The number of items returned by each service call

Return type  list(iam.Group)
Returns  A list of Group resources

mfa_devices

all()
Creates an iterable of all MfaDevice resources in the collection.

Request Syntax

```python
mfa_device_iterator = user.mfa_devices.all()
```

Return type  list(iam.MfaDevice)
Returns  A list of MfaDevice resources

filter(**kwargs)
Creates an iterable of all MfaDevice resources in the collection filtered by kwargs passed to method.

Request Syntax

```python
mfa_device_iterator = user.mfa_devices.filter(Marker='string', MaxItems=123)
```

Parameters

- **Marker (string)** – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.
- **MaxItems (integer)** – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

Return type  list(iam.MfaDevice)
Returns  A list of MfaDevice resources
**limit(****kwargs**

Creates an iterable up to a specified amount of MfaDevice resources in the collection.

**Request Syntax**

```python
mfa_device_iterator = user.mfa_devices.limit(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The limit to the number of resources in the iterable.

**Return type**

list(iam.MfaDevice)

**Returns**

A list of MfaDevice resources

**page_size(****kwargs**

Creates an iterable of all MfaDevice resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
mfa_device_iterator = user.mfa_devices.page_size(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The number of items returned by each service call

**Return type**

list(iam.MfaDevice)

**Returns**

A list of MfaDevice resources

**policies**

**all()**

Creates an iterable of all UserPolicy resources in the collection.

**Request Syntax**

```python
user_policy_iterator = user.policies.all()
```

**Return type**

list(iam.UserPolicy)

**Returns**

A list of UserPolicy resources

**filter(****kwargs**

Creates an iterable of all UserPolicy resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
user_policy_iterator = user.policies.filter(
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the Marker element in the response you received to inform the next call about where to start.

- **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the IsTruncated response element is true.
This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the IsTruncated response element returns true and Marker contains a value to include in the subsequent call that tells the service where to continue from.

**Return type** list(iam.UserPolicy)
**Returns** A list of UserPolicy resources

### limit(**kwargs)**

Creates an iterable up to a specified amount of UserPolicy resources in the collection.

**Request Syntax**

```python
user_policy_iterator = user.policies.limit(
    count=123
)
```

**Parameters**
- **count (integer)** – The limit to the number of resources in the iterable.
**Return type** list(iam.UserPolicy)
**Returns** A list of UserPolicy resources

### page_size(**kwargs)**

Creates an iterable of all UserPolicy resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
user_policy_iterator = user.policies.page_size(
    count=123
)
```

**Parameters**
- **count (integer)** – The number of items returned by each service call
**Return type** list(iam.UserPolicy)
**Returns** A list of UserPolicy resources

### signing_certificates

#### all()

Creates an iterable of all SigningCertificate resources in the collection.

**Request Syntax**

```python
signing_certificate_iterator = user.signing_certificates.all()
```

**Return type** list(iam.SigningCertificate)
**Returns** A list of SigningCertificate resources

#### filter(**kwargs)**

Creates an iterable of all SigningCertificate resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
signing_certificate_iterator = user.signing_certificates.filter(
    Marker='string',
    MaxItems=123
)
```

**Parameters**
• **Marker** *(string)* – Use this parameter only when paginating results and only after you receive a response indicating that the results are truncated. Set it to the value of the **Marker** element in the response you received to inform the next call about where to start.

• **MaxItems** *(integer)* – Use this only when paginating results to indicate the maximum number of items you want in the response. If there are additional items beyond the maximum you specify, the **IsTruncated** response element is **true**.

This parameter is optional. If you do not include it, it defaults to 100. Note that IAM might return fewer results, even when there are more results available. If this is the case, the **IsTruncated** response element returns **true** and **Marker** contains a value to include in the subsequent call that tells the service where to continue from.

**Return type**  
list(iam.SigningCertificate)

**Returns**  
A list of SigningCertificate resources

```python
limit(**kwargs)
```

Creates an iterable up to a specified amount of SigningCertificate resources in the collection.

**Request Syntax**

```python
signing_certificate_iterator = user.signing_certificates.limit(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The limit to the number of resources in the iterable.

**Return type**  
list(iam.SigningCertificate)

**Returns**  
A list of SigningCertificate resources

```python
page_size(**kwargs)
```

Creates an iterable of all SigningCertificate resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
signing_certificate_iterator = user.signing_certificates.page_size(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The number of items returned by each service call

**Return type**  
list(iam.SigningCertificate)

**Returns**  
A list of SigningCertificate resources

```python
UserPolicy
```

**class** IAM.UserPolicy *(user_name, name)*

A resource representing an AWS Identity and Access Management (IAM) UserPolicy:

```python
import boto3

iam = boto3.resource('iam')
user_policy = iam.UserPolicy('user_name','name')
```

**Parameters**

- **user_name** *(string)* – The UserPolicy’s user_name identifier. This must be set.
• **name** *(string)* – The UserPolicy’s name identifier. This **must** be set.

These are the resource’s available identifiers:

• `user_name`
• `name`

These are the resource’s available attributes:

• `policy_document`
• `policy_name`

These are the resource’s available actions:

• `delete()`
• `load()`
• `put()`
• `reload()`

These are the resource’s available sub-resources:

• `User()`

**Identifiers**

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide.*

• **user_name** *(string)* The UserPolicy’s user_name identifier. This **must** be set.

• **name** *(string)* The UserPolicy’s name identifier. This **must** be set.

**Attributes**

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the *Resources Introduction Guide.*

• **policy_document** *(string)*
  The policy document.

• **policy_name** *(string)*
  The name of the policy.

**Actions**

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide.*

• **delete()**
  Deletes the specified inline policy that is embedded in the specified user.

  A user can also have managed policies attached to it. To detach a managed policy from a user, use `DetachUserPolicy` . For more information about policies, refer to Managed Policies and Inline Policies in the *IAM User Guide.*

  **Request Syntax**

  ```python
  response = user_policy.delete()
  ```

  **Returns**  None

• **load()**
  Calls `iam.Client.get_user_policy()` to update the attributes of the UserPolicy resource.
Request Syntax

user_policy.load()

Returns None

**put(****kwargs**)

Adds (or updates) an inline policy document that is embedded in the specified user.

A user can also have a managed policy attached to it. To attach a managed policy to a user, use AttachUserPolicy. To create a new managed policy, use CreatePolicy. For information about policies, refer to Managed Policies and Inline Policies in the IAM User Guide.

For information about limits on the number of inline policies that you can embed in a user, see Limitations on IAM Entities in the IAM User Guide.

**Note:** Because policy documents can be large, you should use POST rather than GET when calling PutUserPolicy. For general information about using the Query API with IAM, go to Making Query Requests in the Using IAM guide.

Request Syntax

```python
response = user_policy.put(
    PolicyDocument='string'
)
```

**Parameters**

**PolicyDocument** *(string) – [REQUIRED]*

The policy document.

Returns None

**reload()**

Calls iam.Client.get_user_policy() to update the attributes of the UserPolicy resource.

Request Syntax

```python
user_policy.reload()
```

Returns None

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

**User()**

Creates a User resource.

```python
user = user_policy.User()
```

Return type IAM.User

Returns A User resource

**VirtualMfaDevice**

class IAM.VirtualMfaDevice *(serial_number)*

A resource representing an AWS Identity and Access Management (IAM) VirtualMfaDevice.
import boto3

iam = boto3.resource('iam')
virtual_mfa_device = iam.VirtualMfaDevice('serial_number')

Parameters

serial_number (string) – The VirtualMfaDevice’s serial_number identifier. This must be set.

These are the resource’s available identifiers:

• serial_number

These are the resource’s available attributes:

• base_32_string_seed
• enable_date
• qr_code_png
• user_attribute

These are the resource’s available references:

• user

These are the resource’s available actions:

• delete()

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

serial_number

(string) The VirtualMfaDevice’s serial_number identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

base_32_string_seed

(bytes) The Base32 seed defined as specified in RFC3548. The Base32StringSeed is Base64-encoded.

enable_date

(datetime) The date and time on which the virtual MFA device was enabled.

qr_code_png

(bytes) A QR code PNG image that encodes

\texttt{otpauth://totp/$virtualMFADeviceName@$AccountName?secret=}$

where $\$virtualMFADeviceName$ is one of the create call arguments, $\$AccountName$ is the user name if set (otherwise, the account ID otherwise), and $\$Base32String$ is the seed in Base32 format. The Base32String value is Base64-encoded.

user_attribute

(dict) Contains information about an IAM user entity.

This data type is used as a response element in the following actions:

• CreateUser
• GetUser
• ListUsers
References

References are related resource instances that have a belongs-to relationship. For more information about references refer to the Resources Introduction Guide.

user

(User) The related user if set, otherwise None.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

delete()

Deletes a virtual MFA device.

**Note:** You must deactivate a user’s virtual MFA device before you can delete it. For information about deactivating MFA devices, see DeactivateMFADevice.

Request Syntax

```python
response = virtual_mfa_device.delete()
```

Returns None

ImportExport

---

3.1. Services
can_paginate (operation_name)
Check if an operation can be paginated.

Parameters
operation_name (string) – The operation name. This is the same name as
the method name on the client. For example, if the method name is create_foo,
and you’d normally invoke the operation as client.create_foo(**kwargs),
if the create_foo operation can be paginated, you can use the call
client.get Paginator("create_foo").

Returns
True if the operation can be paginated, False otherwise.

cancel_job (**kwargs)
This operation cancels a specified job. Only the job owner can cancel it. The operation fails if the job has
already started or is complete.

Request Syntax

response = client.cancel_job(
    JobId='string',
    APIVersion='string'
)

Parameters

• JobId (string) – [REQUIRED] A unique identifier which refers to a particular
job.
• APIVersion (string) – Specifies the version of the client tool.

Return type
dict

Returns

Response Syntax

{
    'Success': True|False
}

Response Structure

• (dict) – Output structure for the CancelJob operation.
  • Success (boolean) – Specifies whether (true) or not (false) AWS Import/Export updated your job.

create_job (**kwargs)
This operation initiates the process of scheduling an upload or download of your data. You include in the
request a manifest that describes the data transfer specifics. The response to the request includes a job ID,
which you can use in other operations, a signature that you use to identify your storage device, and the
address where you should ship your storage device.

Request Syntax

response = client.create_job(
    JobType='Import'|'Export',
    Manifest='string',
    ManifestAddendum='string',
    ValidateOnly=True|False,
    APIVersion='string'
)

Parameters

• JobType (string) – [REQUIRED] Specifies whether the job to initiate is an
import or export job.
• Manifest (string) – [REQUIRED] The UTF-8 encoded text of the manifest file.
• **ManifestAddendum** (*string*) – For internal use only.
• **ValidateOnly** (*boolean*) – [REQUIRED] Validate the manifest and parameter values in the request but do not actually create a job.
• **APIVersion** (*string*) – Specifies the version of the client tool.

**Return type**  
**dict**

**Returns**

**Response Syntax**

```json
{
    'JobId': 'string',
    'JobType': 'Import'|'Export',
    'Signature': 'string',
    'SignatureFileContents': 'string',
    'WarningMessage': 'string',
    'ArtifactList': [
        {
            'Description': 'string',
            'URL': 'string'
        },
    ],
}
```

**Response Structure**

- *(dict)* – Output structure for the CreateJob operation.
  - **JobId** (*string*) – A unique identifier which refers to a particular job.
  - **JobType** (*string*) – Specifies whether the job to initiate is an import or export job.
  - **Signature** (*string*) – An encrypted code used to authenticate the request and response, for example, “DV+TpDfx1/TdSE9ktyK9k/bDTVI=”. Only use this value if you want to create the signature file yourself. Generally you should use the SignatureFileContents value.
  - **SignatureFileContents** (*string*) – The actual text of the SIGNATURE file to be written to disk.
  - **WarningMessage** (*string*) – An optional message notifying you of non-fatal issues with the job, such as use of an incompatible Amazon S3 bucket name.
  - **ArtifactList** (*list*) – A collection of artifacts.
    * *(dict)* – A discrete item that contains the description and URL of an artifact (such as a PDF).
      - **Description** (*string*) – The associated description for this object.
      - **URL** (*string*) – The URL for a given Artifact.

**generate_presigned_url** 
*(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

**Parameters**

- **ClientMethod** (*string*) – The client method to presign for
- **Params** (*dict*) – The parameters normally passed to ClientMethod.
- **ExpiresIn** (*int*) – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** (*string*) – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns**  
The presigned url

**get Paginator** 
*(operation_name)*

Create a paginator for an operation.
Parameters **operation_name** *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginated("create_foo")`.

Raises **OperationNotPageableError** Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

Return type **L{botocore.paginate.Paginator}**

Returns A paginator object.

**get_shipping_label**(**kwargs**)

This operation generates a pre-paid UPS shipping label that you will use to ship your device to AWS for processing.

Request Syntax

```python
response = client.get_shipping_label(
    jobIds=[
        'string',
    ],
    name='string',
    company='string',
    phoneNumber='string',
    country='string',
    stateOrProvince='string',
    city='string',
    postalCode='string',
    street1='string',
    street2='string',
    street3='string',
    APIVersion='string'
)
```

Parameters

- **jobIds** *(list)* – [REQUIRED]
  - *(string)* –
- **name** *(string)* – Specifies the name of the person responsible for shipping this package.
- **company** *(string)* – Specifies the name of the company that will ship this package.
- **phoneNumber** *(string)* – Specifies the phone number of the person responsible for shipping this package.
- **country** *(string)* – Specifies the name of your country for the return address.
- **stateOrProvince** *(string)* – Specifies the name of your state or your province for the return address.
- **city** *(string)* – Specifies the name of your city for the return address.
- **postalCode** *(string)* – Specifies the postal code for the return address.
- **street1** *(string)* – Specifies the first part of the street address for the return address, for example 1234 Main Street.
- **street2** *(string)* – Specifies the optional second part of the street address for the return address, for example Suite 100.
- **street3** *(string)* – Specifies the optional third part of the street address for the return address, for example c/o Jane Doe.
- **APIVersion** *(string)* – Specifies the version of the client tool.

Return type **dict**

Returns
Response Syntax

{  
    'ShippingLabelURL': 'string',
    'Warning': 'string'
}

Response Structure

• (dict) –
  – ShippingLabelURL (string) –
  – Warning (string) –

get_status(**kwargs)

This operation returns information about a job, including where the job is in the processing pipeline, the status of the results, and the signature value associated with the job. You can only return information about jobs you own.

Request Syntax

response = client.get_status(
    JobId='string',
    APIVersion='string'
)

Parameters

• JobId (string) – [REQUIRED] A unique identifier which refers to a particular job.
• APIVersion (string) – Specifies the version of the client tool.

Return type  dict

Returns

Response Syntax

{  
    'JobId': 'string',
    'JobType': 'Import'|'Export',
    'LocationCode': 'string',
    'LocationMessage': 'string',
    'ProgressCode': 'string',
    'ProgressMessage': 'string',
    'Carrier': 'string',
    'TrackingNumber': 'string',
    'LogBucket': 'string',
    'LogKey': 'string',
    'ErrorCount': 123,
    'Signature': 'string',
    'SignatureFileContents': 'string',
    'CurrentManifest': 'string',
    'CreationDate': datetime(2015, 1, 1),
    'ArtifactList': [
        {
            'Description': 'string',
            'URL': 'string'
        },
    ]
}

Response Structure
• *(dict) – Output structure for the GetStatus operation.
  – JobId *(string)* – A unique identifier which refers to a particular job.
  – JobType *(string)* – Specifies whether the job to initiate is an import or export job.
  – LocationCode *(string)* – A token representing the location of the storage device, such as “AtAWS”.
  – LocationMessage *(string)* – A more human readable form of the physical location of the storage device.
  – ProgressCode *(string)* – A token representing the state of the job, such as “Started”.
  – ProgressMessage *(string)* – A more human readable form of the job status.
  – Carrier *(string)* – Name of the shipping company. This value is included when the LocationCode is “Returned”.
  – TrackingNumber *(string)* – The shipping tracking number assigned by AWS Import/Export to the storage device when it’s returned to you. We return this value when the LocationCode is “Returned”.
  – LogBucket *(string)* – Amazon S3 bucket for user logs.
  – LogKey *(string)* – The key where the user logs were stored.
  – ErrorCount *(integer)* – Number of errors. We return this value when the ProgressCode is Success or SuccessWithErrors.
  – Signature *(string)* – An encrypted code used to authenticate the request and response, for example, “DV+TpDfx1/TdSE9ktyK9k/bDTVI=”. Only use this value is you want to create the signature file yourself. Generally you should use the SignatureFileContents value.
  – SignatureFileContents *(string)* – An encrypted code used to authenticate the request and response, for example, “DV+TpDfx1/TdSE9ktyK9k/bDTVI=”. Only use this value is you want to create the signature file yourself. Generally you should use the SignatureFileContents value.
  – CurrentManifest *(string)* – The last manifest submitted, which will be used to process the job.
  – CreationDate *(datetime)* – Timestamp of the CreateJob request in ISO8601 date format. For example “2010-03-28T20:27:35Z”.
  – ArtifactList *(list)* – A collection of artifacts.
    • *(dict)* – A discrete item that contains the description and URL of an artifact (such as a PDF).
      • Description *(string)* – The associated description for this object.
      • URL *(string)* – The URL for a given Artifact.

`get_waiter(waiter_name)`

`list_jobs(**kwargs)`

This operation returns the jobs associated with the requester. AWS Import/Export lists the jobs in reverse chronological order based on the date of creation. For example if Job Test1 was created 2009Dec30 and Test2 was created 2010Feb05, the ListJobs operation would return Test2 followed by Test1.

**Request Syntax**

```python
response = client.list_jobs(
    MaxJobs=123,
    Marker='string',
    APIVersion='string'
)
```
Parameters

- **MaxJobs** *(integer)* – Sets the maximum number of jobs returned in the response. If there are additional jobs that were not returned because MaxJobs was exceeded, the response contains IsTruncatedtrue/IsTruncated. To return the additional jobs, see Marker.

- **Marker** *(string)* – Specifies the JOBID to start after when listing the jobs created with your account. AWS Import/Export lists your jobs in reverse chronological order. See MaxJobs.

- **APIVersion** *(string)* – Specifies the version of the client tool.

Return type  **dict**

Returns

Response Syntax

```python
{
    'Jobs': [
        {
            'JobId': 'string',
            'CreationDate': datetime(2015, 1, 1),
            'IsCanceled': True|False,
            'JobType': 'Import'|'Export'
        },
    ],
    'IsTruncated': True|False
}
```

Response Structure

- *(dict)* – Output structure for the ListJobs operation.
  - **Jobs** *(list)* – A list container for Jobs returned by the ListJobs operation.
    - *(dict)* – Representation of a job returned by the ListJobs operation.
      - **JobId** *(string)* – A unique identifier which refers to a particular job.
      - **CreationDate** *(datetime)* – Timestamp of the CreateJob request in ISO8601 date format. For example “2010-03-28T20:27:35Z”.
      - **IsCanceled** *(boolean)* – Indicates whether the job was canceled.
      - **JobType** *(string)* – Specifies whether the job to initiate is an import or export job.
    - **IsTruncated** *(boolean)* – Indicates whether the list of jobs was truncated. If true, then call ListJobs again using the last JobId element as the marker.

**update_job**(**kwargs**)  
You use this operation to change the parameters specified in the original manifest file by supplying a new manifest file. The manifest file attached to this request replaces the original manifest file. You can only use the operation after a CreateJob request but before the data transfer starts and you can only use it on jobs you own.

Request Syntax

```python
response = client.update_job(
    JobId='string',
    Manifest='string',
    JobType='Import'|'Export',
    ValidateOnly=True|False,
    APIVersion='string'
)
```
Parameters

- **JobId** (*string*) – [REQUIRED] A unique identifier which refers to a particular job.
- **JobType** (*string*) – [REQUIRED] Specifies whether the job to initiate is an import or export job.
- **ValidateOnly** (*boolean*) – [REQUIRED] Validate the manifest and parameter values in the request but do not actually create a job.
- **APIVersion** (*string*) – Specifies the version of the client tool.

Return type  dict

Returns

**Response Syntax**

```python
{
    'Success': True|False,
    'WarningMessage': 'string',
    'ArtifactList': [
        {
            'Description': 'string',
            'URL': 'string'
        },
    ],
}
```

**Response Structure**

- *(dict)* – Output structure for the UpdateJob operation.
  - **Success** (*boolean*) – Specifies whether (true) or not (false) AWS Import/Export updated your job.
  - **WarningMessage** (*string*) – An optional message notifying you of non-fatal issues with the job, such as use of an incompatible Amazon S3 bucket name.
  - **ArtifactList** (*list*) – A collection of artifacts.
    - *(dict)* – A discrete item that contains the description and URL of an artifact (such as a PDF).
      - **Description** (*string*) – The associated description for this object.
      - **URL** (*string*) – The URL for a given Artifact.

**Paginators**

The available paginators are:

- **ImportExportPaginator.ListJobs**

```python
class ImportExportPaginator.ListJobs

    paginator = client.get_paginator('list_jobs')
```

**paginate(**)**kwargs**

Creates an iterator that will paginate through responses from `ImportExport.Client.list_jobs()`.

**Request Syntax**
response_iterator = paginator.paginate(
    APIVersion='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **APIVersion** *(string)* – Specifies the version of the client tool.
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* – The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* – The size of each page.
  - **StartingToken** *(string)* – A token to specify where to start paginating. This is the NextToken from a previous response.

Return type **dict**

Returns

Response Syntax

```
{
    'Jobs': [
        {
            'JobId': 'string',
            'CreationDate': datetime(2015, 1, 1),
            'IsCanceled': True|False,
            'JobType': 'Import'|'Export'
        },
        ...
    ],
    'IsTruncated': True|False,
    'NextToken': 'string'
}
```

Response Structure

- **(dict)** – Output structure for the ListJobs operation.
  - **Jobs** *(list)* – A list container for Jobs returned by the ListJobs operation.
    - **(dict)** – Representation of a job returned by the ListJobs operation.
      - **JobId** *(string)* – A unique identifier which refers to a particular job.
      - **CreationDate** *(datetime)* – Timestamp of the CreateJob request in ISO8601 date format. For example “2010-03-28T20:27:35Z”.
      - **IsCanceled** *(boolean)* – Indicates whether the job was canceled.
      - **JobType** *(string)* – Specifies whether the job to initiate is an import or export job.
– **IsTruncated** *(boolean)* – Indicates whether the list of jobs was truncated. If true, then call ListJobs again using the last JobId element as the marker.
– **NextToken** *(string)* –  
   A token to resume pagination.

## Kinesis

**Table of Contents**
- Kinesis
  - Client
  - Paginators
  - Waiters

### Client

class Kinesis.Client
A low-level client representing Amazon Kinesis:

```python
import boto3
client = boto3.client('kinesis')
```

These are the available methods:
- `add_tags_to_stream()`  
- `can_paginate()`  
- `create_stream()`  
- `delete_stream()`  
- `describe_stream()`  
- `generate_presigned_url()`  
- `getaginator()`  
- `get_record()`  
- `get_shard_iterator()`  
- `get_waiter()`  
- `list_streams()`  
- `list_tags_for_stream()`  
- `merge_shards()`  
- `put_record()`  
- `put_records()`  
- `remove_tags_from_stream()`  
- `split_shard()`

`add_tags_to_stream(**kwargs)`  
Adds or updates tags for the specified Amazon Kinesis stream. Each stream can have up to 10 tags.

If tags have already been assigned to the stream, AddTagsToStream overwrites any existing tags that correspond to the specified tag keys.

**Request Syntax**

```python
response = client.add_tags_to_stream(  
    StreamName='string',  
    Tags={
```
Parameters

- **StreamName** *(string)* – [REQUIRED]
  
The name of the stream.

- **Tags** *(dict)* – [REQUIRED]
  
The set of key-value pairs to use to create the tags.
  ```
  - (string)
  * (string)
  ```

Returns

None

### can_paginate *(operation_name)*

Check if an operation can be paginated.

Parameters

- **operation_name** *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

Returns

True if the operation can be paginated, False otherwise.

### create_stream(**kwargs)**

Creates a Amazon Kinesis stream. A stream captures and transports data records that are continuously emitted from different data sources or producers. Scale-out within an Amazon Kinesis stream is explicitly supported by means of shards, which are uniquely identified groups of data records in an Amazon Kinesis stream.

You specify and control the number of shards that a stream is composed of. Each shard can support reads up to 5 transactions per second, up to a maximum data read total of 2 MB per second. Each shard can support writes up to 1,000 records per second, up to a maximum data write total of 1 MB per second. You can add shards to a stream if the amount of data input increases and you can remove shards if the amount of data input decreases.

The stream name identifies the stream. The name is scoped to the AWS account used by the application. It is also scoped by region. That is, two streams in two different accounts can have the same name, and two streams in the same account, but in two different regions, can have the same name.

CreateStream is an asynchronous operation. Upon receiving a CreateStream request, Amazon Kinesis immediately returns and sets the stream status to CREATING. After the stream is created, Amazon Kinesis sets the stream status to ACTIVE. You should perform read and write operations only on an ACTIVE stream.

You receive a LimitExceededException when making a CreateStream request if you try to do one of the following:

- Have more than five streams in the CREATING state at any point in time.
- Create more shards than are authorized for your account.

For the default shard limit for an AWS account, see Amazon Kinesis Limits. If you need to increase this limit, contact AWS Support.

You can use DescribeStream to check the stream status, which is returned in StreamStatus. CreateStream has a limit of 5 transactions per second per account.

### Request Syntax

```python
response = client.create_stream(
    StreamName='string',
    Tags={
        'string': 'string'
    })
```
ShardCount=123
}

**Parameters**

- **StreamName (string)** – [REQUIRED]
  
  A name to identify the stream. The stream name is scoped to the AWS account used by the application that creates the stream. It is also scoped by region. That is, two streams in two different AWS accounts can have the same name, and two streams in the same AWS account, but in two different regions, can have the same name.

- **ShardCount (integer)** – [REQUIRED]
  
  The number of shards that the stream will use. The throughput of the stream is a function of the number of shards; more shards are required for greater provisioned throughput.

**Returns** None

```python
def delete_stream(**kwargs)

Deletes a stream and all its shards and data. You must shut down any applications that are operating on the stream before you delete the stream. If an application attempts to operate on a deleted stream, it will receive the exception `ResourceNotFoundException`.

If the stream is in the `ACTIVE` state, you can delete it. After a `DeleteStream` request, the specified stream is in the `DELETING` state until Amazon Kinesis completes the deletion.

**Note:** Amazon Kinesis might continue to accept data read and write operations, such as `PutRecord`, `PutRecords`, and `GetRecords`, on a stream in the `DELETING` state until the stream deletion is complete.

When you delete a stream, any shards in that stream are also deleted, and any tags are dissociated from the stream.

You can use the `DescribeStream` operation to check the state of the stream, which is returned in `StreamStatus`.

`DeleteStream` has a limit of 5 transactions per second per account.

**Request Syntax**

```python
response = client.delete_stream(
    StreamName='string'
)
```

**Parameters**

- **StreamName (string)** – [REQUIRED]

  The name of the stream to delete.

**Returns** None

```python
def describe_stream(**kwargs)

Describes the specified stream.

The information about the stream includes its current status, its Amazon Resource Name (ARN), and an array of shard objects. For each shard object, there is information about the hash key and sequence number ranges that the shard spans, and the IDs of any earlier shards that played in a role in creating the shard. A sequence number is the identifier associated with every record ingested in the Amazon Kinesis stream. The sequence number is assigned when a record is put into the stream.

You can limit the number of returned shards using the `Limit` parameter. The number of shards in a stream may be too large to return from a single call to `DescribeStream`. You can detect this by using
```
the `HasMoreShards` flag in the returned output. `HasMoreShards` is set to `true` when there is more data available.

DescribeStream is a paginated operation. If there are more shards available, you can request them using the shard ID of the last shard returned. Specify this ID in the `ExclusiveStartShardId` parameter in a subsequent request to DescribeStream.

DescribeStream has a limit of 10 transactions per second per account.

**Request Syntax**

```python
response = client.describe_stream(
    StreamName='string',
    Limit=123,
    ExclusiveStartShardId='string'
)
```

**Parameters**

- **StreamName** (*string*) – [REQUIRED]

  The name of the stream to describe.

- **Limit** (*integer*) – The maximum number of shards to return.

- **ExclusiveStartShardId** (*string*) – The shard ID of the shard to start with.

**Return type** `dict`

**Response Syntax**

```json
{
    'StreamDescription': {
        'StreamName': 'string',
        'StreamARN': 'string',
        'StreamStatus': 'CREATING'|'DELETING'|'ACTIVE'|'UPDATING',
        'Shards': [
            {
                'ShardId': 'string',
                'ParentShardId': 'string',
                'AdjacentParentShardId': 'string',
                'HashKeyRange': {
                    'StartingHashKey': 'string',
                    'EndingHashKey': 'string'
                },
                'SequenceNumberRange': {
                    'StartingSequenceNumber': 'string',
                    'EndingSequenceNumber': 'string'
                }
            },
            
        ],
        'HasMoreShards': True|False
    }
}
```

**Response Structure**

- `(dict)` – Represents the output for `DescribeStream`.
  - **StreamDescription** `(dict)` –

    The current status of the stream, the stream ARN, an array of shard objects that comprise the stream, and states whether there are more shards available.
StreamName (string) –
The name of the stream being described.

StreamARN (string) –
The Amazon Resource Name (ARN) for the stream being described.

StreamStatus (string) –
The current status of the stream being described.

The stream status is one of the following states:

- CREATING - The stream is being created. Amazon Kinesis immediately returns and sets StreamStatus to CREATING.
- DELETING - The stream is being deleted. The specified stream is in the DELETING state until Amazon Kinesis completes the deletion.
- ACTIVE - The stream exists and is ready for read and write operations or deletion. You should perform read and write operations only on an ACTIVE stream.
- UPDATING - Shards in the stream are being merged or split. Read and write operations continue to work while the stream is in the UPDATING state.

Shards (list) –
The shards that comprise the stream.

- (dict) –
  A uniquely identified group of data records in an Amazon Kinesis stream.
- ShardId (string) –
The unique identifier of the shard within the Amazon Kinesis stream.
- ParentShardId (string) –
The shard Id of the shard’s parent.
- AdjacentParentShardId (string) –
The shard Id of the shard adjacent to the shard’s parent.
- HashKeyRange (dict) –
The range of possible hash key values for the shard, which is a set of ordered contiguous positive integers.
- StartingHashKey (string) –
The starting hash key of the hash key range.
- EndingHashKey (string) –
The ending hash key of the hash key range.
- SequenceNumberRange (dict) –
The range of possible sequence numbers for the shard.
- StartingSequenceNumber (string) –
The starting sequence number for the range.
- EndingSequenceNumber (string) –
The ending sequence number for the range. Shards that are in the OPEN state have an ending sequence number of null.
* HasMoreShards (boolean) –

If set to true, more shards in the stream are available to describe.

**generate_presigned_url** *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

**Parameters**

- **ClientMethod** *(string)* – The client method to presign for
- **Params** *(dict)* – The parameters normally passed to ClientMethod.
- **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns** The presigned url

**get Paginator** *(operation_name)*

Create a paginator for an operation.

**Parameters** **operation_name** *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.getPaginator("create_foo").

**Raises** **OperationNotPageableError** Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

**Return type** L{botocore.paginate.Paginator}

**Returns** A paginator object.

**get_records** (**kwargs**)

Gets data records from a shard.

Specify a shard iterator using the ShardIterator parameter. The shard iterator specifies the position in the shard from which you want to start reading data records sequentially. If there are no records available in the portion of the shard that the iterator points to, GetRecords returns an empty list. Note that it might take multiple calls to get to a portion of the shard that contains records.

You can scale by provisioning multiple shards. Your application should have one thread per shard, each reading continuously from its stream. To read from a stream continually, call GetRecords in a loop. Use GetShardIterator to get the shard iterator to specify in the first GetRecords call. GetRecords returns a new shard iterator in NextShardIterator. Specify the shard iterator returned in NextShardIterator in subsequent calls to GetRecords. Note that if the shard has been closed, the shard iterator can’t return more data and GetRecords returns null in NextShardIterator. You can terminate the loop when the shard is closed, or when the shard iterator reaches the record with the sequence number or other attribute that marks it as the last record to process.

Each data record can be up to 1 MB in size, and each shard can read up to 2 MB per second. You can ensure that your calls don’t exceed the maximum supported size or throughput by using the Limit parameter to specify the maximum number of records that GetRecords can return. Consider your average record size when determining this limit.

The size of the data returned by GetRecords will vary depending on the utilization of the shard. The maximum size of data that GetRecords can return is 10 MB. If a call returns this amount of data, subsequent calls made within the next 5 seconds throw ProvisionedThroughputExceeded Exception. If there is insufficient provisioned throughput on the shard, subsequent calls made within the next 1 second throw ProvisionedThroughputExceededException. Note that GetRecords won’t return any data when it throws an exception. For this reason, we recommend that you wait one second between calls to GetRecords; however, it’s possible that the application will get exceptions for longer than 1 second.

To detect whether the application is falling behind in processing, you can use the
Each Amazon Kinesis record includes a value, ApproximateArrivalTimestamp, that is set when an Amazon Kinesis stream successfully receives and stores a record. This is commonly referred to as a server-side timestamp, which is different than a client-side timestamp, where the timestamp is set when a data producer creates or sends the record to a stream. The timestamp has millisecond precision. There are no guarantees about the timestamp accuracy, or that the timestamp is always increasing. For example, records in a shard or across a stream might have timestamps that are out of order.

**Request Syntax**

```python
response = client.get_records(
    ShardIterator='string',
    Limit=123
)
```

**Parameters**

- **ShardIterator** *(string)* – [REQUIRED]

  The position in the shard from which you want to start sequentially reading data records. A shard iterator specifies this position using the sequence number of a data record in the shard.

- **Limit** *(integer)* – The maximum number of records to return. Specify a value of up to 10,000. If you specify a value that is greater than 10,000, GetRecords throws **InvalidOperationException**.

**Response Syntax**

```json
{
    'Records': [
        {
            'SequenceNumber': 'string',
            'ApproximateArrivalTimestamp': datetime(2015, 1, 1),
            'Data': b'bytes',
            'PartitionKey': 'string'
        },
    ],
    'NextShardIterator': 'string',
    'MillisBehindLatest': 123
}
```

**Response Structure**

- **(dict)** – Represents the output for GetRecords.

  - **Records** *(list)* – The data records retrieved from the shard.

    - **(dict)** – The unit of data of the Amazon Kinesis stream, which is composed of a sequence number, a partition key, and a data blob.

      - **SequenceNumber** *(string)* – The unique identifier of the record in the stream.
- **ApproximateArrivalTimestamp** *(datetime)* –
  The approximate time that the record was inserted into the stream.
- **Data** *(bytes)* –
  The data blob. The data in the blob is both opaque and immutable to the Amazon Kinesis service, which does not inspect, interpret, or change the data in the blob in any way. When the data blob (the payload before base64-encoding) is added to the partition key size, the total size must not exceed the maximum record size (1 MB).
- **PartitionKey** *(string)* –
  Identifies which shard in the stream the data record is assigned to.
- **NextShardIterator** *(string)* –
  The next position in the shard from which to start sequentially reading data records. If set to `null`, the shard has been closed and the requested iterator will not return any more data.
- **MillisBehindLatest** *(integer)* –
  The number of milliseconds the GetRecords response is from the tip of the stream, indicating how far behind current time the consumer is. A value of zero indicates record processing is caught up, and there are no new records to process at this moment.

**get_shard_iterator**( **kwargs)**

Gets a shard iterator. A shard iterator expires five minutes after it is returned to the requester.

A shard iterator specifies the position in the shard from which to start reading data records sequentially. A shard iterator specifies this position using the sequence number of a data record in a shard. A sequence number is the identifier associated with every record ingested in the Amazon Kinesis stream. The sequence number is assigned when a record is put into the stream.

You must specify the shard iterator type. For example, you can set the `ShardIteratorType` parameter to read exactly from the position denoted by a specific sequence number by using the `AT_SEQUENCE_NUMBER` shard iterator type, or right after the sequence number by using the `AFTER_SEQUENCE_NUMBER` shard iterator type, using sequence numbers returned by earlier calls to `PutRecord`, `PutRecords`, `GetRecords`, or `DescribeStream`. You can specify the shard iterator type `TRIM_HORIZON` in the request to cause `ShardIterator` to point to the last untrimmed record in the shard in the system, which is the oldest data record in the shard. Or you can point to just after the most recent record in the shard, by using the `LATEST` shard iterator type, so that you always read the most recent data in the shard.

When you repeatedly read from an Amazon Kinesis stream use a `GetShardIterator` request to get the first shard iterator for use in your first `GetRecords` request and then use the shard iterator returned by the `GetRecords` request in `NextShardIterator` for subsequent reads. A new shard iterator is returned by every `GetRecords` request in `NextShardIterator`, which you use in the `ShardIterator` parameter of the next `GetRecords` request.

If a `GetShardIterator` request is made too often, you receive a `ProvisionedThroughputExceededException`. For more information about throughput limits, see `GetRecords`.

If the shard is closed, the iterator can’t return more data, and `GetShardIterator` returns `null` for its `ShardIterator`. A shard can be closed using `SplitShard` or `MergeShards`. `GetShardIterator` has a limit of 5 transactions per second per account per open shard.
Request Syntax

```python
response = client.get_shard_iterator(
    StreamName='string',
    ShardId='string',
    ShardIteratorType='AT_SEQUENCE_NUMBER'|'AFTER_SEQUENCE_NUMBER'|'TRIM_HORIZON'|'LATEST',
    StartingSequenceNumber='string'
)
```

Parameters

- **StreamName** *(string)* – [REQUIRED]
  The name of the stream.

- **ShardId** *(string)* – [REQUIRED]
  The shard ID of the shard to get the iterator for.

- **ShardIteratorType** *(string)* – [REQUIRED]
  Determines how the shard iterator is used to start reading data records from the shard.

  The following are the valid shard iterator types:
  - `AT_SEQUENCE_NUMBER` - Start reading exactly from the position denoted by a specific sequence number.
  - `AFTER_SEQUENCE_NUMBER` - Start reading right after the position denoted by a specific sequence number.
  - `TRIM_HORIZON` - Start reading at the last untrimmed record in the shard in the system, which is the oldest data record in the shard.
  - `LATEST` - Start reading just after the most recent record in the shard, so that you always read the most recent data in the shard.

- **StartingSequenceNumber** *(string)* – The sequence number of the data record in the shard from which to start reading from.

Return type  dict

Returns

Response Syntax

```python
{
    'ShardIterator': 'string'
}
```

Response Structure

- *(dict)* –
  Represents the output for `GetShardIterator`.

  - **ShardIterator** *(string)* –
    The position in the shard from which to start reading data records sequentially. A shard iterator specifies this position using the sequence number of a data record in a shard.

get_waiter(*waiter_name*)

list_streams(**kwargs*)

Lists your streams.

The number of streams may be too large to return from a single call to `ListStreams`. You can limit the number of returned streams using the `Limit` parameter. If you do not specify a value for the `Limit` parameter, Amazon Kinesis uses the default limit, which is currently 10.
You can detect if there are more streams available to list by using the HasMoreStreams flag from the returned output. If there are more streams available, you can request more streams by using the name of the last stream returned by the ListStreams request in the ExclusiveStartStreamName parameter in a subsequent request to ListStreams. The group of stream names returned by the subsequent request is then added to the list. You can continue this process until all the stream names have been collected in the list.

ListStreams has a limit of 5 transactions per second per account.

**Request Syntax**

```python
response = client.list_streams(
    Limit=123,
    ExclusiveStartStreamName='string'
)
```

**Parameters**

- **Limit (integer)** – The maximum number of streams to list.
- **ExclusiveStartStreamName (string)** – The name of the stream to start the list with.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'StreamNames': [
        'string',
    ],
    'HasMoreStreams': True|False
}
```

**Response Structure**

- `(dict)` – Represents the output for ListStreams.
  - **StreamNames (list)** – The names of the streams that are associated with the AWS account making the ListStreams request.
    - *(string)* –
    - **HasMoreStreams (boolean)** –
      If set to `true`, there are more streams available to list.

**list_tags_for_stream(**kwargs)**

Lists the tags for the specified Amazon Kinesis stream.

**Request Syntax**

```python
response = client.list_tags_for_stream(
    StreamName='string',
    ExclusiveStartTagKey='string',
    Limit=123
)
```

**Parameters**

- **StreamName (string)** – [REQUIRED]
  The name of the stream.
• **ExclusiveStartTagKey** *(string)* – The key to use as the starting point for the list of tags. If this parameter is set, `ListTagsForStream` gets all tags that occur after `ExclusiveStartTagKey`.
• **Limit** *(integer)* – The number of tags to return. If this number is less than the total number of tags associated with the stream, `HasMoreTags` is set to `true`. To list additional tags, set `ExclusiveStartTagKey` to the last key in the response.

**Return type** *dict*

**Response Syntax**

```python
{
    'Tags': [
        {
            'Key': 'string',
            'Value': 'string'
        }
    ],
    'HasMoreTags': True|False
}
```

**Response Structure**

• *(dict)* – Represents the output for `ListTagsForStream`.
  • **Tags** *(list)* –
    A list of tags associated with `StreamName`, starting with the first tag after `ExclusiveStartTagKey` and up to the specified `Limit`.
    • *(dict)* – Metadata assigned to the stream, consisting of a key-value pair.
      • **Key** *(string)* –
        A unique identifier for the tag. Maximum length: 128 characters. Valid characters: Unicode letters, digits, white space, _ . / = + - % @
      • **Value** *(string)* –
        An optional string, typically used to describe or define the tag. Maximum length: 256 characters. Valid characters: Unicode letters, digits, white space, _ . / = + - % @
  • **HasMoreTags** *(boolean)* –
    If set to `true`, more tags are available. To request additional tags, set `ExclusiveStartTagKey` to the key of the last tag returned.

**merge_shards(****kwargs**

Merges two adjacent shards in a stream and combines them into a single shard to reduce the stream’s capacity to ingest and transport data. Two shards are considered adjacent if the union of the hash key ranges for the two shards form a contiguous set with no gaps. For example, if you have two shards, one with a hash key range of 276...381 and the other with a hash key range of 382...454, then you could merge these two shards into a single shard that would have a hash key range of 276...454. After the merge, the single child shard receives data for all hash key values covered by the two parent shards.

`MergeShards` is called when there is a need to reduce the overall capacity of a stream because of excess capacity that is not being used. You must specify the shard to be merged and the adjacent shard
for a stream. For more information about merging shards, see Merge Two Shards in the Amazon Kinesis Developer Guide.

If the stream is in the ACTIVE state, you can call MergeShards. If a stream is in the CREATING, UPDATING, or DELETING state, MergeShards returns a ResourceInUseException. If the specified stream does not exist, MergeShards returns a ResourceNotFoundException.

You can use DescribeStream to check the state of the stream, which is returned in StreamStatus.

MergeShards is an asynchronous operation. Upon receiving a MergeShards request, Amazon Kinesis immediately returns a response and sets the StreamStatus to UPDATING. After the operation is completed, Amazon Kinesis sets the StreamStatus to ACTIVE. Read and write operations continue to work while the stream is in the UPDATING state.

You use DescribeStream to determine the shard IDs that are specified in the MergeShards request.

If you try to operate on too many streams in parallel using CreateStream, DeleteStream, MergeShards or SplitShard, you will receive a LimitExceededException.

MergeShards has limit of 5 transactions per second per account.

Request Syntax

```
response = client.merge_shards(
    StreamName='string',
    ShardToMerge='string',
    AdjacentShardToMerge='string'
)
```

Parameters

- **StreamName** (string) – [REQUIRED]
  
    The name of the stream for the merge.

- **ShardToMerge** (string) – [REQUIRED]
  
    The shard ID of the shard to combine with the adjacent shard for the merge.

- **AdjacentShardToMerge** (string) – [REQUIRED]
  
    The shard ID of the adjacent shard for the merge.

Returns None

put_record(**kwargs)

Writes a single data record from a producer into an Amazon Kinesis stream. Call PutRecord to send data from the producer into the Amazon Kinesis stream for real-time ingestion and subsequent processing, one record at a time. Each shard can support writes up to 1,000 records per second, up to a maximum data write total of 1 MB per second.

You must specify the name of the stream that captures, stores, and transports the data; a partition key; and the data blob itself.

The data blob can be any type of data; for example, a segment from a log file, geographic/location data, website clickstream data, and so on.

The partition key is used by Amazon Kinesis to distribute data across shards. Amazon Kinesis segregates the data records that belong to a data stream into multiple shards, using the partition key associated with each data record to determine which shard a given data record belongs to.

Partition keys are Unicode strings, with a maximum length limit of 256 characters for each key. An MD5 hash function is used to map partition keys to 128-bit integer values and to map associated data records to shards using the hash key ranges of the shards. You can override hashing the partition key to determine the shard by explicitly specifying a hash value using the ExplicitHashKey parameter. For more information, see Adding Data to a Stream in the Amazon Kinesis Developer Guide.
PutRecord returns the shard ID of where the data record was placed and the sequence number that was assigned to the data record.

Sequence numbers generally increase over time. To guarantee strictly increasing ordering, use the SequenceNumberForOrdering parameter. For more information, see Adding Data to a Stream in the Amazon Kinesis Developer Guide.

If a PutRecord request cannot be processed because of insufficient provisioned throughput on the shard involved in the request, PutRecord throws ProvisionedThroughputExceededException.

Data records are accessible for only 24 hours from the time that they are added to an Amazon Kinesis stream.

Request Syntax

```python
response = client.put_record(
    StreamName='string',
    Data=b'bytes',
    PartitionKey='string',
    ExplicitHashKey='string',
    SequenceNumberForOrdering='string'
)
```

Parameters

- **StreamName (string)** – [REQUIRED]
  The name of the stream to put the data record into.
- **Data (bytes)** – [REQUIRED]
  The data blob to put into the record, which is base64-encoded when the blob is serialized. When the data blob (the payload before base64-encoding) is added to the partition key size, the total size must not exceed the maximum record size (1 MB).
- **PartitionKey (string)** – [REQUIRED]
  Determines which shard in the stream the data record is assigned to. Partition keys are Unicode strings with a maximum length limit of 256 characters for each key. Amazon Kinesis uses the partition key as input to a hash function that maps the partition key and associated data to a specific shard. Specifically, an MD5 hash function is used to map partition keys to 128-bit integer values and to map associated data records to shards. As a result of this hashing mechanism, all data records with the same partition key will map to the same shard within the stream.
- **ExplicitHashKey (string)** – The hash value used to explicitly determine the shard the data record is assigned to by overriding the partition key hash.
- **SequenceNumberForOrdering (string)** – Guarantees strictly increasing sequence numbers, for puts from the same client and to the same partition key. Usage: set the SequenceNumberForOrdering of record n to the sequence number of record n-1 (as returned in the result when putting record n-1). If this parameter is not set, records will be coarsely ordered based on arrival time.

Return type  dict

Returns

Response Syntax

```python
{
    'ShardId': 'string',
    'SequenceNumber': 'string'
}
```
Response Structure

- *(dict)* –

  Represents the output for `PutRecord`

  – **ShardId** *(string)* –
    The shard ID of the shard where the data record was placed.

  – **SequenceNumber** *(string)* –
    The sequence number identifier that was assigned to the put data record.
    The sequence number for the record is unique across all records in the stream. A sequence number is the identifier associated with every record put into the stream.

**put_records(**

*Write multiple data records from a producer into an Amazon Kinesis stream in a single call (also referred to as a PutRecords request). Use this operation to send data from a data producer into the Amazon Kinesis stream for data ingestion and processing.*

Each `PutRecords` request can support up to 500 records. Each record in the request can be as large as 1 MB, up to a limit of 5 MB for the entire request, including partition keys. Each shard can support writes up to 1,000 records per second, up to a maximum data write total of 1 MB per second.

You must specify the name of the stream that captures, stores, and transports the data; and an array of request `Records`, with each record in the array requiring a partition key and data blob. The record size limit applies to the total size of the partition key and data blob.

The data blob can be any type of data; for example, a segment from a log file, geographic/location data, website clickstream data, and so on.

The partition key is used by Amazon Kinesis as input to a hash function that maps the partition key and associated data to a specific shard. An MD5 hash function is used to map partition keys to 128-bit integer values and to map associated data records to shards. As a result of this hashing mechanism, all data records with the same partition key map to the same shard within the stream. For more information, see Adding Data to a Stream in the Amazon Kinesis Developer Guide.

Each record in the `Records` array may include an optional parameter, `ExplicitHashKey`, which overrides the partition key to shard mapping. This parameter allows a data producer to determine explicitly the shard where the record is stored. For more information, see Adding Multiple Records with PutRecords in the Amazon Kinesis Developer Guide.

The `PutRecords` response includes an array of response `Records`. Each record in the response array directly correlates with a record in the request array using natural ordering, from the top to the bottom of the request and response. The response `Records` array always includes the same number of records as the request array.

The response `Records` array includes both successfully and unsuccessfully processed records. Amazon Kinesis attempts to process all records in each `PutRecords` request. A single record failure does not stop the processing of subsequent records.

A successfully-processed record includes `ShardId` and `SequenceNumber` values. The `ShardId` parameter identifies the shard in the stream where the record is stored. The `SequenceNumber` parameter is an identifier assigned to the put record, unique to all records in the stream.

An unsuccessfully-processed record includes `ErrorCode` and `ErrorMessage` values. `ErrorCode` reflects the type of error and can be one of the following values: `ProvisionedThroughputExceededException` or `InternalFailure`. `ErrorMessage` provides more detailed information about the `ProvisionedThroughputExceededException` exception including the account ID, stream name, and shard ID of the record that was throttled. For more
information about partially successful responses, see Adding Multiple Records with PutRecords in the Amazon Kinesis Developer Guide.

Data records are accessible for only 24 hours from the time that they are added to an Amazon Kinesis stream.

Request Syntax

```python
response = client.put_records(
    Records=[
        {
            'Data': b'bytes',
            'ExplicitHashKey': 'string',
            'PartitionKey': 'string'
        },
    ],
    StreamName='string'
)
```

Parameters

- **Records**(list) – [REQUIRED]
  
The records associated with the request.
  
  - (dict) –
    
    Represents the output for `PutRecords`.
    
    * **Data**(bytes) – [REQUIRED]
      
      The data blob to put into the record, which is base64-encoded when the blob is serialized. When the data blob (the payload before base64-encoding) is added to the partition key size, the total size must not exceed the maximum record size (1 MB).
    
    * **ExplicitHashKey**(string) –
      
      The hash value used to determine explicitly the shard that the data record is assigned to by overriding the partition key hash.
    
    * **PartitionKey**(string) – [REQUIRED]
      
      Determines which shard in the stream the data record is assigned to. Partition keys are Unicode strings with a maximum length limit of 256 characters for each key. Amazon Kinesis uses the partition key as input to a hash function that maps the partition key and associated data to a specific shard. Specifically, an MD5 hash function is used to map partition keys to 128-bit integer values and to map associated data records to shards. As a result of this hashing mechanism, all data records with the same partition key map to the same shard within the stream.
    
- **StreamName**(string) – [REQUIRED]
  
  The stream name associated with the request.

Return type `dict`

Returns

Response Syntax

```json
{
    'FailedRecordCount': 123,
    'Records': [
    ]
}
```
Response Structure

- (dict) –
  PutRecords results.
  
- FailedRecordCount (integer) –
  The number of unsuccessfully processed records in a PutRecords request.

- Records (list) –
  An array of successfully and unsuccessfully processed record results, correlated with the request by natural ordering. A record that is successfully added to your Amazon Kinesis stream includes SequenceNumber and ShardId in the result. A record that fails to be added to your Amazon Kinesis stream includes ErrorCode and ErrorMessage in the result.

  - (dict) –
    Represents the result of an individual record from a PutRecords request. A record that is successfully added to your Amazon Kinesis stream includes SequenceNumber and ShardId in the result. A record that fails to be added to your Amazon Kinesis stream includes ErrorCode and ErrorMessage in the result.

    - SequenceNumber (string) –
      The sequence number for an individual record result.

    - ShardId (string) –
      The shard ID for an individual record result.

    - ErrorCode (string) –
      The error code for an individual record result. ErrorCodes can be either ProvisionedThroughputExceededException or InternalFailure.

    - ErrorMessage (string) –
      The error message for an individual record result. An ErrorCode value of ProvisionedThroughputExceededException has an error message that includes the account ID, stream name, and shard ID. An ErrorCode value of InternalFailure has the error message "Internal Service Failure".

remove_tags_from_stream(**kwargs)

Deletes tags from the specified Amazon Kinesis stream.

If you specify a tag that does not exist, it is ignored.

Request Syntax
Boto3 Documentation, Release 1.1.4

response = client.remove_tags_from_stream(
    StreamName='string',
    TagKeys=[
        'string',
    ]
)

Parameters

- **StreamName** *(string)* – [REQUIRED]
  
  The name of the stream.

- **TagKeys** *(list)* – [REQUIRED]
  
  A list of tag keys. Each corresponding tag is removed from the stream.

**Returns** None

`split_shard(**kwargs)`

Splits a shard into two new shards in the stream, to increase the stream’s capacity to ingest and transport data. `split_shard` is called when there is a need to increase the overall capacity of stream because of an expected increase in the volume of data records being ingested.

You can also use `split_shard` when a shard appears to be approaching its maximum utilization, for example, when the set of producers sending data into the specific shard are suddenly sending more than previously anticipated. You can also call `split_shard` to increase stream capacity, so that more Amazon Kinesis applications can simultaneously read data from the stream for real-time processing.

You must specify the shard to be split and the new hash key, which is the position in the shard where the shard gets split in two. In many cases, the new hash key might simply be the average of the beginning and ending hash key, but it can be any hash key value in the range being mapped into the shard. For more information about splitting shards, see [Split a Shard](#) in the [Amazon Kinesis Developer Guide](#).

You can use `DescribeStream` to determine the shard ID and hash key values for the `ShardToSplit` and `NewStartingHashKey` parameters that are specified in the `split_shard` request.

`split_shard` is an asynchronous operation. Upon receiving a `split_shard` request, Amazon Kinesis immediately returns a response and sets the stream status to `UPDATING`. After the operation is completed, Amazon Kinesis sets the stream status to `ACTIVE`. Read and write operations continue to work while the stream is in the `UPDATING` state.

You can use `DescribeStream` to check the status of the stream, which is returned in `StreamStatus`. If the stream is in the `ACTIVE` state, you can call `split_shard`. If a stream is in `CREATING` or `UPDATING` or `DELETING` states, `DescribeStream` returns a `ResourceInUseException`.

If the specified stream does not exist, `DescribeStream` returns a `ResourceNotFoundException`. If you try to create more shards than are authorized for your account, you receive a `LimitExceededException`.

For the default shard limit for an AWS account, see [Amazon Kinesis Limits](#). If you need to increase this limit, contact AWS Support.

If you try to operate on too many streams in parallel using `CreateStream`, `DeleteStream`, `MergeShards` or `split_shard`, you receive a `LimitExceededException`.

`split_shard` has limit of 5 transactions per second per account.

**Request Syntax**

response = client.split_shard(
    StreamName='string',
    **kwargs)

Parameters

- **StreamName (string)** – [REQUIRED]
  The name of the stream for the shard split.
- **ShardToSplit (string)** – [REQUIRED]
  The shard ID of the shard to split.
- **NewStartingHashKey (string)** – [REQUIRED]
  A hash key value for the starting hash key of one of the child shards created by the split. The hash key range for a given shard constitutes a set of ordered contiguous positive integers. The value for NewStartingHashKey must be in the range of hash keys being mapped into the shard. The NewStartingHashKey hash key value and all higher hash key values in hash key range are distributed to one of the child shards. All the lower hash key values in the range are distributed to the other child shard.

Returns

None

Paginators

The available paginators are:

- `Kinesis.Paginator.DescribeStream`
- `Kinesis.Paginator.ListStreams`

class `Kinesis.Paginator.DescribeStream`

```python
paginator = client.get_paginator('describe_stream')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `Kinesis.Client.describe_stream()`.

Request Syntax

```python
response_iterator = paginator.paginate(
    StreamName='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **StreamName (string)** – [REQUIRED]
  The name of the stream to describe.
- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
– **MaxItems** *(integer)* –

The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.

– **PageSize** *(integer)* –

The size of each page.

– **StartingToken** *(string)* –

A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** **dict**

**Returns**

**Response Syntax**

```python
{
    'StreamDescription': {
        'StreamName': 'string',
        'StreamARN': 'string',
        'StreamStatus': 'CREATING'|'DELETING'|'ACTIVE'|'UPDATING',
        'Shards': [
            {
                'ShardId': 'string',
                'ParentShardId': 'string',
                'AdjacentParentShardId': 'string',
                'HashKeyRange': {
                    'StartingHashKey': 'string',
                    'EndingHashKey': 'string'
                },
                'SequenceNumberRange': {
                    'StartingSequenceNumber': 'string',
                    'EndingSequenceNumber': 'string'
                }
            },
        ],
        'HasMoreShards': True|False
    },
    'NextToken': 'string'
}
```

**Response Structure**

- *(dict)* –

  Represents the output for `DescribeStream`.

  – **StreamDescription** *(dict)* –

    The current status of the stream, the stream ARN, an array of shard objects that comprise the stream, and states whether there are more shards available.

    - **StreamName** *(string)* –

        The name of the stream being described.

    - **StreamARN** *(string)* –

        The Amazon Resource Name (ARN) for the stream being described.

    - **StreamStatus** *(string)* –

        The current status of the stream being described.
The stream status is one of the following states:

- **CREATING** - The stream is being created. Amazon Kinesis immediately returns and sets `StreamStatus` to `CREATING`.
- **DELETING** - The stream is being deleted. The specified stream is in the `DELETING` state until Amazon Kinesis completes the deletion.
- **ACTIVE** - The stream exists and is ready for read and write operations or deletion. You should perform read and write operations only on an `ACTIVE` stream.
- **UPDATING** - Shards in the stream are being merged or split. Read and write operations continue to work while the stream is in the `UPDATING` state.

* **Shards** *(list)* –

The shards that comprise the stream.

- *(dict)* –
  A uniquely identified group of data records in an Amazon Kinesis stream.

  - **ShardId** *(string)* –
    The unique identifier of the shard within the Amazon Kinesis stream.

  - **ParentShardId** *(string)* –
    The shard Id of the shard’s parent.

  - **AdjacentParentShardId** *(string)* –
    The shard Id of the shard adjacent to the shard’s parent.

  - **HashKeyRange** *(dict)* –
    The range of possible hash key values for the shard, which is a set of ordered contiguous positive integers.

    - **StartingHashKey** *(string)* –
      The starting hash key of the hash key range.

    - **EndingHashKey** *(string)* –
      The ending hash key of the hash key range.

  - **SequenceNumberRange** *(dict)* –
    The range of possible sequence numbers for the shard.

    - **StartingSequenceNumber** *(string)* –
      The starting sequence number for the range.

    - **EndingSequenceNumber** *(string)* –
      The ending sequence number for the range. Shards that are in the OPEN state have an ending sequence number of `null`.

* **HasMoreShards** *(boolean)* –

  If set to `true`, more shards in the stream are available to describe.

- **NextToken** *(string)* –

  A token to resume pagination.

```python
class Kinesis.Paginator.ListStreams
```

3.1. Services 2999
paginator = client.get_paginator('list_streams')

paginate(**kwargs)

Creates an iterator that will paginate through responses from Kinesis.Client.list_streams().

Request Syntax

response_iterator = paginator.paginate(
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

PaginationConfig (dict) – A dictionary that provides parameters to control pagination.

• MaxItems (integer) –
  The total number of items to return. If the total number of items available is
  more than the value specified in max-items then a NextToken will be provided
  in the output that you can use to resume pagination.

• PageSize (integer) –
  The size of each page.

• StartingToken (string) –
  A token to specify where to start paginating. This is the NextToken from a
  previous response.

Returns
dict

Response Syntax

{
    'StreamNames': [
        'string',
    ],
    'HasMoreStreams': True|False,
    'NextToken': 'string'
}

Response Structure

• (dict) –
  Represents the output for ListStreams.

  • StreamNames (list) –
    The names of the streams that are associated with the AWS account making
    the ListStreams request.

  • (string) –

  • HasMoreStreams (boolean) –
    If set to True, there are more streams available to list.

  • NextToken (string) –
    A token to resume pagination.
Waiters

The available waiters are:

- `Kinesis.Waiter.StreamExists`

```python
class Kinesis.Waiter.StreamExists

waiter = client.get_waiter('stream_exists')

wait(**kwargs)
    Polls `Kinesis.Client.describe_stream()` every 10 seconds until a successful state is reached. An error is returned after 18 failed checks.

Request Syntax

waiter.wait(
    StreamName='string',
    Limit=123,
    ExclusiveStartShardId='string'
)
```

Parameters

- **StreamName** *(string)* – [REQUIRED]
  The name of the stream to describe.
- **Limit** *(integer)* – The maximum number of shards to return.
- **ExclusiveStartShardId** *(string)* – The shard ID of the shard to start with.

Returns None

KMS

Class `Kms.Client`

A low-level client representing AWS Key Management Service (KMS):

```python
import boto3

client = boto3.client('kms')
```

These are the available methods:

- `can_paginate()`
- `create_alias()`
- `create_grant()`
- `create_key()`
- `decrypt()`
Boto3 Documentation, Release 1.1.4

• delete_alias()
• describe_key()
• disable_key()
• disable_key_rotation()
• enable_key()
• enable_key_rotation()
• encrypt()
• generate_data_key()
• generate_data_key_without_plaintext()
• generate_presigned_url()
• generate_random()
• get_key_policy()
• get_key_rotation_status()
• get_paginator()
• get_waiter()
• list_aliases()
• list_grants()
• list_key_policies()
• list_keys()
• put_key_policy()
• re_encrypt()
• retire_grant()
• revoke_grant()
• update_alias()
• update_key_description()

can_paginate(operation_name)

Check if an operation can be paginated.

Parameters operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

Returns True if the operation can be paginated, False otherwise.

create_alias(**kwargs)

Creates a display name for a customer master key. An alias can be used to identify a key and should be unique. The console enforces a one-to-one mapping between the alias and a key. An alias name can contain only alphanumeric characters, forward slashes (/), underscores (_), and dashes (-). An alias must start with the word “alias” followed by a forward slash (alias/). An alias that begins with “aws” after the forward slash (alias/aws...) is reserved by Amazon Web Services (AWS).

To associate an alias with a different key, call UpdateAlias.

Note that you cannot create or update an alias that represents a key in another account.

Request Syntax

response = client.create_alias(
    AliasName='string',
    TargetKeyId='string'
)

Parameters

• AliasName (string) – [REQUIRED]

    String that contains the display name. The name must start with the word “alias” followed by a forward slash (alias/). Aliases that begin with “alias/AWS” are
• **KeyId** *(string) – [REQUIRED]*

An identifier of the key for which you are creating the alias. This value cannot be another alias but can be a globally unique identifier or a fully specified ARN to a key.

- **Key ARN Example** - arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012
  - **Globally Unique Key ID Example** - 12345678-1234-1234-1234-123456789012

**Returns** None

**create_grant(**kwargs)**

Adds a grant to a key to specify who can access the key and under what conditions. Grants are alternate permission mechanisms to key policies. For more information about grants, see Grants in the developer guide. If a grant is absent, access to the key is evaluated based on IAM policies attached to the user.

- ListGrants
- RetireGrant
- RevokeGrant

**Request Syntax**

```python
response = client.create_grant(
    KeyId='string',
    GranteePrincipal='string',
    RetiringPrincipal='string',
    Operations=['Decrypt'|'Encrypt'|'GenerateDataKey'|'GenerateDataKeyWithoutPlaintext'|'ReEncryptFrom'|'ReEncryptTo'|'CreateGrant'|'RetireGrant',
    Constraints={
        'EncryptionContextSubset': {
            'string': 'string'
        },
        'EncryptionContextEquals': {
            'string': 'string'
        }
    },
    GrantTokens=['string',]
)
```

**Parameters**

- **KeyId** *(string) – [REQUIRED]*

  A unique identifier for the customer master key. This value can be a globally unique identifier or the fully specified ARN to a key.
  
  - **Key ARN Example** - arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012
  - **Globally Unique Key ID Example** - 12345678-1234-1234-1234-123456789012

- **GranteePrincipal** *(string) – [REQUIRED]*

  Principal given permission by the grant to use the key identified by the KeyId parameter.

- **RetiringPrincipal** *(string)* – Principal given permission to retire the grant. For more information, see RetireGrant.

- **Operations** *(list)* – List of operations permitted by the grant. This can be any combination of one or more of the following values:
– Decrypt
– Encrypt
– GenerateDataKey
– GenerateDataKeyWithoutPlaintext
– ReEncryptFrom
– ReEncryptTo
– CreateGrant
– RetireGrant

– (string) –

• **Constraints**(dict) – Specifies the conditions under which the actions specified by the **Operations** parameter are allowed.
  – **EncryptionContextSubset**(dict) – The constraint equals the full encryption context.
    * (string) –
    · (string) –
  – **EncryptionContextEquals**(dict) – The constraint contains additional key/value pairs that serve to further limit the grant.
    * (string) –
    · (string) –

• **GrantTokens**(list) – For more information, see Grant Tokens.
  – (string) –

**Return type** dict

**Returns**

**Response Syntax**

```
{
    'GrantToken': 'string',
    'GrantId': 'string'
}
```

**Response Structure**

• (dict) –
  – **GrantToken**(string) –
    For more information, see Grant Tokens.
  – **GrantId**(string) –
    Unique grant identifier. You can use the **GrantId** value to revoke a grant.

**create_key(**kwargs)**

Creates a customer master key. Customer master keys can be used to encrypt small amounts of data (less than 4K) directly, but they are most commonly used to encrypt or envelope data keys that are then used to encrypt customer data. For more information about data keys, see **GenerateDataKey** and **GenerateDataKeyWithoutPlaintext**.

**Request Syntax**

```python
response = client.create_key(
    Policy='string',
    Description='string',
    KeyUsage='ENCRYPT_DECRYPT'
)
```

**Parameters**

• **Policy**(string) – Policy to be attached to the key. This is required and delegates back to the account. The key is the root of trust.
• **Description** *(string)* – Description of the key. We recommend that you choose a description that helps your customer decide whether the key is appropriate for a task.

• **KeyUsage** *(string)* – Specifies the intended use of the key. Currently this defaults to ENCRYPT/DECRYPT, and only symmetric encryption and decryption are supported.

**Return type**  
dict

**Returns**

**Response Syntax**

```
{
    'KeyMetadata': {
        'AWSAccountId': 'string',
        'KeyId': 'string',
        'Arn': 'string',
        'CreationDate': datetime(2015, 1, 1),
        'Enabled': True|False,
        'Description': 'string',
        'KeyUsage': 'ENCRYPT_DECRYPT'
    }
}
```

**Response Structure**

• *(dict)* –

  – **KeyMetadata** *(dict)* –

    Metadata associated with the key.

    * **AWSAccountId** *(string)* –
      Account ID number.

    * **KeyId** *(string)* –
      Unique identifier for the key.

    * **Arn** *(string)* –
      Key ARN (Amazon Resource Name).

    * **CreationDate** *(datetime)* –
      Date the key was created.

    * **Enabled** *(boolean)* –
      Value that specifies whether the key is enabled.

    * **Description** *(string)* –
      The description of the key.

    * **KeyUsage** *(string)* –
      A value that specifies what operation(s) the key can perform.

**decrypt** *(**kwargs)*

Decrypts ciphertext. Ciphertext is plaintext that has been previously encrypted by using any of the following functions:

• GenerateDataKey
• GenerateDataKeyWithoutPlaintext
• Encrypt

Note that if a caller has been granted access permissions to all keys (through, for example, IAM user policies that grant Decrypt permission on all resources), then ciphertext encrypted by using keys in other accounts where the key grants access to the caller can be decrypted. To remedy this, we recommend that you do not grant Decrypt access in an IAM user policy. Instead grant Decrypt access only in
key policies. If you must grant Decrypt access in an IAM user policy, you should scope the resource to specific keys or to specific trusted accounts.

**Request Syntax**

```python
response = client.decrypt(
    CiphertextBlob=b'bytes',
    EncryptionContext={
        'string': 'string'
    },
    GrantTokens=[
        'string',
    ],
)
```

**Parameters**

- **CiphertextBlob (bytes)** – [REQUIRED]
  
  Ciphertext to be decrypted. The blob includes metadata.

- **EncryptionContext (dict)** – The encryption context. If this was specified in the Encrypt function, it must be specified here or the decryption operation will fail. For more information, see Encryption Context.
  
  - (string) –
    
    * (string) –

- **GrantTokens (list)** – For more information, see Grant Tokens.
  
  - (string) –

**Return type** dict

**Response Syntax**

```python
{
    'KeyId': 'string',
    'Plaintext': b'bytes'
}
```

**Response Structure**

- (dict) –
  
  - **KeyId (string)** –
    
    ARN of the key used to perform the decryption. This value is returned if no errors are encountered during the operation.

  - **Plaintext (bytes)** –
    
    Decrypted plaintext data. This value may not be returned if the customer master key is not available or if you didn’t have permission to use it.

**delete_alias(**kwargs**)**

Deletes the specified alias. To associate an alias with a different key, call UpdateAlias.

**Request Syntax**

```python
response = client.delete_alias(
    AliasName='string'
)
```

**Parameters**

- **AliasName (string)** – [REQUIRED]
  
  The alias to be deleted. The name must start with the word “alias” followed by a forward slash (alias/). Aliases that begin with “alias/AWS” are reserved.
Returns None

describe_key(**kwargs)

Provides detailed information about the specified customer master key.

Request Syntax

response = client.describe_key(
    KeyId='string'
)

Parameters

KeyId (string) – [REQUIRED]

A unique identifier for the customer master key. This value can be a globally unique identifier, a fully specified ARN to either an alias or a key, or an alias name prefixed by "alias":

• Key ARN Example - arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012
• Alias ARN Example - arn:aws:kms:us-east-1:123456789012:alias/MyAliasName
• Globally Unique Key ID Example - 12345678-1234-1234-1234-123456789012
• Alias Name Example - alias/MyAliasName

Return type dict

Returns

Response Syntax

{
    'KeyMetadata': {
        'AWSAccountId': 'string',
        'KeyId': 'string',
        'Arn': 'string',
        'CreationDate': datetime(2015, 1, 1),
        'Enabled': True|False,
        'Description': 'string',
        'KeyUsage': 'ENCRYPT_DECRYPT'
    }
}

Response Structure

• (dict) –
  • KeyMetadata (dict) –
    Metadata associated with the key.
      • AWSAccountId (string) –
        Account ID number.
      • KeyId (string) –
        Unique identifier for the key.
      • Arn (string) –
        Key ARN (Amazon Resource Name).
      • CreationDate (datetime) –
        Date the key was created.
      • Enabled (boolean) –
        Value that specifies whether the key is enabled.
disabling a key

Marks a key as disabled, thereby preventing its use.

**Request Syntax**

```
response = client.disable_key(
    KeyId='string'
)
```

**Parameters**

- **KeyId (string)** – [REQUIRED]
  
  A unique identifier for the customer master key. This value can be a globally unique identifier or the fully specified ARN to a key.
  
  - **Key ARN Example** - arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012
  
  - **Globally Unique Key ID Example** - 12345678-1234-1234-1234-123456789012

**Returns**

None

disable_key_rotation(**kwargs)

Disables rotation of the specified key.

**Request Syntax**

```
response = client.disable_key_rotation(
    KeyId='string'
)
```

**Parameters**

- **KeyId (string)** – [REQUIRED]
  
  A unique identifier for the customer master key. This value can be a globally unique identifier or the fully specified ARN to a key.
  
  - **Key ARN Example** - arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012
  
  - **Globally Unique Key ID Example** - 12345678-1234-1234-1234-123456789012

**Returns**

None

enable_key(**kwargs)

Marks a key as enabled, thereby permitting its use. You can have up to 25 enabled keys at one time.

**Request Syntax**

```
response = client.enable_key(
    KeyId='string'
)
```

**Parameters**

- **KeyId (string)** – [REQUIRED]
  
  A unique identifier for the customer master key. This value can be a globally unique identifier or the fully specified ARN to a key.
  
  - **Key ARN Example** - arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012
  
  - **Globally Unique Key ID Example** - 12345678-1234-1234-1234-123456789012

**Returns**

None
enable_key_rotation(**kwargs)

Enables rotation of the specified customer master key.

Request Syntax

```python
response = client.enable_key_rotation(
    KeyId='string'
)
```

Parameters  **KeyId (string)** – [REQUIRED]

A unique identifier for the customer master key. This value can be a globally unique identifier or the fully specified ARN to a key.

- Key ARN Example - arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012
- Globally Unique Key ID Example - 12345678-1234-1234-1234-123456789012

Returns None

encrypt(**kwargs)

Encrypts plaintext into ciphertext by using a customer master key. The `Encrypt` function has two primary use cases:

- You can encrypt up to 4 KB of arbitrary data such as an RSA key, a database password, or other sensitive customer information.
- If you are moving encrypted data from one region to another, you can use this API to encrypt in the new region the plaintext data key that was used to encrypt the data in the original region. This provides you with an encrypted copy of the data key that can be decrypted in the new region and used there to decrypt the encrypted data.

Unless you are moving encrypted data from one region to another, you don’t use this function to encrypt a generated data key within a region. You retrieve data keys already encrypted by calling the GenerateDataKey or GenerateDataKeyWithoutPlaintext function. Data keys don’t need to be encrypted again by calling `Encrypt`.

If you want to encrypt data locally in your application, you can use the `GenerateDataKey` function to return a plaintext data encryption key and a copy of the key encrypted under the customer master key (CMK) of your choosing.

Request Syntax

```python
response = client.encrypt(
    KeyId='string',
    Plaintext=b'bytes',
    EncryptionContext={
        'string': 'string'
    },
    GrantTokens=[
        'string',
    ]
)
```

Parameters  **KeyId (string)** – [REQUIRED]

A unique identifier for the customer master key. This value can be a globally unique identifier, a fully specified ARN to either an alias or a key, or an alias name prefixed by “alias:”.

- Key ARN Example - arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012

3.1. Services
– Alias ARN Example - arn:aws:kms:us-east-1:123456789012:alias/MyAliasName
– Globally Unique Key ID Example - 12345678-1234-1234-1234-123456789012
– Alias Name Example - alias/MyAliasName

- **Plaintext (bytes)** – [REQUIRED]
  
  Data to be encrypted.

- **EncryptionContext (dict)** – Name/value pair that specifies the encryption context to be used for authenticated encryption. If used here, the same value must be supplied to the Decrypt API or decryption will fail. For more information, see Encryption Context.
  
  - (string) –
  
  - (string) –

- **GrantTokens (list)** – For more information, see Grant Tokens.
  
  - (string) –

**Return type** dict

**Returns**

**Response Syntax**

```{json}
{
    'CiphertextBlob': b'bytes',
    'KeyId': 'string'
}
```

**Response Structure**

- (dict) –
  
  - **CiphertextBlob (bytes)** –
    
    The encrypted plaintext. If you are using the CLI, the value is Base64 encoded. Otherwise, it is not encoded.
  
  - **KeyId (string)** –
    
    The ID of the key used during encryption.

**generate_data_key (**)kwargs**

Generates a data key that you can use in your application to locally encrypt data. This call returns a plaintext version of the key in the Plaintext field of the response object and an encrypted copy of the key in the CiphertextBlob field. The key is encrypted by using the master key specified by the KeyId field. To decrypt the encrypted key, pass it to the Decrypt API.

We recommend that you use the following pattern to locally encrypt data: call the GenerateDataKey API, use the key returned in the Plaintext response field to locally encrypt data, and then erase the plaintext data key from memory. Store the encrypted data key (contained in the CiphertextBlob field) alongside of the locally encrypted data.

**Note:** You should not call the Encrypt function to re-encrypt your data keys within a region. GenerateDataKey always returns the data key encrypted and tied to the customer master key that will be used to decrypt it. There is no need to decrypt it twice.

If you decide to use the optional EncryptionContext parameter, you must also store the context in full or at least store enough information along with the encrypted data to be able to reconstruct the context when submitting the ciphertext to the Decrypt API. It is a good practice to choose a context that you can reconstruct on the fly to better secure the ciphertext. For more information about how this parameter is used, see Encryption Context.
To decrypt data, pass the encrypted data key to the `Decrypt` API. `Decrypt` uses the associated master key to decrypt the encrypted data key and returns it as plaintext. Use the plaintext data key to locally decrypt your data and then erase the key from memory. You must specify the encryption context, if any, that you specified when you generated the key. The encryption context is logged by CloudTrail, and you can use this log to help track the use of particular data.

**Request Syntax**

```python
response = client.generate_data_key(
    KeyId='string',
    EncryptionContext={
        'string': 'string'
    },
    NumberOfBytes=123,
    KeySpec='AES_256'|'AES_128',
    GrantTokens=[
        'string',
    ]
)
```

**Parameters**

- **KeyId** *(string)* – [REQUIRED]
  A unique identifier for the customer master key. This value can be a globally unique identifier, a fully specified ARN to either an alias or a key, or an alias name prefixed by “alias/”.
  - Key ARN Example - `arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012`
  - Alias ARN Example - `arn:aws:kms:us-east-1:123456789012:alias/MyAliasName`
  - Globally Unique Key ID Example - `12345678-1234-1234-1234-123456789012`
  - Alias Name Example - alias/MyAliasName
- **EncryptionContext** *(dict)* – Name/value pair that contains additional data to be authenticated during the encryption and decryption processes that use the key. This value is logged by AWS CloudTrail to provide context around the data encrypted by the key.
  - *(string)*
- **NumberOfBytes** *(integer)* – Integer that contains the number of bytes to generate. Common values are 128, 256, 512, and 1024. 1024 is the current limit. We recommend that you use the `KeySpec` parameter instead.
- **KeySpec** *(string)* – Value that identifies the encryption algorithm and key size to generate a data key for. Currently this can be AES_128 or AES_256.
- **GrantTokens** *(list)* – For more information, see `Grant Tokens`.

**Return type** dict

**Response Syntax**

```python
{
    'CiphertextBlob': b'bytes',
    'Plaintext': b'bytes',
    'KeyId': 'string'
}
```
Response Structure

- (dict) –
  - CiphertextBlob (bytes) –
    Ciphertext that contains the encrypted data key. You must store the blob
    and enough information to reconstruct the encryption context so that the
    data encrypted by using the key can later be decrypted. You must provide
    both the ciphertext blob and the encryption context to the Decrypt API to
    recover the plaintext data key and decrypt the object.

    If you are using the CLI, the value is Base64 encoded. Otherwise, it is not
    encoded.

- Plaintext (bytes) –
  Plaintext that contains the data key. Use this for encryption and decryption
  and then remove it from memory as soon as possible.

- KeyId (string) –
  System generated unique identifier of the key to be used to decrypt the
  encrypted copy of the data key.

`generate_data_key_without_plaintext` (**kwargs)

Returns a data key encrypted by a customer master key without the plaintext copy of that key. Otherwise,
this API functions exactly like GenerateDataKey. You can use this API to, for example, satisfy an audit
requirement that an encrypted key be made available without exposing the plaintext copy of that key.

Request Syntax

```python
response = client.generate_data_key_without_plaintext(
    KeyId='string',
    EncryptionContext={
        'string': 'string'
    },
   KeySpec='AES_256'|'AES_128',
   NumberOfBytes=123,
   GrantTokens=[
        'string',
    ]
)
```

Parameters

- **KeyId (string)** – [REQUIRED]
  A unique identifier for the customer master key. This value can be a globally
  unique identifier, a fully specified ARN to either an alias or a key, or an alias
  name prefixed by “alias/”.

  - Key ARN Example - arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012
  - Alias ARN Example - arn:aws:kms:us-east-1:123456789012:alias/MyAliasName
  - Globally Unique Key ID Example - 12345678-1234-1234-1234-123456789012
  - Alias Name Example - alias/MyAliasName

- **EncryptionContext (dict)** – Name:value pair that contains additional data to be
  authenticated during the encryption and decryption processes.

  - (string) –
    * (string) –
• **KeySpec (string)** – Value that identifies the encryption algorithm and key size. Currently this can be AES_128 or AES_256.
• **NumberOfBytes (integer)** – Integer that contains the number of bytes to generate. Common values are 128, 256, 512, 1024 and so on. We recommend that you use the **KeySpec** parameter instead.
• **GrantTokens (list)** – For more information, see Grant Tokens.

Return type: dict
Returns:

**Response Syntax**

```python
{
    'CiphertextBlob': b'bytes',
    'KeyId': 'string'
}
```

**Response Structure**

• (dict) –
  • **CiphertextBlob (bytes)** –
    Ciphertext that contains the wrapped data key. You must store the blob and encryption context so that the key can be used in a future decrypt operation.
    If you are using the CLI, the value is Base64 encoded. Otherwise, it is not encoded.
  • **KeyId (string)** –
    System generated unique identifier of the key to be used to decrypt the encrypted copy of the data key.

---

**generate_presigned_url** *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*
Generate a presigned url given a client, its method, and arguments

**Parameters**

• **ClientMethod (string)** – The client method to presign for
• **Params (dict)** – The parameters normally passed to ClientMethod.
• **ExpiresIn (int)** – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
• **HttpMethod (string)** – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns**

The presigned url

**generate_random** (**kwargs**)
Generates an unpredictable byte string.

**Request Syntax**

```python
response = client.generate_random(
    NumberOfBytes=123
)
```

**Parameters**

**NumberOfBytes (integer)** – Integer that contains the number of bytes to generate. Common values are 128, 256, 512, 1024 and so on. The current limit is 1024 bytes.

**Return type**

dict

**Returns**

**Response Syntax**
get_key_policy(**kwargs)
Retrieves a policy attached to the specified key.

Request Syntax

```python
response = client.get_key_policy(
    KeyId='string',
    PolicyName='string'
)
```

Parameters

- **KeyId (string)** – [REQUIRED]
  A unique identifier for the customer master key. This value can be a globally unique identifier or the fully specified ARN to a key.
  - Key ARN Example - arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012
  - Globally Unique Key ID Example - 12345678-1234-1234-1234-123456789012
- **PolicyName (string)** – [REQUIRED]
  String that contains the name of the policy. Currently, this must be “default”. Policy names can be discovered by calling ListKeyPolicies.

Return type  dict

Response Syntax

```python
{
    'Policy': 'string'
}
```

Response Structure

- (dict)
  - Policy (string)
    A policy document in JSON format.

get_key_rotation_status(**kwargs)
Retrieves a Boolean value that indicates whether key rotation is enabled for the specified key.

Request Syntax

```python
response = client.get_key_rotation_status(
    KeyId='string'
)
```
**Parameters**  
**KeyId** *(string)* – [REQUIRED]  
A unique identifier for the customer master key. This value can be a globally unique identifier or the fully specified ARN to a key.

- Key ARN Example - arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012
- Globally Unique Key ID Example - 12345678-1234-1234-1234-123456789012

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'KeyRotationEnabled': True|False
}
```

**Response Structure**

- *(dict)* –
  - **KeyRotationEnabled** *(boolean)* – A Boolean value that specifies whether key rotation is enabled.

**get_paginato**n**(operation_name)**

Create a paginator for an operation.

- **Parameters**  
  **operation_name** *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginate("create_foo")`.

- **Raises**  
  `OperationNotPageableError` Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

- **Return type**  
  L{botocore.paginate.Paginator}

- **Returns**  
  A paginator object.

**get_waiter**(waiter_name)

**list_aliases**(***kwargs)**

Lists all of the key aliases in the account.

- **Request Syntax**

  ```python
  response = client.list_aliases(
      Limit=123,
      Marker='string'
  )
  ```

- **Parameters**
  - **Limit** *(integer)* – Specify this parameter when paginating results to indicate the maximum number of aliases you want in each response. If there are additional aliases beyond the maximum you specify, the `Truncated` response element will be set to `true`.
  - **Marker** *(string)* – Use this parameter when paginating results, and only in a subsequent request after you’ve received a response where the results are truncated. Set it to the value of the `NextMarker` element in the response you just received.

- **Return type**  
dict

- **Returns**

  **Response Syntax**
Response Structure

- (dict) –
  - Aliases (list) –
    A list of key aliases in the user’s account.
    * (dict) – Contains information about an alias.
      - AliasName (string) –
        String that contains the alias.
      - AliasArn (string) –
        String that contains the key ARN.
      - TargetKeyId (string) –
        String that contains the key identifier pointed to by the alias.
  - NextMarker (string) –
    If Truncated is true, this value is present and contains the value to use for the Marker request parameter in a subsequent pagination request.
  - Truncated (boolean) –
    A flag that indicates whether there are more items in the list. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more aliases in the list.

list_grants(**kwargs)
List the grants for a specified key.

Request Syntax

```python
response = client.list_grants(
    KeyId='string',
    Limit=123,
    Marker='string'
)
```

Parameters

- KeyId (string) – [REQUIRED]
  A unique identifier for the customer master key. This value can be a globally unique identifier or the fully specified ARN to a key.
  - Key ARN Example - arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012
  - Globally Unique Key ID Example - 12345678-1234-1234-1234-123456789012
- Limit (integer) – Specify this parameter only when paginating results to indicate the maximum number of grants you want listed in the response. If there are
additional grants beyond the maximum you specify, the Truncated response element will be set to true.

- **Marker (string)** – Use this parameter only when paginating results, and only in a subsequent request after you’ve received a response where the results are truncated. Set it to the value of the NextMarker in the response you just received.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'Grants': [
        {
            'GrantId': 'string',
            'GranteePrincipal': 'string',
            'RetiringPrincipal': 'string',
            'IssuingAccount': 'string',
            'Operations': [
                'Decrypt'|'Encrypt'|'GenerateDataKey'|'GenerateDataKeyWithoutPlaintext'|'ReEncryptFrom'|'ReEncryptTo'|'CreateGrant'|'RetireGrant',
            ],
            'Constraints': {
                'EncryptionContextSubset': {
                    'string': 'string'
                },
                'EncryptionContextEquals': {
                    'string': 'string'
                }
            }
        },
        ...
    ],
    'NextMarker': 'string',
    'Truncated': True|False
}
```

**Response Structure**

- **(dict)** –
  - **Grants (list)** –
    A list of grants.
    - **(dict)** –
      Contains information about each entry in the grant list.
      - **GrantId (string)** –
        Unique grant identifier.
      - **GranteePrincipal (string)** –
        The principal that receives the grant permission.
      - **RetiringPrincipal (string)** –
        The principal that can retire the account.
      - **IssuingAccount (string)** –
        The account under which the grant was issued.
      - **Operations (list)** –
        List of operations permitted by the grant. This can be any combination of one or more of the following values:
        - Decrypt
 list_key_policies (**kwargs)
Retrieves a list of policies attached to a key.

Request Syntax

response = client.list_key_policies(
    KeyId='string',
    Limit=123,
    Marker='string'
)

Parameters

- **KeyId (string)** – [REQUIRED]

A unique identifier for the customer master key. This value can be a globally unique identifier, a fully specified ARN to either an alias or a key, or an alias name prefixed by “alias/”.

  - Key ARN Example - arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012
  - Alias ARN Example - arn:aws:kms:us-east-1:123456789012:alias/MyAliasName
  - Globally Unique Key ID Example - 12345678-1234-1234-1234-123456789012
  - Alias Name Example - alias/MyAliasName

- **Limit (integer)** – Specify this parameter only when paginating results to indicate the maximum number of policies you want listed in the response. If there are additional policies beyond the maximum you specify, the Truncated response element will be set to true.
• **Marker** *(string)* – Use this parameter only when paginating results, and only in a subsequent request after you’ve received a response where the results are truncated. Set it to the value of the NextMarker in the response you just received.

Return type  dict

Returns

Response Syntax

```python
{
    'PolicyNames': [
        'string',
    ],
    'NextMarker': 'string',
    'Truncated': True|False
}
```

Response Structure

• *(dict)* –
  - **PolicyNames** *(list)* –
    A list of policy names. Currently, there is only one policy and it is named “Default”.
  - *(string)* –
  - **NextMarker** *(string)* –
    If Truncated is true, this value is present and contains the value to use for the Marker request parameter in a subsequent pagination request.
  - **Truncated** *(boolean)* –
    A flag that indicates whether there are more items in the list. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more policies in the list.

**list_keys(****kwargs**)**

Lists the customer master keys.

Request Syntax

```python
response = client.list_keys(
    Limit=123,
    Marker='string'
)
```

Parameters

• **Limit** *(integer)* – Specify this parameter only when paginating results to indicate the maximum number of keys you want listed in the response. If there are additional keys beyond the maximum you specify, the Truncated response element will be set to true.

• **Marker** *(string)* – Use this parameter only when paginating results, and only in a subsequent request after you’ve received a response where the results are truncated. Set it to the value of the NextMarker in the response you just received.

Return type  dict

Returns

Response Syntax

```json
{
   'Keys': [
      {
         'KeyId': 'string',
         'KeyArn': 'string'
      }
   ],
   'NextMarker': 'string',
   'Truncated': True|False
}
```

**Response Structure**

- *(dict)* –
  - **Keys (list)** –
    - A list of keys.
      - *(dict)* –
        - **KeyId (string)** –
          - Unique identifier of the key.
        - **KeyArn (string)** –
          - ARN of the key.
  - **NextMarker (string)** –
    - If Truncated is true, this value is present and contains the value to use for the Marker request parameter in a subsequent pagination request.
  - **Truncated (boolean)** –
    - A flag that indicates whether there are more items in the list. If your results were truncated, you can make a subsequent pagination request using the Marker request parameter to retrieve more keys in the list.

**put_key_policy(**kwargs)**

Attaches a policy to the specified key.

**Request Syntax**

```python
response = client.put_key_policy(
    KeyId='string',
    PolicyName='string',
    Policy='string'
)
```

**Parameters**

- **KeyId (string)** – [REQUIRED]
  
  A unique identifier for the customer master key. This value can be a globally unique identifier or the fully specified ARN to a key.
  - Key ARN Example - `arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012`
  - Globally Unique Key ID Example - `12345678-1234-1234-1234-123456789012`

- **PolicyName (string)** – [REQUIRED]
  
  Name of the policy to be attached. Currently, the only supported name is “default”.

---

3020 Chapter 3. API Reference
• **Policy** *(string)* – [REQUIRED]

  The policy, in JSON format, to be attached to the key.

  **Returns** None

`re_encrypt(**kwargs)`

Encrypts data on the server side with a new customer master key without exposing the plaintext of the data on the client side. The data is first decrypted and then encrypted. This operation can also be used to change the encryption context of a ciphertext.

Unlike other actions, ReEncrypt is authorized twice - once as ReEncryptFrom on the source key and once as ReEncryptTo on the destination key. We therefore recommend that you include the "action": "kms:ReEncrypt*" statement in your key policies to permit re-encryption from or to the key. The statement is included automatically when you authorize use of the key through the console but must be included manually when you set a policy by using the PutKeyPolicy function.

**Request Syntax**

```python
response = client.re_encrypt(
    CiphertextBlob=b'bytes',
    SourceEncryptionContext={
        'string': 'string'
    },
    DestinationKeyId='string',
    DestinationEncryptionContext={
        'string': 'string'
    },
    GrantTokens=[
        'string',
    ]
)
```

**Parameters**

- **CiphertextBlob** *(bytes)* – [REQUIRED]
  
  Ciphertext of the data to re-encrypt.

- **SourceEncryptionContext** *(dict)* – Encryption context used to encrypt and decrypt the data specified in the CiphertextBlob parameter.
  
  - *(string)* –
  
  - *(string)* –

- **DestinationKeyId** *(string)* – [REQUIRED]
  
  A unique identifier for the customer master key used to re-encrypt the data. This value can be a globally unique identifier, a fully specified ARN to either an alias or a key, or an alias name prefixed by “alias/”.
  
  - Key ARN Example - arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012
  
  - Alias ARN Example - arn:aws:kms:us-east-1:123456789012:alias/MyAliasName
  
  - Globally Unique Key ID Example - 12345678-1234-1234-1234-123456789012
  
  - Alias Name Example - alias/MyAliasName

- **DestinationEncryptionContext** *(dict)* – Encryption context to be used when the data is re-encrypted.
  
  - *(string)* –
  
  - *(string)* –

- **GrantTokens** *(list)* – For more information, see Grant Tokens.
Return type  dict
Returns
Response Syntax
{
    'CiphertextBlob': b'bytes',
    'SourceKeyId': 'string',
    'KeyId': 'string'
}
Response Structure
• (dict) –
  – CiphertextBlob (bytes) –
    The re-encrypted data. If you are using the CLI, the value is Base64 en-
    coded. Otherwise, it is not encoded.
  – SourceKeyId (string) –
    Unique identifier of the key used to originally encrypt the data.
  – KeyId (string) –
    Unique identifier of the key used to re-encrypt the data.

retire_grant(**kwargs)
Retires a grant. You can retire a grant when you’re done using it to clean up. You should revoke a grant
when you intend to actively deny operations that depend on it. The following are permitted to call this
API:
• The account that created the grant
• The RetiringPrincipal, if present
• The GranteePrincipal, if RetireGrant is a grantee operation
The grant to retire must be identified by its grant token or by a combination of the key ARN and the grant
ID. A grant token is a unique variable-length base64-encoded string. A grant ID is a 64 character unique
identifier of a grant. Both are returned by the CreateGrant function.
Request Syntax
response = client.retire_grant(
    GrantToken='string',
    KeyId='string',
    GrantId='string'
)
Parameters
• GrantToken (string) – Token that identifies the grant to be retired.
• KeyId (string) – A unique identifier for the customer master key associated with
