• **SSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.

• **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

**Returns** None

### ObjectAcl

class S3.ObjectAcl *(bucket_name, object_key)*

A resource representing an Amazon Simple Storage Service (S3) ObjectAcl:

```python
import boto3

s3 = boto3.resource('s3')
object_acl = s3.ObjectAcl('bucket_name','object_key')
```

**Parameters**

- **bucket_name** *(string)* – The ObjectAcl’s bucket_name identifier. This must be set.
- **object_key** *(string)* – The ObjectAcl’s object_key identifier. This must be set.

These are the resource’s available identifiers:

- **bucket_name**
- **object_key**

These are the resource’s available attributes:

- **grants**
- **owner**
- **request_charged**

These are the resource’s available actions:

- **load()**
- **put()**
- **reload()**

These are the resource’s available sub-resources:

- **Object()**

**Identifiers**

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

**bucket_name** *(string)* The ObjectAcl’s bucket_name identifier. This must be set.
**object_key**  
*(string) The ObjectAcl's object_key identifier. This must be set.*

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the `Resources Introduction Guide`.

**grants**  
*(list) A list of grants.*

**owner**  
*(dict)*

**request_charged**  
*(string) If present, indicates that the requester was successfully charged for the request.*

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the `Resources Introduction Guide`.

**load()**

Calls `s3.Client.get_object_acl()` to update the attributes of the ObjectAcl resource.

**Request Syntax**

```python
do_object_acl.load()
```

**Returns** None

**put(**kwargs**)**

uses the acl subresource to set the access control list (ACL) permissions for an object that already exists in a bucket

**Request Syntax**

```python
response = object_acl.put(
    ACL='private'|'public-read'|'public-read-write'|'authenticated-read'|'bucket-owner-read'|'bucket-owner-full-control',
    AccessControlPolicy={
        'Grants': [
            {
                'Grantee': {
                    'DisplayName': 'string',
                    'EmailAddress': 'string',
                    'ID': 'string',
                    'Type': 'CanonicalUser'|'AmazonCustomerByEmail'|'Group',
                    'URI': 'string'
                },
                'Permission': 'FULL_CONTROL'|'WRITE'|'WRITE_ACP'|'READ'|'READ_ACP'
            },
        ],
        'Owner': {
            'DisplayName': 'string',
            'ID': 'string'
        }
    },
    GrantFullControl='string',
    GrantRead='string',
    GrantReadACP='string',
    GrantWrite='string',
)```
GrantWriteACP='string',
RequestPayer='requester'
}

Parameters

- **ACL** *(string)* – The canned ACL to apply to the object.
- **AccessControlPolicy** *(dict)* –
  - **Grants** *(list)* – A list of grants.
    - *(dict)* –
      - **Grantee** *(dict)* –
        - **DisplayName** *(string)* – Screen name of the grantee.
        - **EmailAddress** *(string)* – Email address of the grantee.
        - **ID** *(string)* – The canonical user ID of the grantee.
        - **Type** *(string)* – [REQUIRED] Type of grantee
        - **URI** *(string)* – URI of the grantee group.
        - **Permission** *(string)* – Specifies the permission given to the grantee.
      - **Owner** *(dict)* –
        - **DisplayName** *(string)* –
        - **ID** *(string)* –
- **GrantFullControl** *(string)* – Allows grantee the read, write, read ACP, and write ACP permissions on the bucket.
- **GrantRead** *(string)* – Allows grantee to list the objects in the bucket.
- **GrantReadACP** *(string)* – Allows grantee to read the bucket ACL.
- **GrantWrite** *(string)* – Allows grantee to create, overwrite, and delete any object in the bucket.
- **GrantWriteACP** *(string)* – Allows grantee to write the ACL for the applicable bucket.
- **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

Return type: dict

Returns

Response Syntax

```
{
    'RequestCharged': 'requester'
}
```

Response Structure

- *(dict)* –
  - **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.

reload()
Calls s3.Client.get_object_acl() to update the attributes of the ObjectAcl resource

Request Syntax

object_acl.reload()

Returns None
Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

**Object()**

Creates a Object resource.:

```python
object = object_acl.Object()
```

**Return type** S3.Object

**Returns** A Object resource

**ObjectSummary**

```python
class S3.ObjectSummary(bucket_name, key)
```

A resource representing an Amazon Simple Storage Service (S3) ObjectSummary:

```python
import boto3
s3 = boto3.resource('s3')
object_summary = s3.ObjectSummary('bucket_name','key')
```

**Parameters**

- **bucket_name (string)** – The ObjectSummary’s bucket_name identifier. This must be set.
- **key (string)** – The ObjectSummary’s key identifier. This must be set.

These are the resource’s available identifiers:

- `bucket_name`
- `key`

These are the resource’s available attributes:

- `e_tag`
- `last_modified`
- `owner`
- `size`
- `storage_class`

These are the resource’s available actions:

- `copy_from()`
- `delete()`
- `get()`
- `initiate_multipart_upload()`
- `put()`

These are the resource’s available sub-resources:

- `Acl()`
- `Bucket()`
- `MultipartUpload()`
- `Object()`
- `Version()`

These are the resource’s available waiters:

- `wait_until_exists()`
- `wait_until_not_exists()`

**Identifiers**

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.
**bucket_name**

*(string)* The ObjectSummary's bucket_name identifier. This **must** be set.

**key**

*(string)* The ObjectSummary's key identifier. This **must** be set.

**Attributes**

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the **load**() method. For more information about attributes refer to the Resources Introduction Guide.

**e_tag**

*(string)*

**last_modified**

*(datetime)*

**owner**

*(dict)*

**size**

*(integer)*

**storage_class**

*(string)* The class of storage used to store the object.

**Actions**

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

**copy_from(****kwargs**)**

Creates a copy of an object that is already stored in Amazon S3.

**Request Syntax**

```python
response = object_summary.copy_from(
    ACL='private'|'public-read'|'public-read-write'|'authenticated-read'|'bucket-owner-read'|'bucket-owner-full-control',
    CacheControl='string',
    ContentDisposition='string',
    ContentEncoding='string',
    ContentLanguage='string',
    ContentType='string',
    CopySource='string',
    CopySourceIfMatch='string',
    CopySourceIfModifiedSince=datetime(2015, 1, 1),
    CopySourceIfNoneMatch='string',
    CopySourceIfUnmodifiedSince=datetime(2015, 1, 1),
    Expires=datetime(2015, 1, 1),
    GrantFullControl='string',
    GrantRead='string',
    GrantReadACP='string',
    GrantWriteACP='string',
    Metadata={
        'string': 'string',
    },
    MetadataDirective='COPY'|'REPLACE',
    ServerSideEncryption='AES256'|'aws:kms',
    StorageClass='STANDARD'|'REDUCED_REDUNDANCY'|'STANDARD_IA',
    WebsiteRedirectLocation='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
)```
SSEKMSKeyId='string',
CopySourceSSECustomerAlgorithm='string',
CopySourceSSECustomerKey='string',
CopySourceSSECustomerKeyMD5='string',
RequestPayer='requester'
)

Parameters

- **ACL** *(string)* – The canned ACL to apply to the object.
- **CacheControl** *(string)* – Specifies caching behavior along the request/reply chain.
- **ContentDisposition** *(string)* – Specifies presentational information for the object.
- **ContentEncoding** *(string)* – Specifies what content encodings have been applied to the object and thus what decoding mechanisms must be applied to obtain the media-type referenced by the Content-Type header field.
- **ContentLanguage** *(string)* – The language the content is in.
- **ContentType** *(string)* – A standard MIME type describing the format of the object data.
- **CopySource** *(string)* – [REQUIRED] The name of the source bucket and key name of the source object, separated by a slash (/). Must be URL-encoded.
- **CopySourceIfMatch** *(string)* – Copies the object if its entity tag (ETag) matches the specified tag.
- **CopySourceIfModifiedSince** *(datetime)* – Copies the object if it has been modified since the specified time.
- **CopySourceIfNoneMatch** *(string)* – Copies the object if its entity tag (ETag) is different than the specified ETag.
- **CopySourceIfUnmodifiedSince** *(datetime)* – Copies the object if it hasn’t been modified since the specified time.
- **Expires** *(datetime)* – The date and time at which the object is no longer cacheable.
- **GrantFullControl** *(string)* – Gives the grantee READ, READ_ACP, and WRITE_ACP permissions on the object.
- **GrantRead** *(string)* – Allows grantee to read the object data and its metadata.
- **GrantReadACP** *(string)* – Allows grantee to read the object ACL.
- **GrantWriteACP** *(string)* – Allows grantee to write the ACL for the applicable object.
- **Metadata** *(dict)* – A map of metadata to store with the object in S3.
- **MetadataDirective** *(string)* – Specifies whether the metadata is copied from the source object or replaced with metadata provided in the request.
- **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
- **StorageClass** *(string)* – The type of storage to use for the object. Defaults to ‘STANDARD’.
- **WebsiteRedirectLocation** *(string)* – If the bucket is configured as a website, redirects requests for this object to another object in the same bucket or to an external URL. Amazon S3 stores the value of this header in the object metadata.
- **SSECustomerAlgorithm** *(string)* – Specifies the algorithm to use to when encrypting the object (e.g., AES256).
- **SSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key
must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.

- **SSECustomerKeyMD5** (*string*) – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.

- **SSEKMSKeyId** (*string*) – Specifies the AWS KMS key ID to use for object encryption. All GET and PUT requests for an object protected by AWS KMS will fail if not made via SSL or using SigV4. Documentation on configuring any of the officially supported AWS SDKs and CLI can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/UsingAWSSDK.html#specify-signature-version

- **CopySourceSSECustomerAlgorithm** (*string*) – Specifies the algorithm to use when decrypting the source object (e.g., AES256).

- **CopySourceSSECustomerKey** (*string*) – Specifies the customer-provided encryption key for Amazon S3 to use to decrypt the source object. The encryption key provided in this header must be one that was used when the source object was created.

- **CopySourceSSECustomerKeyMD5** (*string*) – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error.

- **RequestPayer** (*string*) – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'CopyObjectResult': {
        'ETag': 'string',
        'LastModified': datetime(2015, 1, 1)
    },
    'Expiration': 'string',
    'CopySourceVersionId': 'string',
    'ServerSideEncryption': 'AES256'|'aws:kms',
    'SSECustomerAlgorithm': 'string',
    'SSECustomerKeyMD5': 'string',
    'SSEKMSKeyId': 'string',
    'RequestCharged': 'requester'
}
```

**Response Structure**

- *(dict)* –
  - **CopyObjectResult** *(dict)* –
    - **ETag** (*string*) –
    - **LastModified** *(datetime)* –
  - **Expiration** (*string*) – If the object expiration is configured, the response includes this header.
  - **CopySourceVersionId** (*string*) –
– **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).

– **SSECCustomerAlgorithm** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header confirming the encryption algorithm used.

– **SSECCustomerKeyMD5** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header to provide round trip message integrity verification of the customer-provided encryption key.

– **SSEKMSKeyId** *(string)* – If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.

– **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.

```python
def delete(**kwargs):
    Returns the null version (if there is one) of an object and inserts a delete marker, which becomes the latest version of the object. If there isn’t a null version, Amazon S3 does not remove any objects.

    Request Syntax

    response = object_summary.delete(
        MFA='string',
        VersionId='string',
        RequestPayer='requester'
    )
```

Parameters

- **MFA** *(string)* – The concatenation of the authentication device’s serial number, a space, and the value that is displayed on your authentication device.

- **VersionId** *(string)* – VersionId used to reference a specific version of the object.

- **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

Return type dict

Returns

Response Syntax

```python
{
    'DeleteMarker': True|False,
    'VersionId': 'string',
    'RequestCharged': 'requester'
}
```

Response Structure

- *(dict)* –
  - **DeleteMarker** *(boolean)* – Specifies whether the versioned object that was permanently deleted was (true) or was not (false) a delete marker.
  - **VersionId** *(string)* – Returns the version ID of the delete marker created as a result of the DELETE operation.
  - **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.
get (**kwargs)
Retrieves objects from Amazon S3.

Request Syntax

```python
response = object_summary.get(
    IfMatch='string',
    IfModifiedSince=datetime(2015, 1, 1),
    IfNoneMatch='string',
    IfUnmodifiedSince=datetime(2015, 1, 1),
    Range='string',
    ResponseCacheControl='string',
    ResponseContentDisposition='string',
    ResponseContentEncoding='string',
    ResponseContentLanguage='string',
    ResponseContentType='string',
    ResponseExpires=datetime(2015, 1, 1),
    VersionId='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    RequestPayer='requester'
)
```

Parameters

- **IfMatch** *(string)* – Return the object only if its entity tag (ETag) is the same as the one specified, otherwise return a 412 (precondition failed).
- **IfModifiedSince** *(datetime)* – Return the object only if it has been modified since the specified time, otherwise return a 304 (not modified).
- **IfNoneMatch** *(string)* – Return the object only if its entity tag (ETag) is different from the one specified, otherwise return a 304 (not modified).
- **IfUnmodifiedSince** *(datetime)* – Return the object only if it has not been modified since the specified time, otherwise return a 412 (precondition failed).
- **ResponseCacheControl** *(string)* – Sets the Cache-Control header of the response.
- **ResponseContentDisposition** *(string)* – Sets the Content-Disposition header of the response.
- **ResponseContentEncoding** *(string)* – Sets the Content-Encoding header of the response.
- **ResponseContentLanguage** *(string)* – Sets the Content-Language header of the response.
- **ResponseContentType** *(string)* – Sets the Content-Type header of the response.
- **ResponseExpires** *(datetime)* – Sets the Expires header of the response.
- **VersionId** *(string)* – VersionId used to reference a specific version of the object.
- **SSECustomerAlgorithm** *(string)* – Specifies the algorithm to use to when encrypting the object (e.g., AES256).
- **SSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.
- **SSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error.
Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required

- **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Body': b'bytes',
    'DeleteMarker': True|False,
    'AcceptRanges': 'string',
    'Expiration': 'string',
    'Restore': 'string',
    'LastModified': datetime(2015, 1, 1),
    'ContentLength': 123,
    'ETag': 'string',
    'MissingMeta': 123,
    'VersionId': 'string',
    'CacheControl': 'string',
    'ContentDisposition': 'string',
    'ContentEncoding': 'string',
    'ContentLanguage': 'string',
    'ContentRange': 'string',
    'ContentType': 'string',
    'Expires': datetime(2015, 1, 1),
    'WebsiteRedirectLocation': 'string',
    'ServerSideEncryption': 'AES256'|'aws:kms',
    'Metadata': {
        'string': 'string'
    },
    'SSECustomerAlgorithm': 'string',
    'SSECustomerKeyMD5': 'string',
    'SSEKMSKeyId': 'string',
    'StorageClass': 'STANDARD'|'REDUCED_REDUNDANCY'|'STANDARD_IA',
    'RequestCharged': 'requester',
    'ReplicationStatus': 'COMPLETE'|'PENDING'|'FAILED'|'REPLICA'
}
```

**Response Structure**

- *(dict)* –
  - **Body** *(bytes)* – Object data.
  - **DeleteMarker** *(boolean)* – Specifies whether the object retrieved was (true) or was not (false) a Delete Marker. If false, this response header does not appear in the response.
  - **AcceptRanges** *(string)* –
  - **Expiration** *(string)* – If the object expiration is configured (see PUT Bucket lifecycle), the response includes this header. It includes the expiry-date and rule-id key value pairs providing object expiration information. The value of the rule-id is URL encoded.
  - **Restore** *(string)* – Provides information about object restoration operation and expiration time of the restored object copy.
  - **LastModified** *(datetime)* – Last modified date of the object
- **ContentLength** *(integer)* – Size of the body in bytes.
- **ETag** *(string)* – An ETag is an opaque identifier assigned by a web server to a specific version of a resource found at a URL.
- **MissingMeta** *(integer)* – This is set to the number of metadata entries not returned in x-amz-meta headers. This can happen if you create metadata using an API like SOAP that supports more flexible metadata than the REST API. For example, using SOAP, you can create metadata whose values are not legal HTTP headers.
- **VersionId** *(string)* – Version of the object.
- **CacheControl** *(string)* – Specifies caching behavior along the request/reply chain.
- **ContentDisposition** *(string)* – Specifies presentational information for the object.
- **ContentEncoding** *(string)* – Specifies what content encodings have been applied to the object and thus what decoding mechanisms must be applied to obtain the media-type referenced by the Content-Type header field.
- **ContentLanguage** *(string)* – The language the content is in.
- **ContentRange** *(string)* – The portion of the object returned in the response.
- **ContentType** *(string)* – A standard MIME type describing the format of the object data.
- **Expires** *(datetime)* – The date and time at which the object is no longer cacheable.
- **WebsiteRedirectLocation** *(string)* – If the bucket is configured as a website, redirects requests for this object to another object in the same bucket or to an external URL. Amazon S3 stores the value of this header in the object metadata.
- **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
- **Metadata** *(dict)* – A map of metadata to store with the object in S3.
  * *(string)* –
  · *(string)* –
- **SSECustomerAlgorithm** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header confirming the encryption algorithm used.
- **SSECustomerKeyMD5** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header to provide round trip message integrity verification of the customer-provided encryption key.
- **SSEKMSKeyId** *(string)* – If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.
- **StorageClass** *(string)* –
- **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.
- **ReplicationStatus** *(string)* –

**initiate_multipart_upload(**kwargs**)**

Initiates a multipart upload and returns an upload ID.

**Note:** After you initiate multipart upload and upload one or more parts, you must either complete or abort multipart upload in order to stop getting charged for storage of the uploaded parts. Only after you either complete or abort multipart upload, Amazon S3 frees up the parts storage and stops charging you for the parts storage.
Boto3 Documentation, Release 1.1.4

Request Syntax

```python
multipart_upload = object_summary.initiate_multipart_upload(
    ACL='private'|'public-read'|'public-read-write'|'authenticated-read'|'bucket-owner-read'|'bucket-owner-full-control',
    CacheControl='string',
    ContentDisposition='string',
    ContentEncoding='string',
    ContentLanguage='string',
    ContentType='string',
    Expires=datetime(2015, 1, 1),
    GrantFullControl='string',
    GrantRead='string',
    GrantReadACP='string',
    GrantWriteACP='string',
    Metadata={
        'string': 'string'
    },
    ServerSideEncryption='AES256'|'aws:kms',
    StorageClass='STANDARD'|'REDUCED_REDUNDANCY'|'STANDARD_IA',
    WebsiteRedirectLocation='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    SSEKMSKeyId='string',
    RequestPayer='requester'
)
```

Parameters

- **ACL (string)** – The canned ACL to apply to the object.
- **CacheControl (string)** – Specifies caching behavior along the request/reply chain.
- **ContentDisposition (string)** – Specifies presentational information for the object.
- **ContentEncoding (string)** – Specifies what content encodings have been applied to the object and thus what decoding mechanisms must be applied to obtain the media-type referenced by the Content-Type header field.
- **ContentLanguage (string)** – The language the content is in.
- **ContentType (string)** – A standard MIME type describing the format of the object data.
- **Expires (datetime)** – The date and time at which the object is no longer cacheable.
- **GrantFullControl (string)** – Gives the grantee READ, READ_ACP, and WRITE_ACP permissions on the object.
- **GrantRead (string)** – Allows grantee to read the object data and its metadata.
- **GrantReadACP (string)** – Allows grantee to read the object ACL.
- **GrantWriteACP (string)** – Allows grantee to write the ACL for the applicable object.
- **Metadata (dict)** – A map of metadata to store with the object in S3.
  - (string)
  - * (string) –
- **ServerSideEncryption (string)** – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
- **StorageClass (string)** – The type of storage to use for the object. Defaults to `'STANDARD'`.
- **WebsiteRedirectLocation (string)** – If the bucket is configured as a website, redirects requests for this object to another object in the same bucket or to an external URL. Amazon S3 stores the value of this header in the object metadata.

3.1. Services 4115
• **SSECustomerAlgorithm** *(string)* – Specifies the algorithm to use when encrypting the object (e.g., AES256).

• **SSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.

• **SSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.

• **SSEKMSKeyId** *(string)* – Specifies the AWS KMS key ID to use for object encryption. All GET and PUT requests for an object protected by AWS KMS will fail if not made via SSL or using SigV4. Documentation on configuring any of the officially supported AWS SDKs and CLI can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/UsingAWSSDK.html#specify-signature-version](http://docs.aws.amazon.com/AmazonS3/latest/dev/UsingAWSSDK.html#specify-signature-version)

• **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html](http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html)

**Return type** `s3.MultipartUpload`

**Returns** MultipartUpload resource

```python
put(**kwargs)
```

Adds an object to a bucket.

**Request Syntax**

```python
response = object_summary.put(
    ACL='private'/'public-read'/'public-read-write'/'authenticated-read'/'bucket-owner-read'/'bucket-owner-full-control',
    Body=b'bytes',
    CacheControl='string',
    ContentDisposition='string',
    ContentEncoding='string',
    ContentLanguage='string',
    ContentLength=123,
    ContentMD5='string',
    ContentType='string',
    Expires=datetime(2015, 1, 1),
    GrantFullControl='string',
    GrantRead='string',
    GrantReadACP='string',
    GrantWriteACP='string',
    Metadata={
        'string': 'string'
    },
    ServerSideEncryption='AES256'/'aws:kms',
    StorageClass='STANDARD'/'REDUCED_REDUNDANCY'/'STANDARD_IA',
    WebsiteRedirectLocation='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    SSEKMSKeyId='string',
    RequestPayer='requester'
)
```
Parameters

- **ACL** *(string)* – The canned ACL to apply to the object.
- **Body** *(bytes)* – Object data.
- **CacheControl** *(string)* – Specifies caching behavior along the request/reply chain.
- **ContentDisposition** *(string)* – Specifies presentational information for the object.
- **ContentEncoding** *(string)* – Specifies what content encodings have been applied to the object and thus what decoding mechanisms must be applied to obtain the media-type referenced by the Content-Type header field.
- **ContentLanguage** *(string)* – The language the content is in.
- **ContentLength** *(integer)* – Size of the body in bytes. This parameter is useful when the size of the body cannot be determined automatically.
- **ContentMD5** *(string)* –
- **ContentType** *(string)* – A standard MIME type describing the format of the object data.
- **Expires** *(datetime)* – The date and time at which the object is no longer cacheable.
- **GrantFullControl** *(string)* – Gives the grantee READ, READ_ACP, and WRITE_ACP permissions on the object.
- **GrantRead** *(string)* – Allows grantee to read the object data and its metadata.
- **GrantReadACP** *(string)* – Allows grantee to read the object ACL.
- **GrantWriteACP** *(string)* – Allows grantee to write the ACL for the applicable object.
- **Metadata** *(dict)* – A map of metadata to store with the object in S3.
  - *(string)* –
  - *(string)* –
- **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
- **StorageClass** *(string)* – The type of storage to use for the object. Defaults to ‘STANDARD’.
- **WebsiteRedirectLocation** *(string)* – If the bucket is configured as a website, redirects requests for this object to another object in the same bucket or to an external URL. Amazon S3 stores the value of this header in the object metadata.
- **SSECustomerAlgorithm** *(string)* – Specifies the algorithm to use when encrypting the object (e.g., AES256).
- **SSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.
- **SSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required
- **SSEKMSKeyId** *(string)* – Specifies the AWS KMS key ID to use for object encryption. All GET and PUT requests for an object protected by AWS KMS will fail if not made via SSL or using SigV4. Documentation on configuring any of the officially supported AWS SDKs and CLI can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/UsingAWS SDK.html#specify-signature-version
- **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need
not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPays Buckets.html

Return type dict
Returns

Response Syntax

{
    'Expiration': 'string',
    'ETag': 'string',
    'ServerSideEncryption': 'AES256'|'aws:kms',
    'VersionId': 'string',
    'SSEC customerAlgorithm': 'string',
    'SSEC customerKeyMD5': 'string',
    'SSE KMS Key Id': 'string',
    'RequestCharged': 'requester'
}

Response Structure

- (dict) –
  - Expiration (string) – If the object expiration is configured, this will contain the expiration date (expiry-date) and rule ID (rule-id). The value of rule-id is URL encoded.
  - ETag (string) – Entity tag for the uploaded object.
  - ServerSideEncryption (string) – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
  - VersionId (string) – Version of the object.
  - SSEC customerAlgorithm (string) – If server-side encryption with a customer-provided encryption key was requested, the response will include this header confirming the encryption algorithm used.
  - SSEC customerKeyMD5 (string) – If server-side encryption with a customer-provided encryption key was requested, the response will include this header to provide round trip message integrity verification of the customer-provided encryption key.
  - SSE KMS Key Id (string) – If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.
  - RequestCharged (string) – If present, indicates that the requester was successfully charged for the request.

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

Acl()

Creates a ObjectAcl resource:

    object_acl = object_summary.Acl()

Return type S3.ObjectAcl
Returns A ObjectAcl resource

Bucket()

Creates a Bucket resource:
bucket = object_summary.Bucket()

Return type  S3.Bucket
Returns  A Bucket resource

MultipartUpload(id)
Creates a MultipartUpload resource:

multipart_upload = object_summary.MultipartUpload('id')

Parameters  id (string) – The MultipartUpload’s id identifier. This must be set.
Return type  S3.MultipartUpload
Returns  A MultipartUpload resource

Object()
Creates a Object resource:

object = object_summary.Object()

Return type  S3.Object
Returns  A Object resource

Version(id)
Creates a ObjectVersion resource:

object_version = object_summary.Version('id')

Parameters  id (string) – The Version’s id identifier. This must be set.
Return type  S3.ObjectVersion
Returns  A ObjectVersion resource

Waiters
Waiters provide an interface to wait for a resource to reach a specific state. For more information about waiters refer to the Resources Introduction Guide.

wait_until_exists(**kwargs)
Waits until this ObjectSummary is exists. This method calls S3.Waiter.object_exists.wait() which polls. S3.Client.head_object() every 5 seconds until a successful state is reached. An error is returned after 20 failed checks.

Request Syntax

object_summary.wait_until_exists(
    IfMatch='string',
    IfModifiedSince=datetime(2015, 1, 1),
    IfNoneMatch='string',
    IfUnmodifiedSince=datetime(2015, 1, 1),
    Range='string',
    VersionId='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    RequestPayer='requester'
)

Parameters

• IfMatch (string) – Return the object only if its entity tag (ETag) is the same as the one specified, otherwise return a 412 (precondition failed).
• **IfModifiedSince** (*datetime*) – Return the object only if it has been modified since the specified time, otherwise return a 304 (not modified).
• **IfNoneMatch** (*string*) – Return the object only if its entity tag (ETag) is different from the one specified, otherwise return a 304 (not modified).
• **IfUnmodifiedSince** (*datetime*) – Return the object only if it has not been modified since the specified time, otherwise return a 412 (precondition failed).
• **VersionId** (*string*) – VersionId used to reference a specific version of the object.
• **SSECustomerAlgorithm** (*string*) – Specifies the algorithm to use to when encrypting the object (e.g., AES256).
• **SSECustomerKey** (*string*) – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the `x-amz-server-side-encryption-customer-algorithm` header.
• **SSECustomerKeyMD5** (*string*) – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.
• **RequestPayer** (*string*) – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html](http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html)

**Returns** None

`wait_until_not_exists(**kwargs)`

Waits until this ObjectSummary is not exists. This method calls `S3.Waiter.object_not_exists.wait()` which polls `S3.Client.head_object()` every 5 seconds until a successful state is reached. An error is returned after 20 failed checks.

**Request Syntax**

```python
object_summary.wait_until_not_exists(
    IfMatch='string',
    IfModifiedSince=datetime(2015, 1, 1),
    IfNoneMatch='string',
    IfUnmodifiedSince=datetime(2015, 1, 1),
    Range='string',
    VersionId='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    RequestPayer='requester'
)
```

**Parameters**

- **IfMatch** (*string*) – Return the object only if its entity tag (ETag) is the same as the one specified, otherwise return a 412 (precondition failed).
- **IfModifiedSince** (*datetime*) – Return the object only if it has been modified since the specified time, otherwise return a 304 (not modified).
- **IfNoneMatch** (*string*) – Return the object only if its entity tag (ETag) is different from the one specified, otherwise return a 304 (not modified).
• **IfUnmodifiedSince** (*datetime*) – Return the object only if it has not been modified since the specified time, otherwise return a 412 (precondition failed).
• **Range** (*string*) – Downloads the specified range bytes of an object. For more information about the HTTP Range header, go to http://www.w3.org/Protocols/rfc2616/rfc2616-sec14.html#sec14.35.
• **VersionId** (*string*) – VersionId used to reference a specific version of the object.
• **SSECustomerAlgorithm** (*string*) – Specifies the algorithm to use to when encrypting the object (e.g., AES256).
• **SSECustomerKey** (*string*) – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.
• **SSECustomerKeyMD5** (*string*) – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.
• **RequestPayer** (*string*) – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

**Returns** None

### ObjectVersion

class **S3.ObjectVersion** (*bucket_name*, *object_key*, *id*)
A resource representing an Amazon Simple Storage Service (S3) ObjectVersion:

```python
import boto3

s3 = boto3.resource('s3')
object_version = s3.ObjectVersion('bucket_name','object_key','id')
```

**Parameters**

- **bucket_name** (*string*) – The ObjectVersion’s bucket_name identifier. This **must** be set.
- **object_key** (*string*) – The ObjectVersion’s object_key identifier. This **must** be set.
- **id** (*string*) – The ObjectVersion’s id identifier. This **must** be set.

These are the resource’s available identifiers:

- `bucket_name`
- `object_key`
- `id`

These are the resource’s available attributes:

- `etag`
- `is_latest`
- `key`
- `last_modified`
- `owner`
- `size`
- `storage_class`
- `version_id`

3.1. Services
These are the resource’s available actions:

- `delete()`  
- `get()`  
- `head()`

These are the resource’s available sub-resources:

- `Object()`

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide.*

**bucket_name**

*(string)* The ObjectVersion’s bucket_name identifier. This **must** be set.

**object_key**

*(string)* The ObjectVersion’s object_key identifier. This **must** be set.

**id**

*(string)* The ObjectVersion’s id identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the *Resources Introduction Guide.*

**e_tag**

*(string)*

**is_latest**

*(boolean)* Specifies whether the object is (true) or is not (false) the latest version of an object.

**key**

*(string)* The object key.

**last_modified**

*(datetime)* Date and time the object was last modified.

**owner**

*(dict)*

**size**

*(integer)* Size in bytes of the object.

**storage_class**

*(string)* The class of storage used to store the object.

**version_id**

*(string)* Version ID of an object.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide.*

**delete(**kwargs)**

Removes the null version (if there is one) of an object and inserts a delete marker, which becomes the latest version of the object. If there isn’t a null version, Amazon S3 does not remove any objects.

**Request Syntax**

```python
response = object_version.delete(
    MFA='string',
)```
Parameters

- **MFA (string)** – The concatenation of the authentication device’s serial number, a space, and the value that is displayed on your authentication device.
- **RequestPayer (string)** – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

Return type  dict

Returns

Response Syntax

```python
{
    'DeleteMarker': True|False,
    'VersionId': 'string',
    'RequestCharged': 'requester'
}
```

Response Structure

- **dict** –
  - **DeleteMarker (boolean)** – Specifies whether the versioned object that was permanently deleted was (true) or was not (false) a delete marker.
  - **VersionId (string)** – Returns the version ID of the delete marker created as a result of the DELETE operation.
  - **RequestCharged (string)** – If present, indicates that the requester was successfully charged for the request.

get(**kwargs)

Retrieves objects from Amazon S3.

Request Syntax

```python
response = object_version.get(
    IfMatch='string',
    IfModifiedSince=datetime(2015, 1, 1),
    IfNoneMatch='string',
    IfUnmodifiedSince=datetime(2015, 1, 1),
    Range='string',
    ResponseCacheControl='string',
    ResponseContentDisposition='string',
    ResponseContentEncoding='string',
    ResponseContentLanguage='string',
    ResponseContentType='string',
    ResponseExpires=datetime(2015, 1, 1),
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    RequestPayer='requester'
)
```

Parameters

- **IfMatch (string)** – Return the object only if its entity tag (ETag) is the same as the one specified, otherwise return a 412 (precondition failed).
• **IfModifiedSince (datetime)** – Return the object only if it has been modified since the specified time, otherwise return a 304 (not modified).
• **IfNoneMatch (string)** – Return the object only if its entity tag (ETag) is different from the one specified, otherwise return a 304 (not modified).
• **IfUnmodifiedSince (datetime)** – Return the object only if it has not been modified since the specified time, otherwise return a 412 (precondition failed).
• **Range (string)** – Downloads the specified range bytes of an object. For more information about the HTTP Range header, go to http://www.w3.org/Protocols/rfc2616/rfc2616-sec14.html#sec14.35.
• **ResponseCacheControl (string)** – Sets the Cache-Control header of the response.
• **ResponseContentDisposition (string)** – Sets the Content-Disposition header of the response.
• **ResponseContentEncoding (string)** – Sets the Content-Encoding header of the response.
• **ResponseContentLanguage (string)** – Sets the Content-Language header of the response.
• **ResponseContentType (string)** – Sets the Content-Type header of the response.
• **ResponseExpires (datetime)** – Sets the Expires header of the response.
• **SSECustomerAlgorithm (string)** – Specifies the algorithm to use when encrypting the object (e.g., AES256).
• **SSECustomerKey (string)** – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.
• **SSECustomerKeyMD5 (string)** – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required
• **RequestPayer (string)** – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Body': b'bytes',
    'DeleteMarker': True|False,
    'AcceptRanges': 'string',
    'Expiration': 'string',
    'Restore': 'string',
    'LastModified': datetime(2015, 1, 1),
    'ContentLength': 123,
    'ETag': 'string',
    'MissingMeta': 123,
    'VersionId': 'string',
    'CacheControl': 'string',
    'ContentDisposition': 'string',
    'ContentEncoding': 'string',
}```
Response Structure

- **Body** *(bytes)* – Object data.
- **DeleteMarker** *(boolean)* – Specifies whether the object retrieved was (true) or was not (false) a Delete Marker. If false, this response header does not appear in the response.
- **AcceptRanges** *(string)* –
- **Expiration** *(string)* – If the object expiration is configured (see PUT Bucket lifecycle), the response includes this header. It includes the expiry-date and rule-id key value pairs providing object expiration information. The value of the rule-id is URL encoded.
- **Restore** *(string)* – Provides information about object restoration operation and expiration time of the restored object copy.
- **LastModified** *(datetime)* – Last modified date of the object
- **ContentLength** *(integer)* – Size of the body in bytes.
- **ETag** *(string)* – An ETag is an opaque identifier assigned by a web server to a specific version of a resource found at a URL.
- **MissingMeta** *(integer)* – This is set to the number of metadata entries not returned in x-amz-meta headers. This can happen if you create metadata using an API like SOAP that supports more flexible metadata than the REST API. For example, using SOAP, you can create metadata whose values are not legal HTTP headers.
- **VersionId** *(string)* – Version of the object.
- **CacheControl** *(string)* – Specifies caching behavior along the request/reply chain.
- **ContentDisposition** *(string)* – Specifies presentational information for the object.
- **ContentEncoding** *(string)* – Specifies what content encodings have been applied to the object and thus what decoding mechanisms must be applied to obtain the media-type referenced by the Content-Type header field.
- **ContentLanguage** *(string)* – The language the content is in.
- **ContentRange** *(string)* – The portion of the object returned in the response.
- **ContentType** *(string)* – A standard MIME type describing the format of the object data.
- **Expires** *(datetime)* – The date and time at which the object is no longer cacheable.
- **WebsiteRedirectLocation** *(string)* – If the bucket is configured as a web-
The HEAD operation retrieves metadata from an object without returning the object itself. This operation is useful if you’re only interested in an object’s metadata. To use HEAD, you must have READ access to the object.

Request Syntax

```python
response = object_version.head(
    IfMatch='string',
    IfModifiedSince=datetime(2015, 1, 1),
    IfNoneMatch='string',
    IfUnmodifiedSince=datetime(2015, 1, 1),
    Range='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    RequestPayer='requester'
)
```

Parameters

- **IfMatch (string)** – Return the object only if its entity tag (ETag) is the same as the one specified, otherwise return a 412 (precondition failed).
- **IfModifiedSince (datetime)** – Return the object only if it has been modified since the specified time, otherwise return a 304 (not modified).
- **IfNoneMatch (string)** – Return the object only if its entity tag (ETag) is different from the one specified, otherwise return a 304 (not modified).
- **IfUnmodifiedSince (datetime)** – Return the object only if it has not been modified since the specified time, otherwise return a 412 (precondition failed).
- **Range (string)** – Downloads the specified range bytes of an object. For more information about the HTTP Range header, go to http://www.w3.org/Protocols/rfc2616/rfc2616-sec14.html#sec14.35.
- **SSECustomerAlgorithm (string)** – Specifies the algorithm to use to encrypt the object (e.g., AES256).
• **SSECUSTOMERKEY** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.

• **SSECUSTOMERKEYMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.

• **REQUESTPAYER** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html](http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html)

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'DeleteMarker': True|False,
    'AcceptRanges': 'string',
    'Expiration': 'string',
    'Restore': 'string',
    'LastModified': datetime(2015, 1, 1),
    'ContentLength': 123,
    'ETag': 'string',
    'MissingMeta': 123,
    'VersionId': 'string',
    'CacheControl': 'string',
    'ContentDisposition': 'string',
    'ContentEncoding': 'string',
    'ContentLanguage': 'string',
    'ContentType': 'string',
    'Expires': datetime(2015, 1, 1),
    'WebsiteRedirectLocation': 'string',
    'ServerSideEncryption': 'AES256'|'aws:kms',
    'Metadata': {
        'string': 'string'
    },
    'SSECUSTOMERKEYAlgorithm': 'string',
    'SSECUSTOMERKEYMD5': 'string',
    'SEKMSKeyId': 'string',
    'StorageClass': 'STANDARD'|'REDUCED_REDUndancy'|'STANDARD_IA',
    'RequestCharged': 'requester',
    'ReplicationStatus': 'COMPLETE'|'PENDING'|'FAILED'|'REPLICA'
}
```

**Response Structure**

- *(dict)* –
  - **DeleteMarker** *(boolean)* – Specifies whether the object retrieved was (true) or was not (false) a Delete Marker. If false, this response header does not appear in the response.
  - **AcceptRanges** *(string)* –
  - **Expiration** *(string)* – If the object expiration is configured (see PUT Bucket lifecycle), the response includes this header. It includes the expiry-
date and rule-id key value pairs providing object expiration information. The value of the rule-id is URL encoded.

- **Restore** *(string)* – Provides information about object restoration operation and expiration time of the restored object copy.
- **LastModified** *(datetime)* – Last modified date of the object
- **ContentLength** *(integer)* – Size of the body in bytes.
- **ETag** *(string)* – An ETag is an opaque identifier assigned by a web server to a specific version of a resource found at a URL
- **MissingMeta** *(integer)* – This is set to the number of metadata entries not returned in x-amz-meta headers. This can happen if you create metadata using an API like SOAP that supports more flexible metadata than the REST API. For example, using SOAP, you can create metadata whose values are not legal HTTP headers.
- **VersionId** *(string)* – Version of the object.
- **CacheControl** *(string)* – Specifies caching behavior along the request/reply chain.
- **ContentDisposition** *(string)* – Specifies presentational information for the object.
- **ContentEncoding** *(string)* – Specifies what content encodings have been applied to the object and thus what decoding mechanisms must be applied to obtain the media-type referenced by the Content-Type header field.
- **ContentLanguage** *(string)* – The language the content is in.
- **ContentType** *(string)* – A standard MIME type describing the format of the object data.
- **Expires** *(datetime)* – The date and time at which the object is no longer cacheable.
- **WebsiteRedirectLocation** *(string)* – If the bucket is configured as a website, redirects requests for this object to another object in the same bucket or to an external URL. Amazon S3 stores the value of this header in the object metadata.
- **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
- **Metadata** *(dict)* – A map of metadata to store with the object in S3.
  * *(string)* – 
    · *(string)* – 
  - **SSECustomerAlgorithm** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header confirming the encryption algorithm used.
  - **SSECustomerKeyMD5** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header to provide round trip message integrity verification of the customer-provided encryption key.
  - **SSEKMSKeyId** *(string)* – If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.
- **StorageClass** *(string)* –
- **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.
- **ReplicationStatus** *(string)* –

**Sub-resources**

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the *Resources Introduction Guide*. 
Object()

Creates a Object resource:

    object = object_version.Object()

    Return type  S3.Object
    Returns   A Object resource

SimpleDB

class SimpleDB.Client

A low-level client representing Amazon SimpleDB:

    import boto3

    client = boto3.client('sdb')

These are the available methods:

* batch_delete_attributes()
* batch_put_attributes()
* can_paginate()
* create_domain()
* delete_attributes()
* delete_domain()
* domain_metadata()
* generate_presigned_url()
* get_attributes()
* get_paginate()
* get_waiter()
* list_domains()
* put_attributes()
* select()

batch_delete_attributes(**kwargs)

Performs multiple DeleteAttributes operations in a single call, which reduces round trips and latencies. This enables Amazon SimpleDB to optimize requests, which generally yields better throughput.

The following limitations are enforced for this operation:

* 1 MB request size
* 25 item limit per BatchDeleteAttributes operation

Request Syntax

    response = client.batch_delete_attributes( 
        DomainName='string', 
        **kwargs)
Items=[
  {
    'Name': 'string',
    'Attributes': [
      {
        'Name': 'string',
        'AlternateNameEncoding': 'string',
        'Value': 'string',
        'AlternateValueEncoding': 'string'
      }
    ]
  },
  ]
}

Parameters

- **DomainName (string)** – [REQUIRED] The name of the domain in which the attributes are being deleted.
- **Items (list)** – [REQUIRED] A list of items on which to perform the operation.
  - (dict) –
    * **Name (string)** – [REQUIRED]
    * **Attributes (list)** –
      - (dict) –
        * **Name (string)** – [REQUIRED] The name of the attribute.
        * **AlternateNameEncoding (string)** –
        * **AlternateValueEncoding (string)** –

Returns None

**batch_put_attributes(**kwargs)**

The `batch_put_attributes` operation creates or replaces attributes within one or more items. By using this operation, the client can perform multiple `PutAttribute` operation with a single call. This helps yield savings in round trips and latencies, enabling Amazon SimpleDB to optimize requests and generally produce better throughput.

The client may specify the item name with the `Item.X.ItemName` parameter. The client may specify new attributes using a combination of the `Item.X.Attribute.Y.Name` and `Item.X.Attribute.Y.Value` parameters. The client may specify the first attribute for the first item using the parameters `Item.0.Attribute.0.Name` and `Item.0.Attribute.0.Value`, and for the second attribute for the first item by the parameters `Item.0.Attribute.1.Name` and `Item.0.Attribute.1.Value`, and so on.

Attributes are uniquely identified within an item by their name/value combination. For example, a single item can have the attributes `{ "first_name", "first_value" }` and `{ "first_name", "second_value" }`. However, it cannot have two attribute instances where both the `Item.X.Attribute.Y.Name` and `Item.X.Attribute.Y.Value` are the same.

Optionally, the requester can supply the Replace parameter for each individual value. Setting this value to true will cause the new attribute values to replace the existing attribute values. For example, if an item I has the attributes `{ 'a', '1' }, { 'b', '2' } and `{ 'b', '3' } and the requester does a `batch_put_attributes` of `{ 'I', 'b', '4' }` with the Replace parameter set to true, the final attributes of the item will be `{ 'a', '1' } and `{ 'b', '4' }`, replacing the previous values of the 'b' attribute with the new value.

**Warning:** This operation is vulnerable to exceeding the maximum URL size when making a REST request using the HTTP GET method. This operation does not support conditions using `Expected.X.Name`, `Expected.X.Value`, or `Expected.X.Exists`. 

4130 Chapter 3. API Reference
You can execute multiple BatchPutAttributes operations and other operations in parallel. However, large numbers of concurrent BatchPutAttributes calls can result in Service Unavailable (503) responses.

The following limitations are enforced for this operation:
- 256 attribute name-value pairs per item
- 1 MB request size
- 1 billion attributes per domain
- 10 GB of total user data storage per domain
- 25 item limit per BatchPutAttributes operation

Request Syntax

```python
response = client.batch_put_attributes(
    DomainName='string',
    Items=[
        {
            'Name': 'string',
            'Attributes': [
                {
                    'Name': 'string',
                    'Value': 'string',
                    'Replace': True|False
                },
            ],
        },
    ],
)
```

Parameters

- **DomainName (string)** – [REQUIRED] The name of the domain in which the attributes are being stored.
- **Items (list)** – [REQUIRED] A list of items on which to perform the operation.
  - (dict) –
    - **Name (string)** – [REQUIRED] The name of the replaceable item.
    - **Attributes (list)** – [REQUIRED] The list of attributes for a replaceable item.
      - (dict) –
        - **Name (string)** – [REQUIRED] The name of the replaceable attribute.
        - **Replace (boolean)** – A flag specifying whether or not to replace the attribute/value pair or to add a new attribute/value pair. The default setting is false.

Returns None

can_paginate (operation_name)

Check if an operation can be paginated.

Parameters operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginators("create_foo").

Returns True if the operation can be paginated, False otherwise.
**create_domain(**kwargs)**

The `create_domain` operation creates a new domain. The domain name should be unique among the domains associated with the Access Key ID provided in the request. The `create_domain` operation may take 10 or more seconds to complete.

The client can create up to 100 domains per account.

If the client requires additional domains, go to [http://aws.amazon.com/contact-us/simpeldb-limit-request/](http://aws.amazon.com/contact-us/simpeldb-limit-request/).

**Request Syntax**

```python
response = client.create_domain(
    DomainName='string'
)
```

**Parameters**

- **DomainName (string)** – [REQUIRED] The name of the domain to create. The name can range between 3 and 255 characters and can contain the following characters: a-z, A-Z, 0-9, '_', '-', and '.'.

**Returns** None

**delete_attributes(**kwargs)**

Deletes one or more attributes associated with an item. If all attributes of the item are deleted, the item is deleted.

`delete_attributes` is an idempotent operation; running it multiple times on the same item or attribute does not result in an error response.

Because Amazon SimpleDB makes multiple copies of item data and uses an eventual consistency update model, performing a `GetAttributes` or `Select` operation (read) immediately after a `delete_attributes` or `PutAttributes` operation (write) might not return updated item data.

**Request Syntax**

```python
response = client.delete_attributes(
    DomainName='string',
    ItemName='string',
    Attributes=[
        {
            'Name': 'string',
            'AlternateNameEncoding': 'string',
            'Value': 'string',
            'AlternateValueEncoding': 'string'
        },
    ],
    Expected={
        'Name': 'string',
        'Value': 'string',
        'Exists': True|False
    }
)
```

**Parameters**

- **DomainName (string)** – [REQUIRED] The name of the domain in which to perform the operation.
- **ItemName (string)** – [REQUIRED] The name of the item. Similar to rows on a spreadsheet, items represent individual objects that contain one or more value-attribute pairs.
- **Attributes (list)** – A list of Attributes. Similar to columns on a spreadsheet, attributes represent categories of data that can be assigned to items.
• **Expected** *(dict)* – The update condition which, if specified, determines whether the specified attributes will be deleted or not. The update condition must be satisfied in order for this request to be processed and the attributes to be deleted.
  
  - **Name** *(string)* –
    
    The name of the attribute involved in the condition.
  
  - **Value** *(string)* –
    
    The value of an attribute. This value can only be specified when the `Exists` parameter is equal to `true`.
  
  - **Exists** *(boolean)* –
    
    A value specifying whether or not the specified attribute must exist with the specified value in order for the update condition to be satisfied. Specify `true` if the attribute must exist for the update condition to be satisfied. Specify `false` if the attribute should not exist in order for the update condition to be satisfied.

  Returns  None

delete_domain(**kwargs)**

The `DeleteDomain` operation deletes a domain. Any items (and their attributes) in the domain are deleted as well. The `DeleteDomain` operation might take 10 or more seconds to complete.

Request Syntax

```python
response = client.delete_domain(
    DomainName='string'
)
```

Parameters  DomainName *(string)* – [REQUIRED] The name of the domain to delete.

Returns  None
domain_metadata(**kwargs)**

Returns information about the domain, including when the domain was created, the number of items and attributes in the domain, and the size of the attribute names and values.

Request Syntax

```python
response = client.domain_metadata(
    DomainName='string'
)
```

Parameters  DomainName *(string)* – [REQUIRED] The name of the domain for which to display the metadata of.

Return type  dict

Returns

Response Syntax

```json
{
    'ItemCount': 123,
    'ItemNamesSizeBytes': 123,
    'AttributeNameCount': 123,
    'AttributeNamesSizeBytes': 123,
    ...
}
```
'AttributeValueCount': 123,
'AttributeValueValuesSizeBytes': 123,
'Timestamp': 123
}

Response Structure
• (dict) –
  • ItemCount (integer) – The number of all items in the domain.
  • ItemNamesSizeBytes (integer) – The total size of all item names in
    the domain, in bytes.
  • AttributeNameCount (integer) – The number of unique attribute names
    in the domain.
  • AttributeNamesSizeBytes (integer) – The total size of all unique attribute
    names in the domain.
  • AttributeValueCount (integer) – The number of all attribute name/value
    pairs in the domain.
  • AttributeValuesSizeBytes (integer) – The total size of all attribute values
    in the domain, in bytes.
  • Timestamp (integer) – The data and time when metadata was calculated,
    in Epoch (UNIX) seconds.

generate_presigned_url (ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)
Generate a presigned url given a client, its method, and arguments
Parameters
• ClientMethod (string) – The client method to presign for
• Params (dict) – The parameters normally passed to ClientMethod.
• ExpiresIn (int) – The number of seconds the presigned url is valid for. By
  default it expires in an hour (3600 seconds)
• HttpMethod (string) – The http method to use on the generated url. By default,
  the http method is whatever is used in the method’s model.

Returns
The presigned url

get_attributes(**kwargs)
Returns all of the attributes associated with the specified item. Optionally, the attributes returned can be
limited to one or more attributes by specifying an attribute name parameter.

If the item does not exist on the replica that was accessed for this operation, an empty set is returned. The
system does not return an error as it cannot guarantee the item does not exist on other replicas.

Request Syntax

response = client.get_attributes(
    DomainName='string',
    ItemName='string',
    AttributeNames=[
        'string',
    ],
    ConsistentRead=True|False
)
• **ConsistentRead** *(boolean)* – Determines whether or not strong consistency should be enforced when data is read from SimpleDB. If true, any data previously written to SimpleDB will be returned. Otherwise, results will be consistent eventually, and the client may not see data that was written immediately before your read.

Return type  **dict**

Returns

Response Syntax

```json
{
    'Attributes': [
        {
            'Name': 'string',
            'AlternateNameEncoding': 'string',
            'Value': 'string',
            'AlternateValueEncoding': 'string'
        }
    ]
}
```

Response Structure

- *(dict)* –
  - **Attributes** *(list)* – The list of attributes returned by the operation.
    - *(dict)* –
      - **Name** *(string)* – The name of the attribute.
      - **AlternateNameEncoding** *(string)* –
      - **Value** *(string)* – The value of the attribute.
      - **AlternateValueEncoding** *(string)* –

get_paginator *(operation_name)*

Create a paginator for an operation.

**Parameters**  operation_name *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

**Raises**  OperationNotPageableError Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

Return type  L{botocore.paginate.Paginator}

Returns  A paginator object.

get_waiter *(waiter_name)*

list_domains(**kwargs)**

The ListDomains operation lists all domains associated with the Access Key ID. It returns domain names up to the limit set by MaxNumberOfDomains. A NextToken is returned if there are more than MaxNumberOfDomains domains. Calling ListDomains successive times with the NextToken provided by the operation returns up to MaxNumberOfDomains more domain names with each successive operation call.

Request Syntax

```python
response = client.list_domains(
    MaxNumberOfDomains=123,
    NextToken='string'
)
```
Parameters

- **MaxNumberOfDomains** (*integer*) – The maximum number of domain names you want returned. The range is 1 to 100. The default setting is 100.
- **NextToken** (*string*) – A string informing Amazon SimpleDB where to start the next list of domain names.

Return type: `dict`

Returns

Response Syntax

```python
{
    'DomainNames': [
        'string',
    ],
    'NextToken': 'string'
}
```

Response Structure

- *(dict)* –
  - **DomainNames** (*list*) – A list of domain names that match the expression.
    - *(string)* –
  - **NextToken** (*string*) – An opaque token indicating that there are more domains than the specified `MaxNumberOfDomains` still available.

**put_attributes(**kwargs)**

The `PutAttributes` operation creates or replaces attributes in an item. The client may specify new attributes using a combination of the `Attribute.X.Name` and `Attribute.X.Value` parameters. The client specifies the first attribute by the parameters `Attribute.0.Name` and `Attribute.0.Value`, the second attribute by the parameters `Attribute.1.Name` and `Attribute.1.Value`, and so on.

Attributes are uniquely identified in an item by their name/value combination. For example, a single item can have the attributes `{ "first_name", "first_value" }` and `{ "first_name", second_value" }`. However, it cannot have two attribute instances where both the `Attribute.X.Name` and `Attribute.X.Value` are the same.

Optionally, the requestor can supply the `Replace` parameter for each individual attribute. Setting this value to `true` causes the new attribute value to replace the existing attribute value(s). For example, if an item has the attributes `{ 'a', '1' }, { 'b', '2' } and { 'b', '3' } and the requestor calls `PutAttributes` using the attributes `{ 'b', '4' }` with the `Replace` parameter set to `true`, the final attributes of the item are changed to `{ 'a', '1' }` and `{ 'b', '4' }`, which replaces the previous values of the ‘b’ attribute with the new value.

You cannot specify an empty string as an attribute name.

Because Amazon SimpleDB makes multiple copies of client data and uses an eventual consistency update model, an immediate `GetAttributes` or `Select` operation (read) immediately after a `PutAttributes` or `DeleteAttributes` operation (write) might not return the updated data.

The following limitations are enforced for this operation:

- 256 total attribute name-value pairs per item
- One billion attributes per domain
- 10 GB of total user data storage per domain

Request Syntax

```python
response = client.put_attributes(
    DomainName='string',
    ItemName='string',
    Attributes=[
```
Parameters

- **DomainName** *(string) – [REQUIRED]* The name of the domain in which to perform the operation.
- **ItemName** *(string) – [REQUIRED]* The name of the item.
- **Attributes** *(list) – [REQUIRED]* The list of attributes.
  - *(dict)* –
    * **Name** *(string) – [REQUIRED]* The name of the replaceable attribute.
    * **Value** *(string) – [REQUIRED]* The value of the replaceable attribute.
    * **Replace** *(boolean)* – A flag specifying whether or not to replace the attribute/value pair or to add a new attribute/value pair. The default setting is false.
- **Expected** *(dict)* – The update condition which, if specified, determines whether the specified attributes will be updated or not. The update condition must be satisfied in order for this request to be processed and the attributes to be updated.
  - **Name** *(string)* – The name of the attribute involved in the condition.
  - **Value** *(string)* – The value of an attribute. This value can only be specified when the Exists parameter is equal to true.
  - **Exists** *(boolean)* – A value specifying whether or not the specified attribute must exist with the specified value in order for the update condition to be satisfied. Specify true if the attribute must exist for the update condition to be satisfied. Specify false if the attribute should not exist in order for the update condition to be satisfied.

Returns None

**select** (**kwargs)**

The Select operation returns a set of attributes for ItemNames that match the select expression. Select is similar to the standard SQL SELECT statement.

The total size of the response cannot exceed 1 MB in total size. Amazon SimpleDB automatically adjusts the number of items returned per page to enforce this limit. For example, if the client asks to retrieve 2500 items, but each individual item is 10 kB in size, the system returns 100 items and an appropriate NextToken so the client can access the next page of results.

For information on how to construct select expressions, see Using Select to Create Amazon SimpleDB Queries in the Developer Guide.

**Request Syntax**
response = client.select(
    SelectExpression='string',
    NextToken='string',
    ConsistentRead=True|False
)

Parameters

- **SelectExpression** *(string)* – [REQUIRED] The expression used to query the domain.
- **NextToken** *(string)* – A string informing Amazon SimpleDB where to start the next list of ItemNames.
- **ConsistentRead** *(boolean)* – Determines whether or not strong consistency should be enforced when data is read from SimpleDB. If true, any data previously written to SimpleDB will be returned. Otherwise, results will be consistent eventually, and the client may not see data that was written immediately before your read.

Return type **dict**

Returns

**Response Syntax**

```json
{
   'Items': [
   {
       'Name': 'string',
       'AlternateNameEncoding': 'string',
       'Attributes': [
       {
           'Name': 'string',
           'AlternateNameEncoding': 'string',
           'Value': 'string',
           'AlternateValueEncoding': 'string'
       },
       ],
   },
   ],
   'NextToken': 'string'
}
```

**Response Structure**

- *(dict)* –
  - **Items** *(list)* – A list of items that match the select expression.
    - *(dict)* –
      - **Name** *(string)* – The name of the item.
      - **AlternateNameEncoding** *(string)* –
      - **Attributes** *(list)* – A list of attributes.
        - *(dict)* –
          - **Name** *(string)* – The name of the attribute.
          - **AlternateNameEncoding** *(string)* –
          - **Value** *(string)* – The value of the attribute.
          - **AlternateValueEncoding** *(string)* –
  - **NextToken** *(string)* – An opaque token indicating that more items than MaxNumberOfItems were matched, the response size exceeded 1 megabyte, or the execution time exceeded 5 seconds.
Paginators

The available paginators are:

- SimpleDB.Paginator.ListDomains
- SimpleDB.Paginator.Select

```python
class SimpleDB.Paginator.ListDomains

paginator = client.get_paginator('list_domains')
paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `SimpleDB.Client.list_domains()`.

Request Syntax

```python
response_iterator = paginator.paginate(
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

`PaginationConfig (dict)` – A dictionary that provides parameters to control pagination.

- `MaxItems (integer)` – The total number of items to return. If the total number of items available is more than the value specified in `max-items` then a `NextToken` will be provided in the output that you can use to resume pagination.
- `PageSize (integer)` – The size of each page.
- `StartingToken (string)` – A token to specify where to start paginating. This is the `NextToken` from a previous response.

Return type

dict

Returns

Response Syntax

```python
{
    'DomainNames': [
        'string',
    ],
}
```

Response Structure

- `(dict)` –
  - `DomainNames (list)` – A list of domain names that match the expression.
class SimpleDB.Paginator.Select

paginator = client.get_paginator('select')

paginate(**kwargs)

Creates an iterator that will paginate through responses from SimpleDB.Client.select().

Request Syntax

response_iterator = paginator.paginate(
    SelectExpression='string',
    ConsistentRead=True|False,
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **SelectExpression** (string) – [REQUIRED] The expression used to query the domain.
- **ConsistentRead** (boolean) – Determines whether or not strong consistency should be enforced when data is read from SimpleDB. If true, any data previously written to SimpleDB will be returned. Otherwise, results will be consistent eventually, and the client may not see data that was written immediately before your read.
- **PaginationConfig** (dict) – A dictionary that provides parameters to control pagination.
  - **MaxItems** (integer) – The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** (integer) – The size of each page.
  - **StartingToken** (string) – A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict

Returns

Response Syntax

    

    

    

- Items: [  
  
  ```
  
  ```

  ```

    ```

```
Response Structure

* (dict) –
  – Items (list) – A list of items that match the select expression.
    * (dict) –
      · Name (string) – The name of the item.
      · AlternateNameEncoding (string) –
      · Attributes (list) – A list of attributes.
        * (dict) –
          · Name (string) – The name of the attribute.
          · AlternateNameEncoding (string) –
          · Value (string) – The value of the attribute.
          · AlternateValueEncoding (string) –

SES

Table of Contents

- SES
  - Client
  - Paginators
  - Waiters

Client

class SES.Client
A low-level client representing Amazon Simple Email Service (SES):

import boto3

client = boto3.client('ses')

These are the available methods:

- can_paginate()
- delete_identity()
- delete_identity_policy()
- delete_verified_email_address()
- generate_presigned_url()
- get_identity_dkim_attributes()
- get_identity_notification_attributes()
- get_identity_policies()
- get_identity_verification_attributes()
- get_paginate()
- get_send_quota()
- get_send_statistics()
can_paginate(operation_name)

Check if an operation can be paginated.

Parameters operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get Paginator("create_foo").

Returns True if the operation can be paginated, False otherwise.

delete_identity(**kwargs)

Deletes the specified identity (email address or domain) from the list of verified identities.

This action is throttled at one request per second.

Request Syntax

response = client.delete_identity(
    Identity='string'
)

Parameters Identity (string) – [REQUIRED]

The identity to be removed from the list of identities for the AWS Account.

Return type dict

Returns

Response Syntax

{}

Response Structure

• (dict) –

An empty element. Receiving this element indicates that the request completed successfully.

delete_identity_policy(**kwargs)

Deletes the specified sending authorization policy for the given identity (email address or domain). This API returns successfully even if a policy with the specified name does not exist.

Note: This API is for the identity owner only. If you have not verified the identity, this API will return an error.
Sending authorization is a feature that enables an identity owner to authorize other senders to use its identities. For information about using sending authorization, see the Amazon SES Developer Guide.

This action is throttled at one request per second.

Request Syntax

```python
response = client.delete_identity_policy(
    Identity='string',
    PolicyName='string'
)
```

Parameters

- **Identity (string)** – [REQUIRED]
  
  The identity that is associated with the policy that you want to delete. You can specify the identity by using its name or by using its Amazon Resource Name (ARN). Examples: user@example.com, example.com, arn:aws:ses:us-east-1:123456789012:identity/example.com.

  To successfully call this API, you must own the identity.

- **PolicyName (string)** – [REQUIRED]
  
  The name of the policy to be deleted.

Return type: dict

Returns

Response Syntax

```python{}
```

Response Structure

- **(dict)** –
  
  An empty element. Receiving this element indicates that the request completed successfully.

**delete_verified_email_address(**kwargs)

Deletes the specified email address from the list of verified addresses.

**Warning:** The DeleteVerifiedEmailAddress action is deprecated as of the May 15, 2012 release of Domain Verification. The DeleteIdentity action is now preferred.

This action is throttled at one request per second.

Request Syntax

```python
response = client.delete_verified_email_address(
    EmailAddress='string'
)
```

Parameters

- **EmailAddress (string)** – [REQUIRED]
  
  An email address to be removed from the list of verified addresses.

Returns: None

**generate_presigned_url**(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)

Generate a presigned url given a client, its method, and arguments

Parameters
• **ClientMethod** *(string)* – The client method to presign for
• **Params** *(dict)* – The parameters normally passed to `ClientMethod`.
• **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
• **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns** The presigned url

`get_identity_dkim_attributes(**kwargs)`

Returns the current status of Easy DKIM signing for an entity. For domain name identities, this action also returns the DKIM tokens that are required for Easy DKIM signing, and whether Amazon SES has successfully verified that these tokens have been published.

This action takes a list of identities as input and returns the following information for each:
• Whether Easy DKIM signing is enabled or disabled.
• A set of DKIM tokens that represent the identity. If the identity is an email address, the tokens represent the domain of that address.
• Whether Amazon SES has successfully verified the DKIM tokens published in the domain’s DNS.

This information is only returned for domain name identities, not for email addresses.

This action is throttled at one request per second and can only get DKIM attributes for up to 100 identities at a time.

For more information about creating DNS records using DKIM tokens, go to the Amazon SES Developer Guide.

**Request Syntax**

```python
response = client.get_identity_dkim_attributes(
    Identities=[
        'string',
    ]
)
```

**Parameters**

- **Identities** *(list)* – [REQUIRED]
  
  A list of one or more verified identities - email addresses, domains, or both.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'DkimAttributes': {
        'string': {
            'DkimEnabled': True|False,
            'DkimVerificationStatus': 'Pending'|'Success'|'Failed'|'TemporaryFailure'|'NotStarted',
            'DkimTokens': [
                'string',
            ]
        }
    }
}
```

**Response Structure**

- *(dict)* –

  Represents a list of all the DKIM attributes for the specified identity.
Boto3 Documentation, Release 1.1.4

- **DkimAttributes (dict)**
  
The DKIM attributes for an email address or a domain.
  
- *(string)*
  
  - *(dict)*
    
    Represents the DKIM attributes of a verified email address or a domain.
    
- **DkimEnabled (boolean)**
  
    True if DKIM signing is enabled for email sent from the identity; false otherwise.
    
- **DkimVerificationStatus (string)**
  
    Describes whether Amazon SES has successfully verified the DKIM DNS records (tokens) published in the domain name’s DNS. (This only applies to domain identities, not email address identities.)
  
- **DkimTokens (list)**
  
    A set of character strings that represent the domain’s identity. Using these tokens, you will need to create DNS CNAME records that point to DKIM public keys hosted by Amazon SES. Amazon Web Services will eventually detect that you have updated your DNS records; this detection process may take up to 72 hours. Upon successful detection, Amazon SES will be able to DKIM-sign email originating from that domain. (This only applies to domain identities, not email address identities.)
  
    For more information about creating DNS records using DKIM tokens, go to the Amazon SES Developer Guide .
  
- **get_identity_notification_attributes(**kwargs**)**
  
    Given a list of verified identities (email addresses and/or domains), returns a structure describing identity notification attributes.
    
    This action is throttled at one request per second and can only get notification attributes for up to 100 identities at a time.
    
    For more information about using notifications with Amazon SES, see the Amazon SES Developer Guide .

**Request Syntax**

```python
response = client.get_identity_notification_attributes(
    Identities=[
        'string',
    ],
)
```

**Parameters**

- **Identities (list)** – [REQUIRED]
  
  A list of one or more identities. You can specify an identity by using its name or by using its Amazon Resource Name (ARN). Examples: user@example.com , example.com , arn:aws:ses:us-east-1:123456789012:identity/example.com .
  
- **Return type** dict
Returns

Response Syntax

```python
{
    'NotificationAttributes': {
        'string': {
            'BounceTopic': 'string',
            'ComplaintTopic': 'string',
            'DeliveryTopic': 'string',
            'ForwardingEnabled': True|False
        }
    }
}
```

Response Structure

- (dict) –
  Describes whether an identity has Amazon Simple Notification Service (Amazon SNS) topics set for bounce, complaint, and/or delivery notifications, and specifies whether feedback forwarding is enabled for bounce and complaint notifications.

  - **NotificationAttributes**(dict) –
    A map of Identity to IdentityNotificationAttributes.
    * (dict) –
      Represents the notification attributes of an identity, including whether an identity has Amazon Simple Notification Service (Amazon SNS) topics set for bounce, complaint, and/or delivery notifications, and whether feedback forwarding is enabled for bounce and complaint notifications.
      - **BounceTopic**(string) –
        The Amazon Resource Name (ARN) of the Amazon SNS topic where Amazon SES will publish bounce notifications.
      - **ComplaintTopic**(string) –
        The Amazon Resource Name (ARN) of the Amazon SNS topic where Amazon SES will publish complaint notifications.
      - **DeliveryTopic**(string) –
        The Amazon Resource Name (ARN) of the Amazon SNS topic where Amazon SES will publish delivery notifications.
      - **ForwardingEnabled**(boolean) –
        Describes whether Amazon SES will forward bounce and complaint notifications as email. `true` indicates that Amazon SES will forward bounce and complaint notifications as email, while `false` indicates that bounce and complaint notifications will be published only to the specified bounce and complaint Amazon SNS topics.

get_identity_policies(**kwargs)

Returns the requested sending authorization policies for the given identity (email address or domain). The policies are returned as a map of policy names to policy contents. You can retrieve a maximum of 20 policies at a time.
**Note:** This API is for the identity owner only. If you have not verified the identity, this API will return an error.

Sending authorization is a feature that enables an identity owner to authorize other senders to use its identities. For information about using sending authorization, see the Amazon SES Developer Guide.

This action is throttled at one request per second.

### Request Syntax

```python
response = client.get_identity_policies(
    Identity='string',
    PolicyNames=['string',]
)
```

### Parameters

- **Identity** *(string)* – [REQUIRED]
  
  The identity for which the policies will be retrieved. You can specify an identity by using its name or by using its Amazon Resource Name (ARN). Examples: user@example.com, example.com, arn:aws:ses:us-east-1:123456789012:identity/example.com.

  To successfully call this API, you must own the identity.

- **PolicyNames** *(list)* – [REQUIRED]
  
  A list of the names of policies to be retrieved. You can retrieve a maximum of 20 policies at a time. If you do not know the names of the policies that are attached to the identity, you can use `ListIdentityPolicies`.

  *(string)* – name of the policy.

### Return type

`dict`

### Returns

**Response Syntax**

```python
{
    'Policies': {
        'string': 'string'
    }
}
```

**Response Structure**

- *(dict)* –
  
  Represents a map of policy names to policies returned from a successful `GetIdentityPolicies` request.

  - **Policies** *(dict)* –
    
    A map of policy names to policies.

    - *(string)* – name of the policy.

    - *(string)* – JSON representation of a valid policy.

---

**get_identity_verification_attributes(**kwargs**)**

Given a list of identities (email addresses and/or domains), returns the verification status and (for domain identities) the verification token for each identity.
This action is throttled at one request per second and can only get verification attributes for up to 100 identities at a time.

**Request Syntax**

```python
response = client.get_identity_verification_attributes(
    Identities=[
        'string',
    ]
)
```

**Parameters**

**Identities (list)** – [REQUIRED]

A list of identities.
- (string) –

**Returns**

**Response Syntax**

```python
{
    'VerificationAttributes': {
        'string': {
            'VerificationStatus': 'Pending'|'Success'|'Failed'|'TemporaryFailure'|'NotStarted',
            'VerificationToken': 'string'
        }
    }
}
```

**Response Structure**

- (dict) –
  
  Represents the verification attributes for a list of identities.
  - **VerificationAttributes (dict)** –
    
    A map of Identities to IdentityVerificationAttributes objects.
    - (string) –
      
      Represents the verification attributes of a single identity.
      - VerificationStatus (string) –
        
        The verification status of the identity: “Pending”, “Success”, “Failed”, or “TemporaryFailure”.
      - VerificationToken (string) –
        
        The verification token for a domain identity. Null for email address identities.

**get_paginator (operation_name)**

Create a paginator for an operation.

**Parameters**

**operation_name (string)** – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo` and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginater("create_foo")`.

**Raises**

**OperationNotPageableError** Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

**Return type**

L{botocore.paginate.Paginator}

**Returns**

A paginator object.
get_send_quota()

Returns the user’s current sending limits.

This action is throttled at one request per second.

Request Syntax

```python
response = client.get_send_quota()
```

Returns

```
Response Syntax

{
    'Max24HourSend': 123.0,
    'MaxSendRate': 123.0,
    'SentLast24Hours': 123.0
}
```

Response Structure

- (dict) – Represents the user’s current activity limits returned from a successful GetSendQuota request.
  - **Max24HourSend** (float) – The maximum number of emails the user is allowed to send in a 24-hour interval. A value of -1 signifies an unlimited quota.
  - **MaxSendRate** (float) – The maximum number of emails that Amazon SES can accept from the user’s account per second.

Note: The rate at which Amazon SES accepts the user’s messages might be less than the maximum send rate.

- **SentLast24Hours** (float) – The number of emails sent during the previous 24 hours.

get_send_statistics()

Returns the user’s sending statistics. The result is a list of data points, representing the last two weeks of sending activity.

Each data point in the list contains statistics for a 15-minute interval.

This action is throttled at one request per second.

Request Syntax

```python
response = client.get_send_statistics()
```

Returns

```
Response Syntax

``

```
{
    'SendDataPoints': [
        {
            'Timestamp': datetime(2015, 1, 1),
            'DeliveryAttempts': 123,
            'Bounces': 123,
            'Complaints': 123,
            'Rejects': 123
        }
    ],
}
```

Response Structure

- **(dict)** – Represents a list of SendDataPoint items returned from a successful GetSendStatistics request. This list contains aggregated data from the previous two weeks of sending activity.
  - **SendDataPoints (list)** – A list of data points, each of which represents 15 minutes of activity.
      - **Timestamp (datetime)** – Time of the data point.
      - **DeliveryAttempts (integer)** – Number of emails that have been enqueued for sending.
      - **Bounces (integer)** – Number of emails that have bounced.
      - **Complaints (integer)** – Number of unwanted emails that were rejected by recipients.
      - **Rejects (integer)** – Number of emails rejected by Amazon SES.

get_waiter (waiter_name)

list_identities (**kwargs)

Returns a list containing all of the identities (email addresses and domains) for a specific AWS Account, regardless of verification status.

This action is throttled at one request per second.

Request Syntax

```python
response = client.list_identities(
    IdentityType='EmailAddress'|'Domain',
    NextToken='string',
    MaxItems=123
)
```

Parameters

- **IdentityType (string)** – The type of the identities to list. Possible values are “EmailAddress” and “Domain”. If this parameter is omitted, then all identities will be listed.
• **NextToken** *(string)* – The token to use for pagination.

• **MaxItems** *(integer)* – The maximum number of identities per page. Possible values are 1-1000 inclusive.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Identities': [
        'string',
    ],
    'NextToken': 'string'
}
```

**Response Structure**

• *(dict)* – Represents a list of all verified identities for the AWS Account.

  • **Identities** *(list)* – A list of identities.

  • **NextToken** *(string)* – The token used for pagination.

**list_identity_policies(**kwargs)**

Returns a list of sending authorization policies that are attached to the given identity (email address or domain). This API returns only a list. If you want the actual policy content, you can use `GetIdentityPolicies`.

**Note:** This API is for the identity owner only. If you have not verified the identity, this API will return an error.

Sending authorization is a feature that enables an identity owner to authorize other senders to use its identities. For information about using sending authorization, see the Amazon SES Developer Guide.

This action is throttled at one request per second.

**Request Syntax**

```python
response = client.list_identity_policies(
    Identity='string'
)
```

**Parameters**

**Identity** *(string)* – [REQUIRED]

The identity that is associated with the policy for which the policies will be listed. You can specify an identity by using its name or by using its Amazon Resource Name (ARN). Examples: `user@example.com`, `example.com`, `arn:aws:ses:us-east-1:123456789012:identity/example.com`.

To successfully call this API, you must own the identity.

**Return type** dict

**Returns**

**Response Syntax**
list_identity_policies()  
Returns a list of policy names returned from a successful ListIdentityPolicies request.

- **PolicyNames (list)**  
A list of names of policies that apply to the specified identity.
  
* **(string)** – name of the policy.

**list_verified_email_addresses()**  
Returns a list containing all of the email addresses that have been verified.

**Warning:** The ListVerifiedEmailAddresses action is deprecated as of the May 15, 2012 release of Domain Verification. The ListIdentities action is now preferred.

This action is throttled at one request per second.

**Request Syntax**

```python
response = client.list_verified_email_addresses()
```

**Return type** dict  

**Returns**

**Response Syntax**

```python
{
    'VerifiedEmailAddresses': [
        'string',
    ]
}
```

**Response Structure**

- **(dict)**  
Represents a list of all the email addresses verified for the current user.

  - **VerifiedEmailAddresses (list)**  
A list of email addresses that have been verified.
  
* **(string)** –

**put_identity_policy(**kwargs**)**  
Adds or updates a sending authorization policy for the specified identity (email address or domain).

**Note:** This API is for the identity owner only. If you have not verified the identity, this API will return an error.

Sending authorization is a feature that enables an identity owner to authorize other senders to use its identities. For information about using sending authorization, see the Amazon SES Developer Guide.

This action is throttled at one request per second.
Boto3 Documentation, Release 1.1.4

Request Syntax

```python
response = client.put_identity_policy(
    Identity='string',
    PolicyName='string',
    Policy='string'
)
```

Parameters

- **Identity** *(string)* – [REQUIRED]
  
The identity to which the policy will apply. You can specify an identity by using its name or by using its Amazon Resource Name (ARN). Examples: `user@example.com`, `example.com`, `arn:aws:ses:us-east-1:123456789012:identity/example.com`.
  
  To successfully call this API, you must own the identity.

- **PolicyName** *(string)* – [REQUIRED]
  
The name of the policy.
  
The policy name cannot exceed 64 characters and can only include alphanumeric characters, dashes, and underscores.

- **Policy** *(string)* – [REQUIRED]
  
The text of the policy in JSON format. The policy cannot exceed 4 KB.
  
  For information about the syntax of sending authorization policies, see the Amazon SES Developer Guide.

Return type  `dict`

Returns

- **Response Syntax**
  
  ```
  {}
  ```

- **Response Structure**
  
  - *(dict)* –
    
    An empty element. Receiving this element indicates that the request completed successfully.

`sends_email(**kwargs)`

Composes an email message based on input data, and then immediately queues the message for sending.

There are several important points to know about SendsEmail:

- You can only send email from verified email addresses and domains; otherwise, you will get an “Email address not verified” error. If your account is still in the Amazon SES sandbox, you must also verify every recipient email address except for the recipients provided by the Amazon SES mailbox simulator. For more information, go to the Amazon SES Developer Guide.

- The total size of the message cannot exceed 10 MB. This includes any attachments that are part of the message.

- Amazon SES has a limit on the total number of recipients per message. The combined number of To:, CC: and BCC: email addresses cannot exceed 50. If you need to send an email message to a larger audience, you can divide your recipient list into groups of 50 or fewer, and then call Amazon SES repeatedly to send the message to each group.

- For every message that you send, the total number of recipients (To:, CC: and BCC:) is counted against your sending quota - the maximum number of emails you can send in a 24-hour period. For information about your sending quota, go to the Amazon SES Developer Guide.

3.1. Services
Request Syntax

```python
response = client.send_email(
    Source='string',
    Destination={
        'ToAddresses': [ 'string', ],
        'CcAddresses': [ 'string', ],
        'BccAddresses': [ 'string', ]
    },
    Message={
        'Subject': {
            'Data': 'string',
            'Charset': 'string'
        },
        'Body': {
            'Text': {
                'Data': 'string',
                'Charset': 'string'
            },
            'Html': {
                'Data': 'string',
                'Charset': 'string'
            }
        }
    },
    ReplyToAddresses=[ 'string', ],
    ReturnPath='string',
    SourceArn='string',
    ReturnPathArn='string'
)
```

Parameters

- **Source** *(string)* – [REQUIRED]

  The email address that is sending the email. This email address must be either individually verified with Amazon SES, or from a domain that has been verified with Amazon SES. For information about verifying identities, see the Amazon SES Developer Guide.

  If you are sending on behalf of another user and have been permitted to do so by a sending authorization policy, then you must also specify the **SourceArn** parameter. For more information about sending authorization, see the Amazon SES Developer Guide.

  In all cases, the email address must be 7-bit ASCII. If the text must contain any other characters, then you must use MIME encoded-word syntax (RFC 2047) instead of a literal string. MIME encoded-word syntax uses the following form: =?charset?encoding?encoded-text?= . For more information, see RFC 2047.

- **Destination** *(dict)* – [REQUIRED]
The destination for this email, composed of To:, CC:, and BCC: fields.

- **ToAddresses** (list) –
  
  The To: field(s) of the message.
  
  - *(string)* –

- **CcAddresses** (list) –
  
  The CC: field(s) of the message.
  
  - *(string)* –

- **BccAddresses** (list) –
  
  The BCC: field(s) of the message.
  
  - *(string)* –

- **Message** (dict) – [REQUIRED]
  
  The message to be sent.

  - **Subject** (dict) – [REQUIRED]
    
    The subject of the message: A short summary of the content, which will appear in the recipient’s inbox.
    
    - *(string)* – [REQUIRED]
      
      The textual data of the content.
      
      - *(string)* –

  - **Body** (dict) – [REQUIRED]
    
    The message body.
    
    - **Text** (dict) –
      
      The content of the message, in text format. Use this for text-based email clients, or clients on high-latency networks (such as mobile devices).
      
      - *(string)* – [REQUIRED]
        
        The textual data of the content.
        
        - *(string)* –

      - **Html** (dict) –
        
        The content of the message, in HTML format. Use this for email clients that can process HTML. You can include clickable links, formatted text, and much more in an HTML message.
        
        - *(string)* – [REQUIRED]
          
          The textual data of the content.
          
          - *(string)* –

  - **ReplyToAddresses** (list) – The reply-to email address(es) for the message. If the recipient replies to the message, each reply-to address will receive the reply.
    
    - *(string)* –

  - **ReturnPath** (string) – The email address to which bounces and complaints are to be forwarded when feedback forwarding is enabled. If the message cannot be delivered to the recipient, then an error message will be returned from the recipient’s ISP; this message will then be forwarded to the email address specified by the ReturnPath parameter. The ReturnPath parameter is never overwritten. This email address must be either individually verified with Amazon SES, or from a domain that has been verified with Amazon SES.
• **SourceArn** *(string)* – This parameter is used only for sending authorization. It is the ARN of the identity that is associated with the sending authorization policy that permits you to send for the email address specified in the **Source** parameter.

For example, if the owner of example.com (which has ARN `arn:aws:ses:us-east-1:123456789012:identity/example.com`) attaches a policy to it that authorizes you to send from `user@example.com`, then you would specify the **SourceArn** to be `arn:aws:ses:us-east-1:123456789012:identity/example.com`, and the **Source** to be `user@example.com`.

For more information about sending authorization, see the [Amazon SES Developer Guide](https://docs.aws.amazon.com/ses/latest/DeveloperGuide/)

• **ReturnPathArn** *(string)* – This parameter is used only for sending authorization. It is the ARN of the identity that is associated with the sending authorization policy that permits you to use the email address specified in the **ReturnPath** parameter.

For example, if the owner of example.com (which has ARN `arn:aws:ses:us-east-1:123456789012:identity/example.com`) attaches a policy to it that authorizes you to use `feedback@example.com`, then you would specify the **ReturnPathArn** to be `arn:aws:ses:us-east-1:123456789012:identity/example.com`, and the **ReturnPath** to be `feedback@example.com`.

For more information about sending authorization, see the [Amazon SES Developer Guide](https://docs.aws.amazon.com/ses/latest/DeveloperGuide/)

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'MessageId': 'string'
}
```

**Response Structure**

• *(dict)* –
  
  Represents a unique message ID returned from a successful **SendEmail** request.

  – **MessageId** *(string)* –

    The unique message identifier returned from the **SendEmail** action.

**send_raw_email**(**kwargs)**

Sends an email message, with header and content specified by the client. The **SendRawEmail** action is useful for sending multipart MIME emails. The raw text of the message must comply with Internet email standards; otherwise, the message cannot be sent.

There are several important points to know about **SendRawEmail**:

• You can only send email from verified email addresses and domains; otherwise, you will get an “Email address not verified” error. If your account is still in the Amazon SES sandbox, you must also verify every recipient email address except for the recipients provided by the Amazon SES mailbox simulator. For more information, go to the [Amazon SES Developer Guide](https://docs.aws.amazon.com/ses/latest/DeveloperGuide/).

• The total size of the message cannot exceed 10 MB. This includes any attachments that are part of the message.
• Amazon SES has a limit on the total number of recipients per message. The combined number of To:, CC: and BCC: email addresses cannot exceed 50. If you need to send an email message to a larger audience, you can divide your recipient list into groups of 50 or fewer, and then call Amazon SES repeatedly to send the message to each group.

• The To:, CC:, and BCC: headers in the raw message can contain a group list. Note that each recipient in a group list counts towards the 50-recipient limit.

• For every message that you send, the total number of recipients (To:, CC: and BCC:) is counted against your sending quota - the maximum number of emails you can send in a 24-hour period. For information about your sending quota, go to the Amazon SES Developer Guide.

• If you are using sending authorization to send on behalf of another user, SendRawEmail enables you to specify the cross-account identity for the email’s “Source,” “From,” and “Return-Path” parameters in one of two ways: you can pass optional parameters SourceArn, FromArn, and/or ReturnPathArn to the API, or you can include the following X-headers in the header of your raw email:
  * X-SES-SOURCE-ARN
  * X-SES-FROM-ARN
  * X-SES-RETURN-PATH-ARN

**Warning:** Do not include these X-headers in the DKIM signature, because they are removed by Amazon SES before sending the email.

For the most common sending authorization use case, we recommend that you specify the SourceIdentityArn and do not specify either the FromIdentityArn or ReturnPathIdentityArn. (The same note applies to the corresponding X-headers.) If you only specify the SourceIdentityArn, Amazon SES will simply set the “From” address and the “Return Path” address to the identity specified in SourceIdentityArn. For more information about sending authorization, see the Amazon SES Developer Guide.

**Request Syntax**

```python
response = client.send_raw_email(
    Source='string',
    Destinations=['string', 'string'],
    RawMessage={
        'Data': b'bytes'
    },
    FromArn='string',
    SourceArn='string',
    ReturnPathArn='string'
)
```

**Parameters**

- **Source (string)** – The identity’s email address. If you do not provide a value for this parameter, you must specify a “From” address in the raw text of the message. (You can also specify both.)

  By default, the string must be 7-bit ASCII. If the text must contain any other characters, then you must use MIME encoded-word syntax (RFC 2047) instead of a literal string. MIME encoded-word syntax uses the following form: `=?charset?encoding?encoded-text=?`. For more information, see RFC 2047.

  **Note:** If you specify the Source parameter and have feedback forwarding enabled, then bounces and complaints will be sent to this email address. This takes precedence over any Return-Path header that you might include in the raw text of the message.
• **Destinations** *(list)* – A list of destinations for the message, consisting of To:, CC:, and BCC: addresses.
  
  – *(string)* –

• **RawMessage** *(dict)* – [REQUIRED]

The raw text of the message. The client is responsible for ensuring the following:

  – Message must contain a header and a body, separated by a blank line.
  – All required header fields must be present.
  – Each part of a multipart MIME message must be formatted properly.
  – MIME content types must be among those supported by Amazon SES. For more information, go to the Amazon SES Developer Guide.
  – Content must be base64-encoded, if MIME requires it.

  – **Data** *(bytes)* – [REQUIRED]

The raw data of the message. The client must ensure that the message format complies with Internet email standards regarding email header fields, MIME types, MIME encoding, and base64 encoding (if necessary).

The To:, CC:, and BCC: headers in the raw message can contain a group list.

If you are using `SendRawEmail` with sending authorization, you can include X-headers in the raw message to specify the “Source,” “From,” and “Return-Path” addresses. For more information, see the documentation for `SendRawEmail`.

**Warning:** Do not include these X-headers in the DKIM signature, because they are removed by Amazon SES before sending the email.

For more information, go to the Amazon SES Developer Guide.

• **FromArn** *(string)* – This parameter is used only for sending authorization. It is the ARN of the identity that is associated with the sending authorization policy that permits you to specify a particular “From” address in the header of the raw email.

Instead of using this parameter, you can use the X-header `X-SES-FROM-ARN` in the raw message of the email. If you use both the `FromArn` parameter and the corresponding X-header, Amazon SES uses the value of the `FromArn` parameter.

**Note:** For information about when to use this parameter, see the description of `SendRawEmail` in this guide, or see the Amazon SES Developer Guide.

• **SourceArn** *(string)* – This parameter is used only for sending authorization. It is the ARN of the identity that is associated with the sending authorization policy that permits you to send for the email address specified in the `Source` parameter.

For example, if the owner of example.com (which has ARN `arn:aws:ses:us-east-1:123456789012:identity/example.com`) attaches a policy to it that authorizes you to send from user@example.com, then you would specify the `SourceArn` to be `arn:aws:ses:us-east-1:123456789012:identity/example.com`, and the `Source` to be `user@example.com`.

Instead of using this parameter, you can use the X-header
X-SES-SOURCE-ARN in the raw message of the email. If you use both the SourceArn parameter and the corresponding X-header, Amazon SES uses the value of the SourceArn parameter.

**Note:** For information about when to use this parameter, see the description of SendRawEmail in this guide, or see the Amazon SES Developer Guide.

- **ReturnPathArn** *(string)* – This parameter is used only for sending authorization. It is the ARN of the identity that is associated with the sending authorization policy that permits you to use the email address specified in the ReturnPath parameter.

For example, if the owner of example.com (which has ARN arn:aws:ses:us-east-1:123456789012:identity/example.com) attaches a policy to it that authorizes you to use feedback@example.com, then you would specify the ReturnPathArn to be arn:aws:ses:us-east-1:123456789012:identity/example.com, and the ReturnPath to be feedback@example.com.

Instead of using this parameter, you can use the X-header X-SES-RETURN-PATH-ARN in the raw message of the email. If you use both the ReturnPathArn parameter and the corresponding X-header, Amazon SES uses the value of the ReturnPathArn parameter.

**Note:** For information about when to use this parameter, see the description of SendRawEmail in this guide, or see the Amazon SES Developer Guide.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'MessageId': 'string'
}
```

**Response Structure**

- *(dict)* –

  Represents a unique message ID returned from a successful SendRawEmail request.

    - **MessageId** *(string)* –

      The unique message identifier returned from the SendRawEmail action.

**set_identity_dkim_enabled(** **kwargs**)**

Enables or disables Easy DKIM signing of email sent from an identity:

- If Easy DKIM signing is enabled for a domain name identity (e.g., example.com), then Amazon SES will DKIM-sign all email sent by addresses under that domain name (e.g., user@example.com).

- If Easy DKIM signing is enabled for an email address, then Amazon SES will DKIM-sign all email sent by that email address.

For email addresses (e.g., user@example.com), you can only enable Easy DKIM signing if the corresponding domain (e.g., example.com) has been set up for Easy DKIM using the AWS Console or the VerifyDomainDkim action.

This action is throttled at one request per second.

For more information about Easy DKIM signing, go to the Amazon SES Developer Guide.
Request Syntax

```python
response = client.set_identity_dkim_enabled(
    Identity='string',
    DkimEnabled=True|False
)
```

**Parameters**

- **Identity (string)** – [REQUIRED]
  
The identity for which DKIM signing should be enabled or disabled.

- **DkimEnabled (boolean)** – [REQUIRED]
  
  Sets whether DKIM signing is enabled for an identity. Set to `true` to enable DKIM signing for this identity; `false` to disable it.

**Return type**  
dict  

**Response Syntax**

```python
{}
```

**Response Structure**

- **(dict)** –
  
  An empty element. Receiving this element indicates that the request completed successfully.

**set_identity_feedback_forwarding_enabled(**kwargs**)**

Given an identity (email address or domain), enables or disables whether Amazon SES forwards bounce and complaint notifications as email. Feedback forwarding can only be disabled when Amazon Simple Notification Service (Amazon SNS) topics are specified for both bounces and complaints.

**Note:** Feedback forwarding does not apply to delivery notifications. Delivery notifications are only available through Amazon SNS.

This action is throttled at one request per second.

For more information about using notifications with Amazon SES, see the Amazon SES Developer Guide.

**Request Syntax**

```python
response = client.set_identity_feedback_forwarding_enabled(
    Identity='string',
    ForwardingEnabled=True|False
)
```

**Parameters**

- **Identity (string)** – [REQUIRED]
  
  The identity for which to set bounce and complaint notification forwarding. Examples: user@example.com, example.com.

- **ForwardingEnabled (boolean)** – [REQUIRED]
  
  Sets whether Amazon SES will forward bounce and complaint notifications as email. `true` specifies that Amazon SES will forward bounce and complaint notifications as email, in addition to any Amazon SNS topic publishing otherwise specified. `false` specifies that Amazon SES will publish bounce and complaint
notifications only through Amazon SNS. This value can only be set to false when Amazon SNS topics are set for both Bounce and Complaint notification types.

Return type  dict

Returns

Response Syntax

{}

Response Structure

• (dict) –

An empty element. Receiving this element indicates that the request completed successfully.

`set_identity_notification_topic(**kwargs)`

Given an identity (email address or domain), sets the Amazon Simple Notification Service (Amazon SNS) topic to which Amazon SES will publish bounce, complaint, and/or delivery notifications for emails sent with that identity as the Source.

**Note:** Unless feedback forwarding is enabled, you must specify Amazon SNS topics for bounce and complaint notifications. For more information, see `SetIdentityFeedbackForwardingEnabled`.

This action is throttled at one request per second.

For more information about feedback notification, see the Amazon SES Developer Guide.

Request Syntax

```python
response = client.set_identity_notification_topic(
    Identity='string',
    NotificationType='Bounce'|'Complaint'|'Delivery',
    SnsTopic='string'
)
```

Parameters

• **Identity** *(string)* – [REQUIRED]

The identity for which the Amazon SNS topic will be set. You can specify an identity by using its name or by using its Amazon Resource Name (ARN). Examples: `user@example.com`, `example.com`, `arn:aws:ses:us-east-1:123456789012:identity/example.com`.

• **NotificationType** *(string)* – [REQUIRED]

The type of notifications that will be published to the specified Amazon SNS topic.

• **SnsTopic** *(string)* – The Amazon Resource Name (ARN) of the Amazon SNS topic. If the parameter is omitted from the request or a null value is passed, SnsTopic is cleared and publishing is disabled.
Response Structure

- (dict) –
  An empty element. Receiving this element indicates that the request completed successfully.

verify_domain_dkim(**kwargs)

Returns a set of DKIM tokens for a domain. DKIM tokens are character strings that represent your domain’s identity. Using these tokens, you will need to create DNS CNAME records that point to DKIM public keys hosted by Amazon SES. Amazon Web Services will eventually detect that you have updated your DNS records; this detection process may take up to 72 hours. Upon successful detection, Amazon SES will be able to DKIM-sign email originating from that domain.

This action is throttled at one request per second.

To enable or disable Easy DKIM signing for a domain, use the SetIdentityDkimEnabled action.

For more information about creating DNS records using DKIM tokens, go to the Amazon SES Developer Guide.

Request Syntax

response = client.verify_domain_dkim(
    Domain='string'
)

Parameters Domain (string) – [REQUIRED]

The name of the domain to be verified for Easy DKIM signing.

Return type dict

Returns

Response Syntax

{
    'DkimTokens': [
        'string',
    ]
}

Response Structure

- (dict) –

  Represents the DNS records that must be published in the domain name’s DNS to complete DKIM setup.

  - DkimTokens (list) –

    A set of character strings that represent the domain’s identity. If the identity is an email address, the tokens represent the domain of that address.

    Using these tokens, you will need to create DNS CNAME records that point to DKIM public keys hosted by Amazon SES. Amazon Web Services will eventually detect that you have updated your DNS records; this detection process may take up to 72 hours. Upon successful detection, Amazon SES will be able to DKIM-sign emails originating from that domain.

    For more information about creating DNS records using DKIM tokens, go to the Amazon SES Developer Guide.

- (string) –
**verify_domain_identity(**kwargs)**

Verifies a domain.

This action is throttled at one request per second.

**Request Syntax**

```python
response = client.verify_domain_identity(
    Domain='string'
)
```

**Parameters**

- **Domain** *(string)* – [REQUIRED]
  
  The domain to be verified.

**Return type**

- **dict**
  
  Returns

**Response Syntax**

```json
{
    'VerificationToken': 'string'
}
```

**Response Structure**

- *(dict)* –

  Represents a token used for domain ownership verification.

    - **VerificationToken** *(string)* –

      A TXT record that must be placed in the DNS settings for the domain, in order to complete domain verification.

**verify_email_address(**kwargs)**

Verifies an email address. This action causes a confirmation email message to be sent to the specified address.

**Warning:** The VerifyEmailAddress action is deprecated as of the May 15, 2012 release of Domain Verification. The VerifyEmailIdentity action is now preferred.

This action is throttled at one request per second.

**Request Syntax**

```python
response = client.verify_email_address(
    EmailAddress='string'
)
```

**Parameters**

- **EmailAddress** *(string)* – [REQUIRED]
  
  The email address to be verified.

**Returns**

- **None**

**verify_email_identity(**kwargs)**

Verifies an email address. This action causes a confirmation email message to be sent to the specified address.

This action is throttled at one request per second.

**Request Syntax**
response = client.verify_email_identity(
    EmailAddress='string'
)

Parameters

EmailAddress (string) – [REQUIRED]

The email address to be verified.

Return type
dict

Returns

Response Syntax

{}

Response Structure

• (dict) –

An empty element. Receiving this element indicates that the request completed successfully.

Paginators

The available paginators are:

• SESPaginator.ListIdentities
class SESPaginator.ListIdentities

paginator = client.get_paginator('list_identities')

paginate (**kwargs)

Creates an iterator that will paginate through responses from SES.Client.list_identities().

Request Syntax

response_iterator = paginator.paginate(
    IdentityType='EmailAddress'|'Domain',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

• IdentityType (string) – The type of the identities to list. Possible values are “EmailAddress” and “Domain”. If this parameter is omitted, then all identities will be listed.

• PaginationConfig (dict) – A dictionary that provides parameters to control pagination.

  – MaxItems (integer) –

    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
- **PageSize** *(integer)* –
  The size of each page.
- **StartingToken** *(string)* –
  A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** dict

**Returns**

**Response Syntax**

```
{
 'Identities': [
   'string',
 ],
}
```

**Response Structure**

- *(dict)* –
  Represents a list of all verified identities for the AWS Account.
  - **Identities** *(list)* –
    A list of identities.
    - *(string)* –

**Waiters**

The available waiters are:

- **SES.Waiter.IdentityExists**

```python
class SES.Waiter.IdentityExists

waiter = client.get_waiter('identity_exists')

wait(**kwargs)
```

Polls `SES.Client.get_identity_verification_attributes()` every 3 seconds until a successful state is reached. An error is returned after 20 failed checks.

**Request Syntax**

```
waiter.wait(
    Identities=[
      'string',
    ]
)
```

**Parameters**

- **Identities** *(list)* – [REQUIRED]
  A list of identities.
    - *(string)* –

**Returns**

None
SNS

Table of Contents

• SNS
  – Client
  – Paginators
  – Service Resource
  – PlatformApplication
  – PlatformEndpoint
  – Subscription
  – Topic

Client

class SNS.Client

A low-level client representing Amazon Simple Notification Service (SNS):

```python
import boto3

client = boto3.client('sns')
```

These are the available methods:

• add_permission()
• can_paginate()
• confirm_subscription()
• create_platform_application()
• create_platform_endpoint()
• create_topic()
• delete_endpoint()
• delete_platform_application()
• delete_topic()
• generate_presigned_url()
• get_endpoint_attributes()
• get_paginator()
• get_platform_application_attributes()
• get_subscription_attributes()
• get_topic_attributes()
• get_waiter()
• list_endpoints_by_platform_application()
• list_platform_applications()
• list_subscriptions()
• list_subscriptions_by_topic()
• list_topics()
• publish()
• remove_permission()
• set_endpoint_attributes()
• set_platform_application_attributes()
• set_subscription_attributes()
• set_topic_attributes()
• subscribe()
• unsubscribe()

add_permission (**kwargs)

Adds a statement to a topic’s access control policy, granting access for the specified AWS accounts to the specified actions.

Request Syntax

```python
response = client.add_permission(
    TopicArn='string',
    Label='string',
    AWSAccountId=['string',
    ],
    ActionName=['string',
    ]
)
```

Parameters

- **TopicArn** *(string)* – [REQUIRED]
  
  The ARN of the topic whose access control policy you wish to modify.

- **Label** *(string)* – [REQUIRED]
  
  A unique identifier for the new policy statement.

- **AWSAccountId** *(list)* – [REQUIRED]
  
  The AWS account IDs of the users (principals) who will be given access to the specified actions. The users must have AWS accounts, but do not need to be signed up for this service.

- **ActionName** *(list)* – [REQUIRED]
  
  The action you want to allow for the specified principal(s).

  Valid values: any Amazon SNS action name.

Returns  None

can_paginate (operation_name)

Check if an operation can be paginated.

```python
Parameters operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you'd normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

Returns True if the operation can be paginated, False otherwise.
```

confirm_subscription (**kwargs)

Verifies an endpoint owner’s intent to receive messages by validating the token sent to the endpoint by an earlier Subscribe action. If the token is valid, the action creates a new subscription and returns its Amazon Resource Name (ARN). This call requires an AWS signature only when the AuthenticateOnUnsubscribe flag is set to “true”.

Request Syntax

```python
response = client.confirm_subscription(
    TopicArn='string',
    Token='string',
    )
```
Parameters

- **TopicArn** (*string*) – [REQUIRED]
  The ARN of the topic for which you wish to confirm a subscription.

- **Token** (*string*) – [REQUIRED]
  Short-lived token sent to an endpoint during the **Subscribe** action.

- **AuthenticateOnUnsubscribe** (*string*) – Disallows unauthenticated unsubscribes of the subscription. If the value of this parameter is `true` and the request has an AWS signature, then only the topic owner and the subscription owner can unsubscribe the endpoint. The unsubscribe action requires AWS authentication.

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'SubscriptionArn': 'string'
}
```

**Response Structure**

- *(dict)* – Response for **ConfirmSubscriptions** action.
  - **SubscriptionArn** (*string*) –
    The ARN of the created subscription.

---

**create_platform_application(**kwargs**)**

Creates a platform application object for one of the supported push notification services, such as APNS and GCM, to which devices and mobile apps may register. You must specify PlatformPrincipal and PlatformCredential attributes when using the **CreatePlatformApplication** action. The PlatformPrincipal is received from the notification service. For APNS/APNS_SANDBOX, PlatformPrincipal is “SSL certificate”. For GCM, PlatformPrincipal is not applicable. For ADM, PlatformPrincipal is “client id”. The PlatformCredential is also received from the notification service. For APNS/APNS_SANDBOX, PlatformCredential is “private key”. For GCM, PlatformCredential is “API key”. For ADM, PlatformCredential is “client secret”. The PlatformApplicationArn that is returned when using **CreatePlatformApplication** is then used as an attribute for the **CreatePlatformEndpoint** action. For more information, see Using Amazon SNS Mobile Push Notifications.

**Request Syntax**

```python
response = client.create_platform_application(
    Name='string',
    Platform='string',
    Attributes={
        'string': 'string'
    }
)
```

**Parameters**

- **Name** (*string*) – [REQUIRED]
  Application names must be made up of only uppercase and lowercase ASCII letters, numbers, underscores, hyphens, and periods, and must be between 1 and 256 characters long.
• **Platform** *(string)* – [REQUIRED]

The following platforms are supported: ADM (Amazon Device Messaging), APNS (Apple Push Notification Service), APNS_SANDBOX, and GCM (Google Cloud Messaging).

• **Attributes** *(dict)* – [REQUIRED]

For a list of attributes, see `SetPlatformApplicationAttributes`

- *(string)*
- *(string)*

Return type: dict

Returns:

Response Syntax:

```
{
    'PlatformApplicationArn': 'string'
}
```

Response Structure:

- *(dict)*

Response from `CreatePlatformApplication` action.

- **PlatformApplicationArn** *(string)*

PlatformApplicationArn is returned.

create_platform_endpoint(**kwargs)**

Creates an endpoint for a device and mobile app on one of the supported push notification services, such as GCM and APNS. `CreatePlatformEndpoint` requires the `PlatformApplicationArn` that is returned from `CreatePlatformApplication`. The EndpointArn that is returned when using `CreatePlatformEndpoint` can then be used by the `Publish` action to send a message to a mobile app or by the `Subscribe` action for subscription to a topic. The `CreatePlatformEndpoint` action is idempotent, so if the requester already owns an endpoint with the same device token and attributes, that endpoint’s ARN is returned without creating a new endpoint. For more information, see Using Amazon SNS Mobile Push Notifications.

When using `CreatePlatformEndpoint` with Baidu, two attributes must be provided: ChannelId and UserId. The token field must also contain the ChannelId. For more information, see Creating an Amazon SNS Endpoint for Baidu.

Request Syntax:

```python
response = client.create_platform_endpoint(
    PlatformApplicationArn='string',
    Token='string',
    CustomUserData='string',
    Attributes={
        'string': 'string'
    }
)
```

Parameters:

- **PlatformApplicationArn** *(string)* – [REQUIRED]

  PlatformApplicationArn returned from `CreatePlatformApplication` is used to create a new endpoint.

- **Token** *(string)* – [REQUIRED]
Unique identifier created by the notification service for an app on a device. The specific name for Token will vary, depending on which notification service is being used. For example, when using APNS as the notification service, you need the device token. Alternatively, when using GCM or ADM, the device token equivalent is called the registration ID.

- **CustomUserData** *(string)* – Arbitrary user data to associate with the endpoint. Amazon SNS does not use this data. The data must be in UTF-8 format and less than 2KB.
- **Attributes** *(dict)* – For a list of attributes, see SetEndpointAttributes.
  
  - *(string)* –

**Return type** dict

**Returns**

**Response Syntax**

```python
{
   'EndpointArn': 'string'
}
```

**Response Structure**

- *(dict)* –

Response from CreateEndpoint action.

- **EndpointArn** *(string)* –

  EndpointArn returned from CreateEndpoint action.

**create_topic(**kwargs)**

Creates a topic to which notifications can be published. Users can create at most 3000 topics. For more information, see [http://aws.amazon.com/sns](http://aws.amazon.com/sns). This action is idempotent, so if the requester already owns a topic with the specified name, that topic’s ARN is returned without creating a new topic.

**Request Syntax**

```python
response = client.create_topic(
   Name='string'
)
```

**Parameters** **Name** *(string)* – [REQUIRED]

The name of the topic you want to create.

Constraints: Topic names must be made up of only uppercase and lowercase ASCII letters, numbers, underscores, and hyphens, and must be between 1 and 256 characters long.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
   'TopicArn': 'string'
}
```

**Response Structure**

- *(dict)* –

Response from CreateTopic action.
delete_endpoint (**kwargs)
Deletes the endpoint from Amazon SNS. This action is idempotent. For more information, see Using Amazon SNS Mobile Push Notifications.

Request Syntax

```python
response = client.delete_endpoint(
    EndpointArn='string'
)
```

Parameters  
**EndpointArn (string)** – [REQUIRED]

EndpointArn of endpoint to delete.

Returns  
None

delete_platform_application (**kwargs)
Deletes a platform application object for one of the supported push notification services, such as APNS and GCM. For more information, see Using Amazon SNS Mobile Push Notifications.

Request Syntax

```python
response = client.delete_platform_application(
    PlatformApplicationArn='string'
)
```

Parameters  
**PlatformApplicationArn (string)** – [REQUIRED]

PlatformApplicationArn of platform application object to delete.

Returns  
None

delete_topic (**kwargs)
Deletes a topic and all its subscriptions. Deleting a topic might prevent some messages previously sent to the topic from being delivered to subscribers. This action is idempotent, so deleting a topic that does not exist does not result in an error.

Request Syntax

```python
response = client.delete_topic(
    TopicArn='string'
)
```

Parameters  
**TopicArn (string)** – [REQUIRED]

The ARN of the topic you want to delete.

Returns  
None

generate_presigned_url (ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)
Generate a presigned url given a client, its method, and arguments

Parameters

- **ClientMethod (string)** – The client method to presign for
- **Params (dict)** – The parameters normally passed to ClientMethod.
- **ExpiresIn (int)** – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod (string)** – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns  
The presigned url
get_endpoint_attributes(**kwargs)
Retrieves the endpoint attributes for a device on one of the supported push notification services, such as
GCM and APNS. For more information, see Using Amazon SNS Mobile Push Notifications.

Request Syntax

response = client.get_endpoint_attributes(
    EndpointArn='string'
)

Parameters

EndpointArn (string) – [REQUIRED]
EndpointArn for GetEndpointAttributes input.

Return type: dict

Returns

Response Syntax

{
    'Attributes': {
        'string': 'string'
    }
}

Response Structure

• (dict) –

  Response from GetEndpointAttributes of the EndpointArn.

  Attributes (dict) –

    Attributes include the following:

    * CustomUserData – arbitrary user data to associate with the end-
      point. Amazon SNS does not use this data. The data must be in
      UTF-8 format and less than 2KB.

    * Enabled – flag that enables/disables delivery to the endpoint.
      Amazon SNS will set this to false when a notification service in-
      dicates to Amazon SNS that the endpoint is invalid. Users can set it
      back to true, typically after updating Token.

    * Token – device token, also referred to as a registration id, for an
      app and mobile device. This is returned from the notification service
      when an app and mobile device are registered with the notification
      service.

    * (string) –

      • (string) –

get_paginator(operation_name)
Create a paginator for an operation.

Parameters

operation_name (string) – The operation name. This is the same name as
the method name on the client. For example, if the method name is create_foo,
and you’d normally invoke the operation as client.create_foo(**kwargs),
if the create_foo operation can be paginated, you can use the call
client.get_paginatar("create_foo").

Raises

OperationNotPageableError Raised if the operation is not pageable. You can use
the client.can_paginate method to check if an operation is pageable.

Return type: L{botocore.paginate.Paginator}

Returns: A paginator object.
get_platform_application_attributes(**kwargs)
Retrieves the attributes of the platform application object for the supported push notification services, such as APNS and GCM. For more information, see Using Amazon SNS Mobile Push Notifications.

Request Syntax

response = client.get_platform_application_attributes(
    PlatformApplicationArn='string'
)

Parameters  PlatformApplicationArn (string) – [REQUIRED]

PlatformApplicationArn for GetPlatformApplicationAttributesInput.

Return type  dict

Returns

Response Syntax

{
    'Attributes': {
        'string': 'string'
    }
}

Response Structure

• (dict) –

Response for GetPlatformApplicationAttributes action.

– Attributes (dict) –

Attributes include the following:

  • EventEndpointCreated – Topic ARN to which EndpointCreated event notifications should be sent.
  • EventEndpointDeleted – Topic ARN to which EndpointDeleted event notifications should be sent.
  • EventEndpointUpdated – Topic ARN to which EndpointUpdated event notifications should be sent.
  • EventDeliveryFailure – Topic ARN to which DeliveryFailure event notifications should be sent upon Direct Publish delivery failure (permanent) to one of the application’s endpoints.

  • (string) –
    • (string) –

get_subscription_attributes(**kwargs)
Returns all of the properties of a subscription.

Request Syntax

response = client.get_subscription_attributes(
    SubscriptionArn='string'
)

Parameters  SubscriptionArn (string) – [REQUIRED]

The ARN of the subscription whose properties you want to get.

Return type  dict

Returns

Response Syntax
Response Structure

- (dict) –

Response for GetSubscriptionAttributes action.

- Attributes (dict) –

A map of the subscription’s attributes. Attributes in this map include the following:

- SubscriptionArn – the subscription’s ARN
- TopicArn – the topic ARN that the subscription is associated with
- Owner – the AWS account ID of the subscription’s owner
- ConfirmationWasAuthenticated – true if the subscription confirmation request was authenticated
- DeliveryPolicy – the JSON serialization of the subscription’s delivery policy
- EffectiveDeliveryPolicy – the JSON serialization of the effective delivery policy that takes into account the topic delivery policy and account system defaults

get_topic_attributes(**kwargs)

Returns all of the properties of a topic. Topic properties returned might differ based on the authorization of the user.

Request Syntax

response = client.get_topic_attributes(
    TopicArn='string'
)

Parameters

TopicArn (string) – [REQUIRED]

The ARN of the topic whose properties you want to get.

Return type

dict

Returns

Response Syntax

{
    'Attributes': {
        'string': 'string'
    }
}

Response Structure

- (dict) –

Response for GetTopicAttributes action.

- Attributes (dict) –
A map of the topic’s attributes. Attributes in this map include the following:

- **TopicArn** – the topic’s ARN
- **Owner** – the AWS account ID of the topic’s owner
- **Policy** – the JSON serialization of the topic’s access control policy
- **DisplayName** – the human-readable name used in the “From” field for notifications to email and email-json endpoints
- **SubscriptionsPending** – the number of subscriptions pending confirmation on this topic
- **SubscriptionsConfirmed** – the number of confirmed subscriptions on this topic
- **SubscriptionsDeleted** – the number of deleted subscriptions on this topic
- **DeliveryPolicy** – the JSON serialization of the topic’s delivery policy
- **EffectiveDeliveryPolicy** – the JSON serialization of the effective delivery policy that takes into account system defaults

### get_waiter

#### get_waiter(waiter_name)

**get_waiter** is an asynchronous method for waiting on a waiter. Waiters are specific to the AWS services, and they monitor a specific condition until it reaches an expected state.

### list_endpoints_by_platform_application

#### list_endpoints_by_platform_application(**kwargs)

Lists the endpoints and endpoint attributes for devices in a supported push notification service, such as GCM and APNS. The results for **ListEndpointsByPlatformApplication** are paginated and return a limited list of endpoints, up to 100. If additional records are available after the first page results, then a NextToken string will be returned. To receive the next page, you call **ListEndpointsByPlatformApplication** again using the NextToken string received from the previous call. When there are no more records to return, NextToken will be null. For more information, see Using Amazon SNS Mobile Push Notifications.

**Request Syntax**

```python
response = client.list_endpoints_by_platform_application(
    PlatformApplicationArn='string',
    NextToken='string'
)
```

**Parameters**

- **PlatformApplicationArn (string)** – [REQUIRED]
  
  PlatformApplicationArn for **ListEndpointsByPlatformApplication** action.

- **NextToken (string)** – NextToken string is used when calling **ListEndpointsByPlatformApplication** action to retrieve additional records that are available after the first page results.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'Endpoints': [
        {
            'EndpointArn': 'string',
            'Attributes': {
```
Response Structure

  - **Endpoints** *(list)* – Endpoints returned for ListEndpointsByPlatformApplication action.
    - *(dict)* – Endpoint for mobile app and device.
      - **EndpointArn** *(string)* – EndpointArn for mobile app and device.
      - **Attributes** *(dict)* – Attributes for endpoint.
        - *(string)* –
        - *(string)* –
  - **NextToken** *(string)* – NextToken string is returned when calling ListEndpointsByPlatformApplication action if additional records are available after the first page results.

**list_platform_applications**(\**kwargs\**)

Lists the platform application objects for the supported push notification services, such as APNS and GCM. The results for ListPlatformApplications are paginated and return a limited list of applications, up to 100. If additional records are available after the first page results, then a NextToken string will be returned. To receive the next page, you call ListPlatformApplications using the NextToken string received from the previous call. When there are no more records to return, NextToken will be null. For more information, see Using Amazon SNS Mobile Push Notifications.

Request Syntax

```python
response = client.list_platform_applications(
    NextToken='string'
)
```

**Parameters**  
**NextToken** *(string)* – NextToken string is used when calling ListPlatformApplications action to retrieve additional records that are available after the first page results.

**Return type**  
dict

**Returns**

Response Syntax

```python
{
    'PlatformApplications': {
        'PlatformApplicationArn': 'string',
        'Attributes': {
            'string': 'string'
        }
    }
}
```
Response Structure

- (dict) –
  Response for ListPlatformApplications action.
  - PlatformApplications (list) –
    Platform applications returned when calling ListPlatformApplications action.
    * (dict) –
      Platform application object.
      - PlatformApplicationArn (string) –
        PlatformApplicationArn for platform application object.
      - Attributes (dict) –
        Attributes for platform application object.
        * (string) –
        * (string) –
    - NextToken (string) –
      NextToken string is returned when calling ListPlatformApplications action if additional records are available after the first page results.

list_subscriptions(**kwargs)

Returns a list of the requester’s subscriptions. Each call returns a limited list of subscriptions, up to 100. If there are more subscriptions, a NextToken is also returned. Use the NextToken parameter in a new ListSubscriptions call to get further results.

Request Syntax

```python
response = client.list_subscriptions(
    NextToken='string'
)
```

Parameters

- NextToken (string) – Token returned by the previous ListSubscriptions request.

Return type
dict

Returns

Response Syntax

```python
{
    'Subscriptions': [
        {
            'SubscriptionArn': 'string',
            'Owner': 'string',
            'Protocol': 'string',
            'Endpoint': 'string',
            'TopicArn': 'string'
        },
    ],
    'NextToken': 'string'
}
```
Response Structure

• (dict) –

Response for ListSubscriptions action

– Subscriptions (list) –

A list of subscriptions.

* (dict) –

A wrapper type for the attributes of an Amazon SNS subscription.

• SubscriptionArn (string) –

The subscription’s ARN.

• Owner (string) –

The subscription’s owner.

• Protocol (string) –

The subscription’s protocol.

• Endpoint (string) –

The subscription’s endpoint (format depends on the protocol).

• TopicArn (string) –

The ARN of the subscription’s topic.

– NextToken (string) –

Token to pass along to the next ListSubscriptions request. This element is returned if there are more subscriptions to retrieve.

list_subscriptions_by_topic(**kwargs)

Returns a list of the subscriptions to a specific topic. Each call returns a limited list of subscriptions, up to 100. If there are more subscriptions, a NextToken is also returned. Use the NextToken parameter in a new ListSubscriptionsByTopic call to get further results.

Request Syntax

response = client.list_subscriptions_by_topic(  
    TopicArn='string',  
    NextToken='string'  
)

Parameters

• TopicArn (string) – [REQUIRED]

    The ARN of the topic for which you wish to find subscriptions.

• NextToken (string) – Token returned by the previous ListSubscriptionsByTopic request.

Return type dict

Returns

Response Syntax

{
    'Subscriptions': [  
        {  
            'SubscriptionArn': 'string',  
            'Owner': 'string',  
            'Protocol': 'string',  
            'Endpoint': 'string',  
            'TopicArn': 'string'
        }
    ]
}
Response Structure

- (dict) – Response for ListSubscriptionsByTopic action.
  - Subscriptions (list) – A list of subscriptions.
    * (dict) – A wrapper type for the attributes of an Amazon SNS subscription.
      - SubscriptionArn (string) – The subscription’s ARN.
      - Owner (string) – The subscription’s owner.
      - Protocol (string) – The subscription’s protocol.
      - Endpoint (string) – The subscription’s endpoint (format depends on the protocol).
      - TopicArn (string) – The ARN of the subscription’s topic.
  - NextToken (string) – Token to pass along to the next ListSubscriptionsByTopic request. This element is returned if there are more subscriptions to retrieve.

list_topics(**kwargs)

Returns a list of the requester’s topics. Each call returns a limited list of topics, up to 100. If there are more topics, a NextToken is also returned. Use the NextToken parameter in a new ListTopics call to get further results.

Request Syntax

```python
response = client.list_topics(
    NextToken='string'
)
```

Parameters

- NextToken (string) – Token returned by the previous ListTopics request.

Return type

dict

Returns

Response Syntax

```python
{
    'Topics': [
        {
            'TopicArn': 'string'
        },
        {
            'TopicArn': 'string'
        },
        {
            'TopicArn': 'string'
        },
    ],
    'NextToken': 'string'
}
```
Response Structure

• (dict) –
  Response for ListTopics action.
  – Topics (list) –
    A list of topic ARNs.
      * (dict) –
        A wrapper type for the topic’s Amazon Resource Name (ARN). To retrieve a topic’s attributes, use GetTopicAttributes.
          • TopicArn (string) –
            The topic’s ARN.
  – NextToken (string) –
    Token to pass along to the next ListTopics request. This element is returned if there are additional topics to retrieve.

publish(**kwargs)
Sends a message to all of a topic’s subscribed endpoints. When a messageId is returned, the message has been saved and Amazon SNS will attempt to deliver it to the topic’s subscribers shortly. The format of the outgoing message to each subscribed endpoint depends on the notification protocol selected.

To use the Publish action for sending a message to a mobile endpoint, such as an app on a Kindle device or mobile phone, you must specify the EndpointArn. The EndpointArn is returned when making a call with the CreatePlatformEndpoint action. The second example below shows a request and response for publishing to a mobile endpoint.

Request Syntax

response = client.publish(
    TopicArn='string',
    TargetArn='string',
    Message='string',
    Subject='string',
    MessageStructure='string',
    MessageAttributes={
        'string': {
            'DataType': 'string',
            'StringValue': 'string',
            'BinaryValue': b'bytes'
        }
    }
)

Parameters

• TopicArn (string) – The topic you want to publish to.
• TargetArn (string) – Either TopicArn or EndpointArn, but not both.
• Message (string) – [REQUIRED]
  The message you want to send to the topic.

  If you want to send the same message to all transport protocols, include the text of the message as a String value.

  If you want to send different messages for each transport protocol, set the value of the MessageStructure parameter to json and use a JSON object for the Message parameter. See the Examples section for the format of the JSON object.
Constraints: Messages must be UTF-8 encoded strings at most 256 KB in size (262144 bytes, not 262144 characters).

JSON-specific constraints:
- Keys in the JSON object that correspond to supported transport protocols must have simple JSON string values.
- The values will be parsed (unescaped) before they are used in outgoing messages.
- Outbound notifications are JSON encoded (meaning that the characters will be reescaped for sending).
- Values have a minimum length of 0 (the empty string, "", is allowed).
- Values have a maximum length bounded by the overall message size (so, including multiple protocols may limit message sizes).
- Non-string values will cause the key to be ignored.
- Keys that do not correspond to supported transport protocols are ignored.
- Duplicate keys are not allowed.
- Failure to parse or validate any key or value in the message will cause the Publish call to return an error (no partial delivery).

- **Subject** *(string)* – Optional parameter to be used as the “Subject” line when the message is delivered to email endpoints. This field will also be included, if present, in the standard JSON messages delivered to other endpoints.

  Constraints: Subjects must be ASCII text that begins with a letter, number, or punctuation mark; must not include line breaks or control characters; and must be less than 100 characters long.

- **MessageStructure** *(string)* – Set MessageStructure to json if you want to send a different message for each protocol. For example, using one publish action, you can send a short message to your SMS subscribers and a longer message to your email subscribers. If you set MessageStructure to json, the value of the Message parameter must:
  - be a syntactically valid JSON object; and
  - contain at least a top-level JSON key of “default” with a value that is a string.

  You can define other top-level keys that define the message you want to send to a specific transport protocol (e.g., “http”).

  For information about sending different messages for each protocol using the AWS Management Console, go to Create Different Messages for Each Protocol in the Amazon Simple Notification Service Getting Started Guide.

  Valid value: json

- **MessageAttributes** *(dict)* – Message attributes for Publish action.
  - *(string)* –
  - *(dict)* –

  The user-specified message attribute value. For string data types, the value attribute has the same restrictions on the content as the message body. For more information, see Publish.

  Name, type, and value must not be empty or null. In addition, the message body should not be empty or null. All parts of the message attribute, including name, type, and value, are included in the message size restriction, which is currently 256 KB (262,144 bytes).

  For more information, see Using Amazon SNS Message Attributes.

  - **DataType** *(string)* – [REQUIRED]
Amazon SNS supports the following logical data types: String, Number, and Binary. For more information, see Message Attribute Data Types.

- **StringValue (string)** – Strings are Unicode with UTF8 binary encoding. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters.

- **BinaryValue (bytes)** – Binary type attributes can store any binary data, for example, compressed data, encrypted data, or images.

### remove_permission(**kwargs)**
Removes a statement from a topic’s access control policy.

**Request Syntax**

```python
response = client.remove_permission(
    TopicArn='string',
    Label='string'
)
```

**Parameters**

- **TopicArn (string)** – [REQUIRED]
  The ARN of the topic whose access control policy you wish to modify.
- **Label (string)** – [REQUIRED]
  The unique label of the statement you want to remove.

**Returns** None

### set_endpoint_attributes(**kwargs)**
Sets the attributes for an endpoint for a device on one of the supported push notification services, such as GCM and APNS. For more information, see Using Amazon SNS Mobile Push Notifications.

**Request Syntax**

```python
response = client.set_endpoint_attributes(
    EndpointArn='string',
    Attributes={
        'string': 'string'
    }
```

**Response Syntax**

```python
{
    'MessageId': 'string'
}
```

**Response Structure**

- **(dict)** – Response for Publish action.
  - **MessageId (string)** – Unique identifier assigned to the published message.
    Length Constraint: Maximum 100 characters
Parameters

- **EndpointArn** *(string)* – [REQUIRED]
  
  EndpointArn used for SetEndpointAttributes action.

- **Attributes** *(dict)* – [REQUIRED]
  
  A map of the endpoint attributes. Attributes in this map include the following:
  
  - **CustomUserData** – arbitrary user data to associate with the endpoint. Amazon SNS does not use this data. The data must be in UTF-8 format and less than 2KB.
  - **Enabled** – flag that enables/disables delivery to the endpoint. Amazon SNS will set this to false when a notification service indicates to Amazon SNS that the endpoint is invalid. Users can set it back to true, typically after updating Token.
  - **Token** – device token, also referred to as a registration id, for an app and mobile device. This is returned from the notification service when an app and mobile device are registered with the notification service.
  
- *(string)* – *

**Returns** None

```python
set_platform_application_attributes(**kwargs)
```

Sets the attributes of the platform application object for the supported push notification services, such as APNS and GCM. For more information, see Using Amazon SNS Mobile Push Notifications.

Request Syntax

```python
response = client.set_platform_application_attributes(
    PlatformApplicationArn='string',
    Attributes={
        'string': 'string'
    }
)
```

Parameters

- **PlatformApplicationArn** *(string)* – [REQUIRED]
  
  PlatformApplicationArn for SetPlatformApplicationAttributes action.

- **Attributes** *(dict)* – [REQUIRED]
  
  A map of the platform application attributes. Attributes in this map include the following:
  
  - **PlatformCredential** – The credential received from the notification service. For APNS/APNS_SANDBOX, PlatformCredential is “private key”. For GCM, PlatformCredential is “API key”. For ADM, PlatformCredential is “client secret”.
  - **PlatformPrincipal** – The principal received from the notification service. For APNS/APNS_SANDBOX, PlatformPrincipal is “SSL certificate”. For GCM, PlatformPrincipal is not applicable. For ADM, PlatformPrincipal is “client id”.
  - **EventEndpointCreated** – Topic ARN to which EndpointCreated event notifications should be sent.
  - **EventEndpointDeleted** – Topic ARN to which EndpointDeleted event notifications should be sent.
– EventEndpointUpdated – Topic ARN to which EndpointUpdate event notifications should be sent.
– EventDeliveryFailure – Topic ARN to which DeliveryFailure event notifications should be sent upon Direct Publish delivery failure (permanent) to one of the application’s endpoints.

– (string) – *

Returns None

set_subscription_attributes(**kwargs)
Allows a subscription owner to set an attribute of the topic to a new value.

Request Syntax

response = client.set_subscription_attributes(
    SubscriptionArn='string',
    AttributeName='string',
    AttributeValue='string'
)

Parameters

• SubscriptionArn (string) – [REQUIRED]
  The ARN of the subscription to modify.
• AttributeName (string) – [REQUIRED]
  The name of the attribute you want to set. Only a subset of the subscriptions attributes are mutable.

  Valid values: DeliveryPolicy, RawMessageDelivery
  • AttributeValue (string) – The new value for the attribute in JSON format.

Returns None

set_topic_attributes(**kwargs)
Allows a topic owner to set an attribute of the topic to a new value.

Request Syntax

response = client.set_topic_attributes(
    TopicArn='string',
    AttributeName='string',
    AttributeValue='string'
)

Parameters

• TopicArn (string) – [REQUIRED]
  The ARN of the topic to modify.
• AttributeName (string) – [REQUIRED]
  The name of the attribute you want to set. Only a subset of the topic’s attributes are mutable.

  Valid values: Policy, DisplayName, DeliveryPolicy
  • AttributeValue (string) – The new value for the attribute.

Returns None

subscribe(**kwargs)
Prepares to subscribe an endpoint by sending the endpoint a confirmation message. To actually create a
subscription, the endpoint owner must call the `ConfirmSubscription` action with the token from the confirmation message. Confirmation tokens are valid for three days.

**Request Syntax**

```python
response = client.subscribe(
    TopicArn='string',
    Protocol='string',
    Endpoint='string'
)
```

**Parameters**

- **TopicArn** *(string)* – [REQUIRED]
  The ARN of the topic you want to subscribe to.

- **Protocol** *(string)* – [REQUIRED]
  The protocol you want to use. Supported protocols include:
  - `http` – delivery of JSON-encoded message via HTTP POST
  - `https` – delivery of JSON-encoded message via HTTPS POST
  - `email` – delivery of message via SMTP
  - `email-json` – delivery of JSON-encoded message via SMTP
  - `sms` – delivery of message via SMS
  - `sqs` – delivery of JSON-encoded message to an Amazon SQS queue
  - `application` – delivery of JSON-encoded message to an EndpointArn for a mobile app and device.

- **Endpoint** *(string)* – The endpoint that you want to receive notifications. Endpoints vary by protocol:
  - For the `http` protocol, the endpoint is an URL beginning with “http://”
  - For the `https` protocol, the endpoint is a URL beginning with “https://”
  - For the `email` protocol, the endpoint is an email address
  - For the `email-json` protocol, the endpoint is an email address
  - For the `sms` protocol, the endpoint is a phone number of an SMS-enabled device
  - For the `sqs` protocol, the endpoint is the ARN of an Amazon SQS queue
  - For the `application` protocol, the endpoint is the EndpointArn of a mobile app and device.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'SubscriptionArn': 'string'
}
```

**Response Structure**

  - **SubscriptionArn** *(string)* – The ARN of the subscription, if the service was able to create a subscription immediately (without requiring endpoint owner confirmation).

**unsubscribe(****kwargs**)

Deletes a subscription. If the subscription requires authentication for deletion, only the owner of the subscription or the topic’s owner can unsubscribe, and an AWS signature is required. If the `Unsubscribe` call does not require authentication and the requester is not the subscription owner, a final cancellation
message is delivered to the endpoint, so that the endpoint owner can easily resubscribe to the topic if the
Unsubscribe request was unintended.

Request Syntax

```python
response = client.unsubscribe(
    SubscriptionArn='string'
)
```

Parameters

- **SubscriptionArn (string)** – [REQUIRED]
  
The ARN of the subscription to be deleted.

Returns

None

Paginators

The available paginators are:

- `SNS.Paginator.ListEndpointsByPlatformApplication`
- `SNS.Paginator.ListPlatformApplications`
- `SNS.Paginator.ListSubscriptions`
- `SNS.Paginator.ListSubscriptionsByTopic`
- `SNS.Paginator.ListTopics`

```python
class SNS.Paginator.ListEndpointsByPlatformApplication

paginator = client.get_paginator('list_endpoints_by_platform_application')
```

**paginate(** **kwargs**)**

Creates an iterator that will paginate through responses from `SNS.Client.list_endpoints_by_platform_application()`.

Request Syntax

```python
response_iterator = paginator.paginate(
    PlatformApplicationArn='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **PlatformApplicationArn (string)** – [REQUIRED]
  
  PlatformApplicationArn for ListEndpointsByPlatformApplicationInput action.

- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  
  - **MaxItems (integer)** –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
- **PageSize** *(integer)* –
  The size of each page.
- **StartingToken** *(string)* –
  A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Endpoints': [  
        {
            'EndpointArn': 'string',  
            'Attributes': {
                'string': 'string'
            }
        },
    ],
}
```

**Response Structure**

- *(dict)* –
  Response for ListEndpointsByPlatformApplication action.
  - **Endpoints** *(list)* –
    Endpoints returned for ListEndpointsByPlatformApplication action.
    - *(dict)* –
      Endpoint for mobile app and device.
      - **EndpointArn** *(string)* –
        EndpointArn for mobile app and device.
      - **Attributes** *(dict)* –
        Attributes for endpoint.
        - *(string)* –
        - *(string)* –

```python
class SNS.Paginator.ListPlatformApplications

paginator = client.get_paginator('list_platform_applications')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `SNS.Client.list_platform_applications()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }

```
Parameters  

**PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

- **MaxItems** *(integer)* –
  The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.

- **PageSize** *(integer)* –
  The size of each page.

- **StartingToken** *(string)* –
  A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type**  
`dict`

**Returns**

**Response Syntax**

```python
{
  'PlatformApplications': [
    {
      'PlatformApplicationArn': 'string',
      'Attributes': {
        'string': 'string'
      }
    },
    ...
  ],
}
```

**Response Structure**

- *(dict)* –
  Response for `ListPlatformApplications` action.

  - **PlatformApplications** *(list)* –
    Platform applications returned when calling `ListPlatformApplications` action.

      - *(dict)* –
        Platform application object.

          - **PlatformApplicationArn** *(string)* –
            PlatformApplicationArn for platform application object.

          - **Attributes** *(dict)* –
            Attributes for platform application object.

```python
class SNS.Paginator.ListSubscriptions

    paginator = client.get_paginator('list_subscriptions')```
**paginate** (**kwargs**)  
Creates an iterator that will paginate through responses from SNS.Client.list_subscriptions().

**Request Syntax**

```python
response_iterator = paginator.paginate(
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**  
**PaginationConfig** (**dict**) – A dictionary that provides parameters to control pagination.

- **MaxItems** (**integer**) –  
The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

- **PageSize** (**integer**) –  
The size of each page.

- **StartingToken** (**string**) –  
A token to specify where to start paginating. This is the NextToken from a previous response.

**Response Syntax**

```python
{
    'Subscriptions': [
        {
            'SubscriptionArn': 'string',
            'Owner': 'string',
            'Protocol': 'string',
            'Endpoint': 'string',
            'TopicArn': 'string'
        },
    ],
}
```

**Response Structure**

- (**dict**) –  
Response for ListSubscriptions action

  - **Subscriptions** (**list**) –  
  A list of subscriptions.

  - (**dict**) –  
  A wrapper type for the attributes of an Amazon SNS subscription.

    - **SubscriptionArn** (**string**) –  
    The subscription’s ARN.
· **Owner** *(string)* –
  The subscription’s owner.
· **Protocol** *(string)* –
  The subscription’s protocol.
· **Endpoint** *(string)* –
  The subscription’s endpoint (format depends on the protocol).
· **TopicArn** *(string)* –
  The ARN of the subscription’s topic.

```python
class SNS.Paginator.ListSubscriptionsByTopic

paginator = client.get_paginator('list_subscriptions_by_topic')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `SNS.Client.list_subscriptions_by_topic()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    TopicArn='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **TopicArn** *(string)* – [REQUIRED]
  The ARN of the topic for which you wish to find subscriptions.
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –
    The size of each page.
  - **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Subscriptions': [
        {
            'SubscriptionArn': 'string',
        }
    ]
}
```
Response Structure

- (dict) –
  Response for ListSubscriptionsByTopic action.
  - Subscriptions (list) –
    A list of subscriptions.
    * (dict) –
      A wrapper type for the attributes of an Amazon SNS subscription.
      - SubscriptionArn (string) –
        The subscription’s ARN.
      - Owner (string) –
        The subscription’s owner.
      - Protocol (string) –
        The subscription’s protocol.
      - Endpoint (string) –
        The subscription’s endpoint (format depends on the protocol).
      - TopicArn (string) –
        The ARN of the subscription’s topic.

class SNS.Paginator.ListTopics

paginator = client.get_paginator('list_topics')

paginate(**kwargs)

Creates an iterator that will paginate through responses from SNS.Client.list_topics().

Request Syntax

response_iterator = paginator.paginate(
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

PaginationConfig (dict) – A dictionary that provides parameters to control pagination.
  - MaxItems (integer) –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
• **PageSize** (*integer*) –
  The size of each page.
• **StartingToken** (*string*) –
  A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type**  dict

**Returns**

**Response Syntax**

```
{
   'Topics': [
       {
           'TopicArn': 'string'
       },
   ],
}
```

**Response Structure**

• (**dict**) –
  Response for ListTopics action.
  
  – **Topics** (*list*) –
    A list of topic ARNs.
    
    • (**dict**) –
      A wrapper type for the topic’s Amazon Resource Name (ARN). To retrieve a topic’s attributes, use `GetTopicAttributes`.
      
      - **TopicArn** (*string*) –
        The topic’s ARN.

**Service Resource**

```python
import boto3

sns = boto3.resource('sns')
```

These are the resource’s available actions:

• `create_platform_application()`
• `create_topic()`

These are the resource’s available sub-resources:

• `PlatformApplication()`
• `PlatformEndpoint()`
• `Subscription()`
• `Topic()`

These are the resource’s available collections:

• `platform_applications`
• `subscriptions`
• `topics`
Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

**create_platform_application(**kwargs)**

Creates a platform application object for one of the supported push notification services, such as APNS and GCM, to which devices and mobile apps may register. You must specify PlatformPrincipal and PlatformCredential attributes when using the `create_platform_application` action. The PlatformPrincipal is received from the notification service. For APNS/APNS_SANDBOX, PlatformPrincipal is “SSL certificate”. For GCM, PlatformPrincipal is not applicable. For ADM, PlatformPrincipal is “client id”. The PlatformCredential is also received from the notification service. For APNS/APNS_SANDBOX, PlatformCredential is “private key”. For GCM, PlatformCredential is “API key”. For ADM, PlatformCredential is “client secret”. The PlatformApplicationArn that is returned when using `create_platform_application` is then used as an attribute for the `create_platform_endpoint` action. For more information, see Using Amazon SNS Mobile Push Notifications.

Request Syntax

```python
platform_application = sns.create_platform_application(
    Name='string',
    Platform='string',
    Attributes={
        'string': 'string'
    }
)
```

Parameters

- **Name (string) – [REQUIRED]**
  
  Application names must be made up of only uppercase and lowercase ASCII letters, numbers, underscores, hyphens, and periods, and must be between 1 and 256 characters long.

- **Platform (string) – [REQUIRED]**
  
  The following platforms are supported: ADM (Amazon Device Messaging), APNS (Apple Push Notification Service), APNS_SANDBOX, and GCM (Google Cloud Messaging).

- **Attributes (dict) – [REQUIRED]**
  
  For a list of attributes, see `set_platform_application_attributes`

  - (string) –
    
    * (string) –

  Returns PlatformApplication resource

**create_topic(**kwargs)**

Creates a topic to which notifications can be published. Users can create at most 3000 topics. For more information, see [http://aws.amazon.com/sns](http://aws.amazon.com/sns). This action is idempotent, so if the requester already owns a topic with the specified name, that topic’s ARN is returned without creating a new topic.

Request Syntax

```python
topic = sns.create_topic(
    Name='string'
)
```
Parameters

Name (string) – [REQUIRED]

The name of the topic you want to create.

Constraints: Topic names must be made up of only uppercase and lowercase ASCII letters, numbers, underscores, and hyphens, and must be between 1 and 256 characters long.

Return type sns.Topic

Returns Topic resource

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

PlatformApplication (arn)

Creates a PlatformApplication resource:

platform_application = sns.PlatformApplication('arn')

Parameters

arn (string) – The PlatformApplication’s arn identifier. This must be set.

Return type SNS.PlatformApplication

Returns A PlatformApplication resource

PlatformEndpoint (arn)

Creates a PlatformEndpoint resource:

platform_endpoint = sns.PlatformEndpoint('arn')

Parameters

arn (string) – The PlatformEndpoint’s arn identifier. This must be set.

Return type SNS.PlatformEndpoint

Returns A PlatformEndpoint resource

Subscription (arn)

Creates a Subscription resource:

subscription = sns.Subscription('arn')

Parameters

arn (string) – The Subscription’s arn identifier. This must be set.

Return type SNS.Subscription

Returns A Subscription resource

Topic (arn)

Creates a Topic resource:

topic = sns.Topic('arn')

Parameters

arn (string) – The Topic’s arn identifier. This must be set.

Return type SNS.Topic

Returns A Topic resource

Collections

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the Resources Introduction Guide.

platform_applications
**all()**
Creates an iterable of all PlatformApplication resources in the collection.

**Request Syntax**

```python
platform_application_iterator = sns.platform_applications.all()
```

**Return type** list(sns.PlatformApplication)
**Returns** A list of PlatformApplication resources

**filter(**kwargs**)**
Creates an iterable of all PlatformApplication resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
platform_application_iterator = sns.platform_applications.filter(
    NextToken='string'
)
```

**Parameters**
- **NextToken** (string) – NextToken string is used when calling ListPlatformApplications action to retrieve additional records that are available after the first page results.

**Return type** list(sns.PlatformApplication)
**Returns** A list of PlatformApplication resources

**limit(**kwargs**)**
Creates an iterable up to a specified amount of PlatformApplication resources in the collection.

**Request Syntax**

```python
platform_application_iterator = sns.platform_applications.limit(
    count=123
)
```

**Parameters**
- **count** (integer) – The limit to the number of resources in the iterable.

**Return type** list(sns.PlatformApplication)
**Returns** A list of PlatformApplication resources

**page_size(**kwargs**)**
Creates an iterable of all PlatformApplication resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
platform_application_iterator = sns.platform_applications.page_size(
    count=123
)
```

**Parameters**
- **count** (integer) – The number of items returned by each service call

**Return type** list(sns.PlatformApplication)
**Returns** A list of PlatformApplication resources

**subscriptions**

**all()**
Creates an iterable of all Subscription resources in the collection.

**Request Syntax**
subscription_iterator = sns.subscriptions.all()

Return type list(sns.Subscription)
Returns A list of Subscription resources

filter(**kwargs)
Creates an iterable of all Subscription resources in the collection filtered by kwargs passed to method.

Request Syntax

subscription_iterator = sns.subscriptions.filter(
    NextToken='string'
)

Parameters NextToken (string) – Token returned by the previous ListSubscriptions request.

Returns A list of Subscription resources

limit(**kwargs)
Creates an iterable up to a specified amount of Subscription resources in the collection.

Request Syntax

subscription_iterator = sns.subscriptions.limit(
    count=123
)

Parameters count (integer) – The limit to the number of resources in the iterable.

Returns A list of Subscription resources

page_size(**kwargs)
Creates an iterable of all Subscription resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

subscription_iterator = sns.subscriptions.page_size(
    count=123
)

Parameters count (integer) – The number of items returned by each service call

Returns A list of Subscription resources

topics

all()
Creates an iterable of all Topic resources in the collection.

Request Syntax

topic_iterator = sns.topics.all()

Return type list(sns.Topic)
Returns A list of Topic resources
**filter(**kwargs)**

Creates an iterable of all Topic resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```
    topic_iterator = sns.topics.filter(
        NextToken='string'
    )
```

**Parameters**

- **NextToken** *(string)* – Token returned by the previous ListTopics request.

**Return type** list(sns.Topic)

**Returns** A list of Topic resources

**limit(**kwargs)**

Creates an iterable up to a specified amount of Topic resources in the collection.

**Request Syntax**

```
    topic_iterator = sns.topics.limit(
        count=123
    )
```

**Parameters**

- **count** *(integer)* – The limit to the number of resources in the iterable.

**Return type** list(sns.Topic)

**Returns** A list of Topic resources

**page_size(**kwargs)**

Creates an iterable of all Topic resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```
    topic_iterator = sns.topics.page_size(
        count=123
    )
```

**Parameters**

- **count** *(integer)* – The number of items returned by each service call

**Return type** list(sns.Topic)

**Returns** A list of Topic resources

---

**PlatformApplication**

**class** SNS.PlatformApplication *(arn)*

A resource representing an Amazon Simple Notification Service (SNS) PlatformApplication:

```
    import boto3

    sns = boto3.resource('sns')
    platform_application = sns.PlatformApplication('arn')
```

**Parameters**

- **arn** *(string)* – The PlatformApplication’s arn identifier. This **must** be set.

These are the resource’s available identifiers:

- **arn**

These are the resource’s available attributes:

- **attributes**
These are the resource’s available actions:

• `create_platform_endpoint()`
• `delete()`
• `load()`
• `reload()`
• `set_attributes()`

These are the resource’s available collections:

• `endpoints`

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

`arn`

(string) The PlatformApplication’s arn identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the Resources Introduction Guide.

`attributes`

(dict)

Attributes include the following:

• `EventEndpointCreated` – Topic ARN to which EndpointCreated event notifications should be sent.
• `EventEndpointDeleted` – Topic ARN to which EndpointDeleted event notifications should be sent.
• `EventEndpointUpdated` – Topic ARN to which EndpointUpdate event notifications should be sent.
• `EventDeliveryFailure` – Topic ARN to which DeliveryFailure event notifications should be sent upon Direct Publish delivery failure (permanent) to one of the application’s endpoints.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

`create_platform_endpoint(**kwargs)`

Creates an endpoint for a device and mobile app on one of the supported push notification services, such as GCM and APNS. CreatePlatformEndpoint requires the PlatformApplicationArn that is returned from CreatePlatformApplication. The EndpointArn that is returned when using CreatePlatformEndpoint can then be used by the Publish action to send a message to a mobile app or by the Subscribe action for subscription to a topic. The CreatePlatformEndpoint action is idempotent, so if the requester already owns an endpoint with the same device token and attributes, that endpoint’s ARN is returned without creating a new endpoint. For more information, see Using Amazon SNS Mobile Push Notifications.

When using CreatePlatformEndpoint with Baidu, two attributes must be provided: ChannelId and UserId. The token field must also contain the ChannelId. For more information, see Creating an Amazon SNS Endpoint for Baidu.

Request Syntax

```python
platform_endpoint = platform_application.create_platform_endpoint(
    Token='string',
    CustomUserData='string',
    Attributes={
```
Parameters

- **Token** *(string)* – [REQUIRED]
  
  Unique identifier created by the notification service for an app on a device. The specific name for Token will vary, depending on which notification service is being used. For example, when using APNS as the notification service, you need the device token. Alternatively, when using GCM or ADM, the device token equivalent is called the registration ID.

- **CustomUserData** *(string)* – Arbitrary user data to associate with the endpoint. Amazon SNS does not use this data. The data must be in UTF-8 format and less than 2KB.

- **Attributes** *(dict)* – For a list of attributes, see SetEndpointAttributes.

  * (string) –

  Return type `sns.PlatformEndpoint`

  Returns PlatformEndpoint resource

delete()

Deletes a platform application object for one of the supported push notification services, such as APNS and GCM. For more information, see Using Amazon SNS Mobile Push Notifications.

Request Syntax

```
response = platform_application.delete()
```

Returns None

load()

Calls `sns.Client.get_platform_application_attributes()` to update the attributes of the PlatformApplication resource

Request Syntax

```
platform_application.load()
```

Returns None

reload()

Calls `sns.Client.get_platform_application_attributes()` to update the attributes of the PlatformApplication resource

Request Syntax

```
platform_application.reload()
```

Returns None

set_attributes(**kwargs)

Sets the attributes of the platform application object for the supported push notification services, such as APNS and GCM. For more information, see Using Amazon SNS Mobile Push Notifications.

Request Syntax
response = platform_application.set_attributes(
    Attributes={
        'string': 'string'
    }
)

Parameters  Attributes (dict) – [REQUIRED]

A map of the platform application attributes. Attributes in this map include the following:

- PlatformCredential – The credential received from the notification service. For APNS/APNS_SANDBOX, PlatformCredential is “private key”. For GCM, PlatformCredential is “API key”. For ADM, PlatformCredential is “client secret”.
- PlatformPrincipal – The principal received from the notification service. For APNS/APNS_SANDBOX, PlatformPrincipal is “SSL certificate”. For GCM, PlatformPrincipal is not applicable. For ADM, PlatformPrincipal is “client id”.
- EventEndpointCreated – Topic ARN to which EndpointCreated event notifications should be sent.
- EventEndpointDeleted – Topic ARN to which EndpointDeleted event notifications should be sent.
- EventEndpointUpdated – Topic ARN to which EndpointUpdate event notifications should be sent.
- EventDeliveryFailure – Topic ARN to which DeliveryFailure event notifications should be sent upon Direct Publish delivery failure (permanent) to one of the application’s endpoints.

Returns  None

Collections

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the Resources Introduction Guide.

endpoints

all ()

Creates an iterable of all PlatformEndpoint resources in the collection.

Request Syntax

platform_endpoint_iterator = platform_application.endpoints.all()

Return type  list(sns.PlatformEndpoint)

Returns  A list of PlatformEndpoint resources

filter (**kwargs)

Creates an iterable of all PlatformEndpoint resources in the collection filtered by kwargs passed to method.

Request Syntax

platform_endpoint_iterator = platform_application.endpoints.filter(
    NextToken='string'
)
Parameters **NextToken (string)** – NextToken string is used when calling ListEndpointsByPlatformApplication action to retrieve additional records that are available after the first page results.

Return type list(sns.PlatformEndpoint)

Returns A list of PlatformEndpoint resources

**limit (**kwargs**)

Creates an iterable up to a specified amount of PlatformEndpoint resources in the collection.

**Request Syntax**

```python
platform_endpoint_iterator = platform_application.endpoints.limit(count=123)
```

Parameters **count (integer)** – The limit to the number of resources in the iterable.

Return type list(sns.PlatformEndpoint)

Returns A list of PlatformEndpoint resources

**paginate (**kwargs**)

Creates an iterable of all PlatformEndpoint resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
platform_endpoint_iterator = platform_application.endpoints.page_size(count=123)
```

Parameters **count (integer)** – The number of items returned by each service call

Return type list(sns.PlatformEndpoint)

Returns A list of PlatformEndpoint resources

PlatformEndpoint

**class** sns.PlatformEndpoint (arn)

A resource representing an Amazon Simple Notification Service (SNS) PlatformEndpoint:

```python
import boto3

sns = boto3.resource('sns')
platform_endpoint = sns.PlatformEndpoint('arn')
```

Parameters **arn (string)** – The PlatformEndpoint’s arn identifier. This must be set.

These are the resource’s available identifiers:

*arn*

These are the resource’s available attributes:

*attributes*

These are the resource’s available actions:

*delete()*

*load()*

*publish()*

*reload()*

*set_attributes()*
Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

\textbf{arn}

\textit{string} The PlatformEndpoint’s arn identifier. This \textbf{must} be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the \texttt{load()} method. For more information about attributes refer to the Resources Introduction Guide.

\textbf{attributes}

\textit{dict}

Attributes include the following:

• \textit{CustomUserData} – arbitrary user data to associate with the endpoint. Amazon SNS does not use this data. The data must be in UTF-8 format and less than 2KB.
• \textit{Enabled} – flag that enables/disables delivery to the endpoint. Amazon SNS will set this to false when a notification service indicates to Amazon SNS that the endpoint is invalid. Users can set it back to true, typically after updating \textit{Token}.
• \textit{Token} – device token, also referred to as a registration id, for an app and mobile device. This is returned from the notification service when an app and mobile device are registered with the notification service.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

\textbf{delete()}

Deletes the endpoint from Amazon SNS. This action is idempotent. For more information, see Using Amazon SNS Mobile Push Notifications.

\textbf{Request Syntax}

\begin{verbatim}
response = platform_endpoint.delete()
\end{verbatim}

\textbf{Returns} None

\textbf{load()}

Calls \texttt{sns.Client.get_endpoint_attributes()} to update the attributes of the PlatformEndpoint resource.

\textbf{Request Syntax}

\begin{verbatim}
platform_endpoint.load()
\end{verbatim}

\textbf{Returns} None

\textbf{publish(**kwargs)}

Sends a message to all of a topic’s subscribed endpoints. When a \textit{messageId} is returned, the message has been saved and Amazon SNS will attempt to deliver it to the topic’s subscribers shortly. The format of the outgoing message to each subscribed endpoint depends on the notification protocol selected.

To use the \texttt{Publish} action for sending a message to a mobile endpoint, such as an app on a Kindle device or mobile phone, you must specify the \texttt{EndpointArn}. The \texttt{EndpointArn} is returned when making a call with the \texttt{CreatePlatformEndpoint} action. The second example below shows a request and response for publishing to a mobile endpoint.

\textbf{Request Syntax}
response = platform_endpoint.publish(
    TopicArn='string',
    Message='string',
    Subject='string',
    MessageStructure='string',
    MessageAttributes={
        'string': {
            'DataType': 'string',
            'StringValue': 'string',
            'BinaryValue': b'bytes'
        }
    }
)

Parameters

- **TopicArn (string)** – The topic you want to publish to.
- **Message (string)** – [REQUIRED]

  The message you want to send to the topic.

  If you want to send the same message to all transport protocols, include the text of the message as a String value.

  If you want to send different messages for each transport protocol, set the value of the **MessageStructure** parameter to **json** and use a JSON object for the **Message** parameter. See the Examples section for the format of the JSON object.

  Constraints: Messages must be UTF-8 encoded strings at most 256 KB in size (262144 bytes, not 262144 characters).

  JSON-specific constraints:
  - Keys in the JSON object that correspond to supported transport protocols must have simple JSON string values.
  - The values will be parsed (unescape) before they are used in outgoing messages.
  - Outbound notifications are JSON encoded (meaning that the characters will be reescaped for sending).
  - Values have a minimum length of 0 (the empty string, "", is allowed).
  - Values have a maximum length bounded by the overall message size (so, including multiple protocols may limit message sizes).
  - Non-string values will cause the key to be ignored.
  - Keys that do not correspond to supported transport protocols are ignored.
  - Duplicate keys are not allowed.
  - Failure to parse or validate any key or value in the message will cause the **Publish** call to return an error (no partial delivery).

- **Subject (string)** – Optional parameter to be used as the “Subject” line when the message is delivered to email endpoints. This field will also be included, if present, in the standard JSON messages delivered to other endpoints.

  Constraints: Subjects must be ASCII text that begins with a letter, number, or punctuation mark; must not include line breaks or control characters; and must be less than 100 characters long.

- **MessageStructure (string)** – Set **MessageStructure** to **json** if you want to send a different message for each protocol. For example, using one publish action, you can send a short message to your SMS subscribers and a longer message to your email subscribers. If you set **MessageStructure** to **json**,
the value of the `Message` parameter must:

– be a syntactically valid JSON object; and

– contain at least a top-level JSON key of “default” with a value that is a string.

You can define other top-level keys that define the message you want to send to a specific transport protocol (e.g., “http”).

For information about sending different messages for each protocol using the AWS Management Console, go to Create Different Messages for Each Protocol in the Amazon Simple Notification Service Getting Started Guide.

Valid value: `json`

- **MessageAttributes (dict)** – Message attributes for Publish action.
  
  - *(string)* –
    
    * (dict) –

    The user-specified message attribute value. For string data types, the value attribute has the same restrictions on the content as the message body. For more information, see Publish.

    Name, type, and value must not be empty or null. In addition, the message body should not be empty or null. All parts of the message attribute, including name, type, and value, are included in the message size restriction, which is currently 256 KB (262,144 bytes).

    For more information, see Using Amazon SNS Message Attributes.

- **DataType (string)** – [REQUIRED]

  Amazon SNS supports the following logical data types: String, Number, and Binary. For more information, see Message Attribute Data Types.

- **StringValue (string)** –

  Strings are Unicode with UTF8 binary encoding. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters.

- **BinaryValue (bytes)** –

  Binary type attributes can store any binary data, for example, compressed data, encrypted data, or images.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'MessageId': 'string'
}
```

**Response Structure**

- *(dict)* –

  Response for Publish action.

  - **MessageId (string)** –

    Unique identifier assigned to the published message.

    Length Constraint: Maximum 100 characters
**reload()**

Calls `sns.Client.get_endpoint_attributes()` to update the attributes of the PlatformEndpoint resource.

**Request Syntax**

```python
platform_endpoint.reload()
```

**Returns** None

**set_attributes(**kwargs)**

Sets the attributes for an endpoint for a device on one of the supported push notification services, such as GCM and APNS. For more information, see Using Amazon SNS Mobile Push Notifications.

**Request Syntax**

```python
response = platform_endpoint.set_attributes(
    Attributes={
        'string': 'string'
    }
)
```

**Parameters** Attributes (dict) – [REQUIRED]

A map of the endpoint attributes. Attributes in this map include the following:

- **CustomUserData** – arbitrary user data to associate with the endpoint. Amazon SNS does not use this data. The data must be in UTF-8 format and less than 2KB.
- **Enabled** – flag that enables/disables delivery to the endpoint. Amazon SNS will set this to false when a notification service indicates to Amazon SNS that the endpoint is invalid. Users can set it back to true, typically after updating Token.
- **Token** – device token, also referred to as a registration id, for an app and mobile device. This is returned from the notification service when an app and mobile device are registered with the notification service.

**Returns** None

---

**Subscription**

**class SNS.Subscription(arn)**

A resource representing an Amazon Simple Notification Service (SNS) Subscription:

```python
import boto3

sns = boto3.resource('sns')
sns.Subscription('arn')
```

**Parameters** **arn** (string) – The Subscription’s arn identifier. This must be set.

These are the resource’s available identifiers:

- **arn**

These are the resource’s available attributes:

- **attributes**

These are the resource’s available actions:
• `delete()`  
• `load()`  
• `reload()`  
• `set_attributes()`

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

`arn`  
*string* The Subscription’s arn identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the Resources Introduction Guide.

`attributes`  
*dict*  
A map of the subscription’s attributes. Attributes in this map include the following:

• `SubscriptionArn` – the subscription’s ARN  
• `TopicArn` – the topic ARN that the subscription is associated with  
• `Owner` – the AWS account ID of the subscription’s owner  
• `ConfirmationWasAuthenticated` – true if the subscription confirmation request was authenticated  
• `DeliveryPolicy` – the JSON serialization of the subscription’s delivery policy  
• `EffectiveDeliveryPolicy` – the JSON serialization of the effective delivery policy that takes into account the topic delivery policy and account system defaults

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

`delete()`  
Deletes a subscription. If the subscription requires authentication for deletion, only the owner of the subscription or the topic’s owner can unsubscribe, and an AWS signature is required. If the Unsubscribe call does not require authentication and the requester is not the subscription owner, a final cancellation message is delivered to the endpoint, so that the endpoint owner can easily resubscribe to the topic if the Unsubscribe request was unintended.

Request Syntax

```python
response = subscription.delete()
```

Returns None

`load()`  
Calls `sns.Client.get_subscription_attributes()` to update the attributes of the Subscription resource

Request Syntax

```python
subscription.load()
```

Returns None

`reload()`  
Calls `sns.Client.get_subscription_attributes()` to update the attributes of the Subscription resource
Request Syntax

subscription.reload()

Returns None

set_attributes(**kwargs)

Allows a subscription owner to set an attribute of the topic to a new value.

Request Syntax

response = subscription.set_attributes(
    AttributeName='string',
    AttributeValue='string'
)

Parameters

- **AttributeName (string)** – [REQUIRED]
  
The name of the attribute you want to set. Only a subset of the subscriptions attributes are mutable.
  
  Valid values: DeliveryPolicy | RawMessageDelivery

- **AttributeValue (string)** – The new value for the attribute in JSON format.

Returns None

**Topic**

class SNS.Topic(arn)

A resource representing an Amazon Simple Notification Service (SNS) Topic:

```python
import boto3

sns = boto3.resource('sns')
topic = sns.Topic('arn')
```

Parameters **arn (string)** – The Topic’s arn identifier. This **must** be set.

These are the resource’s available identifiers:

- **arn**

These are the resource’s available attributes:

- **attributes**

These are the resource’s available actions:

- **add_permission()**
- **confirm_subscription()**
- **delete()**
- **load()**
- **publish()**
- **reload()**
- **remove_permission()**
- **set_attributes()**
- **subscribe()**

These are the resource’s available collections:

- **subscriptions**
Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

**arn**

*(string)* The Topic’s arn identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the **load()** method. For more information about attributes refer to the Resources Introduction Guide.

**attributes**

*(dict)*

A map of the topic’s attributes. Attributes in this map include the following:

- **TopicArn** – the topic’s ARN
- **Owner** – the AWS account ID of the topic’s owner
- **Policy** – the JSON serialization of the topic’s access control policy
- **DisplayName** – the human-readable name used in the “From” field for notifications to email and email-json endpoints
- **SubscriptionsPending** – the number of subscriptions pending confirmation on this topic
- **SubscriptionsConfirmed** – the number of confirmed subscriptions on this topic
- **SubscriptionsDeleted** – the number of deleted subscriptions on this topic
- **DeliveryPolicy** – the JSON serialization of the topic’s delivery policy
- **EffectiveDeliveryPolicy** – the JSON serialization of the effective delivery policy that takes into account system defaults

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

**add_permission(****kwargs***)

Adds a statement to a topic’s access control policy, granting access for the specified AWS accounts to the specified actions.

Request Syntax

```python
response = topic.add_permission(
    Label='string',
    AWSAccountId=[
        'string',
    ],
    ActionName=[
        'string',
    ]
)
```

**Parameters**

- **Label** *(string)* – [REQUIRED]
  
  A unique identifier for the new policy statement.

- **AWSAccountId** *(list)* – [REQUIRED]

  The AWS account IDs of the users (principals) who will be given access to the specified actions. The users must have AWS accounts, but do not need to be signed up for this service.
  
  - *(string)* –
• **ActionName** *(list)* – [REQUIRED]
  
The action you want to allow for the specified principal(s).
  
  Valid values: any Amazon SNS action name.
  
  Returns *(string)* –

confirm_subscription(**kwargs)**

Verifies an endpoint owner’s intent to receive messages by validating the token sent to the end-point by an earlier Subscribe action. If the token is valid, the action creates a new subscription and returns its Amazon Resource Name (ARN). This call requires an AWS signature only when the AuthenticateOnUnsubscribe flag is set to “true”.

Request Syntax

```python
subscription = topic.confirm_subscription(
    Token='string',
    AuthenticateOnUnsubscribe='string'
)
```

Parameters

- **Token** *(string)* – [REQUIRED]
  
  Short-lived token sent to an endpoint during the Subscribe action.
  
- **AuthenticateOnUnsubscribe** *(string)* – Disallows unauthenticated unsubscribes of the subscription. If the value of this parameter is true and the request has an AWS signature, then only the topic owner and the subscription owner can unsubscribe the endpoint. The unsubscribe action requires AWS authentication.

Return type **sns.Subscription**

Returns Subscription resource

delete()**

Deletes a topic and all its subscriptions. Deleting a topic might prevent some messages previously sent to the topic from being delivered to subscribers. This action is idempotent, so deleting a topic that does not exist does not result in an error.

Request Syntax

```python
response = topic.delete()
```

Returns **None**

load()**

Calls sns.Client.get_topic_attributes() to update the attributes of the Topic resource

Request Syntax

```python
topic.load()
```

Returns **None**

publish(**kwargs)**

Sends a message to all of a topic’s subscribed endpoints. When a messageId is returned, the message has been saved and Amazon SNS will attempt to deliver it to the topic’s subscribers shortly. The format of the outgoing message to each subscribed endpoint depends on the notification protocol selected.

To use the Publish action for sending a message to a mobile endpoint, such as an app on a Kindle device or mobile phone, you must specify the EndpointArn. The EndpointArn is returned when making
a call with the `CreatePlatformEndpoint` action. The second example below shows a request and response for publishing to a mobile endpoint.

**Request Syntax**

```python
response = topic.publish(
    TargetArn='string',
    Message='string',
    Subject='string',
    MessageStructure='string',
    MessageAttributes={
        'string': {
            'DataType': 'string',
            'StringValue': 'string',
            'BinaryValue': b'bytes'
        }
    }
)
```

**Parameters**

- **TargetArn** *(string)* – Either TopicArn or EndpointArn, but not both.
- **Message** *(string)* – [REQUIRED]

  The message you want to send to the topic.

  If you want to send the same message to all transport protocols, include the text of the message as a String value.

  If you want to send different messages for each transport protocol, set the value of the `MessageStructure` parameter to `json` and use a JSON object for the `Message` parameter. See the Examples section for the format of the JSON object.

  Constraints: Messages must be UTF-8 encoded strings at most 256 KB in size (262144 bytes, not 262144 characters).

  JSON-specific constraints:
  - Keys in the JSON object that correspond to supported transport protocols must have simple JSON string values.
  - The values will be parsed (unescape) before they are used in outgoing messages.
  - Outbound notifications are JSON encoded (meaning that the characters will be reescaped for sending).
  - Values have a minimum length of 0 (the empty string, "", is allowed).
  - Values have a maximum length bounded by the overall message size (so, including multiple protocols may limit message sizes).
  - Non-string values will cause the key to be ignored.
  - Keys that do not correspond to supported transport protocols are ignored.
  - Duplicate keys are not allowed.
  - Failure to parse or validate any key or value in the message will cause the `Publish` call to return an error (no partial delivery).

- **Subject** *(string)* – Optional parameter to be used as the “Subject” line when the message is delivered to email endpoints. This field will also be included, if present, in the standard JSON messages delivered to other endpoints.

  Constraints: Subjects must be ASCII text that begins with a letter, number, or punctuation mark; must not include line breaks or control characters; and must be less than 100 characters long.
• **MessageStructure** *(string)* – Set **MessageStructure** to **json** if you want to send a different message for each protocol. For example, using one publish action, you can send a short message to your SMS subscribers and a longer message to your email subscribers. If you set **MessageStructure** to **json**, the value of the **Message** parameter must:
  – be a syntactically valid JSON object; and
  – contain at least a top-level JSON key of “default” with a value that is a string.
You can define other top-level keys that define the message you want to send to a specific transport protocol (e.g., “http”).
For information about sending different messages for each protocol using the AWS Management Console, go to **Create Different Messages for Each Protocol** in the *Amazon Simple Notification Service Getting Started Guide*.

Valid value: **json**

• **MessageAttributes** *(dict)* – Message attributes for Publish action.
  – *(string)* –
    · *(dict)* –
      The user-specified message attribute value. For string data types, the value attribute has the same restrictions on the content as the message body. For more information, see **Publish**.
      
      Name, type, and value must not be empty or null. In addition, the message body should not be empty or null. All parts of the message attribute, including name, type, and value, are included in the message size restriction, which is currently 256 KB (262,144 bytes).
      For more information, see **Using Amazon SNS Message Attributes**.
  · **DataType** *(string)* – [REQUIRED]
    Amazon SNS supports the following logical data types: String, Number, and Binary. For more information, see **Message Attribute Data Types**.
  · **StringValue** *(string)* –
    Strings are Unicode with UTF8 binary encoding. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters).
  · **BinaryValue** *(bytes)* –
    Binary type attributes can store any binary data, for example, compressed data, encrypted data, or images.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'MessageId': 'string'
}
```

**Response Structure**

• *(dict)* –
  Response for Publish action.
MessageId (string)

Unique identifier assigned to the published message.
Length Constraint: Maximum 100 characters
eload()

Calls sns.Client.get_topic_attributes() to update the attributes of the Topic resource

Request Syntax

topic.reload()

Returns  None

remove_permission(**kwargs)

Removes a statement from a topic’s access control policy.

Request Syntax

response = topic.remove_permission(
    Label='string'
)

Parameters  Label (string) – [REQUIRED]

The unique label of the statement you want to remove.

Returns  None

set_attributes(**kwargs)

Allows a topic owner to set an attribute of the topic to a new value.

Request Syntax

response = topic.set_attributes(
    AttributeName='string',
    AttributeValue='string'
)

Parameters  

• AttributeName (string) – [REQUIRED]

The name of the attribute you want to set. Only a subset of the topic’s attributes are mutable.
Valid values: Policy|DisplayName|DeliveryPolicy

• AttributeValue (string) – The new value for the attribute.

Returns  None

subscribe(**kwargs)

Prepares to subscribe an endpoint by sending the endpoint a confirmation message. To actually create a subscription, the endpoint owner must call the ConfirmSubscription action with the token from the confirmation message. Confirmation tokens are valid for three days.

Request Syntax

subscription = topic.subscribe(
    Protocol='string',
    Endpoint='string'
)

Parameters
• **Protocol** *(string)* – [REQUIRED]

The protocol you want to use. Supported protocols include:
- `http` – delivery of JSON-encoded message via HTTP POST
- `https` – delivery of JSON-encoded message via HTTPS POST
- `email` – delivery of message via SMTP
- `email-json` – delivery of JSON-encoded message via SMTP
- `sms` – delivery of message via SMS
- `sqs` – delivery of JSON-encoded message to an Amazon SQS queue
- `application` – delivery of JSON-encoded message to an EndpointArn for a mobile app and device.

• **Endpoint** *(string)* – The endpoint that you want to receive notifications. Endpoints vary by protocol:
  - For the `http` protocol, the endpoint is an URL beginning with “http://”
  - For the `https` protocol, the endpoint is a URL beginning with “https://”
  - For the `email` protocol, the endpoint is an email address
  - For the `email-json` protocol, the endpoint is an email address
  - For the `sms` protocol, the endpoint is a phone number of an SMS-enabled device
  - For the `sqs` protocol, the endpoint is the ARN of an Amazon SQS queue
  - For the `application` protocol, the endpoint is the EndpointArn of a mobile app and device.

```
Return type sns.Subscription
Returns Subscription resource
```

Collections

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the *Resources Introduction Guide*.

```
subscriptions

all()  
Creates an iterable of all Subscription resources in the collection.

Request Syntax

subscription_iterator = topic.subscriptions.all()

  Return type list(sns.Subscription)
  Returns A list of Subscription resources

filter(**kwargs)  
Creates an iterable of all Subscription resources in the collection filtered by kwargs passed to method.

Request Syntax

subscription_iterator = topic.subscriptions.filter(
    NextToken='string'
)

Parameters NextToken *(string)* – Token returned by the previous ListSubscriptionsByTopic request.

  Return type list(sns.Subscription)
  Returns A list of Subscription resources
```
**limit(** **kwargs**)

Creates an iterable up to a specified amount of Subscription resources in the collection.

**Request Syntax**

```python
subscription_iterator = topic.subscriptions.limit(
    count=123
)
```

**Parameters**

*count* (`integer`) – The limit to the number of resources in the iterable.

**Return type**

`list(sns.Subscription)`

**Returns**

A list of Subscription resources

**page_size(** **kwargs**)

Creates an iterable of all Subscription resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
subscription_iterator = topic.subscriptions.page_size(
    count=123
)
```

**Parameters**

*count* (`integer`) – The number of items returned by each service call

**Return type**

`list(sns.Subscription)`

**Returns**

A list of Subscription resources

---

**SQS**

**Table of Contents**

- SQS
  - Client
  - Service Resource
  - Message
  - Queue

**Client**

```python
class SQS.Client

A low-level client representing Amazon Simple Queue Service (SQS):

```import boto3```

```python
client = boto3.client('sqs')
```

These are the available methods:

- `add_permission()`
- `can_paginate()`
- `change_message_visibility()`
- `change_message_visibility_batch()`
- `create_queue()`
- `delete_message()`
add_permission(**kwargs)

Adds a permission to a queue for a specific principal. This allows for sharing access to the queue.

When you create a queue, you have full control access rights for the queue. Only you (as owner of the queue) can grant or deny permissions to the queue. For more information about these permissions, see Shared Queues in the Amazon SQS Developer Guide.

Note: AddPermission writes an Amazon SQS-generated policy. If you want to write your own policy, use SetQueueAttributes to upload your policy. For more information about writing your own policy, see Using The Access Policy Language in the Amazon SQS Developer Guide.

Note: Some API actions take lists of parameters. These lists are specified using the param.n notation. Values of n are integers starting from 1. For example, a parameter list with two elements looks like this:

Attribute.1=this
Attribute.2=that

Request Syntax

response = client.add_permission(
    QueueUrl='string',
    Label='string',
    AWSAccountIds=[
        'string',
    ],
    Actions=[
        'string',
    ]
)

Parameters

- **QueueUrl** *(string) – [REQUIRED]*
  
The URL of the Amazon SQS queue to take action on.

- **Label** *(string) – [REQUIRED]*
  
The unique identification of the permission you're setting (e.g., AliceSendMessage). Constraints: Maximum 80 characters; alphanumeric characters, hyphens (-), and underscores (_) are allowed.

- **AWSAccountIds** *(list) – [REQUIRED]*
The AWS account number of the principal who will be given permission. The principal must have an AWS account, but does not need to be signed up for Amazon SQS. For information about locating the AWS account identification, see Your AWS Identifiers in the Amazon SQS Developer Guide.

- (string) –

**Actions** *(list) – [REQUIRED]*

The action the client wants to allow for the specified principal. The following are valid values: * | SendMessage | ReceiveMessage | DeleteMessage | ChangeMessageVisibility | GetQueueAttributes | GetQueueUrl. For more information about these actions, see Understanding Permissions in the Amazon SQS Developer Guide.

Specifying SendMessage, DeleteMessage, or ChangeMessageVisibility for the ActionName.n also grants permissions for the corresponding batch versions of those actions: SendMessageBatch, DeleteMessageBatch, and ChangeMessageVisibilityBatch.

- (string) –

**Returns** None

can_paginate *(operation_name)*

Check if an operation can be paginated.

**Parameters** operation_name *(string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").**

**Returns** True if the operation can be paginated, False otherwise.

change_message_visibility (**kwargs)**

Changes the visibility timeout of a specified message in a queue to a new value. The maximum allowed timeout value you can set the value to is 12 hours. This means you can’t extend the timeout of a message in an existing queue to more than a total visibility timeout of 12 hours. (For more information visibility timeout, see Visibility Timeout in the Amazon SQS Developer Guide.)

For example, let’s say you have a message and its default message visibility timeout is 30 minutes. You could call ChangeMessageVisibility with a value of two hours and the effective timeout would be two hours and 30 minutes. When that time comes near you could again extend the time out by calling ChangeMessageVisibility, but this time the maximum allowed timeout would be 9 hours and 30 minutes.

**Note:** There is a 120,000 limit for the number of inflight messages per queue. Messages are inflight after they have been received from the queue by a consuming component, but have not yet been deleted from the queue. If you reach the 120,000 limit, you will receive an OverLimit error message from Amazon SQS. To help avoid reaching the limit, you should delete the messages from the queue after they have been processed. You can also increase the number of queues you use to process the messages.

**Warning:** If you attempt to set the VisibilityTimeout to an amount more than the maximum time left, Amazon SQS returns an error. It will not automatically recalculate and increase the timeout to the maximum time remaining.
Warning: Unlike with a queue, when you change the visibility timeout for a specific message, that timeout value is applied immediately but is not saved in memory for that message. If you don’t delete a message after it is received, the visibility timeout for the message the next time it is received reverts to the original timeout value, not the value you set with the ChangeMessageVisibility action.

Request Syntax

```python
response = client.change_message_visibility(
    QueueUrl='string',
    ReceiptHandle='string',
    VisibilityTimeout=123
)
```

Parameters

- **QueueUrl** *(string)* – [REQUIRED]
  The URL of the Amazon SQS queue to take action on.
- **ReceiptHandle** *(string)* – [REQUIRED]
  The receipt handle associated with the message whose visibility timeout should be changed. This parameter is returned by the ReceiveMessage action.
- **VisibilityTimeout** *(integer)* – [REQUIRED]
  The new value (in seconds - from 0 to 43200 - maximum 12 hours) for the message’s visibility timeout.

Returns  None

cancel_message(* **kwargs)*

Changes the status of a message from 'Active' to 'Canceled' in the queue.

Note: Some API actions take lists of parameters. These lists are specified using the param.n notation. Values of n are integers starting from 1. For example, a parameter list with two elements looks like this:

```
Attribute.1=this
Attribute.2=that
```

Request Syntax

```python
response = client.cancel_message(* **kwargs)
```

Parameters

- **QueueUrl** *(string)* – [REQUIRED]
  The URL of the Amazon SQS queue to take action on.
- **Entries** *(list)* – [REQUIRED]
  A list of dictionaries containing the following keys:
  - **Id** *(string)*
  - **ReceiptHandle** *(string)*
  - **VisibilityTimeout** *(integer)*

Warning: Because the batch request can result in a combination of successful and unsuccessful actions, you should check for batch errors even when the call returns an HTTP status code of 200.
• **QueueUrl** *(string)* – [REQUIRED]

The URL of the Amazon SQS queue to take action on.

• **Entries** *(list)* – [REQUIRED]

A list of receipt handles of the messages for which the visibility timeout must be changed.

  – *(dict)* –

Encloses a receipt handle and an entry id for each message in ChangeMessageVisibilityBatch.

**Warning:** All of the following parameters are list parameters that must be prefixed with `ChangeMessageVisibilityBatchRequestEntry.n`, where `n` is an integer value starting with 1. For example, a parameter list for this action might look like this:

```python
ChangeMessageVisibilityBatchRequestEntry.1.Id=change_visibility_msg_2
ChangeMessageVisibilityBatchRequestEntry.1.ReceiptHandle=Your_Receipt_Handle
ChangeMessageVisibilityBatchRequestEntry.1.VisibilityTimeout=45
```

  * **Id** *(string)* – [REQUIRED]

An identifier for this particular receipt handle. This is used to communicate the result. Note that the `Id`s of a batch request need to be unique within the request.

  * **ReceiptHandle** *(string)* – [REQUIRED]

A receipt handle.

  * **VisibilityTimeout** *(integer)* –

The new value (in seconds) for the message’s visibility timeout.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Successful': [
        {'Id': 'string'},
    ],
    'Failed': [
        {'Id': 'string',
        'SenderFault': True|False,
        'Code': 'string',
        'Message': 'string'}
    ]
}
```

**Response Structure**

• *(dict)* –
For each message in the batch, the response contains a ChangeMessageVisibilityBatchResultEntry tag if the message succeeds or a BatchResultErrorEntry tag if the message fails.

- **Successful (list)** –

A list of ChangeMessageVisibilityBatchResultEntry items.

* (dict) –

Encloses the id of an entry in ChangeMessageVisibilityBatch.

- **Id (string)** –

  Represents a message whose visibility timeout has been changed successfully.

- **Failed (list)** –

A list of BatchResultErrorEntry items.

* (dict) –

  This is used in the responses of batch API to give a detailed description of the result of an action on each entry in the request.

- **Id (string)** –

  The id of an entry in a batch request.

- **SenderFault (boolean)** –

  Whether the error happened due to the sender’s fault.

- **Code (string)** –

  An error code representing why the action failed on this entry.

- **Message (string)** –

  A message explaining why the action failed on this entry.

### create_queue (**kwargs)**

Creates a new queue, or returns the URL of an existing one. When you request `create_queue`, you provide a name for the queue. To successfully create a new queue, you must provide a name that is unique within the scope of your own queues.

**Note:** If you delete a queue, you must wait at least 60 seconds before creating a queue with the same name.

You may pass one or more attributes in the request. If you do not provide a value for any attribute, the queue will have the default value for that attribute. Permitted attributes are the same that can be set using `set_queue_attributes`.

**Note:** Use `get_queue_url` to get a queue’s URL. `get_queue_url` requires only the `QueueName` parameter.

If you provide the name of an existing queue, along with the exact names and values of all the queue’s attributes, `create_queue` returns the queue URL for the existing queue. If the queue name, attribute names, or attribute values do not match an existing queue, `create_queue` returns an error.

**Note:** Some API actions take lists of parameters. These lists are specified using the `param.n` notation. Values of `n` are integers starting from 1. For example, a parameter list with two elements looks like this:

```
Attribute.1=this
Attribute.2=that
```
response = client.create_queue(
    QueueName='string',
    Attributes={
        'string': 'string'
    }
)

Parameters

- **QueueName** *(string)* – [REQUIRED]
  
  The name for the queue to be created.

- **Attributes** *(dict)* – A map of attributes with their corresponding values.

  The following lists the names, descriptions, and values of the special request parameters the `create_queue` action uses:
  
  - **DelaySeconds** - The time in seconds that the delivery of all messages in the queue will be delayed. An integer from 0 to 900 (15 minutes). The default for this attribute is 0 (zero).
  
  - **MaximumMessageSize** - The limit of how many bytes a message can contain before Amazon SQS rejects it. An integer from 1024 bytes (1 KiB) up to 262144 bytes (256 KiB). The default for this attribute is 262144 (256 KiB).
  
  - **MessageRetentionPeriod** - The number of seconds Amazon SQS retains a message. Integer representing seconds, from 60 (1 minute) to 1209600 (14 days). The default for this attribute is 345600 (4 days).
  
  - **Policy** - The queue’s policy. A valid AWS policy. For more information about policy structure, see Overview of AWS IAM Policies in the *Amazon IAM User Guide*.
  
  - **ReceiveMessageWaitTimeSeconds** - The time for which a `ReceiveMessage` call will wait for a message to arrive. An integer from 0 to 20 (seconds). The default for this attribute is 0.
  
  - **VisibilityTimeout** - The visibility timeout for the queue. An integer from 0 to 43200 (12 hours). The default for this attribute is 30. For more information about visibility timeout, see Visibility Timeout in the *Amazon SQS Developer Guide*.

  - *(string)*
    
    The name of a queue attribute.

  - *(string)*
    
    The value of a queue attribute.

Return type  dict

Returns

**Response Syntax**

```
{
    'QueueUrl': 'string'
}
```

**Response Structure**

- *(dict)*

  Returns the QueueUrl element of the created queue.

  - **QueueUrl** *(string)*
    
    The URL for the created Amazon SQS queue.
**delete_message**(**kwargs**)  
Deletes the specified message from the specified queue. You specify the message by using the message’s receipt handle and not the message ID you received when you sent the message. Even if the message is locked by another reader due to the visibility timeout setting, it is still deleted from the queue. If you leave a message in the queue for longer than the queue’s configured retention period, Amazon SQS automatically deletes it.

**Note:** The receipt handle is associated with a specific instance of receiving the message. If you receive a message more than once, the receipt handle you get each time you receive the message is different. When you request DeleteMessage, if you don’t provide the most recently received receipt handle for the message, the request will still succeed, but the message might not be deleted.

**Warning:** It is possible you will receive a message even after you have deleted it. This might happen on rare occasions if one of the servers storing a copy of the message is unavailable when you request to delete the message. The copy remains on the server and might be returned to you again on a subsequent receive request. You should create your system to be idempotent so that receiving a particular message more than once is not a problem.

**Request Syntax**

```python
response = client.delete_message(
    QueueUrl='string',
    ReceiptHandle='string'
)
```

**Parameters**

- **QueueUrl** *(string)* – [REQUIRED]
  - The URL of the Amazon SQS queue to take action on.
- **ReceiptHandle** *(string)* – [REQUIRED]
  - The receipt handle associated with the message to delete.

**Returns**  
None

**delete_message_batch**(**kwargs**)  
Deletes up to ten messages from the specified queue. This is a batch version of DeleteMessage. The result of the delete action on each message is reported individually in the response.

**Warning:** Because the batch request can result in a combination of successful and unsuccessful actions, you should check for batch errors even when the call returns an HTTP status code of 200.

**Note:** Some API actions take lists of parameters. These lists are specified using the `param.n` notation. Values of n are integers starting from 1. For example, a parameter list with two elements looks like this:

```
Attribute.1=this
Attribute.2=that
```

**Request Syntax**

```python
response = client.delete_message_batch(
    QueueUrl='string',
    Entries=[
        {
            'Id': 'string',
            'ReceiptHandle': 'string'
        }
    ]
)
```

3.1. Services
'ReceiptHandle': 'string'
},
]

Parameters

- **QueueUrl** (*string*) – [REQUIRED]
  The URL of the Amazon SQS queue to take action on.
- **Entries** (*list*) – [REQUIRED]
  A list of receipt handles for the messages to be deleted.
  - (*dict*) –
    Encloses a receipt handle and an identifier for it.
    - **Id** (*string*) – [REQUIRED]
      An identifier for this particular receipt handle. This is used to communicate the result. Note that the Ids of a batch request need to be unique within the request.
    - **ReceiptHandle** (*string*) – [REQUIRED]
      A receipt handle.

Return type: dict

Response Syntax

```json
{
  'Successful': [  
    {  
      'Id': 'string'
    },
  ],
  'Failed': [  
    {  
      'Id': 'string',
      'SenderFault': True|False,
      'Code': 'string',
      'Message': 'string'
    },
  ]
}
```

Response Structure

- (*dict*) –
  For each message in the batch, the response contains a DeleteMessageBatchResultEntry tag if the message is deleted or a BatchResultErrorEntry tag if the message cannot be deleted.
  - **Successful** (*list*) –
    A list of DeleteMessageBatchResultEntry items.
    - (*dict*) –
      Encloses the id an entry in DeleteMessageBatch .
      - **Id** (*string*) –
        Represents a successfully deleted message.
- **Failed (list)** –
  A list of BatchResultErrorEntry items.

  * (dict) –

  This is used in the responses of batch API to give a detailed description of the result of an action on each entry in the request.

  - **Id (string)** –
    The id of an entry in a batch request.
  - **SenderFault (boolean)** –
    Whether the error happened due to the sender’s fault.
  - **Code (string)** –
    An error code representing why the action failed on this entry.
  - **Message (string)** –
    A message explaining why the action failed on this entry.

**delete_queue(****kwargs**)**

Deletes the queue specified by the **queue URL**, regardless of whether the queue is empty. If the specified queue does not exist, Amazon SQS returns a successful response.

**Warning:** Use **DeleteQueue** with care; once you delete your queue, any messages in the queue are no longer available.

When you delete a queue, the deletion process takes up to 60 seconds. Requests you send involving that queue during the 60 seconds might succeed. For example, a SendMessage request might succeed, but after the 60 seconds, the queue and that message you sent no longer exist. Also, when you delete a queue, you must wait at least 60 seconds before creating a queue with the same name.

We reserve the right to delete queues that have had no activity for more than 30 days. For more information, see **How Amazon SQS Queues Work** in the **Amazon SQS Developer Guide**.

**Request Syntax**

```python
response = client.delete_queue(
    QueueUrl='string'
)
```

- **Parameters**
  - **QueueUrl (string)** – [REQUIRED]
    The URL of the Amazon SQS queue to take action on.

- **Returns**
  - None

**generate_presigned_url (ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)**

Generate a presigned url given a client, its method, and arguments

- **Parameters**
  - **ClientMethod (string)** – The client method to presign for
  - **Params (dict)** – The parameters normally passed to **ClientMethod**.
  - **ExpiresIn (int)** – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
  - **HttpMethod (string)** – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

- **Returns**
  - The presigned url

**get_paginator (operation_name)**

Create a paginator for an operation.
Parameters operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

Raises OperationNotPageableError Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

Return type L{botocore.paginate.Paginator}

Returns A paginator object.

get_queue_attributes (**kwargs)

Gets attributes for the specified queue. The following attributes are supported:

• All - returns all values.
• ApproximateNumberOfMessages - returns the approximate number of visible messages in a queue. For more information, see Resources Required to Process Messages in the Amazon SQS Developer Guide.
• ApproximateNumberOfMessagesNotVisible - returns the approximate number of messages that are not timed-out and not deleted. For more information, see Resources Required to Process Messages in the Amazon SQS Developer Guide.
• VisibilityTimeout - returns the visibility timeout for the queue. For more information about visibility timeout, see Visibility Timeout in the Amazon SQS Developer Guide.
• CreatedTimestamp - returns the time when the queue was created (epoch time in seconds).
• LastModifiedTimestamp - returns the time when the queue was last changed (epoch time in seconds).
• Policy - returns the queue’s policy.
• MaximumMessageSize - returns the limit of how many bytes a message can contain before Amazon SQS rejects it.
• MessageRetentionPeriod - returns the number of seconds Amazon SQS retains a message.
• QueueArn - returns the queue’s Amazon resource name (ARN).
• ApproximateNumberOfMessagesDelayed - returns the approximate number of messages that are pending to be added to the queue.
• DelaySeconds - returns the default delay on the queue in seconds.
• ReceiveMessageWaitTimeSeconds - returns the time for which a ReceiveMessage call will wait for a message to arrive.
• RedrivePolicy - returns the parameters for dead letter queue functionality of the source queue. For more information about RedrivePolicy and dead letter queues, see Using Amazon SQS Dead Letter Queues in the Amazon SQS Developer Guide.

Note: Going forward, new attributes might be added. If you are writing code that calls this action, we recommend that you structure your code so that it can handle new attributes gracefully.

Note: Some API actions take lists of parameters. These lists are specified using the param.n notation. Values of n are integers starting from 1. For example, a parameter list with two elements looks like this:

Attribute.1=this
Attribute.2=that

Request Syntax

response = client.get_queue_attributes(
    QueueUrl='string',
    AttributeNames=[
        'Policy'|'VisibilityTimeout'|'MaximumMessageSize'|'MessageRetentionPeriod'|'Approximate
    ]
)
Parameters

- **QueueUrl** *(string)* – [REQUIRED]
  The URL of the Amazon SQS queue to take action on.
- **AttributeNames** *(list)* – A list of attributes to retrieve information for.
  - *(string)* –

Return type  *dict*

Returns

Response Syntax

```
{
  'Attributes': {
    'string': 'string'
  }
}
```

Response Structure

- *(dict)* – A list of returned queue attributes.
  - **Attributes** *(dict)* –
    A map of attributes to the respective values.
    - *(string)* –
      The name of a queue attribute.
    - *(string)* –
      The value of a queue attribute.

get_queue_url(**kwargs)**

Returns the URL of an existing queue. This action provides a simple way to retrieve the URL of an Amazon SQS queue.

To access a queue that belongs to another AWS account, use the `QueueOwnerAWSAccountId` parameter to specify the account ID of the queue’s owner. The queue’s owner must grant you permission to access the queue. For more information about shared queue access, see AddPermission or go to Shared Queues in the Amazon SQS Developer Guide.

Request Syntax

```
response = client.get_queue_url(
    QueueName='string',
    QueueOwnerAWSAccountId='string'
)
```

Parameters

- **QueueName** *(string)* – [REQUIRED]
  The name of the queue whose URL must be fetched. Maximum 80 characters; alphanumeric characters, hyphens (-), and underscores (_) are allowed.
- **QueueOwnerAWSAccountId** *(string)* – The AWS account ID of the account that created the queue.

Return type  *dict*

Returns

Response Syntax
get_waiter(waiter_name)

list_dead_letter_source_queues(**kwargs)

Returns a list of your queues that have the RedrivePolicy queue attribute configured with a dead letter queue.

For more information about using dead letter queues, see Using Amazon SQS Dead Letter Queues.

Request Syntax

response = client.list_dead_letter_source_queues(
    QueueUrl='string'
)

Parameters

Return type
dict

Returns

Response Syntax

{
    'queueUrls': [‘string’,
    ]
}

Response Structure

- (dict) – A list of your dead letter source queues.

    - queueUrls (list) – A list of source queue URLs that have the RedrivePolicy queue attribute configured with a dead letter queue.

list_queues(**kwargs)

Returns a list of your queues. The maximum number of queues that can be returned is 1000. If you specify a value for the optional QueueNamePrefix parameter, only queues with a name beginning with the specified value are returned.

Request Syntax

response = client.list_queues(
    QueueNamePrefix='string'
)

Parameters

- **QueueNamePrefix (string)** – A string to use for filtering the list results. Only those queues whose name begins with the specified string are returned.

Return type
dict

Response Structure

- (dict) – A list of your queues.

    - QueueUrl (string) – The URL for the queue.
Returns

Response Syntax

```python
{
  'QueueUrls': [
    'string',
  ]
}
```

Response Structure

- (dict) – A list of your queues.
  - QueueUrls (list) –
    A list of queue URLs, up to 1000 entries.
    * (string) –

`purge_queue(**kwargs)`

Deletes the messages in a queue specified by the queue URL.

**Warning:** When you use the **PurgeQueue** API, the deleted messages in the queue cannot be retrieved.

When you purge a queue, the message deletion process takes up to 60 seconds. All messages sent to the queue before calling `PurgeQueue` will be deleted; messages sent to the queue while it is being purged may be deleted. While the queue is being purged, messages sent to the queue before `PurgeQueue` was called may be received, but will be deleted within the next minute.

Request Syntax

```python
response = client.purge_queue(
    QueueUrl='string'
)
```

**Parameters** QueueUrl (string) – [REQUIRED]

The queue URL of the queue to delete the messages from when using the **PurgeQueue** API.

**Returns** None

`receive_message(**kwargs)`

Retrieves one or more messages, with a maximum limit of 10 messages, from the specified queue. Long poll support is enabled by using the **WaitTimeSeconds** parameter. For more information, see Amazon **SQS** Long Poll in the [Amazon **SQS** Developer Guide](https://docs.aws.amazon.com/sqs/latest/developerguide/sqs-long-poll.html).

Short poll is the default behavior where a weighted random set of machines is sampled on a **ReceiveMessage** call. This means only the messages on the sampled machines are returned. If the number of messages in the queue is small (less than 1000), it is likely you will get fewer messages than you requested per **ReceiveMessage** call. If the number of messages in the queue is extremely small, you might not receive any messages in a particular **ReceiveMessage** response; in which case you should repeat the request.

For each message returned, the response includes the following:

- Message body
- MD5 digest of the message body. For information about MD5, go to [http://www.faqs.org/rfcs/rfc1321.html](http://www.faqs.org/rfcs/rfc1321.html).
- Message ID you received when you sent the message to the queue.
- Receipt handle.
- Message attributes.
• MD5 digest of the message attributes.

The receipt handle is the identifier you must provide when deleting the message. For more information, see Queue and Message Identifiers in the Amazon SQS Developer Guide.

You can provide the VisibilityTimeout parameter in your request, which will be applied to the messages that Amazon SQS returns in the response. If you do not include the parameter, the overall visibility timeout for the queue is used for the returned messages. For more information, see Visibility Timeout in the Amazon SQS Developer Guide.

**Note:** Going forward, new attributes might be added. If you are writing code that calls this action, we recommend that you structure your code so that it can handle new attributes gracefully.

**Request Syntax**

```python
response = client.receive_message(
    QueueUrl='string',
    AttributeNames=[
        'Policy'|'VisibilityTimeout'|'MaximumMessageSize'|'MessageRetentionPeriod'|'ApproximateFirstReceiveTimestamp'|'ApproximateReceiveCount'|'SenderId'|'SentTimestamp'|'ApproximateNumberOfMessages'|'ApproximateNumberOfMessagesDelayed'|'DelaySeconds'|'ReceiveMessageWaitTimeSeconds'|'RedrivePolicy',
    MessageAttributeNames=[
        'string',
    ],
    MaxNumberOfMessages=123,
    VisibilityTimeout=123,
    WaitTimeSeconds=123
)
```

**Parameters**

- **QueueUrl (string) – [REQUIRED]**
  The URL of the Amazon SQS queue to take action on.
- **AttributeNames (list) – A list of attributes that need to be returned along with each message.**

The following lists the names and descriptions of the attributes that can be returned:

- **(string)** –
  - **All** - returns all values.
  - **ApproximateFirstReceiveTimestamp** - returns the time when the message was first received from the queue (epoch time in milliseconds).
  - **ApproximateReceiveCount** - returns the number of times a message has been received from the queue but not deleted.
  - **SenderId** - returns the AWS account number (or the IP address, if anonymous access is allowed) of the sender.
  - **SentTimestamp** - returns the time when the message was sent to the queue (epoch time in milliseconds).

- **(string)** –
  - **MessageAttributeNames (list) –** The name of the message attribute, where \( N \) is the index. The message attribute name can contain the following characters: A-Z, a-z, 0-9, underscore (_), hyphen (-), and period (.). The name must not start or end with a period, and it should not have successive periods. The name is case sensitive and must be unique among all attribute names for the message. The name can be up to 256 characters long. The name cannot start with “AWS.” or “Amazon.” (or any variations in casing), because these prefixes are reserved for use by Amazon Web Services.
When using `ReceiveMessage`, you can send a list of attribute names to receive, or you can return all of the attributes by specifying “All” or “.*” in your request. You can also use “foo.*” to return all message attributes starting with the “foo” prefix.

- **MaxNumberOfMessages (integer)** – The maximum number of messages to return. Amazon SQS never returns more messages than this value but may return fewer. Values can be from 1 to 10. Default is 1.

  All of the messages are not necessarily returned.

- **VisibilityTimeout (integer)** – The duration (in seconds) that the received messages are hidden from subsequent retrieve requests after being retrieved by a `ReceiveMessage` request.

- **WaitTimeSeconds (integer)** – The duration (in seconds) for which the call will wait for a message to arrive in the queue before returning. If a message is available, the call will return sooner than `WaitTimeSeconds`.

**Return type**  
dict

**Returns**

**Response Syntax**

```json
{
 'Messages': [
  {
   'MessageId': 'string',
   'ReceiptHandle': 'string',
   'MD5OfBody': 'string',
   'Body': 'string',
   'Attributes': {
     'string': 'string'
   },
   'MD5OfMessageAttributes': 'string',
   'MessageAttributes': {
     'string': {
       'StringValue': 'string',
       'BinaryValue': b'bytes',
       'StringListValues': [?
         'string',
       ],
       'BinaryListValues': [?
         b'bytes',
       ],
       'DataType': 'string'
     }
   }
  }
]}
```

**Response Structure**

- **(dict)** – A list of received messages.
  - **Messages (list)** –
    - A list of messages.
      - **(dict)** –
        - An Amazon SQS message.
          - **MessageId (string)** –
A unique identifier for the message. Message IDs are considered unique across all AWS accounts for an extended period of time.

- **ReceiptHandle** *(string)* –  
  An identifier associated with the act of receiving the message. A new receipt handle is returned every time you receive a message. When deleting a message, you provide the last received receipt handle to delete the message.

- **MD5OfBody** *(string)* –  
  An MD5 digest of the non-URL-encoded message body string.

- **Body** *(string)* –  
  The message’s contents (not URL-encoded).

- **Attributes** *(dict)* –  
  SenderId, SentTimestamp, ApproximateReceiveCount, and/or ApproximateFirstReceiveTimestamp are each returned as an integer representing the epoch time in milliseconds.

- **MD5OfMessageAttributes** *(string)* –  
  An MD5 digest of the non-URL-encoded message attribute string. This can be used to verify that Amazon SQS received the message correctly. Amazon SQS first URL decodes the message before creating the MD5 digest. For information about MD5, go to [http://www.faqs.org/rfcs/rfc1321.html](http://www.faqs.org/rfcs/rfc1321.html).  

- **MessageAttributes** *(dict)* –  
  Each message attribute consists of a Name, Type, and Value. For more information, see [Message Attribute Items](#).

- **StringValue** *(string)* –  
  Strings are Unicode with UTF8 binary encoding. For a list of code values, see [Chapter 3. API Reference](#).
http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters

- **BinaryValue (bytes)** –
  
  Binary type attributes can store any binary data, for example, compressed data, encrypted data, or images.

- **StringListValues (list)** –
  
  Not implemented. Reserved for future use.

- **(string)** –

- **BinaryListValues (list)** –
  
  Not implemented. Reserved for future use.

- **(bytes)** –

- **DataType (string)** –

Amazon SQS supports the following logical data types: String, Number, and Binary. In addition, you can append your own custom labels. For more information, see Message Attribute Data Types.

```python
remove_permission(**kwargs)
```

Reverts any permissions in the queue policy that matches the specified `Label` parameter. Only the owner of the queue can remove permissions.

**Request Syntax**

```python
response = client.remove_permission(
    QueueUrl='string',
    Label='string'
)
```

**Parameters**

- **QueueUrl (string)** – [REQUIRED]
  
  The URL of the Amazon SQS queue to take action on.

- **Label (string)** – [REQUIRED]
  
  The identification of the permission to remove. This is the label added with the AddPermission action.

**Returns** None

```python
send_message(**kwargs)
```

Delivers a message to the specified queue. With Amazon SQS, you now have the ability to send large payload messages that are up to 256KB (262,144 bytes) in size. To send large payloads, you must use an AWS SDK that supports SigV4 signing. To verify whether SigV4 is supported for an AWS SDK, check the SDK release notes.

**Warning:** The following list shows the characters (in Unicode) allowed in your message, according to the W3C XML specification. For more information, go to [http://www.w3.org/TR/REC-xml/#charsets](http://www.w3.org/TR/REC-xml/#charsets)

If you send any characters not included in the list, your request will be rejected.

- #x9 | #xA | #xD | [#x20 to #xD7FF] | [#xE000 to #xFFFD] | [#x10000 to #x10FFFF]

**Request Syntax**

```python
response = client.send_message(
    QueueUrl='string',
    MessageBody='string',
    DelaySeconds=123,
```
MessageAttributes={
    'string': {
        'StringValue': 'string',
        'BinaryValue': b'bytes',
        'StringListValues': [
            'string',
        ],
        'BinaryListValues': [b'bytes',
        ],
        'DataType': 'string'
    }
}

Parameters

• **QueueUrl** *(string) – [REQUIRED]*
  The URL of the Amazon SQS queue to take action on.

• **MessageBody** *(string) – [REQUIRED]*
  The message to send. String maximum 256 KB in size. For a list of allowed characters, see the preceding important note.

• **DelaySeconds** *(integer) –* The number of seconds (0 to 900 - 15 minutes) to delay a specific message. Messages with a positive DelaySeconds value become available for processing after the delay time is finished. If you don’t specify a value, the default value for the queue applies.

• **MessageAttributes** *(dict) –* Each message attribute consists of a Name, Type, and Value. For more information, see Message Attribute Items.
  
  – *(string) –*
  
  * (dict) –*

  The user-specified message attribute value. For string data types, the value attribute has the same restrictions on the content as the message body. For more information, see SendMessage.

  Name, type, and value must not be empty or null. In addition, the message body should not be empty or null. All parts of the message attribute, including name, type, and value, are included in the message size restriction, which is currently 256 KB (262,144 bytes).

  • **StringValue** *(string) –*

  Strings are Unicode with UTF8 binary encoding. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters.

  • **BinaryValue** *(bytes) –*

  Binary type attributes can store any binary data, for example, compressed data, encrypted data, or images.

  • **StringListValues** *(list) –*

  Not implemented. Reserved for future use.

  • **BinaryListValues** *(list) –*

  Not implemented. Reserved for future use.
· **DataType** *(string)* – [REQUIRED]

Amazon SQS supports the following logical data types: String, Number, and Binary. In addition, you can append your own custom labels. For more information, see Message Attribute Data Types.

**Response Syntax**

```python
{
    'MD5OfMessageBody': 'string',
    'MD5OfMessageAttributes': 'string',
    'MessageId': 'string'
}
```

**Response Structure**

- *(dict)* –

  The MD5OfMessageBody and MessageId elements.

  - **MD5OfMessageBody** *(string)* –

    An MD5 digest of the non-URL-encoded message body string. This can be used to verify that Amazon SQS received the message correctly. Amazon SQS first URL decodes the message before creating the MD5 digest. For information about MD5, go to [http://www.faqs.org/rfcs/rfc1321.html](http://www.faqs.org/rfcs/rfc1321.html).

  - **MD5OfMessageAttributes** *(string)* –

    An MD5 digest of the non-URL-encoded message attribute string. This can be used to verify that Amazon SQS received the message correctly. Amazon SQS first URL decodes the message before creating the MD5 digest. For information about MD5, go to [http://www.faqs.org/rfcs/rfc1321.html](http://www.faqs.org/rfcs/rfc1321.html).

  - **MessageId** *(string)* –

    An element containing the message ID of the message sent to the queue. For more information, see Queue and Message Identifiers in the Amazon SQS Developer Guide.

**send_message_batch** (**kwargs**)

Delivers up to ten messages to the specified queue. This is a batch version of SendMessage. The result of the send action on each message is reported individually in the response. The maximum allowed individual message size is 256 KB (262,144 bytes).

The maximum total payload size (i.e., the sum of all a batch’s individual message lengths) is also 256 KB (262,144 bytes).

If the **DelaySeconds** parameter is not specified for an entry, the default for the queue is used.

---

**Warning:** The following list shows the characters (in Unicode) that are allowed in your message, according to the W3C XML specification. For more information, go to [http://www.faqs.org/rfcs/rfc1321.html](http://www.faqs.org/rfcs/rfc1321.html). If you send any characters that are not included in the list, your request will be rejected.

\[
\text{#x9 | #xA | #xD | [#x20 to #xD7FF] | [#xE000 to #xFFFFD] | [#x10000 to #x10FFFF]}
\]
Warning: Because the batch request can result in a combination of successful and unsuccessful actions, you should check for batch errors even when the call returns an HTTP status code of 200.

Note: Some API actions take lists of parameters. These lists are specified using the `param.n` notation. Values of n are integers starting from 1. For example, a parameter list with two elements looks like this:

```
Attribute.1=this
Attribute.2=that
```

Request Syntax
```
response = client.send_message_batch(
    QueueUrl='string',
    Entries=[
        {
            'Id': 'string',
            'MessageBody': 'string',
            'DelaySeconds': 123,
            'MessageAttributes': {
                'string': {
                    'StringValue': 'string',
                    'BinaryValue': b'bytes',
                    'StringListValues': [
                        'string',
                    ],
                    'BinaryListValues': [b'bytes'],
                    'DataType': 'string'
                }
            }
        }
    ]
)
```

Parameters
- **QueueUrl (string) – [REQUIRED]**
  The URL of the Amazon SQS queue to take action on.
- **Entries (list) – [REQUIRED]**
  A list of SendMessageBatchRequestEntry items.
    - (dict) –
      Contains the details of a single Amazon SQS message along with a Id.
      - **Id (string) – [REQUIRED]**
        An identifier for the message in this batch. This is used to communicate the result. Note that the Id s of a batch request need to be unique within the request.
      - **MessageBody (string) – [REQUIRED]**
        Body of the message.
      - **DelaySeconds (integer) –**
        The number of seconds for which the message has to be delayed.
      - **MessageAttributes (dict) –**
Each message attribute consists of a Name, Type, and Value. For more information, see Message Attribute Items.

- **(string)** –
  - **(dict)** –

  The user-specified message attribute value. For string data types, the value attribute has the same restrictions on the content as the message body. For more information, see SendMessage.

Name, type, and value must not be empty or null. In addition, the message body should not be empty or null. All parts of the message attribute, including name, type, and value, are included in the message size restriction, which is currently 256 KB (262,144 bytes).

- **StringValue** *(string)* –

  Strings are Unicode with UTF8 binary encoding. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters.

- **BinaryValue** *(bytes)* –

  Binary type attributes can store any binary data, for example, compressed data, encrypted data, or images.

- **StringListValues** *(list)* –

  Not implemented. Reserved for future use.

- **BinaryListValues** *(list)* –

  Not implemented. Reserved for future use.

- **DataType** *(string)* – [REQUIRED]

  Amazon SQS supports the following logical data types: String, Number, and Binary. In addition, you can append your own custom labels. For more information, see Message Attribute Data Types.

Return type  *dict*

Returns

Response Syntax

```
{
  'Successful': [
    {
      'Id': 'string',
      'MessageId': 'string',
      'MD5OfMessageBody': 'string',
      'MD5OfMessageAttributes': 'string'
    },
  ],
  'Failed': [
    {
      'Id': 'string',
      'SenderFault': True|False,
      'Code': 'string',
      'Message': 'string'
    }
  ]
}
```
Response Structure

- (dict)
  
  For each message in the batch, the response contains a SendMessageBatchResultEntry tag if the message succeeds or a BatchResultErrorEntry tag if the message fails.
  
  - Successful (list)
    
    A list of SendMessageBatchResultEntry items.
    
    - (dict)
      
      Encloses a message ID for successfully enqueued message of a SendMessageBatch.
      
      - Id (string)
        
        An identifier for the message in this batch.
      
      - MessageId (string)
        
        An identifier for the message.
      
      - MD5OfMessageBody (string)
        
        An MD5 digest of the non-URL-encoded message body string. This can be used to verify that Amazon SQS received the message correctly. Amazon SQS first URL decodes the message before creating the MD5 digest. For information about MD5, go to [http://www.faqs.org/rfcs/rfc1321.html](http://www.faqs.org/rfcs/rfc1321.html).
      
      - MD5OfMessageAttributes (string)
        
        An MD5 digest of the non-URL-encoded message attribute string. This can be used to verify that Amazon SQS received the message batch correctly. Amazon SQS first URL decodes the message before creating the MD5 digest. For information about MD5, go to [http://www.faqs.org/rfcs/rfc1321.html](http://www.faqs.org/rfcs/rfc1321.html).
    
  - Failed (list)
    
    A list of BatchResultErrorEntry items with the error detail about each message that could not be enqueued.
    
    - (dict)
      
      This is used in the responses of batch API to give a detailed description of the result of an action on each entry in the request.
      
      - Id (string)
        
        The id of an entry in a batch request.
      
      - SenderFault (boolean)
        
        Whether the error happened due to the sender’s fault.
      
      - Code (string)
        
        An error code representing why the action failed on this entry.
      
      - Message (string)
        
        A message explaining why the action failed on this entry.

**set_queue_attributes (**)kwargs**

Sets the value of one or more queue attributes. When you change a queue’s attributes, the change can take
up to 60 seconds for most of the attributes to propagate throughout the SQS system. Changes made to the MessageRetentionPeriod attribute can take up to 15 minutes.

**Note:** Going forward, new attributes might be added. If you are writing code that calls this action, we recommend that you structure your code so that it can handle new attributes gracefully.

### Request Syntax

```python
response = client.set_queue_attributes(
    QueueUrl='string',
    Attributes={
        'string': 'string'
    }
)
```

#### Parameters

- **QueueUrl (string)** – [REQUIRED]
  
  The URL of the Amazon SQS queue to take action on.

- **Attributes (dict)** – [REQUIRED]
  
  A map of attributes to set.

The following lists the names, descriptions, and values of the special request parameters the `setQueueAttributes` action uses:

- **DelaySeconds** - The time in seconds that the delivery of all messages in the queue will be delayed. An integer from 0 to 900 (15 minutes). The default for this attribute is 0 (zero).

- **MaximumMessageSize** - The limit of how many bytes a message can contain before Amazon SQS rejects it. An integer from 1024 bytes (1 KiB) up to 262144 bytes (256 KiB). The default for this attribute is 262144 (256 KiB).

- **MessageRetentionPeriod** - The number of seconds Amazon SQS retains a message. Integer representing seconds, from 60 (1 minute) to 1209600 (14 days). The default for this attribute is 345600 (4 days).

- **Policy** - The queue’s policy. A valid AWS policy. For more information about policy structure, see Overview of AWS IAM Policies in the Amazon IAM User Guide.

- **ReceiveMessageWaitTimeSeconds** - The time for which a ReceiveMessage call will wait for a message to arrive. An integer from 0 to 20 (seconds). The default for this attribute is 0.

- **VisibilityTimeout** - The visibility timeout for the queue. An integer from 0 to 43200 (12 hours). The default for this attribute is 30. For more information about visibility timeout, see Visibility Timeout in the Amazon SQS Developer Guide.

- **RedrivePolicy** - The parameters for dead letter queue functionality of the source queue. For more information about RedrivePolicy and dead letter queues, see Using Amazon SQS Dead Letter Queues in the Amazon SQS Developer Guide.

- **(string)** –
  
  The name of a queue attribute.

- **(string)** –
  
  The value of a queue attribute.

#### Returns

None
Service Resource

class SQS.ServiceResource
A resource representing Amazon Simple Queue Service (SQS):

```python
import boto3

sqs = boto3.resource('sqs')
```

These are the resource’s available actions:
- `create_queue()`
- `get_queue_by_name()`

These are the resource’s available sub-resources:
- `Message()`
- `Queue()`

These are the resource’s available collections:
- `queues`

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

`create_queue(**kwargs)`

Creates a new queue, or returns the URL of an existing one. When you request `CreateQueue`, you provide a name for the queue. To successfully create a new queue, you must provide a name that is unique within the scope of your own queues.

**Note:** If you delete a queue, you must wait at least 60 seconds before creating a queue with the same name.

You may pass one or more attributes in the request. If you do not provide a value for any attribute, the queue will have the default value for that attribute. Permitted attributes are the same that can be set using `SetQueueAttributes`.

**Note:** Use `GetQueueUrl` to get a queue’s URL. `GetQueueUrl` requires only the `QueueName` parameter.

If you provide the name of an existing queue, along with the exact names and values of all the queue’s attributes, `CreateQueue` returns the queue URL for the existing queue. If the queue name, attribute names, or attribute values do not match an existing queue, `CreateQueue` returns an error.

**Note:** Some API actions take lists of parameters. These lists are specified using the `param.n` notation. Values of `n` are integers starting from 1. For example, a parameter list with two elements looks like this:

```python
Attribute.1=this
Attribute.2=that
```

Request Syntax

```python
queue = sqs.create_queue(
    QueueName='string',
    Attributes={
        'string': 'string'
    }
)
```
Parameters

- **QueueName (string)** – [REQUIRED]
  
  The name for the queue to be created.

- **Attributes (dict)** – A map of attributes with their corresponding values.

  The following lists the names, descriptions, and values of the special request parameters the `CreateQueue` action uses:
  
  - **DelaySeconds** - The time in seconds that the delivery of all messages in the queue will be delayed. An integer from 0 to 900 (15 minutes). The default for this attribute is 0 (zero).
  
  - **MaximumMessageSize** - The limit of how many bytes a message can contain before Amazon SQS rejects it. An integer from 1024 bytes (1 KiB) up to 262144 bytes (256 KiB). The default for this attribute is 262144 (256 KiB).
  
  - **MessageRetentionPeriod** - The number of seconds Amazon SQS retains a message. Integer representing seconds, from 60 (1 minute) to 1209600 (14 days). The default for this attribute is 345600 (4 days).
  
  - **Policy** - The queue’s policy. A valid AWS policy. For more information about policy structure, see Overview of AWS IAM Policies in the Amazon IAM User Guide.
  
  - **ReceiveMessageWaitTimeSeconds** - The time for which a ReceiveMessage call will wait for a message to arrive. An integer from 0 to 20 (seconds). The default for this attribute is 0.
  
  - **VisibilityTimeout** - The visibility timeout for the queue. An integer from 0 to 43200 (12 hours). The default for this attribute is 30. For more information about visibility timeout, see Visibility Timeout in the Amazon SQS Developer Guide.

  - **(string)** – The name of a queue attribute.

    - **(string)** – The value of a queue attribute.

Return type  sqs.Queue

Returns  Queue resource

get_queue_by_name(**kwargs)**

Returns the URL of an existing queue. This action provides a simple way to retrieve the URL of an Amazon SQS queue.

To access a queue that belongs to another AWS account, use the `QueueOwnerAWSAccountId` parameter to specify the account ID of the queue’s owner. The queue’s owner must grant you permission to access the queue. For more information about shared queue access, see AddPermission or go to Shared Queues in the Amazon SQS Developer Guide.

Request Syntax

```python
code
queue = sqs.get_queue_by_name(
    QueueName='string',
    QueueOwnerAWSAccountId='string'
)
```

Parameters

- **QueueName (string)** – [REQUIRED]

  The name of the queue whose URL must be fetched. Maximum 80 characters; alphanumeric characters, hyphens (-), and underscores (_) are allowed.
• **QueueOwnerAWSAccountId** *(string)* – The AWS account ID of the account that created the queue.

  **Return type** `sqs.Queue`

  **Returns** Queue resource

**Sub-resources**

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the *Resources Introduction Guide*.

**Message** *(queue_url, receipt_handle)*

Creates a Message resource:

```python
message = sqs.Message('queue_url', 'receipt_handle')
```

**Parameters**

• **queue_url** *(string)* – The Message’s queue_url identifier. This **must** be set.

• **receipt_handle** *(string)* – The Message’s receipt_handle identifier. This **must** be set.

  **Return type** `SQS.Message`

  **Returns** A Message resource

**Queue** *(url)*

Creates a Queue resource:

```python
queue = sqs.Queue('url')
```

**Parameters**

• **url** *(string)* – The Queue’s url identifier. This **must** be set.

  **Return type** `SQS.Queue`

  **Returns** A Queue resource

**Collections**

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the *Resources Introduction Guide*.

**queues**

**all()**

Creates an iterable of all Queue resources in the collection.

**Request Syntax**

```python
queue_iterator = sqs.queues.all()
```

  **Return type** `list(sqs.Queue)`

  **Returns** A list of Queue resources

**filter(****kwargs**)**

Creates an iterable of all Queue resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
queue_iterator = sqs.queues.filter(
    QueueNamePrefix='string'
)
```

**Parameters**

• **QueueNamePrefix** *(string)* – A string to use for filtering the list results. Only those queues whose name begins with the specified string are returned.
Return type  list(sqs.Queue)
Returns  A list of Queue resources

**limit** (**kwargs**)
Creates an iterable up to a specified amount of Queue resources in the collection.

Request Syntax

```python
queue_iterator = sqs.queues.limit(
    count=123
)
```

Parameters  count (integer) – The limit to the number of resources in the iterable.

Return type  list(sqs.Queue)
Returns  A list of Queue resources

**page_size** (**kwargs**)
Creates an iterable of all Queue resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

```python
queue_iterator = sqs.queues.page_size(
    count=123
)
```

Parameters  count (integer) – The number of items returned by each service call

Return type  list(sqs.Queue)
Returns  A list of Queue resources

Message

```python
class SQS.Message (queue_url, receipt_handle)
```

A resource representing an Amazon Simple Queue Service (SQS) Message:

```python
import boto3

sqs = boto3.resource('sqs')
message = sqs.Message('queue_url', 'receipt_handle')
```

Parameters

- **queue_url** (string) – The Message’s queue_url identifier. This **must** be set.
- **receipt_handle** (string) – The Message’s receipt_handle identifier. This **must** be set.

These are the resource’s available identifiers:

- queue_url
- receipt_handle

These are the resource’s available attributes:

- attributes
- body
- md5_of_body
- md5_of_message_attributes
- message_attributes
- message_id

These are the resource’s available actions:

- change_visibility()
Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

queue_url

(string) The Message’s queue_url identifier. This must be set.

receipt_handle

(string) The Message’s receipt_handle identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

attributes

(dict)

SenderId, SentTimestamp, ApproximateReceiveCount, and/or ApproximateFirstReceiveTimestamp. SentTimestamp and ApproximateFirstReceiveTimestamp are each returned as an integer representing the epoch time in milliseconds.

body

(string)

The message’s contents (not URL-encoded).

md5_of_body

(string)

An MD5 digest of the non-URL-encoded message body string.

md5_of_message_attributes

(string)

An MD5 digest of the non-URL-encoded message attribute string. This can be used to verify that Amazon SQS received the message correctly. Amazon SQS first URL decodes the message before creating the MD5 digest. For information about MD5, go to http://www.faqs.org/rfcs/rfc1321.html.

message_attributes

(dict)

Each message attribute consists of a Name, Type, and Value. For more information, see Message Attribute Items.

message_id

(string)

A unique identifier for the message. Message IDs are considered unique across all AWS accounts for an extended period of time.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

change_visibility(**kwargs)

Changes the visibility timeout of a specified message in a queue to a new value. The maximum allowed timeout value you can set the value to is 12 hours. This means you can’t extend the timeout of a message.
in an existing queue to more than a total visibility timeout of 12 hours. (For more information visibility timeout, see Visibility Timeout in the Amazon SQS Developer Guide.)

For example, let’s say you have a message and its default message visibility timeout is 30 minutes. You could call changeMessageVisibility with a value of two hours and the effective timeout would be two hours and 30 minutes. When that time comes near you could again extend the time out by calling changeMessageVisibility, but this time the maximum allowed timeout would be 9 hours and 30 minutes.

**Note:** There is a 120,000 limit for the number of inflight messages per queue. Messages are inflight after they have been received from the queue by a consuming component, but have not yet been deleted from the queue. If you reach the 120,000 limit, you will receive an OverLimit error message from Amazon SQS. To help avoid reaching the limit, you should delete the messages from the queue after they have been processed. You can also increase the number of queues you use to process the messages.

| Warning: | If you attempt to set the VisibilityTimeout to an amount more than the maximum time left, Amazon SQS returns an error. It will not automatically recalculate and increase the timeout to the maximum time remaining. |
| Warning: | Unlike with a queue, when you change the visibility timeout for a specific message, that timeout value is applied immediately but is not saved in memory for that message. If you don’t delete a message after it is received, the visibility timeout for the message the next time it is received reverts to the original timeout value, not the value you set with the changeMessageVisibility action. |

**Request Syntax**

```python
response = message.change_visibility(
    VisibilityTimeout=123
)
```

**Parameters** VisibilityTimeout (*integer*) – [REQUIRED]

The new value (in seconds - from 0 to 43200 - maximum 12 hours) for the message’s visibility timeout.

**Returns** None

**delete()**

Deletes the specified message from the specified queue. You specify the message by using the message’s receipt handle and not the message ID you received when you sent the message. Even if the message is locked by another reader due to the visibility timeout setting, it is still deleted from the queue. If you leave a message in the queue for longer than the queue’s configured retention period, Amazon SQS automatically deletes it.

**Note:** The receipt handle is associated with a specific instance of receiving the message. If you receive a message more than once, the receipt handle you get each time you receive the message is different. When you request deleteMessage, if you don’t provide the most recently received receipt handle for the message, the request will still succeed, but the message might not be deleted.

| Warning: | It is possible you will receive a message even after you have deleted it. This might happen on rare occasions if one of the servers storing a copy of the message is unavailable when you request to delete the message. The copy remains on the server and might be returned to you again on a subsequent receive request. You should create your system to be idempotent so that receiving a particular message more than once is not a problem. |

**Request Syntax**
response = message.delete()

**Returns**  None

**Sub-resources**

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the *Resources Introduction Guide*.

**Queue**

- Creates a Queue resource:

```
queue = message.Queue()
```

**Return type**  SQS.Queue

**Returns**  A Queue resource

**Queue**

**class**  SQS.Queue(*url*)

A resource representing an Amazon Simple Queue Service (SQS) Queue:

```
import boto3

sqs = boto3.resource('sqs')
queue = sqs.Queue('url')
```

**Parameters**  *url* (*string*) – The Queue’s url identifier. This must be set.

These are the resource’s available identifiers:

- *url*

These are the resource’s available attributes:

- *attributes*

These are the resource’s available actions:

- *add_permission()*
- *change_message_visibility_batch()*
- *delete()*
- *delete_messages()*
- *load()*
- *purge()*
- *receive_messages()*
- *reload()*
- *remove_permission()*
- *send_message()*
- *send_messages()*
- *set_attributes()*

These are the resource’s available sub-resources:

- *Message()*

These are the resource’s available collections:

- *dead_letter_source_queues*

**Identifiers**

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide*.
**url**

*(string)* The Queue’s url identifier. This **must** be set.

**Attributes**

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the Resources Introduction Guide.

**attributes**

*(dict)*

A map of attributes to the respective values.

**Actions**

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

**add_permission(**kwargs**)**

Adds a permission to a queue for a specific principal. This allows for sharing access to the queue.

When you create a queue, you have full control access rights for the queue. Only you (as owner of the queue) can grant or deny permissions to the queue. For more information about these permissions, see Shared Queues in the Amazon SQS Developer Guide.

**Note:** AddPermission writes an Amazon SQS-generated policy. If you want to write your own policy, use SetQueueAttributes to upload your policy. For more information about writing your own policy, see Using The Access Policy Language in the Amazon SQS Developer Guide.

**Note:** Some API actions take lists of parameters. These lists are specified using the `param.n` notation. Values of `n` are integers starting from 1. For example, a parameter list with two elements looks like this:

```
Attribute.1=this
Attribute.2=that
```

**Request Syntax**

```
response = queue.add_permission(
    Label='string',
    AWSAccountIds=[
        'string',
    ],
    Actions=[
        'string',
    ]
)
```

**Parameters**

- **Label (string) – [REQUIRED]**

  The unique identification of the permission you’re setting (e.g., AliceSendMessage). Constraints: Maximum 80 characters; alphanumeric characters, hyphens (-), and underscores (_) are allowed.

- **AWSAccountIds (list) – [REQUIRED]**

  The AWS account number of the principal who will be given permission. The principal must have an AWS account, but does not need to be signed up for Amazon SQS. For information about locating the AWS account identification, see Your AWS Identifiers in the Amazon SQS Developer Guide.
- (string) –

- **Actions (list)** – [REQUIRED]

The action the client wants to allow for the specified principal. The following are valid values: * | SendMessage | ReceiveMessage | DeleteMessage | ChangeMessageVisibility | GetQueueAttributes | GetQueueUrl . For more information about these actions, see Understanding Permissions in the Amazon SQS Developer Guide.

Specifying SendMessage, DeleteMessage, or ChangeMessageVisibility for the ActionName also grants permissions for the corresponding batch versions of those actions: SendMessageBatch, DeleteMessageBatch, and ChangeMessageVisibilityBatch.

- (string) –

**Returns** None

```python
change_message_visibility_batch(**kwargs)
```

Changes the visibility timeout of multiple messages. This is a batch version of ChangeMessageVisibility. The result of the action on each message is reported individually in the response. You can send up to 10 ChangeMessageVisibility requests with each ChangeMessageVisibilityBatch action.

**Warning:** Because the batch request can result in a combination of successful and unsuccessful actions, you should check for batch errors even when the call returns an HTTP status code of 200.

**Note:** Some API actions take lists of parameters. These lists are specified using the param.n notation. Values of n are integers starting from 1. For example, a parameter list with two elements looks like this:

```
Attribute.1=this
Attribute.2=that
```

**Request Syntax**

```python
response = queue.change_message_visibility_batch(
    Entries=[
        {
            'Id': 'string',
            'ReceiptHandle': 'string',
            'VisibilityTimeout': 123
        },
    ]
)
```

- **Parameters** Entries (list) – [REQUIRED]

A list of receipt handles of the messages for which the visibility timeout must be changed.

```
* (dict) –
```

Encloses a receipt handle and an entry id for each message in ChangeMessageVisibilityBatch.

---

4246 Chapter 3. API Reference
Warning: All of the following parameters are list parameters that must be prefixed with ChangeMessageVisibilityBatchRequestEntry.n, where n is an integer value starting with 1. For example, a parameter list for this action might look like this:

```
ChangeMessageVisibilityBatchRequestEntry.1.Id=change_visibility_msg_2
ChangeMessageVisibilityBatchRequestEntry.1.ReceiptHandle=Your_Receipt_Handle
ChangeMessageVisibilityBatchRequestEntry.1.VisibilityTimeout=45
```

- **Id (string)** – [REQUIRED]
  
  An identifier for this particular receipt handle. This is used to communicate the result. Note that the Id s of a batch request need to be unique within the request.

- **ReceiptHandle (string)** – [REQUIRED]
  
  A receipt handle.

- **VisibilityTimeout (integer)** –
  
  The new value (in seconds) for the message’s visibility timeout.

Return type: dict

Returns

Response Syntax

```
{
  'Successful': [
    {'Id': 'string'},
  ],
  'Failed': [
    {'Id': 'string',
     'SenderId': True|False,
     'Code': 'string',
     'Message': 'string'
    }
  ]
}
```

Response Structure

- (dict) –

  For each message in the batch, the response contains a ChangeMessageVisibilityBatchResultEntry tag if the message succeeds or a BatchResultErrorEntry tag if the message fails.

- **Successful (list)** –

  A list of ChangeMessageVisibilityBatchResultEntry items.

    - (dict) –

      Encloses the id of an entry in ChangeMessageVisibilityBatch.

      - **Id (string)** –

      Represents a message whose visibility timeout has been changed successfully.
– **Failed** *(list)* –
  A list of BatchResultErrorEntry items.

* *(dict)* –
  This is used in the responses of batch API to give a detailed description of the result of an action on each entry in the request.

  · **Id** *(string)* –
    The id of an entry in a batch request.
  
  · **SenderFault** *(boolean)* –
    Whether the error happened due to the sender’s fault.
  
  · **Code** *(string)* –
    An error code representing why the action failed on this entry.
  
  · **Message** *(string)* –
    A message explaining why the action failed on this entry.

**delete()**

Deletes the queue specified by the queue URL, regardless of whether the queue is empty. If the specified queue does not exist, Amazon SQS returns a successful response.

**Warning:** Use DeleteQueue with care; once you delete your queue, any messages in the queue are no longer available.

When you delete a queue, the deletion process takes up to 60 seconds. Requests you send involving that queue during the 60 seconds might succeed. For example, a SendMessage request might succeed, but after the 60 seconds, the queue and that message you sent no longer exist. Also, when you delete a queue, you must wait at least 60 seconds before creating a queue with the same name.

We reserve the right to delete queues that have had no activity for more than 30 days. For more information, see How Amazon SQS Queues Work in the Amazon SQS Developer Guide.

**Request Syntax**

```python
response = queue.delete()
```

**Returns** None

**delete_messages(***kwargs***)

Deletes up to ten messages from the specified queue. This is a batch version of DeleteMessage. The result of the delete action on each message is reported individually in the response.

**Warning:** Because the batch request can result in a combination of successful and unsuccessful actions, you should check for batch errors even when the call returns an HTTP status code of 200.

**Note:** Some API actions take lists of parameters. These lists are specified using the param.n notation. Values of n are integers starting from 1. For example, a parameter list with two elements looks like this:

```python
Attribute.1=this
Attribute.2=that
```

**Request Syntax**
response = queue.delete_messages(
    Entries=[
        {
            'Id': 'string',
            'ReceiptHandle': 'string'
        },
    ]
)

Parameters

**Entries** *(list)* – [REQUIRED]

A list of receipt handles for the messages to be deleted.
- *(dict)* –
  Encloses a receipt handle and an identifier for it.
  - **Id** *(string)* – [REQUIRED]
    An identifier for this particular receipt handle. This is used to communicate the result. Note that the Ids of a batch request need to be unique within the request.
  - **ReceiptHandle** *(string)* – [REQUIRED]
    A receipt handle.

Return type
dict

Returns

**Response Syntax**

```python
{
    'Successful': [
        {
            'Id': 'string'
        },
    ],
    'Failed': [
        {
            'Id': 'string',
            'SenderFault': True|False,
            'Code': 'string',
            'Message': 'string'
        },
    ]
}
```

**Response Structure**

- *(dict)* –
  For each message in the batch, the response contains a DeleteMessageBatchResultEntry tag if the message is deleted or a BatchResultErrorEntry tag if the message cannot be deleted.
  - **Successful** *(list)* –
    A list of DeleteMessageBatchResultEntry items.
      - *(dict)* –
        Encloses the id an entry in DeleteMessageBatch.
          - **Id** *(string)* –
            Represents a successfully deleted message.
– Failed *(list)* –

A list of BatchResultErrorEntry items.

* *(dict)* –

This is used in the responses of batch API to give a detailed description of the result of an action on each entry in the request.

- **Id** *(string)* –
  
The id of an entry in a batch request.

- **SenderFault** *(boolean)* –
  
  Whether the error happened due to the sender’s fault.

- **Code** *(string)* –
  
  An error code representing why the action failed on this entry.

- **Message** *(string)* –
  
  A message explaining why the action failed on this entry.

### load()

Calls `sqs.Client.get_queue_attributes()` to update the attributes of the Queue resource

**Request Syntax**

```python
queue.load()
```

**Returns** None

### purge()

Deletes the messages in a queue specified by the queue URL.

**Warning:** When you use the `PurgeQueue` API, the deleted messages in the queue cannot be retrieved.

When you purge a queue, the message deletion process takes up to 60 seconds. All messages sent to the queue before calling `PurgeQueue` will be deleted; messages sent to the queue while it is being purged may be deleted. While the queue is being purged, messages sent to the queue before `PurgeQueue` was called may be received, but will be deleted within the next minute.

**Request Syntax**

```python
response = queue.purge()
```

**Returns** None

### receive_messages(**kwargs)**

Retrieves one or more messages, with a maximum limit of 10 messages, from the specified queue. Long poll support is enabled by using the `WaitTimeSeconds` parameter. For more information, see Amazon SQS Long Poll in the Amazon SQS Developer Guide.

Short poll is the default behavior where a weighted random set of machines is sampled on a `ReceiveMessage` call. This means only the messages on the sampled machines are returned. If the number of messages in the queue is small (less than 1000), it is likely you will get fewer messages than you requested per `ReceiveMessage` call. If the number of messages in the queue is extremely small, you might not receive any messages in a particular `ReceiveMessage` response; in which case you should repeat the request.

For each message returned, the response includes the following:

- **Message body**
• MD5 digest of the message body. For information about MD5, go to http://www.faqs.org/rfcs/rfc1321.html.
• Message ID you received when you sent the message to the queue.
• Receipt handle.
• Message attributes.
  • MD5 digest of the message attributes.
  The receipt handle is the identifier you must provide when deleting the message. For more information, see Queue and Message Identifiers in the Amazon SQS Developer Guide.

You can provide the VisibilityTimeout parameter in your request, which will be applied to the messages that Amazon SQS returns in the response. If you do not include the parameter, the overall visibility timeout for the queue is used for the returned messages. For more information, see Visibility Timeout in the Amazon SQS Developer Guide.

**Note:** Going forward, new attributes might be added. If you are writing code that calls this action, we recommend that you structure your code so that it can handle new attributes gracefully.

### Request Syntax

```python
message = queue.receive_messages(
    AttributeNames=[
        'Policy'|'VisibilityTimeout'|'MaximumMessageSize'|'MessageRetentionPeriod'|'ApproximateFirstReceiveTimestamp'|'ApproximateReceiveCount'|'SenderId'|'SentTimestamp'|'ApproximateNumberOfMessages'|'ApproximateNumberOfMessagesDelayed'|'DelaySeconds'|'ReceiveMessageWaitTimeSeconds'|'RedrivePolicy',
    ],
    MessageAttributeNames=[
        'string',
    ],
    MaxNumberOfMessages=123,
    VisibilityTimeout=123,
    WaitTimeSeconds=123
)
```

### Parameters
- **AttributeNames (list)** – A list of attributes that need to be returned along with each message.

The following lists the names and descriptions of the attributes that can be returned:

- **All** - returns all values.
- **ApproximateFirstReceiveTimestamp** - returns the time when the message was first received from the queue (epoch time in milliseconds).
- **ApproximateReceiveCount** - returns the number of times a message has been received from the queue but not deleted.
- **SenderId** - returns the AWS account number (or the IP address, if anonymous access is allowed) of the sender.
- **SentTimestamp** - returns the time when the message was sent to the queue (epoch time in milliseconds).

- **(string)** –

- **MessageAttributeNames (list)** – The name of the message attribute, where \( N \) is the index. The message attribute name can contain the following characters: A-Z, a-z, 0-9, underscore (_), hyphen (-), and period (.). The name must not start or end with a period, and it should not have successive periods. The name is case sensitive and must be unique among all attribute names for the message. The name can be up to 256 characters long. The name cannot start with “AWS:” or “Amazon:” (or any variations in casing), because these prefixes are reserved
for use by Amazon Web Services.

When using `ReceiveMessage`, you can send a list of attribute names to receive, or you can return all of the attributes by specifying “All” or “.*” in your request. You can also use “foo.*” to return all message attributes starting with the “foo” prefix.

- **MaxNumberOfMessages (integer)** – The maximum number of messages to return. Amazon SQS never returns more messages than this value but may return fewer. Values can be from 1 to 10. Default is 1.

  All of the messages are not necessarily returned.

- **VisibilityTimeout (integer)** – The duration (in seconds) that the received messages are hidden from subsequent retrieve requests after being retrieved by a `ReceiveMessage` request.

- **WaitTimeSeconds (integer)** – The duration (in seconds) for which the call will wait for a message to arrive in the queue before returning. If a message is available, the call will return sooner than `WaitTimeSeconds`.

**Return type**: list(sqs.Message)

**Returns**: A list of Message resources

**reload()**

Calls `sqs.Client.get_queue_attributes()` to update the attributes of the Queue resource

**Request Syntax**

```python
queue.reload()
```

**Returns**: None

**remove_permission(**kwargs**)**

Revokes any permissions in the queue policy that matches the specified `Label` parameter. Only the owner of the queue can remove permissions.

**Request Syntax**

```python
response = queue.remove_permission(
    Label='string'
)
```

**Parameters**

- **Label (string)** – [REQUIRED]

  The identification of the permission to remove. This is the label added with the AddPermission action.

**Returns**: None

**send_message(**kwargs**)**

Delivers a message to the specified queue. With Amazon SQS, you now have the ability to send large payload messages that are up to 256KB (262,144 bytes) in size. To send large payloads, you must use an AWS SDK that supports SigV4 signing. To verify whether SigV4 is supported for an AWS SDK, check the SDK release notes.

**Warning**: The following list shows the characters (in Unicode) allowed in your message, according to the W3C XML specification. For more information, go to [http://www.w3.org/TR/REC-xml/#charsets](http://www.w3.org/TR/REC-xml/#charsets)

If you send any characters not included in the list, your request will be rejected.

- #x9 | #xA | #xD | [%x20 to %xD7FF] | [%xE000 to %xFFFD] | [%x10000 to %x10FFFF]

**Request Syntax**
response = queue.send_message(
    MessageBody='string',
    DelaySeconds=123,
    MessageAttributes={
        'string': {
            'StringValue': 'string',
            'BinaryValue': b'bytes',
            'StringListValues': [
                'string',
            ],
            'BinaryListValues': [
                b'bytes',
            ],
            'DataType': 'string'
        }
    }
)

Parameters

- **MessageBody (string)** – [REQUIRED]
  
  The message to send. String maximum 256 KB in size. For a list of allowed characters, see the preceding important note.

- **DelaySeconds (integer)** – The number of seconds (0 to 900 - 15 minutes) to delay a specific message. Messages with a positive DelaySeconds value become available for processing after the delay time is finished. If you don’t specify a value, the default value for the queue applies.

- **MessageAttributes (dict)** – Each message attribute consists of a Name, Type, and Value. For more information, see Message Attribute Items.
  
  - (string) –
    * (dict) –
      
      The user-specified message attribute value. For string data types, the value attribute has the same restrictions on the content as the message body. For more information, see SendMessage.

      Name, type, and value must not be empty or null. In addition, the message body should not be empty or null. All parts of the message attribute, including name, type, and value, are included in the message size restriction, which is currently 256 KB (262,144 bytes).

      - **StringValue (string)** –
        
        Strings are Unicode with UTF8 binary encoding. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters.

      - **BinaryValue (bytes)** –
        
        Binary type attributes can store any binary data, for example, compressed data, encrypted data, or images.

      - **StringListValues (list)** –
        
        Not implemented. Reserved for future use.

      - (string) –
        
        - **BinaryListValues (list)** –
          
          Not implemented. Reserved for future use.

      - (bytes) –
· **DataType** *(string)* – [REQUIRED]

Amazon SQS supports the following logical data types: String, Number, and Binary. In addition, you can append your own custom labels. For more information, see Message Attribute Data Types.

Return type: dict

Returns

**Response Syntax**

```python
{
    'MD5OfMessageBody': 'string',
    'MD5OfMessageAttributes': 'string',
    'MessageId': 'string'
}
```

**Response Structure**

- *(dict)* –
  - `MD5OfMessageBody` *(string)* –
    An MD5 digest of the non-URL-encoded message body string. This can be used to verify that Amazon SQS received the message correctly. Amazon SQS first URL decodes the message before creating the MD5 digest. For information about MD5, go to [http://www.faqs.org/rfcs/rfc1321.html](http://www.faqs.org/rfcs/rfc1321.html).
  
  - `MD5OfMessageAttributes` *(string)* –
    An MD5 digest of the non-URL-encoded message attribute string. This can be used to verify that Amazon SQS received the message correctly. Amazon SQS first URL decodes the message before creating the MD5 digest. For information about MD5, go to [http://www.faqs.org/rfcs/rfc1321.html](http://www.faqs.org/rfcs/rfc1321.html).

  - `MessageId` *(string)* –
    An element containing the message ID of the message sent to the queue. For more information, see Queue and Message Identifiers in the Amazon SQS Developer Guide.

**send_messages** (**kwargs**)

Delivers up to ten messages to the specified queue. This is a batch version of SendMessage. The result of the send action on each message is reported individually in the response. The maximum allowed individual message size is 256 KB (262,144 bytes).

The maximum total payload size (i.e., the sum of all a batch’s individual message lengths) is also 256 KB (262,144 bytes).

If the DelaySeconds parameter is not specified for an entry, the default for the queue is used.

---

**Warning:** The following list shows the characters (in Unicode) that are allowed in your message, according to the W3C XML specification. For more information, go to [http://www.faqs.org/rfcs/rfc1321.html](http://www.faqs.org/rfcs/rfc1321.html). If you send any characters that are not included in the list, your request will be rejected.

```text
#x9 | #xA | #xD | [#x20 to #xD7FF] | [#xE000 to #xFFFD] | [#x10000 to #x10FFFF]
```
Warning: Because the batch request can result in a combination of successful and unsuccessful actions, you should check for batch errors even when the call returns an HTTP status code of 200.

Note: Some API actions take lists of parameters. These lists are specified using the `param.n` notation. Values of `n` are integers starting from 1. For example, a parameter list with two elements looks like this:

```
Attribute.1=this
Attribute.2=that
```

Request Syntax

```python
response = queue.send_messages(
    Entries=[
        {
            'Id': 'string',
            'MessageBody': 'string',
            'DelaySeconds': 123,
            'MessageAttributes': {
                'string': {
                    'StringValue': 'string',
                    'BinaryValue': b'bytes',
                    'StringListValues': ['string'],
                    'BinaryListValues': [b'bytes'],
                    'DataType': 'string'
                }
            }
        },
    ]
)
```

Parameters Entries (list) – [REQUIRED]

A list of `SendMessageBatchRequestEntry` items.

- (dict) –

  Contains the details of a single Amazon SQS message along with a `Id`.

  - **Id (string) – [REQUIRED]**

    An identifier for the message in this batch. This is used to communicate the result. Note that the `Id` s of a batch request need to be unique within the request.

  - **MessageBody (string) – [REQUIRED]**

    Body of the message.

  - **DelaySeconds (integer) –**

    The number of seconds for which the message has to be delayed.

  - **MessageAttributes (dict) –**

    Each message attribute consists of a Name, Type, and Value. For more information, see Message Attribute Items.

    * (string) –
      - (dict) –
The user-specified message attribute value. For string data types, the value attribute has the same restrictions on the content as the message body. For more information, see SendMessage.

Name, type, and value must not be empty or null. In addition, the message body should not be empty or null. All parts of the message attribute, including name, type, and value, are included in the message size restriction, which is currently 256 KB (262,144 bytes).

- **StringValue** *(string)*

  Strings are Unicode with UTF8 binary encoding. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters.

- **BinaryValue** *(bytes)*

  Binary type attributes can store any binary data, for example, compressed data, encrypted data, or images.

- **StringListValues** *(list)*

  Not implemented. Reserved for future use.

- **BinaryListValues** *(list)*

  Not implemented. Reserved for future use.

- **DataType** *(string)* – [REQUIRED]

  Amazon SQS supports the following logical data types: String, Number, and Binary. In addition, you can append your own custom labels. For more information, see Message Attribute Data Types.

**Response Syntax**

```json
{
  'Successful': [
    {
      'Id': 'string',
      'MessageId': 'string',
      'MD5OfMessageBody': 'string',
      'MD5OfMessageAttributes': 'string'
    },
  ],
  'Failed': [
    {
      'Id': 'string',
      'SenderFault': True|False,
      'Code': 'string',
      'Message': 'string'
    },
  ]
}
```

**Response Structure**

Return type: dict

Returns
• (dict) –
  
  For each message in the batch, the response contains a SendMessageBatchResultEntry tag if the message succeeds or a BatchResultErrorEntry tag if the message fails.

  – **Successful** (list) –
  
  A list of SendMessageBatchResultEntry items.

  * (dict) –

  Encloses a message ID for successfully enqueued message of a SendMessageBatch.

  · **Id** (string) –

    An identifier for the message in this batch.

  · **MessageId** (string) –

    An identifier for the message.

  · **MD5OfMessageBody** (string) –

    An MD5 digest of the non-URL-encoded message body string. This can be used to verify that Amazon SQS received the message correctly. Amazon SQS first URL decodes the message before creating the MD5 digest. For information about MD5, go to [http://www.faqs.org/rfcs/rfc1321.html](http://www.faqs.org/rfcs/rfc1321.html).

  · **MD5OfMessageAttributes** (string) –

    An MD5 digest of the non-URL-encoded message attribute string. This can be used to verify that Amazon SQS received the message batch correctly. Amazon SQS first URL decodes the message before creating the MD5 digest. For information about MD5, go to [http://www.faqs.org/rfcs/rfc1321.html](http://www.faqs.org/rfcs/rfc1321.html).

– **Failed** (list) –

  A list of BatchResultErrorEntry items with the error detail about each message that could not be enqueued.

  * (dict) –

  This is used in the responses of batch API to give a detailed description of the result of an action on each entry in the request.

  · **Id** (string) –

    The id of an entry in a batch request.

  · **SenderFault** (boolean) –

    Whether the error happened due to the sender’s fault.

  · **Code** (string) –

    An error code representing why the action failed on this entry.

  · **Message** (string) –

    A message explaining why the action failed on this entry.

**set_attributes(** **kwargs**)

Sets the value of one or more queue attributes. When you change a queue’s attributes, the change can take up to 60 seconds for most of the attributes to propagate throughout the SQS system. Changes made to the MessageRetentionPeriod attribute can take up to 15 minutes.

**Note:** Going forward, new attributes might be added. If you are writing code that calls this action, we recommend that you structure your code so that it can handle new attributes gracefully.
Request Syntax

```python
response = queue.set_attributes(
    Attributes={
        'string': 'string'
    }
)
```

Parameters  Attributes (dict) – [REQUIRED]

A map of attributes to set.

The following lists the names, descriptions, and values of the special request parameters the `setQueueAttributes` action uses:

- **DelaySeconds** - The time in seconds that the delivery of all messages in the queue will be delayed. An integer from 0 to 900 (15 minutes). The default for this attribute is 0 (zero).
- **MaximumMessageSize** - The limit of how many bytes a message can contain before Amazon SQS rejects it. An integer from 1024 bytes (1 KiB) up to 262144 bytes (256 KiB). The default for this attribute is 262144 (256 KiB).
- **MessageRetentionPeriod** - The number of seconds Amazon SQS retains a message. Integer representing seconds, from 60 (1 minute) to 1209600 (14 days). The default for this attribute is 345600 (4 days).
- **Policy** - The queue’s policy. A valid AWS policy. For more information about policy structure, see Overview of AWS IAM Policies in the Amazon IAM User Guide.
- **ReceiveMessageWaitTimeSeconds** - The time for which a ReceiveMessage call will wait for a message to arrive. An integer from 0 to 20 (seconds). The default for this attribute is 0.
- **VisibilityTimeout** - The visibility timeout for the queue. An integer from 0 to 43200 (12 hours). The default for this attribute is 30. For more information about visibility timeout, see Visibility Timeout in the Amazon SQS Developer Guide.
- **RedrivePolicy** - The parameters for dead letter queue functionality of the source queue. For more information about RedrivePolicy and dead letter queues, see Using Amazon SQS Dead Letter Queues in the Amazon SQS Developer Guide.

- *(string)* –
  
  The name of a queue attribute.

  - *(string)* –
    
    The value of a queue attribute.

Returns  None

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

**Message** *(receipt_handle)*

Creates a Message resource:

```python
message = queue.Message('receipt_handle')
```

Parameters  receipt_handle (string) – The Message’s receipt_handle identifier. This must be set.
Return type: SQS.Message
Returns: A Message resource

Collections

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the Resources Introduction Guide.

dead_letter_source_queues

all()

Creates an iterable of all Queue resources in the collection.

Request Syntax

queue_iterator = queue.dead_letter_source_queues.all()

Return type: list(sqs.Queue)
Returns: A list of Queue resources

filter()

Creates an iterable of all Queue resources in the collection filtered by kwargs passed to method.

Request Syntax

queue_iterator = queue.dead_letter_source_queues.filter()

Return type: list(sqs.Queue)
Returns: A list of Queue resources

limit(**kwargs)

Creates an iterable up to a specified amount of Queue resources in the collection.

Request Syntax

queue_iterator = queue.dead_letter_source_queues.limit(count=123)

Parameters: count (integer) – The limit to the number of resources in the iterable.
Return type: list(sqs.Queue)
Returns: A list of Queue resources

page_size(**kwargs)

Creates an iterable of all Queue resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

queue_iterator = queue.dead_letter_source_queues.page_size(count=123)

Parameters: count (integer) – The number of items returned by each service call
Return type: list(sqs.Queue)
Returns: A list of Queue resources
class SSM.Client

A low-level client representing Amazon Simple Systems Management Service (SSM):

```python
import boto3

client = boto3.client('ssm')
```

These are the available methods:

- `can_paginate()`
- `create_association()`
- `create_association_batch()`
- `create_document()`
- `delete_association()`
- `delete_document()`
- `describe_association()`
- `describe_document()`
- `generate_presigned_url()`
- `get_document()`
- `get_paginated_url()`
- `get_waiter()`
- `list_associations()`
- `list_documents()`
- `update_association_status()`

### can_paginate(operation_name)

Check if an operation can be paginated.

**Parameters**

- `operation_name` *(string)* - The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you'd normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginated_url("create_foo")`.

**Returns**

- `True` if the operation can be paginated, `False` otherwise.

### create_association(**kwargs)

Associates the specified configuration document with the specified instance.

When you associate a configuration document with an instance, the configuration agent on the instance processes the configuration document and configures the instance as specified.

If you associate a configuration document with an instance that already has an associated configuration document, we replace the current configuration document with the new configuration document.

**Request Syntax**
response = client.create_association(
    Name='string',
    InstanceId='string'
)

Parameters

• **Name** *(string) – [REQUIRED]*

  The name of the configuration document.

• **InstanceId** *(string) – [REQUIRED]*

  The ID of the instance.

Return type  *dict*

Returns

Response Syntax

```python
{
    'AssociationDescription': {
        'Name': 'string',
        'InstanceId': 'string',
        'Date': datetime(2015, 1, 1),
        'Status': {
            'Date': datetime(2015, 1, 1),
            'Name': 'Pending'|'Success'|'Failed',
            'Message': 'string',
            'AdditionalInfo': 'string'
        }
    }
}
```

Response Structure

• *(dict)* –
  
  – **AssociationDescription** *(dict)* –

    Information about the association.

    • **Name** *(string)* –

      The name of the configuration document.

    • **InstanceId** *(string)* –

      The ID of the instance.

    • **Date** *(datetime)* –

      The date when the association was made.

    • **Status** *(dict)* –

      The association status.

      · **Date** *(datetime)* –

        The date when the status changed.

      · **Name** *(string)* –

        The status.

      · **Message** *(string)* –

        The reason for the status.

      · **AdditionalInfo** *(string)* –

        A user-defined string.
**create_association_batch**(**kwargs**)  
Associates the specified configuration documents with the specified instances.

When you associate a configuration document with an instance, the configuration agent on the instance processes the configuration document and configures the instance as specified.

If you associate a configuration document with an instance that already has an associated configuration document, we replace the current configuration document with the new configuration document.

**Request Syntax**

```python
response = client.create_association_batch(
    Entries=[
        {
            'Name': 'string',
            'InstanceId': 'string'
        },
    ]
)
```

**Parameters**  

**Entries** (list) – [REQUIRED]  
One or more associations.

- (dict) –  
  Describes the association of a configuration document and an instance.

  - **Name** (string) –  
    The name of the configuration document.

  - **InstanceId** (string) –  
    The ID of the instance.

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'Successful': [
        {
            'Name': 'string',
            'InstanceId': 'string',
            'Date': datetime(2015, 1, 1),
            'Status': {
                'Date': datetime(2015, 1, 1),
                'Name': 'Pending'|'Success'|'Failed',
                'Message': 'string',
                'AdditionalInfo': 'string'
            }
        },
    ],
    'Failed': [
        {
            'Entry': {
                'Name': 'string',
                'InstanceId': 'string'
            },
            'Message': 'string',
            'Fault': 'Client'|'Server'|'Unknown'
        },
    ]
}
```
Response Structure

- `(dict)` –
  - **Successful** `(list)` –
    Information about the associations that succeeded.
    * `(dict)` –
      Describes an association.
      - **Name** `(string)` –
        The name of the configuration document.
      - **InstanceId** `(string)` –
        The ID of the instance.
      - **Date** `(datetime)` –
        The date when the association was made.
      - **Status** `(dict)` –
        The association status.
        - **Date** `(datetime)` –
          The date when the status changed.
        - **Name** `(string)` –
          The status.
        - **Message** `(string)` –
          The reason for the status.
        - **AdditionalInfo** `(string)` –
          A user-defined string.
    - **Failed** `(list)` –
      Information about the associations that failed.
      * `(dict)` –
        Describes a failed association.
        - **Entry** `(dict)` –
          The association.
        - **Name** `(string)` –
          The name of the configuration document.
        - **InstanceId** `(string)` –
          The ID of the instance.
        - **Message** `(string)` –
          A description of the failure.
        - **Fault** `(string)` –
          The source of the failure.

`create_document` (**kwargs**)

`create_document` creates a configuration document.

After you create a configuration document, you can use `CreateAssociation` to associate it with one or more running instances.

**Request Syntax**
response = client.create_document(
    Content='string',
    Name='string'
)

Parameters

• **Content** *(string)* – [REQUIRED]
  A valid JSON file. For more information about the contents of this file, see Configuration Document.

• **Name** *(string)* – [REQUIRED]
  A name for the configuration document.

Return type  dict

Returns

Response Syntax

```
{
    'DocumentDescription': {
        'Sha1': 'string',
        'Name': 'string',
        'CreatedDate': datetime(2015, 1, 1),
        'Status': 'Creating'|'Active'|'Deleting'
    }
}
```

Response Structure

• *(dict)*

  – **DocumentDescription** *(dict)*

    Information about the configuration document.
    
    • **Sha1** *(string)*

      The SHA1 hash of the document, which you can use for verification purposes.
    
    • **Name** *(string)*

      The name of the configuration document.
    
    • **CreatedDate** *(datetime)*

      The date when the configuration document was created.
    
    • **Status** *(string)*

      The status of the configuration document.

**delete_association**(**kwargs**)  
Disassociates the specified configuration document from the specified instance.

When you disassociate a configuration document from an instance, it does not change the configuration of the instance. To change the configuration state of an instance after you disassociate a configuration document, you must create a new configuration document with the desired configuration and associate it with the instance.

Request Syntax

```
response = client.delete_association(
    Name='string',
    InstanceId='string'
)
```
Parameters

- **Name (string)** – [REQUIRED]
  The name of the configuration document.
- **InstanceId (string)** – [REQUIRED]
  The ID of the instance.

**Return type**  dict

**Returns**

**Response Syntax**

```python
{}
```

**Response Structure**

- **(dict)** –

  **delete_document(**kwargs)**

  Deletes the specified configuration document.

  You must use DeleteAssociation to disassociate all instances that are associated with the configuration document before you can delete it.

  **Request Syntax**

  ```python
  response = client.delete_document(
      Name='string'
  )
  ```

  **Parameters**  Name (string) – [REQUIRED]

  The name of the configuration document.

  **Return type**  dict

  **Returns**

  **Response Syntax**

  ```python
  {}
  ```

  **Response Structure**

  - **(dict)** –

  1. **describe_association(**kwargs)**

     Describes the associations for the specified configuration document or instance.

     **Request Syntax**

     ```python
     response = client.describe_association(
         Name='string',
         InstanceId='string'
     )
     ```

     **Parameters**  Name (string) – [REQUIRED]

     The name of the configuration document.

     **Return type**  dict
Returns

Response Syntax

{
    'AssociationDescription': {
        'Name': 'string',
        'InstanceId': 'string',
        'Date': datetime(2015, 1, 1),
        'Status': {
            'Date': datetime(2015, 1, 1),
            'Name': 'Pending'|'Success'|'Failed',
            'Message': 'string',
            'AdditionalInfo': 'string'
        }
    }
}

Response Structure

• (dict) –
  – AssociationDescription (dict) –

  Information about the association.
  * Name (string) –
    The name of the configuration document.
  * InstanceId (string) –
    The ID of the instance.
  * Date (datetime) –
    The date when the association was made.
  * Status (dict) –
    The association status.
    · Date (datetime) –
      The date when the status changed.
    · Name (string) –
      The status.
    · Message (string) –
      The reason for the status.
    · AdditionalInfo (string) –
      A user-defined string.

describe_document(**kwargs)

Describes the specified configuration document.

Request Syntax

response = client.describe_document(
    Name='string'
)

Parameters

Name (string) – [REQUIRED]

  The name of the configuration document.

Return type

dict
Returns

Response Syntax

```

{'Document': {
    'Sha1': 'string',
    'Name': 'string',
    'CreatedDate': datetime(2015, 1, 1),
    'Status': 'Creating'|'Active'|'Deleting'
}}
```

Response Structure

- (dict) – Document (dict) – Information about the configuration document.
  - Sha1 (string) – The SHA1 hash of the document, which you can use for verification purposes.
  - Name (string) – The name of the configuration document.
  - CreatedDate (datetime) – The date when the configuration document was created.
  - Status (string) – The status of the configuration document.

**generate_presigned_url** (ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)
Generate a presigned url given a client, its method, and arguments

Parameters

- ClientMethod (string) – The client method to presign for
- Params (dict) – The parameters normally passed to ClientMethod.
- ExpiresIn (int) – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- HttpMethod (string) – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns The presigned url

**get_document** (**kwargs)
Gets the contents of the specified configuration document.

Request Syntax

```python
response = client.get_document(
    Name='string'
)
```

Parameters  

Name (string) – [REQUIRED]  
The name of the configuration document.

Return type  
dict

Returns

Response Syntax
{  
    'Name': 'string',  
    'Content': 'string'  
}

Response Structure

- (dict) –
  - **Name (string)** –
    The name of the configuration document.
  - **Content (string)** –
    The contents of the configuration document.

**get_paginator (operation_name)**

Create a paginator for an operation.

Parameters **operation_name (string)** – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you'd normally invoke the operation as `client.create_foo(**kwargs)`, if the create_foo operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

Raises **OperationNotPageableError** Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

Return type **L{botocore.paginate.Paginator}**

Returns A paginator object.

**get_waiter (waiter_name)**

**list_associations (**kwargs**)**

Lists the associations for the specified configuration document or instance.

Request Syntax

```python
response = client.list_associations(
    AssociationFilterList=[
        {
            'key': 'InstanceId'|'Name',
            'value': 'string'
        },
    ],
    MaxResults=123,
    NextToken='string'
)
```

Parameters

- **AssociationFilterList (list)** – [REQUIRED]
  One or more filters. Use a filter to return a more specific list of results.
  - (dict) –
    Describes a filter.
    - **key (string)** – [REQUIRED]
      The name of the filter.
    - **value (string)** – [REQUIRED]
      The filter value.
• **MaxResults** *(integer)* – The maximum number of items to return for this call. The call also returns a token that you can specify in a subsequent call to get the next set of results.

• **NextToken** *(string)* – The token for the next set of items to return. (You received this token from a previous call.)

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Associations': [
        {
            'Name': 'string',
            'InstanceId': 'string'
        },
    ],
    'NextToken': 'string'
}
```

**Response Structure**

- *(dict)* –
  - **Associations** *(list)* –
    The associations.
    - *(dict)* –
      Describes an association of a configuration document and an instance.
      - **Name** *(string)* –
        The name of the configuration document.
      - **InstanceId** *(string)* –
        The ID of the instance.
  - **NextToken** *(string)* –
    The token to use when requesting the next set of items. If there are no additional items to return, the string is empty.

**list_documents** (**kwargs**)

Describes one or more of your configuration documents.

**Request Syntax**

```python
response = client.list_documents(
    DocumentFilterList=[
        {'key': 'Name',
         'value': 'string'},
    ],
    MaxResults=123,
    NextToken='string'
)
```

**Parameters**

- **DocumentFilterList** *(list)* – One or more filters. Use a filter to return a more specific list of results.
Describes a filter.

- **key** *(string)* – [REQUIRED]
  The name of the filter.

- **value** *(string)* – [REQUIRED]
  The value of the filter.

- **MaxResults** *(integer)* – The maximum number of items to return for this call. The call also returns a token that you can specify in a subsequent call to get the next set of results.

- **NextToken** *(string)* – The token for the next set of items to return. (You received this token from a previous call.)

**Return type** *dict*

**Returns**

**Response Syntax**

```
{
    'DocumentIdentifiers': [
        {'Name': 'string'},
        ...
    ],
    'NextToken': 'string'
}
```

**Response Structure**

- *(dict)* –
  - **DocumentIdentifiers** *(list)* –
    The names of the configuration documents.

- *(dict)* –
  - Describes the name of a configuration document.
    - **Name** *(string)* –
      The name of the configuration document.

- **NextToken** *(string)* –
  The token to use when requesting the next set of items. If there are no additional items to return, the string is empty.

**update_association_status(**kwargs**)**

Updates the status of the configuration document associated with the specified instance.

**Request Syntax**

```python
response = client.update_association_status(
    Name='string',
    InstanceId='string',
    AssociationStatus={
        'Date': datetime(2015, 1, 1),
        'Name': 'Pending'|'Success'|'Failed',
        'Message': 'string',
        'AdditionalInfo': 'string'
    }
)
```

**Parameters**
• **Name** (*string*) – [REQUIRED]
  The name of the configuration document.

• **InstanceId** (*string*) – [REQUIRED]
  The ID of the instance.

• **AssociationStatus** (*dict*) – [REQUIRED]
  The association status.
    - **Date** (*datetime*) – [REQUIRED]
      The date when the status changed.
    - **Name** (*string*) – [REQUIRED]
      The status.
    - **Message** (*string*) – [REQUIRED]
      The reason for the status.
    - **AdditionalInfo** (*string*) –
      A user-defined string.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'AssociationDescription': {
        'Name': 'string',
        'InstanceId': 'string',
        'Date': datetime(2015, 1, 1),
        'Status': {
            'Date': datetime(2015, 1, 1),
            'Name': 'Pending'|'Success'|'Failed',
            'Message': 'string',
            'AdditionalInfo': 'string'
        }
    }
}
```

**Response Structure**

• (*dict*) –
  - **AssociationDescription** (*dict*) –
    Information about the association.
    * **Name** (*string*) –
      The name of the configuration document.
    * **InstanceId** (*string*) –
      The ID of the instance.
    * **Date** (*datetime*) –
      The date when the association was made.
    * **Status** (*dict*) –
      The association status.
        · **Date** (*datetime*) –
          The date when the status changed.
        · **Name** (*string*) –
          The status.
StorageGateway

Table of Contents

- StorageGateway
  - Client
  - Paginators

Client

class StorageGateway.Client
A low-level client representing AWS Storage Gateway:

```python
import boto3

client = boto3.client('storagegateway')
```

These are the available methods:

- activate_gateway()
- add_cache()
- add_tags_to_resource()
- add_upload_buffer()
- add_working_storage()
- can_paginate()
- cancel_archival()
- cancel_retrieval()
- create_cached_iscsi_volume()
- create_snapshot()
- create_snapshot_from_volume_recovery_point()
- create_stored_iscsi_volume()
- create_tapes()
- delete_bandwidth_rate_limit()
- delete_chap_credentials()
- delete_gateway()
- delete_snapshot_schedule()
- delete_tape()
- delete_tape_archive()
- delete_volume()
- describe_bandwidth_rate_limit()
- describe_cache()
- describe_cached_iscsi_volumes()
- describe_chap_credentials()
- describe_gateway_information()
- describe_maintenance_start_time()
- describe_snapshot_schedule()
activate_gateway(**kwargs)

This operation activates the gateway you previously deployed on your host. For more information, see Activate the AWS Storage Gateway. In the activation process, you specify information such as the region you want to use for storing snapshots, the time zone for scheduled snapshots, the gateway snapshot schedule window, an activation key, and a name for your gateway. The activation process also associates your gateway with your account; for more information, see UpdateGatewayInformation.

Note: You must turn on the gateway VM before you can activate your gateway.

Request Syntax

```python
response = client.activate_gateway(
    ActivationKey='string',
    GatewayName='string',
    GatewayTimezone='string',
    GatewayRegion='string',
    GatewayType='string',
    TapeDriveType='string',
    MediumChangerType='string'
)
```

Parameters

- **ActivationKey (string)** – [REQUIRED]

  Your gateway activation key. You can obtain the activation key by sending an
HTTP GET request with redirects enabled to the gateway IP address (port 80). The redirect URL returned in the response provides you the activation key for your gateway in the query string parameter `activationKey`. It may also include other activation-related parameters, however, these are merely defaults – the arguments you pass to the `ActivateGateway` API call determine the actual configuration of your gateway.

- **GatewayName** *(string)* – [REQUIRED]
  A unique identifier for your gateway. This name becomes part of the gateway Amazon Resources Name (ARN) which is what you use as an input to other operations.

- **GatewayTimezone** *(string)* – [REQUIRED]
  One of the values that indicates the time zone you want to set for the gateway. The time zone is used, for example, for scheduling snapshots and your gateway’s maintenance schedule.

- **GatewayRegion** *(string)* – [REQUIRED]
  One of the values that indicates the region where you want to store the snapshot backups. The gateway region specified must be the same region as the region in your `Host` header in the request. For more information about available regions and endpoints for AWS Storage Gateway, see Regions and Endpoints in the Amazon Web Services Glossary.

- **GatewayType** *(string)* – One of the values that defines the type of gateway to activate. The type specified is critical to all later functions of the gateway and cannot be changed after activation. The default value is STORED.

- **TapeDriveType** *(string)* – The value that indicates the type of tape drive to use for gateway-VTL. This field is optional.

  - Valid Values: “IBM-ULT3580-TD5”

- **MediumChangerType** *(string)* – The value that indicates the type of medium changer to use for gateway-VTL. This field is optional.

  - Valid Values: “STK-L700”, “AWS-Gateway-VTL”

**Return type** `dict`

**Returns**

**Response Syntax**

```
{
  'GatewayARN': 'string'
}
```

**Response Structure**

- *(dict)*

  AWS Storage Gateway returns the Amazon Resource Name (ARN) of the activated gateway. It is a string made of information such as your account, gateway name, and region. This ARN is used to reference the gateway in other API operations as well as resource-based authorization.

  - **GatewayARN** *(string)*

    The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
add_cache(**kwargs)

This operation configures one or more gateway local disks as cache for a cached-volume gateway. This operation is supported only for the gateway-cached volume architecture (see Storage Gateway Concepts).

In the request, you specify the gateway Amazon Resource Name (ARN) to which you want to add cache, and one or more disk IDs that you want to configure as cache.

Request Syntax

```python
response = client.add_cache(
    GatewayARN='string',
    DiskIds=[
        'string',
    ],
)
```

Parameters

- **GatewayARN** *(string) – [REQUIRED]*
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

- **DiskIds** *(list) – [REQUIRED]*
  - *(string) –

Return type  dict

Returns

Response Syntax

```python
{
    'GatewayARN': 'string'
}
```

Response Structure

- *(dict) –
  - **GatewayARN** *(string) –
    The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

add_tags_to_resource(**kwargs)

This operation adds one or more tags to the specified resource. You use tags to add metadata to resources, which you can use to categorize these resources. For example, you can categorize resources by purpose, owner, environment, or team. Each tag consists of a key and a value, which you define. You can add tags to the following AWS Storage Gateway resources:

- Storage gateways of all types
- Storage Volumes
- Virtual Tapes

You can create a maximum of 10 tags for each resource. Virtual tapes and storage volumes that are recovered to a new gateway maintain their tags.

Request Syntax

```python
response = client.add_tags_to_resource(
    ResourceARN='string',
    Tags=[
        {'Key': 'string',
```
Parameters

- **ResourceARN (string)** – [REQUIRED]
  
  The Amazon Resource Name (ARN) of the resource you want to add tags to.

- **Tags (list)** – [REQUIRED]
  
  The key-value pair that represents the tag you want to add to the resource. The value can be an empty string.

**Note:** Valid characters for key and value are letters, spaces, and numbers representable in UTF-8 format, and the following special characters: + - = . _ : / @.

- (dict) –
  
  - **Key (string)** – [REQUIRED]
  - **Value (string)** – [REQUIRED]

Return type: dict

Returns

**Response Syntax**

```python
{
 'ResourceARN': 'string'
}
```

**Response Structure**

- (dict) –

  - AddTagsToResourceOutput
    
    - **ResourceARN (string)** –
      
      The Amazon Resource Name (ARN) of the resource you want to add tags to.

```
add_upload_buffer (**kwargs)**

This operation configures one or more gateway local disks as upload buffer for a specified gateway. This operation is supported for both the gateway-stored and gateway-cached volume architectures.

In the request, you specify the gateway Amazon Resource Name (ARN) to which you want to add upload buffer, and one or more disk IDs that you want to configure as upload buffer.

**Request Syntax**

```python
response = client.add_upload_buffer(
    GatewayARN='string',
    DiskIds=[
        'string',
    ]
)
```

**Parameters**

- **GatewayARN (string)** – [REQUIRED]
add_working_storage (**kwargs)

This operation configures one or more gateway local disks as working storage for a gateway. This operation is supported only for the gateway-stored volume architecture. This operation is deprecated method in cached-volumes API version (20120630). Use AddUploadBuffer instead.

**Note:** Working storage is also referred to as upload buffer. You can also use the AddUploadBuffer operation to add upload buffer to a stored-volume gateway.

In the request, you specify the gateway Amazon Resource Name (ARN) to which you want to add working storage, and one or more disk IDs that you want to configure as working storage.

**Request Syntax**

```python
response = client.add_working_storage(
    GatewayARN='string',
    DiskIds=[
        'string',
    ]
)
```

**Parameters**

- **GatewayARN (string) – [REQUIRED]**
  
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

- **DiskIds (list) – [REQUIRED]**
  
  An array of strings that identify disks that are to be configured as working storage. Each string have a minimum length of 1 and maximum length of 300. You can get the disk IDs from the ListLocalDisks API.
```python
{
    'GatewayARN': 'string'
}

**Response Structure**

- *(dict)* –
  - A JSON object containing the of the gateway for which working storage was configured.
    - **GatewayARN (string)** –
      - The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

**can_paginate (operation_name)**

Check if an operation can be paginated.

- **Parameters**
  - operation_name *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you'd normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

- **Returns**
  - True if the operation can be paginated, False otherwise.

**cancel_archival (**kwargs**)**

Cancels archiving of a virtual tape to the virtual tape shelf (VTS) after the archiving process is initiated.

- **Request Syntax**

  ```python
  response = client.cancel_archival(
      GatewayARN='string',
      TapeARN='string'
  )
  ```

- **Parameters**
  - **GatewayARN (string)** – [REQUIRED]
    - The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
  - **TapeARN (string)** – [REQUIRED]
    - The Amazon Resource Name (ARN) of the virtual tape you want to cancel archiving for.

- **Return type**
  - `dict`

- **Returns**

  - **Response Syntax**

    ```python
    {
        'TapeARN': 'string'
    }
    ```

  - **Response Structure**

    - *(dict)* –
      - CancelArchivalOutput
        - **TapeARN (string)** –
          - The Amazon Resource Name (ARN) of the virtual tape for which archiving was canceled.
```
cancel_retrieval(**kwargs)
Cancels retrieval of a virtual tape from the virtual tape shelf (VTS) to a gateway after the retrieval process is initiated. The virtual tape is returned to the VTS.

Request Syntax

```python
response = client.cancel_retrieval(
    GatewayARN='string',
    TapeARN='string'
)
```

Parameters
- **GatewayARN (string)** – [REQUIRED]
The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
- **TapeARN (string)** – [REQUIRED]
The Amazon Resource Name (ARN) of the virtual tape you want to cancel retrieval for.

Return type dict

Returns

Response Syntax

```python
{
    'TapeARN': 'string'
}
```

Response Structure
- (dict) –
  - CancelRetrievalOutput
    - **TapeARN (string)** –
      The Amazon Resource Name (ARN) of the virtual tape for which retrieval was canceled.

create_cached_iscsi_volume(**kwargs)
This operation creates a cached volume on a specified cached gateway. This operation is supported only for the gateway-cached volume architecture.

**Note:** Cache storage must be allocated to the gateway before you can create a cached volume. Use the AddCache operation to add cache storage to a gateway.

In the request, you must specify the gateway, size of the volume in bytes, the iSCSI target name, an IP address on which to expose the target, and a unique client token. In response, AWS Storage Gateway creates the volume and returns information about it such as the volume Amazon Resource Name (ARN), its size, and the iSCSI target ARN that initiators can use to connect to the volume target.

Request Syntax

```python
response = client.create_cached_iscsi_volume(
    GatewayARN='string',
    VolumeSizeInBytes=123,
    SnapshotId='string',
    TargetName='string',
    NetworkInterfaceId='string',
```
ClientToken='string'
)

Parameters

- **GatewayARN** *(string)* – [REQUIRED]
  
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
- **VolumeSizeInBytes** *(integer)* – [REQUIRED]
- **SnapshotId** *(string)* –
- **TargetName** *(string)* – [REQUIRED]
- **NetworkInterfaceId** *(string)* – [REQUIRED]
- **ClientToken** *(string)* – [REQUIRED]

Return type  **dict**

Returns

Response Syntax

```
{
    'VolumeARN': 'string',
    'TargetARN': 'string'
}
```

Response Structure

- *(dict)* –
  - **VolumeARN** *(string)* –
  - **TargetARN** *(string)* –

create_snapshot (**kwargs**)

This operation initiates a snapshot of a volume.

AWS Storage Gateway provides the ability to back up point-in-time snapshots of your data to Amazon Simple Storage (S3) for durable off-site recovery, as well as import the data to an Amazon Elastic Block Store (EBS) volume in Amazon Elastic Compute Cloud (EC2). You can take snapshots of your gateway volume on a scheduled or ad-hoc basis. This API enables you to take ad-hoc snapshot. For more information, see Working With Snapshots in the AWS Storage Gateway Console.

In the CreateSnapshot request you identify the volume by providing its Amazon Resource Name (ARN). You must also provide description for the snapshot. When AWS Storage Gateway takes the snapshot of specified volume, the snapshot and description appears in the AWS Storage Gateway Console. In response, AWS Storage Gateway returns you a snapshot ID. You can use this snapshot ID to check the snapshot progress or later use it when you want to create a volume from a snapshot.

**Note:** To list or delete a snapshot, you must use the Amazon EC2 API. For more information, see DescribeSnapshots or DeleteSnapshot in the EC2 API reference.

Request Syntax

```
response = client.create_snapshot(
    VolumeARN='string',
    SnapshotDescription='string'
)
```

Parameters

- **VolumeARN** *(string)* – [REQUIRED]

  The Amazon Resource Name (ARN) of the volume. Use the ListVolumes operation to return a list of gateway volumes.
• **SnapshotDescription** *(string)* – [REQUIRED]

  Textual description of the snapshot that appears in the Amazon EC2 console, Elastic Block Store snapshots panel in the **Description** field, and in the AWS Storage Gateway snapshot **Details** pane, **Description** field

Return type: `dict`

**Returns**

**Response Syntax**

```
{
  'VolumeARN': 'string',
  'SnapshotId': 'string'
}
```

**Response Structure**

• *(dict)* –

  A JSON object containing the following fields:
  
  – **VolumeARN** *(string)* –
    
    The Amazon Resource Name (ARN) of the volume of which the snapshot was taken.
  
  – **SnapshotId** *(string)* –
    
    The snapshot ID that is used to refer to the snapshot in future operations such as describing snapshots (Amazon Elastic Compute Cloud API **DescribeSnapshots**) or creating a volume from a snapshot (Create-StorediSCSIVolume).

**create_snapshot_from_volume_recovery_point(** **kwargs**)**

This operation initiates a snapshot of a gateway from a volume recovery point. This operation is supported only for the gateway-cached volume architecture (see ).

A volume recovery point is a point in time at which all data of the volume is consistent and from which you can create a snapshot. To get a list of volume recovery point for gateway-cached volumes, use ListVolumeRecoveryPoints.

In the CreateSnapshotFromVolumeRecoveryPoint request, you identify the volume by providing its Amazon Resource Name (ARN). You must also provide a description for the snapshot. When AWS Storage Gateway takes a snapshot of the specified volume, the snapshot and its description appear in the AWS Storage Gateway console. In response, AWS Storage Gateway returns you a snapshot ID. You can use this snapshot ID to check the snapshot progress or later use it when you want to create a volume from a snapshot.

**Note:** To list or delete a snapshot, you must use the Amazon EC2 API. For more information, in *Amazon Elastic Compute Cloud API Reference*.

**Request Syntax**

```
response = client.create_snapshot_from_volume_recovery_point(
    VolumeARN='string',
    SnapshotDescription='string'
)
```

**Parameters**

• **VolumeARN** *(string)* – [REQUIRED]

• **SnapshotDescription** *(string)* – [REQUIRED]

Return type: `dict`
Returns

Response Syntax

```python
{
    'SnapshotId': 'string',
    'VolumeARN': 'string',
    'VolumeRecoveryPointTime': 'string'
}
```

Response Structure

- `(dict)` –
  - **SnapshotId** *(string)* –
  - **VolumeARN** *(string)* –
  - **VolumeRecoveryPointTime** *(string)* –

create_stored_iscsi_volume(**kwargs)

This operation creates a volume on a specified gateway. This operation is supported only for the gateway-stored volume architecture.

The size of the volume to create is inferred from the disk size. You can choose to preserve existing data on the disk, create volume from an existing snapshot, or create an empty volume. If you choose to create an empty gateway volume, then any existing data on the disk is erased.

In the request you must specify the gateway and the disk information on which you are creating the volume. In response, AWS Storage Gateway creates the volume and returns volume information such as the volume Amazon Resource Name (ARN), its size, and the iSCSI target ARN that initiators can use to connect to the volume target.

Request Syntax

```python
response = client.create_stored_iscsi_volume(
    GatewayARN='string',
    DiskId='string',
    SnapshotId='string',
    PreserveExistingData=True|False,
    TargetName='string',
    NetworkInterfaceId='string'
)
```

Parameters

- **GatewayARN** *(string)* – [REQUIRED]
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

- **DiskId** *(string)* – [REQUIRED]
  The unique identifier for the gateway local disk that is configured as a stored volume. Use ListLocalDisks to list disk IDs for a gateway.

- **SnapshotId** *(string)* – The snapshot ID (e.g. “snap-1122aabb”) of the snapshot to restore as the new stored volume. Specify this field if you want to create the iSCSI storage volume from a snapshot otherwise do not include this field. To list snapshots for your account use DescribeSnapshots in the Amazon Elastic Compute Cloud API Reference.

- **PreserveExistingData** *(boolean)* – [REQUIRED]
  Specify this field as true if you want to preserve the data on the local disk. Otherwise, specifying this field as false creates an empty volume.

  *Valid Values*: true, false
• **TargetName** *(string)* – [REQUIRED]

The name of the iSCSI target used by initiators to connect to the target and as a suffix for the target ARN. For example, specifying `TargetName` as `myvolume` results in the target ARN of `arn:aws:storagegateway:us-east-1:111122223333:gateway/mygateway/target/iqn.1997-05.com.amazon:myvolume`. The target name must be unique across all volumes of a gateway.

• **NetworkInterfaceId** *(string)* – [REQUIRED]

The network interface of the gateway on which to expose the iSCSI target. Only IPv4 addresses are accepted. Use `DescribeGatewayInformation` to get a list of the network interfaces available on a gateway.

**Valid Values** : A valid IP address.

**Return type**  
`dict`

**Returns**

**Response Syntax**

```python
{
    'VolumeARN': 'string',
    'VolumeSizeInBytes': 123,
    'TargetARN': 'string'
}
```

**Response Structure**

- *(dict)* –

  A JSON object containing the following fields:
  - **VolumeARN** *(string)* –
    
    The Amazon Resource Name (ARN) of the configured volume.
  - **VolumeSizeInBytes** *(integer)* –
    
    The size of the volume in bytes.
  - **TargetARN** *(string)* –
    
    The Amazon Resource Name (ARN) of the volume target that includes the iSCSI name that initiators can use to connect to the target.

**create_tapes(**kwargs**)**

Creates one or more virtual tapes. You write data to the virtual tapes and then archive the tapes.

**Note:** Cache storage must be allocated to the gateway before you can create virtual tapes. Use the AddCache operation to add cache storage to a gateway.

**Request Syntax**

```python
response = client.create_tapes(
    GatewayARN='string',
    TapeSizeInBytes=123,
    ClientToken='string',
    NumTapesToCreate=123,
    TapeBarcodePrefix='string'
)
```

**Parameters**
• **GatewayARN** *(string)* – [REQUIRED]

  The unique Amazon Resource Name (ARN) that represents the gateway to associate the virtual tapes with. Use the ListGateways operation to return a list of gateways for your account and region.

• **TapeSizeInBytes** *(integer)* – [REQUIRED]

  The size, in bytes, of the virtual tapes you want to create.

  **Note:** The size must be gigabyte (1024*1024*1024 byte) aligned.

• **ClientToken** *(string)* – [REQUIRED]

  A unique identifier that you use to retry a request. If you retry a request, use the same `ClientToken` you specified in the initial request.

  **Note:** Using the same `ClientToken` prevents creating the tape multiple times.

• **NumTapesToCreate** *(integer)* – [REQUIRED]

  The number of virtual tapes you want to create.

• **TapeBarcodePrefix** *(string)* – [REQUIRED]

  A prefix you append to the barcode of the virtual tape you are creating. This makes a barcode unique.

  **Note:** The prefix must be 1 to 4 characters in length and must be upper-case letters A-Z.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'TapeARNs': [
        'string',
    ]
}
```

**Response Structure**

• *(dict)* –

  CreateTapeOutput

    - **TapeARNs** *(list)* –

      A list of unique Amazon Resource Named (ARN) that represents the virtual tapes that were created.

      * *(string)* –

**delete_bandwidth_rate_limit**(**kwargs**)

This operation deletes the bandwidth rate limits of a gateway. You can delete either the upload and download bandwidth rate limit, or you can delete both. If you delete only one of the limits, the other limit remains unchanged. To specify which gateway to work with, use the Amazon Resource Name (ARN) of the gateway in your request.

**Request Syntax**
response = client.delete_bandwidth_rate_limit(
    GatewayARN='string',
    BandwidthType='string'
)

Parameters

- **GatewayARN** (string) – [REQUIRED]
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

- **BandwidthType** (string) – [REQUIRED]

Return type  dict
Returns

Response Syntax

```
{
    'GatewayARN': 'string'
}
```

Response Structure

- (dict) –
  A JSON object containing the of the gateway whose bandwidth rate information was deleted.
  - **GatewayARN** (string) –
    The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

**delete_chap_credentials(**kwargs)**

This operation deletes Challenge-Handshake Authentication Protocol (CHAP) credentials for a specified iSCSI target and initiator pair.

Request Syntax

response = client.delete_chap_credentials(
    TargetARN='string',
    InitiatorName='string'
)

Parameters

- **TargetARN** (string) – [REQUIRED]
  The Amazon Resource Name (ARN) of the iSCSI volume target. Use the DescribeStoredProcedureVolumes operation to return to retrieve the TargetARN for specified VolumeARN.

- **InitiatorName** (string) – [REQUIRED]
  The iSCSI initiator that connects to the target.

Return type  dict
Returns

Response Syntax

```
{
    'TargetARN': 'string',
    'InitiatorName': 'string'
}
```
Response Structure

- (dict) –
  A JSON object containing the following fields:
  - TargetARN (string) –
    The Amazon Resource Name (ARN) of the target.
  - InitiatorName (string) –
    The iSCSI initiator that connects to the target.

**delete_gateway** (**kwargs**)
This operation deletes a gateway. To specify which gateway to delete, use the Amazon Resource Name (ARN) of the gateway in your request. The operation deletes the gateway; however, it does not delete the gateway virtual machine (VM) from your host computer.

After you delete a gateway, you cannot reactivate it. Completed snapshots of the gateway volumes are not deleted upon deleting the gateway, however, pending snapshots will not complete. After you delete a gateway, your next step is to remove it from your environment.

**Warning:** You no longer pay software charges after the gateway is deleted; however, your existing Amazon EBS snapshots persist and you will continue to be billed for these snapshots. You can choose to remove all remaining Amazon EBS snapshots by canceling your Amazon EC2 subscription. If you prefer not to cancel your Amazon EC2 subscription, you can delete your snapshots using the Amazon EC2 console. For more information, see the AWS Storage Gateway Detail Page.

Request Syntax

```python
response = client.delete_gateway(
    GatewayARN='string'
)
```

**Parameters**

- **GatewayARN (string)** – [REQUIRED]
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

**Return type**

dict

**Returns**

**Response Syntax**

```python
{
    'GatewayARN': 'string'
}
```

**Response Structure**

- (dict) –
  A JSON object containing the id of the deleted gateway.
  - GatewayARN (string) –
    The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

**delete_snapshot_schedule** (**kwargs**)
This operation deletes a snapshot of a volume.

You can take snapshots of your gateway volumes on a scheduled or ad-hoc basis. This API enables you to delete a snapshot schedule for a volume. For more information, see Working with Snapshots.
In the `DeleteSnapshotSchedule` request, you identify the volume by providing its Amazon Resource Name (ARN).

**Note:** To list or delete a snapshot, you must use the Amazon EC2 API. See *Amazon Elastic Compute Cloud API Reference*.

### Request Syntax

```python
response = client.delete_snapshot_schedule(
    VolumeARN='string'
)
```

**Parameters**

- **VolumeARN** *(string)* – [REQUIRED]

**Return type**

dict

**Returns**

**Response Syntax**

```python
{  
    'VolumeARN': 'string'
}
```

**Response Structure**

- *(dict)* –
  - VolumeARN *(string)* –

### delete_tape(**kwargs)**

Deletes the specified virtual tape.

**Request Syntax**

```python
response = client.delete_tape(
    GatewayARN='string',
    TapeARN='string'
)
```

**Parameters**

- **GatewayARN** *(string)* – [REQUIRED]
  The unique Amazon Resource Name (ARN) of the gateway that the virtual tape to delete is associated with. Use the `ListGateways` operation to return a list of gateways for your account and region.

- **TapeARN** *(string)* – [REQUIRED]
  The Amazon Resource Name (ARN) of the virtual tape to delete.

**Return type**

dict

**Returns**

**Response Syntax**

```python
{  
    'TapeARN': 'string'
}
```

**Response Structure**

- *(dict)* –
  - DeleteTapeOutput
delete_tape_archive(**kwargs)

Deletes the specified virtual tape from the virtual tape shelf (VTS).

**Request Syntax**

```python
response = client.delete_tape_archive(
    TapeARN='string'
)
```

**Parameters**

- **TapeARN (string)** – [REQUIRED]
  
  The Amazon Resource Name (ARN) of the virtual tape to delete from the virtual tape shelf (VTS).

**Return type**

- dict

**Returns**

**Response Syntax**

```python
{
    'TapeARN': 'string'
}
```

**Response Structure**

- (dict) –
  
  DeleteTapeArchiveOutput

  - **TapeARN (string)** –
  
    The Amazon Resource Name (ARN) of the virtual tape that was deleted from the virtual tape shelf (VTS).

delete_volume(**kwargs)**

This operation deletes the specified gateway volume that you previously created using the Create-CachediSCSIVolume or CreateStorediSCSIVolume API. For gateway-stored volumes, the local disk that was configured as the storage volume is not deleted. You can reuse the local disk to create another storage volume.

Before you delete a gateway volume, make sure there are no iSCSI connections to the volume you are deleting. You should also make sure there is no snapshot in progress. You can use the Amazon Elastic Compute Cloud (Amazon EC2) API to query snapshots on the volume you are deleting and check the snapshot status. For more information, go to DescribeSnapshots in the Amazon Elastic Compute Cloud API Reference.

In the request, you must provide the Amazon Resource Name (ARN) of the storage volume you want to delete.

**Request Syntax**

```python
response = client.delete_volume(
    VolumeARN='string'
)
```

**Parameters**

- **VolumeARN (string)** – [REQUIRED]
  
  The Amazon Resource Name (ARN) of the volume. Use the ListVolumes operation to return a list of gateway volumes.

**Return type**

- dict
Returns

Response Syntax

```json
{
   'VolumeARN': 'string'
}
```

Response Structure

- (dict) –

A JSON object containing the of the storage volume that was deleted

- **VolumeARN** *(string)* –

The Amazon Resource Name (ARN) of the storage volume that was deleted. It is the same ARN you provided in the request.

describe_bandwidth_rate_limit(**kwargs)**

This operation returns the bandwidth rate limits of a gateway. By default, these limits are not set, which means no bandwidth rate limiting is in effect.

This operation only returns a value for a bandwidth rate limit only if the limit is set. If no limits are set for the gateway, then this operation returns only the gateway ARN in the response body. To specify which gateway to describe, use the Amazon Resource Name (ARN) of the gateway in your request.

Request Syntax

```python
response = client.describe_bandwidth_rate_limit(
    GatewayARN='string'
)
```

Parameters

- **GatewayARN** *(string)* – [REQUIRED]

  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

Return type
dict

Returns

Response Syntax

```json
{
   'GatewayARN': 'string',
   'AverageUploadRateLimitInBitsPerSec': 123,
   'AverageDownloadRateLimitInBitsPerSec': 123
}
```

Response Structure

- (dict) –

A JSON object containing the following fields:

- **GatewayARN** *(string)* –

  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

- **AverageUploadRateLimitInBitsPerSec** *(integer)* –

  The average upload bandwidth rate limit in bits per second. This field does not appear in the response if the upload rate limit is not set.
AverageDownloadRateLimitInBitsPerSec (integer)

The average download bandwidth rate limit in bits per second. This field does not appear in the response if the download rate limit is not set.

describe_cache(**kwargs)

This operation returns information about the cache of a gateway. This operation is supported only for the gateway-cached volume architecture.

The response includes disk IDs that are configured as cache, and it includes the amount of cache allocated and used.

Request Syntax

```python
response = client.describe_cache(
    GatewayARN='string'
)
```

Parameters

**GatewayARN** (string) – [REQUIRED]

The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

Return type

dict

Returns

Response Syntax

```json
{
    'GatewayARN': 'string',
    'DiskIds': [
        'string',
    ],
    'CacheAllocatedInBytes': 123,
    'CacheUsedPercentage': 123.0,
    'CacheDirtyPercentage': 123.0,
    'CacheHitPercentage': 123.0,
    'CacheMissPercentage': 123.0
}
```

Response Structure

- (dict) –
  - **GatewayARN** (string) –
    The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
  - **DiskIds** (list) –
    * (string) –
    - **CacheAllocatedInBytes** (integer) –
    - **CacheUsedPercentage** (float) –
    - **CacheDirtyPercentage** (float) –
    - **CacheHitPercentage** (float) –
    - **CacheMissPercentage** (float) –

describe_cached_iscsi_volumes(**kwargs)

This operation returns a description of the gateway volumes specified in the request. This operation is supported only for the gateway-cached volume architecture.

The list of gateway volumes in the request must be from one gateway. In the response Amazon Storage Gateway returns volume information sorted by volume Amazon Resource Name (ARN).
Request Syntax

```python
response = client.describe_cached_iscsi_volumes(
    VolumeARNs=[
        'string',
    ]
)
```

Parameters

* **VolumeARNs** *(list) – [REQUIRED]*)
  * *(string) –

Return type  

dict

Returns

Response Syntax

```json
{
    'CachediSCSIVolumes': [
        {
            'VolumeARN': 'string',
            'VolumeId': 'string',
            'VolumeType': 'string',
            'VolumeStatus': 'string',
            'VolumeSizeInBytes': 123,
            'VolumeProgress': 123.0,
            'SourceSnapshotId': 'string',
            'VolumeiSCSIAttributes': {
                'TargetARN': 'string',
                'NetworkInterfaceId': 'string',
                'NetworkInterfacePort': 123,
                'LunNumber': 123,
                'ChapEnabled': True|False
            }
        },
    ]
}
```

Response Structure

* *(dict) –

A JSON object containing the following fields:

- **CachediSCSIVolumes** *(list) –

  An array of objects where each object contains metadata about one cached volume.

  * *(dict) –

    - **VolumeARN** *(string) –
    - **VolumeId** *(string) –
    - **VolumeType** *(string) –
    - **VolumeStatus** *(string) –
    - **VolumeSizeInBytes** *(integer) –
    - **VolumeProgress** *(float) –
    - **SourceSnapshotId** *(string) –
    - **VolumeiSCSIAttributes** *(dict) –

      Lists iSCSI information about a volume.

    - **TargetARN** *(string) –

      The Amazon Resource Name (ARN) of the volume target.
- **NetworkInterfaceId** *(string)* – The network interface identifier.
- **NetworkInterfacePort** *(integer)* – The port used to communicate with iSCSI targets.
- **LunNumber** *(integer)* – The logical disk number.
- **ChapEnabled** *(boolean)* – Indicates whether mutual CHAP is enabled for the iSCSI target.

### describe_chap_credentials(**kwargs)**

This operation returns an array of Challenge-Handshake Authentication Protocol (CHAP) credentials information for a specified iSCSI target, one for each target-initiator pair.

**Request Syntax**

```python
response = client.describe_chap_credentials(
    TargetARN='string'
)
```

**Parameters**

- **TargetARN** *(string)* – [REQUIRED]
  - The Amazon Resource Name (ARN) of the iSCSI volume target. Use the DescribeStorediSCSIVolumes operation to return to retrieve the TargetARN for specified VolumeARN.

**Return type**

dict

**Returns**

**Response Syntax**

```python
{
    'ChapCredentials': [
        {
            'TargetARN': 'string',
            'SecretToAuthenticateInitiator': 'string',
            'InitiatorName': 'string',
            'SecretToAuthenticateTarget': 'string'
        },
    ]
}
```

**Response Structure**

- *(dict)* – A JSON object containing a:
  - **ChapCredentials** *(list)* – An array of ChapInfo objects that represent CHAP credentials. Each object in the array contains CHAP credential information for one target-initiator pair. If no CHAP credentials are set, an empty array is returned. CHAP credential information is provided in a JSON object with the following fields:
    - **InitiatorName** : The iSCSI initiator that connects to the target.
    - **SecretToAuthenticateInitiator** : The secret key that the initiator (for example, the Windows client) must provide to participate in mutual CHAP with the target.
**SecretToAuthenticateTarget** : The secret key that the target must provide to participate in mutual CHAP with the initiator (e.g. Windows client).

**TargetARN** : The Amazon Resource Name (ARN) of the storage volume.

**(dict)** –

Describes Challenge-Handshake Authentication Protocol (CHAP) information that supports authentication between your gateway and iSCSI initiators.

- **TargetARN** *(string)* –
  The Amazon Resource Name (ARN) of the volume.

  *Valid Values: 50 to 500 lowercase letters, numbers, periods (.), and hyphens (-).*

- **SecretToAuthenticateInitiator** *(string)* –
  The secret key that the initiator (for example, the Windows client) must provide to participate in mutual CHAP with the target.

- **InitiatorName** *(string)* –
  The iSCSI initiator that connects to the target.

- **SecretToAuthenticateTarget** *(string)* –
  The secret key that the target must provide to participate in mutual CHAP with the initiator (e.g. Windows client).

### describe_gateway_information(**kwargs)

This operation returns metadata about a gateway such as its name, network interfaces, configured time zone, and the state (whether the gateway is running or not). To specify which gateway to describe, use the Amazon Resource Name (ARN) of the gateway in your request.

**Request Syntax**

```python
response = client.describe_gateway_information(
    GatewayARN='string'
)
```

**Parameters** **GatewayARN** *(string)* – [REQUIRED]

The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'GatewayARN': 'string',
    'GatewayId': 'string',
    'GatewayName': 'string',
    'GatewayTimezone': 'string',
    'GatewayState': 'string',
    'GatewayNetworkInterfaces': [{
        'Ipv4Address': 'string',
        'MacAddress': 'string',

```
Response Structure

- (dict) –

A JSON object containing the following fields:

- **GatewayARN** (string) –
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

- **GatewayId** (string) –
  The gateway ID.

- **GatewayName** (string) –
  The gateway name.

- **GatewayTimezone** (string) –
  One of the values that indicates the time zone configured for the gateway.

- **GatewayState** (string) –
  One of the values that indicates the operating state of the gateway.

- **GatewayNetworkInterfaces** (list) –
  A NetworkInterface array that contains descriptions of the gateway network interfaces.

  * (dict) –

  Describes a gateway’s network interface.

  - **Ipv4Address** (string) –
    The Internet Protocol version 4 (IPv4) address of the interface.

  - **MacAddress** (string) –
    The Media Access Control (MAC) address of the interface.

  Note: This is currently unsupported and will not be returned in output.

  - **Ipv6Address** (string) –
    The Internet Protocol version 6 (IPv6) address of the interface. *Currently not supported*.

- **GatewayType** (string) –
  The type of the gateway.

- **NextUpdateAvailabilityDate** (string) –
  The date on which an update to the gateway is available. This date is in the time zone of the gateway. If the gateway is not available for an update this field is not returned in the response.

- **LastSoftwareUpdate** (string) –
The date on which the last software update was applied to the gateway. If the gateway has never been updated, this field does not return a value in the response.

describe_maintenance_start_time(**kwargs)
This operation returns your gateway’s weekly maintenance start time including the day and time of the week. Note that values are in terms of the gateway’s time zone.

Request Syntax

response = client.describe_maintenance_start_time(
    GatewayARN='string'
)

Parameters

GatewayARN (string) – [REQUIRED]

The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

Return type

dict

Returns

Response Syntax

{
    'GatewayARN': 'string',
    'HourOfDay': 123,
    'MinuteOfHour': 123,
    'DayOfWeek': 123,
    'Timezone': 'string'
}

Response Structure

• (dict) –
  – GatewayARN (string) –
    The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
  – HourOfDay (integer) –
  – MinuteOfHour (integer) –
  – DayOfWeek (integer) –
  – Timezone (string) –

describe_snapshot_schedule(**kwargs)
This operation describes the snapshot schedule for the specified gateway volume. The snapshot schedule information includes intervals at which snapshots are automatically initiated on the volume.

Request Syntax

response = client.describe_snapshot_schedule(
    VolumeARN='string'
)

Parameters

VolumeARN (string) – [REQUIRED]

The Amazon Resource Name (ARN) of the volume. Use the ListVolumes operation to return a list of gateway volumes.

Return type

dict
describe_stored_iscsi_volumes(**kwargs)

This operation returns the description of the gateway volumes specified in the request. The list of gateway volumes in the request must be from one gateway. In the response Amazon Storage Gateway returns volume information sorted by volume ARNs.

Request Syntax

response = client.describe_stored_iscsi_volumes(
    VolumeARNs=[
        'string',
    ]
)

Parameters

VolumeARNs (list) – [REQUIRED]

An array of strings where each string represents the Amazon Resource Name (ARN) of a stored volume. All of the specified stored volumes must from the same gateway. Use ListVolumes to get volume ARNs for a gateway.

Return type
dict

Returns

Response Syntax

{
    'VolumeARN': 'string',
    'VolumeId': 'string',
    'VolumeType': 'string',
    'VolumeStatus': 'string',
    'VolumeSizeInBytes': 123,
    'VolumeProgress': 123.0,
    'VolumeDiskId': 'string',
    'SourceSnapshotId': 'string',
    'PreservedExistingData': True|False,
    'VolumeiSCSIAttributes': {
        'TargetARN': 'string',
    }
}
Response Structure

- (dict) –
  - StorediSCSIVolumes (list) –
    * (dict) –
      - VolumeARN (string) –
      - VolumeId (string) –
      - VolumeType (string) –
      - VolumeStatus (string) –
      - VolumeSizeInBytes (integer) –
      - VolumeProgress (float) –
      - VolumeDiskId (string) –
      - SourceSnapshotId (string) –
      - PreservedExistingData (boolean) –
      - VolumeiSCSIAttributes (dict) –

Lists iSCSI information about a volume.

- TargetARN (string) –
  The Amazon Resource Name (ARN) of the volume target.

- NetworkInterfaceId (string) –
  The network interface identifier.

- NetworkInterfacePort (integer) –
  The port used to communicate with iSCSI targets.

- LunNumber (integer) –
  The logical disk number.

- ChapEnabled (boolean) –
  Indicates whether mutual CHAP is enabled for the iSCSI target.

describe_tape_archives(**kwargs)

Returns a description of specified virtual tapes in the virtual tape shelf (VTS).

If a specific TapeARN is not specified, AWS Storage Gateway returns a description of all virtual tapes found in the VTS associated with your account.

Request Syntax

```python
response = client.describe_tape_archives(
    TapeARNs=[
        'string',
    ],
    Marker='string',
    Limit=123
)
```

Parameters
• **TapeARNs** *(list)* – Specifies one or more unique Amazon Resource Names (ARNs) that represent the virtual tapes you want to describe.
  
  – *(string)* –

• **Marker** *(string)* – An opaque string that indicates the position at which to begin describing virtual tapes.

• **Limit** *(integer)* – Specifies that the number of virtual tapes described be limited to the specified number.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'TapeArchives': [  
        {
            'TapeARN': 'string',
            'TapeBarcode': 'string',
            'TapeSizeInBytes': 123,
            'CompletionTime': datetime(2015, 1, 1),
            'RetrievedTo': 'string',
            'TapeStatus': 'string'
        },
        
    ],
    'Marker': 'string'
}
```

**Response Structure**

• *(dict)* –

**DescribeTapeArchivesOutput**

• **TapeArchives** *(list)* –

  An array of virtual tape objects in the virtual tape shelf (VTS). The description includes the Amazon Resource Name(ARN) of the virtual tapes. The information returned includes the Amazon Resource Names (ARNs) of the tapes, size of the tapes, status of the tapes, progress of the description and tape barcode.

  * *(dict)* –

  Represents a virtual tape that is archived in the virtual tape shelf (VTS).

  • **TapeARN** *(string)* –

    The Amazon Resource Name (ARN) of an archived virtual tape.

  • **TapeBarcode** *(string)* –

    The barcode that identifies the archived virtual tape.

  • **TapeSizeInBytes** *(integer)* –

    The size, in bytes, of the archived virtual tape.

  • **CompletionTime** *(datetime)* –

    The time that the archiving of the virtual tape was completed.

    The string format of the completion time is in the ISO8601 extended YYYY-MM-DD’T’HH:MM:SS’Z’ format.

  • **RetrievedTo** *(string)* –
The Amazon Resource Name (ARN) of the gateway-VTL that the virtual tape is being retrieved to.

The virtual tape is retrieved from the virtual tape shelf (VTS).

- **TapeStatus** (string) –
  
  The current state of the archived virtual tape.

- **Marker** (string) –
  
  An opaque string that indicates the position at which the virtual tapes that were fetched for description ended. Use this marker in your next request to fetch the next set of virtual tapes in the virtual tape shelf (VTS). If there are no more virtual tapes to describe, this field does not appear in the response.

`describe_tape_recovery_points(**kwargs)`

Returns a list of virtual tape recovery points that are available for the specified gateway-VTL.

A recovery point is a point in time view of a virtual tape at which all the data on the virtual tape is consistent. If your gateway crashes, virtual tapes that have recovery points can be recovered to a new gateway.

**Request Syntax**

```python
response = client.describe_tape_recovery_points(
    GatewayARN='string',
    Marker='string',
    Limit=123
)
```

**Parameters**

- **GatewayARN** (string) – [REQUIRED]
  
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

- **Marker** (string) – An opaque string that indicates the position at which to begin describing the virtual tape recovery points.

- **Limit** (integer) – Specifies that the number of virtual tape recovery points that are described be limited to the specified number.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'GatewayARN': 'string',
    'TapeRecoveryPointInfos': [
        {
            'TapeARN': 'string',
            'TapeRecoveryPointTime': datetime(2015, 1, 1),
            'TapeSizeInBytes': 123,
            'TapeStatus': 'string'
        },
        {
            'TapeARN': 'string',
            'TapeRecoveryPointTime': datetime(2015, 1, 1),
            'TapeSizeInBytes': 123,
            'TapeStatus': 'string'
        },
    ],
    'Marker': 'string'
}
```

**Response Structure**
• *(dict)* –

**DescribeTapeRecoveryPointsOutput**

- **GatewayARN** *(string)* –
  
The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

- **TapeRecoveryPointInfos** *(list)* –
  
  An array of TapeRecoveryPointInfos that are available for the specified gateway.

  * *(dict)* –

  Describes a recovery point.

  - **TapeARN** *(string)* –
    
    The Amazon Resource Name (ARN) of the virtual tape.

  - **TapeRecoveryPointTime** *(datetime)* –
    
    The time when the point-in-time view of the virtual tape was replicated for later recovery.

    The string format of the tape recovery point time is in the ISO8601 extended YYYY-MM-DD'T'HH:MM:SS'Z' format.

  - **TapeSizeInBytes** *(integer)* –
    
    The size, in bytes, of the virtual tapes to recover.

  - **TapeStatus** *(string)* –

  - **Marker** *(string)* –

    An opaque string that indicates the position at which the virtual tape recovery points that were listed for description ended.

    Use this marker in your next request to list the next set of virtual tape recovery points in the list. If there are no more recovery points to describe, this field does not appear in the response.

**describe_tapes(**kwargs**)**

Returns a description of the specified Amazon Resource Name (ARN) of virtual tapes. If a **TapeARN** is not specified, returns a description of all virtual tapes associated with the specified gateway.

**Request Syntax**

```python
response = client.describe_tapes(
    GatewayARN='string',
    TapeARNs=[
        'string',
    ],
    Marker='string',
    Limit=123,
)
```

**Parameters**

- **GatewayARN** *(string) – [REQUIRED]*
  
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

- **TapeARNs** *(list) –* Specifies one or more unique Amazon Resource Names (ARNs) that represent the virtual tapes you want to describe. If this prame-
if not specified, AWS Storage Gateway returns a description of all virtual tapes associated with the specified gateway.

- \((string)\) –

- **Marker** *(string)* – A marker value, obtained in a previous call to \(\text{DescribeTapes}\). This marker indicates which page of results to retrieve.

If not specified, the first page of results is retrieved.

- **Limit** *(integer)* – Specifies that the number of virtual tapes described be limited to the specified number.

**Note:** Amazon Web Services may impose its own limit, if this field is not set.

**Return type** `dict`

**Returns**

**Response Syntax**

```
{
    'Tapes': [
        {
            'TapeARN': 'string',
            'TapeBarcode': 'string',
            'TapeSizeInBytes': 123,
            'TapeStatus': 'string',
            'VTLDevice': 'string',
            'Progress': 123.0
        },
    ],
    'Marker': 'string'
}
```

**Response Structure**

- *(dict)* –

  **DescribeTapesOutput**

  - **Tapes** *(list)* –

    An array of virtual tape descriptions.

    - *(dict)* –

      Describes a virtual tape object.

      - **TapeARN** *(string)* –

        The Amazon Resource Name (ARN) of the virtual tape.

      - **TapeBarcode** *(string)* –

        The barcode that identifies a specific virtual tape.

      - **TapeSizeInBytes** *(integer)* –

        The size, in bytes, of the virtual tape.

      - **TapeStatus** *(string)* –

        The current state of the virtual tape.

      - **VTLDevice** *(string)* –

        The virtual tape library (VTL) device that the virtual tape is associated with.

      - **Progress** *(float)* –

        For archiving virtual tapes, indicates how much data remains to be uploaded before archiving is complete.
Range: 0 (not started) to 100 (complete).

- **Marker (string)** –
  An opaque string which can be used as part of a subsequent DescribeTapes call to retrieve the next page of results.

  If a response does not contain a marker, then there are no more results to be retrieved.

describe_upload_buffer (**kwargs)

This operation returns information about the upload buffer of a gateway. This operation is supported for both the gateway-stored and gateway-cached volume architectures.

The response includes disk IDs that are configured as upload buffer space, and it includes the amount of upload buffer space allocated and used.

Request Syntax

```python
response = client.describe_upload_buffer(
    GatewayARN='string'
)
```

**Parameters**

- **GatewayARN (string)** – [REQUIRED]
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

**Return type**

dict

**Returns**

Response Syntax

```python
{
    'GatewayARN': 'string',
    'DiskIds': [
        'string',
    ],
    'UploadBufferUsedInBytes': 123,
    'UploadBufferAllocatedInBytes': 123
}
```

**Response Structure**

- (dict) –
  - **GatewayARN (string)** –
    The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
  - **DiskIds (list)** –
    - *(string)* –
  - **UploadBufferUsedInBytes (integer)** –
  - **UploadBufferAllocatedInBytes (integer)** –

describe_vtl_devices (**kwargs)

Returns a description of virtual tape library (VTL) devices for the specified gateway. In the response, AWS Storage Gateway returns VTL device information.

The list of VTL devices must be from one gateway.

Request Syntax
response = client.describe_vtl_devices(
    GatewayARN='string',
    VTLDeviceARNs=[
        'string',
    ],
    Marker='string',
    Limit=123
)

Parameters

- **GatewayARN** *(string)* – [REQUIRED]
  
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

- **VTLDeviceARNs** *(list)* – An array of strings, where each string represents the Amazon Resource Name (ARN) of a VTL device.

**Note:** All of the specified VTL devices must be from the same gateway. If no VTL devices are specified, the result will contain all devices on the specified gateway.

- **Marker** *(string)* – An opaque string that indicates the position at which to begin describing the VTL devices.

- **Limit** *(integer)* – Specifies that the number of VTL devices described be limited to the specified number.

Return type  dict

Returns

Response Syntax

```python
{
    'GatewayARN': 'string',
    'VTLDevices': [
        {
            'VTLDeviceARN': 'string',
            'VTLDeviceType': 'string',
            'VTLDeviceVendor': 'string',
            'VTLDeviceProductIdentifier': 'string',
            'DeviceiSCSIAttributes': {
                'TargetARN': 'string',
                'NetworkInterfaceId': 'string',
                'NetworkInterfacePort': 123,
                'ChapEnabled': True|False
            }
        },
    ],
    'Marker': 'string'
}
```

Response Structure

- *(dict)* –

  DescribeVTLDevicesOutput

  - **GatewayARN** *(string)* –

    The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
- **VTLDevices** *(list)* –
  An array of VTL device objects composed of the Amazon Resource Name(ARN) of the VTL devices.
  *

- **(dict)** –
  Represents a device object associated with a gateway-VTL.

  - **VTLDeviceARN** *(string)* –
    Specifies the unique Amazon Resource Name (ARN) of the device (tape drive or media changer).

  - **VTLDeviceType** *(string)* –
  
  - **VTLDeviceVendor** *(string)* –
  
  - **VTLDeviceProductIdentifier** *(string)* –
  
  - **DeviceiSCSIAttributes** *(dict)* –
    A list of iSCSI information about a VTL device.

  - **TargetARN** *(string)* –
    Specifies the unique Amazon Resource Name(ARN) that encodes the iSCSI qualified name(iqn) of a tape drive or media changer target.

  - **NetworkInterfaceId** *(string)* –
    The network interface identifier of the VTL device.

  - **NetworkInterfacePort** *(integer)* –
    The port used to communicate with iSCSI VTL device targets.

  - **ChapEnabled** *(boolean)* –
    Indicates whether mutual CHAP is enabled for the iSCSI target.

- **Marker** *(string)* –
  An opaque string that indicates the position at which the VTL devices that were fetched for description ended. Use the marker in your next request to fetch the next set of VTL devices in the list. If there are no more VTL devices to describe, this field does not appear in the response.

**describe_working_storage** (**kwargs)**

This operation returns information about the working storage of a gateway. This operation is supported only for the gateway-stored volume architecture. This operation is deprecated in cached-volumes API version (20120630). Use DescribeUploadBuffer instead.

**Note:** Working storage is also referred to as upload buffer. You can also use the DescribeUploadBuffer operation to add upload buffer to a stored-volume gateway.

The response includes disk IDs that are configured as working storage, and it includes the amount of working storage allocated and used.

**Request Syntax**

```python
response = client.describe_working_storage(
    GatewayARN='string'
)
```

**Parameters**  
**GatewayARN** *(string)* – [REQUIRED]

The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
Return type  dict

Returns

Response Syntax

{
    'GatewayARN': 'string',
    'DiskIds': [
        'string',
    ],
    'WorkingStorageUsedInBytes': 123,
    'WorkingStorageAllocatedInBytes': 123
}

Response Structure

- *(dict)* –

  A JSON object containing the following fields:

  - **GatewayARN** *(string)* –

    The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

  - **DiskIds** *(list)* –

    An array of the gateway’s local disk IDs that are configured as working storage. Each local disk ID is specified as a string (minimum length of 1 and maximum length of 300). If no local disks are configured as working storage, then the DiskIds array is empty.

    * *(string)* –

  - **WorkingStorageUsedInBytes** *(integer)* –

    The total working storage in bytes in use by the gateway. If no working storage is configured for the gateway, this field returns 0.

  - **WorkingStorageAllocatedInBytes** *(integer)* –

    The total working storage in bytes allocated for the gateway. If no working storage is configured for the gateway, this field returns 0.

disable_gateway(**kwargs)**

Disables a gateway when the gateway is no longer functioning. For example, if your gateway VM is damaged, you can disable the gateway so you can recover virtual tapes.

Use this operation for a gateway-VTL that is not reachable or not functioning.

**Warning:** Once a gateway is disabled it cannot be enabled.

Request Syntax

response = client.disable_gateway(
    GatewayARN='string'
)

Parameters  **GatewayARN** *(string)*  – [REQUIRED]

The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

Return type  dict
Returns

Response Syntax

```
{
    'GatewayARN': 'string'
}
```

Response Structure

- (dict) –
  - DisableGatewayOutput
    - **GatewayARN** (string) –
      The unique Amazon Resource Name of the disabled gateway.

`generate_presigned_url` *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

**Parameters**

- **ClientMethod** (string) – The client method to presign for
- **Params** (dict) – The parameters normally passed to `ClientMethod`
- **ExpiresIn** (int) – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** (string) – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns**

The presigned url

`get_paginator` *(operation_name)*

Create a paginator for an operation.

**Parameters**

- **operation_name** (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

**Raises**

- **OperationNotPageableError** Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

**Return type**

L{botocore.paginate.Paginator}

**Returns**

A paginator object.

`get_waiter` *(waiter_name)*

`list_gateways(**kwars)**

This operation lists gateways owned by an AWS account in a region specified in the request. The returned list is ordered by gateway Amazon Resource Name (ARN).

By default, the operation returns a maximum of 100 gateways. This operation supports pagination that allows you to optionally reduce the number of gateways returned in a response.

If you have more gateways than are returned in a response-that is, the response returns only a truncated list of your gateways-the response contains a marker that you can specify in your next request to fetch the next page of gateways.

**Request Syntax**

```
response = client.list_gateways(
    Marker='string',
    Limit=123
)
```

**Parameters**
- **Marker** *(string)* – An opaque string that indicates the position at which to begin the returned list of gateways.
- **Limit** *(integer)* – Specifies that the list of gateways returned be limited to the specified number of items.

**Return type**  `dict`
**Returns**

**Response Syntax**

```py
{
    'Gateways': [
        {
            'GatewayARN': 'string',
            'GatewayType': 'string',
            'GatewayOperationalState': 'string',
            'GatewayName': 'string'
        },
    ],
    'Marker': 'string'
}
```

**Response Structure**

- *(dict)* –
  - **Gateways** *(list)* –
    - *(dict)* –
      - **GatewayARN** *(string)* –
        The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
      - **GatewayType** *(string)* –
      - **GatewayOperationalState** *(string)* –
      - **GatewayName** *(string)* –
    - **Marker** *(string)* –

**list_local_disks** *(**kwargs**)*

This operation returns a list of the gateway’s local disks. To specify which gateway to describe, you use the Amazon Resource Name (ARN) of the gateway in the body of the request.

The request returns a list of all disks, specifying which are configured as working storage, cache storage, or stored volume or not configured at all. The response includes a `DiskStatus` field. This field can have a value of present (the disk is available to use), missing (the disk is no longer connected to the gateway), or mismatch (the disk node is occupied by a disk that has incorrect metadata or the disk content is corrupted).

**Request Syntax**

```py
response = client.list_local_disks(
    GatewayARN='string'
)
```

**Parameters**  
- **GatewayARN** *(string)* – [REQUIRED]
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

**Return type**  `dict`
**Returns**

**Response Syntax**
Response Structure

- (dict) –
  - **GatewayARN** *(string)* –
    The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
  - **Disks** *(list)* –
    * (dict) –
    - **DiskId** *(string)* –
    - **DiskPath** *(string)* –
    - **DiskNode** *(string)* –
    - **DiskStatus** *(string)* –
    - **DiskSizeInBytes** *(integer)* –
    - **DiskAllocationType** *(string)* –
    - **DiskAllocationResource** *(string)* –

`list_tags_for_resource(**kwargs)`
This operation lists the tags that have been added to the specified resource.

Request Syntax

```python
response = client.list_tags_for_resource(
    ResourceARN='string',
    Marker='string',
    Limit=123
)
```

Parameters

- **ResourceARN** *(string)* – The Amazon Resource Name (ARN) of the resource for which you want to list tags.
- **Marker** *(string)* – An opaque string that indicates the position at which to begin returning the list of tags.
- **Limit** *(integer)* – Specifies that the list of tags returned be limited to the specified number of items.

Return type  dict

Returns

Response Syntax

```python
{
    'ResourceARN': 'string',
    'Marker': 'string',
}
'Tags': [
  {'Key': 'string',
   'Value': 'string'},
],
}

Response Structure
- (dict) –
  ListTagsForResourceOutput
  - ResourceARN (string) –
    the Amazon Resource Name (ARN) of the resource for which you want to list tags.
  - Marker (string) –
    An opaque string that indicates the position at which to stop returning the list of tags.
  - Tags (list) –
    An array that contains the tags for the specified resource.
      - (dict) –
        · Key (string) –
        · Value (string) –

list_volume_initiators(**kwargs)
This operation lists iSCSI initiators that are connected to a volume. You can use this operation to determine whether a volume is being used or not.

Request Syntax
response = client.list_volume_initiators(
    VolumeARN='string'
)

Parameters
VolumeARN (string) – [REQUIRED]
The Amazon Resource Name (ARN) of the volume. Use the ListVolumes operation to return a list of gateway volumes for the gateway.

Return type dict
Returns

Response Syntax
{
  'Initiators': [
    'string',
  ]
}

Response Structure
- (dict) –
  ListVolumeInitiatorsOutput
  - Initiators (list) –
    The host names and port numbers of all iSCSI initiators that are connected to the gateway.
* (string) –

list_volume_recovery_points(**kwargs)
This operation lists the recovery points for a specified gateway. This operation is supported only for the
gateway-cached volume architecture.

Each gateway-cached volume has one recovery point. A volume recovery point is a point in time at which
all data of the volume is consistent and from which you can create a snapshot. To create a snapshot from
a volume recovery point use the CreateSnapshotFromVolumeRecoveryPoint operation.

Request Syntax

```
response = client.list_volume_recovery_points(
    GatewayARN='string'
)
```

Parameters  

- **GatewayARN (string)** – [REQUIRED]
The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation
to return a list of gateways for your account and region.

Return type  dict

Returns

Response Syntax

```
{
    'GatewayARN': 'string',
    'VolumeRecoveryPointInfos': [  
        {  
            'VolumeARN': 'string',
            'VolumeSizeInBytes': 123,
            'VolumeUsageInBytes': 123,
            'VolumeRecoveryPointTime': 'string'
        },
    ]
}
```

Response Structure

- *(dict)* –
  - **GatewayARN (string)** –
    The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
  - **VolumeRecoveryPointInfos (list)** –
    - *(dict)* –
      - **VolumeARN (string)** –
      - **VolumeSizeInBytes (integer)** –
      - **VolumeUsageInBytes (integer)** –
      - **VolumeRecoveryPointTime (string)** –

list_volumes(**kwargs)
This operation lists the iSCSI stored volumes of a gateway. Results are sorted by volume ARN. The
response includes only the volume ARNs. If you want additional volume information, use the De-
scribeStorediSCSIVolumes API.

The operation supports pagination. By default, the operation returns a maximum of up to 100 volumes.
You can optionally specify the Limit field in the body to limit the number of volumes in the response.
If the number of volumes returned in the response is truncated, the response includes a Marker field. You
can use this Marker value in your subsequent request to retrieve the next set of volumes.
Request Syntax

```python
response = client.list_volumes(
    GatewayARN='string',
    Marker='string',
    Limit=123
)
```

Parameters

- **GatewayARN (string)** – [REQUIRED]
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
- **Marker (string)** – A string that indicates the position at which to begin the returned list of volumes. Obtain the marker from the response of a previous List iSCSI Volumes request.
- **Limit (integer)** – Specifies that the list of volumes returned be limited to the specified number of items.

Return type  dict
Returns

Response Syntax

```python
{
    'GatewayARN': 'string',
    'Marker': 'string',
    'VolumeInfos': [
        {
            'VolumeARN': 'string',
            'VolumeType': 'string'
        }
    ]
}
```

Response Structure

- (dict) –
  - **GatewayARN (string)** –
    The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
  - **Marker (string)** –
  - **VolumeInfos (list)** –
    * (dict) –
    - **VolumeARN (string)** –
    - **VolumeType (string)** –

remove_tags_from_resource(**kwargs)
This operation removes one or more tags from the specified resource.

Request Syntax

```python
response = client.remove_tags_from_resource(
    ResourceARN='string',
    TagKeys=[
        'string',
    ]
)
```
Parameters

- **ResourceARN** *(string)* – The Amazon Resource Name (ARN) of the resource you want to remove the tags from.
- **TagKeys** *(list)* – The keys of the tags you want to remove from the specified resource. A tag is composed of a key/value pair.

Return type **dict**

Returns

Response Syntax

```python
{
    'ResourceARN': 'string'
}
```

Response Structure

- *(dict)* –

**RemoveTagsFromResourceOutput**

- **ResourceARN** *(string)* –

  The Amazon Resource Name (ARN) of the resource that the tags were removed from.

**reset_cache** *(**kwargs)*

This operation resets all cache disks that have encountered a error and makes the disks available for reconfiguration as cache storage. If your cache disk encounters a error, the gateway prevents read and write operations on virtual tapes in the gateway. For example, an error can occur when a disk is corrupted or removed from the gateway. When a cache is reset, the gateway loses its cache storage. At this point you can reconfigure the disks as cache disks.

**Warning:** If the cache disk you are resetting contains data that has not been uploaded to Amazon S3 yet, that data can be lost. After you reset cache disks, there will be no configured cache disks left in the gateway, so you must configure at least one new cache disk for your gateway to function properly.

Request Syntax

```python
response = client.reset_cache(
    GatewayARN='string'
)
```

**Parameters**

- **GatewayARN** *(string)* – [REQUIRED]

  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

Return type **dict**

Returns

Response Syntax

```python
{
    'GatewayARN': 'string'
}
```

Response Structure

- *(dict)* –
GatewayARN (string)

The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

retrieve_tape_archive (**kwargs)

Retrieves an archived virtual tape from the virtual tape shelf (VTS) to a gateway-VTL. Virtual tapes archived in the VTS are not associated with any gateway. However, after a tape is retrieved, it is associated with a gateway, even though it is also listed in the VTS.

Once a tape is successfully retrieved to a gateway, it cannot be retrieved again to another gateway. You must archive the tape again before you can retrieve it to another gateway.

Request Syntax

```python
response = client.retrieve_tape_archive(
    TapeARN='string',
    GatewayARN='string'
)
```

Parameters

- **TapeARN** (string) – [REQUIRED]
  
The Amazon Resource Name (ARN) of the virtual tape you want to retrieve from the virtual tape shelf (VTS).

- **GatewayARN** (string) – [REQUIRED]
  
The Amazon Resource Name (ARN) of the gateway you want to retrieve the virtual tape to. Use the ListGateways operation to return a list of gateways for your account and region.

You retrieve archived virtual tapes to only one gateway and the gateway must be a gateway-VTL.

Return type: dict

Returns

Response Syntax

```python
{
    'TapeARN': 'string'
}
```

Response Structure

- (dict) –
  
RetrieveTapeArchiveOutput
  
- **TapeARN** (string) –
    
The Amazon Resource Name (ARN) of the retrieved virtual tape.

retrieve_tape_recovery_point (**kwargs)

Retrieves the recovery point for the specified virtual tape.

A recovery point is a point in time view of a virtual tape at which all the data on the tape is consistent. If your gateway crashes, virtual tapes that have recovery points can be recovered to a new gateway.

**Note:** The virtual tape can be retrieved to only one gateway. The retrieved tape is read-only. The virtual tape can be retrieved to only a gateway-VTL. There is no charge for retrieving recovery points.

Request Syntax
response = client.retrieve_tape_recovery_point(
    TapeARN='string',
    GatewayARN='string'
)

Parameters

- **TapeARN** *(string)* – [REQUIRED]
  
  The Amazon Resource Name (ARN) of the virtual tape for which you want to retrieve the recovery point.

- **GatewayARN** *(string)* – [REQUIRED]
  
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

Return type  *dict*

Returns

Response Syntax

```
{
    'TapeARN': 'string'
}
```

Response Structure

- *(dict)* –

  RetrieveTapeRecoveryPointOutput
   
   - **TapeARN** *(string)* –
     
     The Amazon Resource Name (ARN) of the virtual tape for which the recovery point was retrieved.

**shutdown_gateway** (**kwargs**)

This operation shuts down a gateway. To specify which gateway to shut down, use the Amazon Resource Name (ARN) of the gateway in the body of your request.

The operation shuts down the gateway service component running in the storage gateway’s virtual machine (VM) and not the VM.

**Note:** If you want to shut down the VM, it is recommended that you first shut down the gateway component in the VM to avoid unpredictable conditions.

After the gateway is shutdown, you cannot call any other API except StartGateway, DescribeGatewayInformation, and ListGateways. For more information, see ActivateGateway. Your applications cannot read from or write to the gateway’s storage volumes, and there are no snapshots taken.

**Note:** When you make a shutdown request, you will get a 200 OK success response immediately. However, it might take some time for the gateway to shut down. You can call the DescribeGatewayInformation API to check the status. For more information, see ActivateGateway.

If do not intend to use the gateway again, you must delete the gateway (using DeleteGateway) to no longer pay software charges associated with the gateway.

Request Syntax

```
response = client.shutdown_gateway(
    GatewayARN='string'
)
```
Parameters GatewayARN (string) – [REQUIRED]

The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

Return type dict

Returns

Response Syntax

{
  'GatewayARN': 'string'
}

Response Structure

- (dict) –
  A JSON object containing the of the gateway that was shut down.
- GatewayARN (string) –
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

start_gateway (**kwargs)

This operation starts a gateway that you previously shut down (see ShutdownGateway). After the gateway starts, you can then make other API calls, your applications can read from or write to the gateway’s storage volumes and you will be able to take snapshot backups.

**Note:** When you make a request, you will get a 200 OK success response immediately. However, it might take some time for the gateway to be ready. You should call DescribeGatewayInformation and check the status before making any additional API calls. For more information, see ActivateGateway.

To specify which gateway to start, use the Amazon Resource Name (ARN) of the gateway in your request.

Request Syntax

response = client.start_gateway(
    GatewayARN='string'
)

Parameters GatewayARN (string) – [REQUIRED]

The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

Return type dict

Returns

Response Syntax

{
  'GatewayARN': 'string'
}

Response Structure

- (dict) –
  A JSON object containing the of the gateway that was restarted.
update_bandwidth_rate_limit(**kwargs)

This operation updates the bandwidth rate limits of a gateway. You can update both the upload and
download bandwidth rate limit or specify only one of the two. If you don’t set a bandwidth rate limit, the
existing rate limit remains.

By default, a gateway’s bandwidth rate limits are not set. If you don’t set any limit, the gateway does not
have any limitations on its bandwidth usage and could potentially use the maximum available bandwidth.

To specify which gateway to update, use the Amazon Resource Name (ARN) of the gateway in your
request.

Request Syntax

response = client.update_bandwidth_rate_limit(
    GatewayARN='string',
    AverageUploadRateLimitInBitsPerSec=123,
    AverageDownloadRateLimitInBitsPerSec=123
)

Parameters

- **GatewayARN (string)** – [REQUIRED]
  - The Amazon Resource Name (ARN) of the gateway. Use the ListGateways op-
    eration to return a list of gateways for your account and region.

- **AverageUploadRateLimitInBitsPerSec (integer)** – The average upload band-
  width rate limit in bits per second.

- **AverageDownloadRateLimitInBitsPerSec (integer)** – The average download
  bandwidth rate limit in bits per second.

Return type: dict

Returns

Response Syntax

```python
{
    'GatewayARN': 'string'
}
```

Response Structure

- (dict) –
  - A JSON object containing the of the gateway whose throttle information was
    updated.

- **GatewayARN (string)** –
  - The Amazon Resource Name (ARN) of the gateway. Use the ListGate-
    ways operation to return a list of gateways for your account and region.

update_chap_credentials(**kwargs)

This operation updates the Challenge-Handshake Authentication Protocol (CHAP) credentials for a spec-
ified iSCSI target. By default, a gateway does not have CHAP enabled; however, for added security, you
might use it.

**Warning:** When you update CHAP credentials, all existing connections on the target are closed and
initiators must reconnect with the new credentials.
Request Syntax

```python
response = client.update_chap_credentials(
    TargetARN='string',
    SecretToAuthenticateInitiator='string',
    InitiatorName='string',
    SecretToAuthenticateTarget='string'
)
```

Parameters

- **TargetARN** *(string)* – [REQUIRED]
  
  The Amazon Resource Name (ARN) of the iSCSI volume target. Use the DescribeStoredProcedure operation to return the TargetARN for specified VolumeARN.

- **SecretToAuthenticateInitiator** *(string)* – [REQUIRED]
  
  The secret key that the initiator (for example, the Windows client) must provide to participate in mutual CHAP with the target.

  **Note:** The secret key must be between 12 and 16 bytes when encoded in UTF-8.

- **InitiatorName** *(string)* – [REQUIRED]
  
  The iSCSI initiator that connects to the target.

- **SecretToAuthenticateTarget** *(string)* – The secret key that the target must provide to participate in mutual CHAP with the initiator (e.g. Windows client).

  **Note:** The secret key must be between 12 and 16 bytes when encoded in UTF-8.

Return type  **dict**

Returns

Response Syntax

```python
{
    'TargetARN': 'string',
    'InitiatorName': 'string'
}
```

Response Structure

- *(dict)* –

  A JSON object containing the following fields:

  - **TargetARN** *(string)* –

    The Amazon Resource Name (ARN) of the target. This is the same target specified in the request.

  - **InitiatorName** *(string)* –

    The iSCSI initiator that connects to the target. This is the same initiator name specified in the request.

**update_gateway_information(**

This operation updates a gateway’s metadata, which includes the gateway’s name and time zone. To specify which gateway to update, use the Amazon Resource Name (ARN) of the gateway in your request.

Request Syntax
response = client.update_gateway_information(
    GatewayARN='string',
    GatewayName='string',
    GatewayTimezone='string'
)

Parameters

- **GatewayARN (string)** – [REQUIRED]
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
- **GatewayName (string)** – A unique identifier for your gateway. This name becomes part of the gateway Amazon Resources Name (ARN) which is what you use as an input to other operations.
- **GatewayTimezone (string)** –

Return type  dict

Returns

Response Syntax

```python
{
    'GatewayARN': 'string',
    'GatewayName': 'string'
}
```

Response Structure

- **(dict)** –
  A JSON object containing the of the gateway that was updated.
  - **GatewayARN (string)** –
    The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
  - **GatewayName (string)** –

update_gateway_software_now(**kwargs)

This operation updates the gateway virtual machine (VM) software. The request immediately triggers the software update.

**Note:** When you make this request, you get a 200 OK success response immediately. However, it might take some time for the update to complete. You can call DescribeGatewayInformation to verify the gateway is in the STATE_RUNNING state.

**Warning:** A software update forces a system restart of your gateway. You can minimize the chance of any disruption to your applications by increasing your iSCSI Initiators’ timeouts. For more information about increasing iSCSI Initiator timeouts for Windows and Linux, see Customizing Your Windows iSCSI Settings and Customizing Your Linux iSCSI Settings, respectively.

Request Syntax

```python
response = client.update_gateway_software_now(
    GatewayARN='string'
)
```

Parameters  **GatewayARN (string)** – [REQUIRED]
The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

**Return type**: `dict`

**Returns**

**Response Syntax**

```python
{
    'GatewayARN': 'string'
}
```

**Response Structure**

- `(dict)` – A JSON object containing the of the gateway that was updated.
  - `GatewayARN (string)` – The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

---

**update_maintenance_start_time(**kwargs)**

This operation updates a gateway’s weekly maintenance start time information, including day and time of the week. The maintenance time is the time in your gateway’s time zone.

**Request Syntax**

```python
response = client.update_maintenance_start_time(
    GatewayARN='string',
    HourOfDay=123,
    MinuteOfHour=123,
    DayOfWeek=123
)
```

**Parameters**

- `GatewayARN (string)` – `[REQUIRED]`
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

- `HourOfDay (integer)` – `[REQUIRED]`
  The hour component of the maintenance start time represented as `hh`, where `hh` is the hour (00 to 23). The hour of the day is in the time zone of the gateway.

- `MinuteOfHour (integer)` – `[REQUIRED]`
  The minute component of the maintenance start time represented as `mm`, where `mm` is the minute (00 to 59). The minute of the hour is in the time zone of the gateway.

- `DayOfWeek (integer)` – `[REQUIRED]`
  The maintenance start time day of the week.

**Return type**: `dict`

**Returns**

**Response Syntax**

```python
{
    'GatewayARN': 'string'
}
```

**Response Structure**
update_snapshot_schedule (**kwargs)

This operation updates a snapshot schedule configured for a gateway volume. The default snapshot schedule for volume is once every 24 hours, starting at the creation time of the volume. You can use this API to change the snapshot schedule configured for the volume.

In the request you must identify the gateway volume whose snapshot schedule you want to update, and the schedule information, including when you want the snapshot to begin on a day and the frequency (in hours) of snapshots.

Request Syntax

```python
response = client.update_snapshot_schedule(
    VolumeARN='string',
    StartAt=123,
    RecurrenceInHours=123,
    Description='string'
)
```

Parameters

- **VolumeARN (string)** – [REQUIRED]
  
The Amazon Resource Name (ARN) of the volume. Use the ListVolumes operation to return a list of gateway volumes.

- **StartAt (integer)** – [REQUIRED]
  
The hour of the day at which the snapshot schedule begins represented as \(hh\), where \(hh\) is the hour (0 to 23). The hour of the day is in the time zone of the gateway.

- **RecurrenceInHours (integer)** – [REQUIRED]
  
Frequency of snapshots. Specify the number of hours between snapshots.

- **Description (string)** – Optional description of the snapshot that overwrites the existing description.

Return type  dict

Returns

Response Syntax

```python
{
    'VolumeARN': 'string'
}
```

Response Structure

- **(dict)** –
  
A JSON object containing the of the updated storage volume.

- **VolumeARN (string)** –
**update_vtl_device_type(**kwargs)**

This operation updates the type of medium changer in a gateway-VTL. When you activate a gateway-VTL, you select a medium changer type for the gateway-VTL. This operation enables you to select a different type of medium changer after a gateway-VTL is activated.

**Request Syntax**

```python
response = client.update_vtl_device_type(
    VTLDeviceARN='string',
    DeviceType='string'
)
```

**Parameters**

- **VTLDeviceARN (string)** – [REQUIRED]
  
  The Amazon Resource Name (ARN) of the medium changer you want to select.

- **DeviceType (string)** – [REQUIRED]
  
  The type of medium changer you want to select.

**Valid Values** : “STK-L700”, “AWS-Gateway-VTL”

**Return type**

dict

**Response Syntax**

```python
{
    'VTLDeviceARN': 'string'
}
```

**Response Structure**

- *(dict)* –
  
  - **UpdateVTLDeviceTypeOutput**
    
    - **VTLDeviceARN (string)** –
      
      The Amazon Resource Name (ARN) of the medium changer you have selected.

**Paginators**

The available paginators are:

- `StorageGateway.Paginator.DescribeTapeArchives`
- `StorageGateway.Paginator.DescribeTapeRecoveryPoints`
- `StorageGateway.Paginator.DescribeTapes`
- `StorageGateway.Paginator.DescribeVTLDevices`
- `StorageGateway.Paginator.ListGateways`
- `StorageGateway.Paginator.ListVolumes`

```python
class StorageGateway.Paginator.DescribeTapeArchives

    paginator = client.get_paginator('describe_tape_archives')
```
**paginate(**kwargs)**

Creates an iterator that will paginate through responses from StorageGateway.Client.describe_tape_archives().

**Request Syntax**

```python
response_iterator = paginator.paginate(
    TapeARNs=[
        'string',
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **TapeARNs (list)** – Specifies one or more unique Amazon Resource Names (ARNs) that represent the virtual tapes you want to describe.
  - (string)
- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** – The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize (integer)** – The size of each page.
  - **StartingToken (string)** – A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'TapeArchives': [
        {
            'TapeARN': 'string',
            'TapeBarcode': 'string',
            'TapeSizeInBytes': 123,
            'CompletionTime': datetime(2015, 1, 1),
            'RetrievedTo': 'string',
            'TapeStatus': 'string'
        },
        {
            'TapeARN': 'string',
            'TapeBarcode': 'string',
            'TapeSizeInBytes': 123,
            'CompletionTime': datetime(2015, 1, 1),
            'RetrievedTo': 'string',
            'TapeStatus': 'string'
        }
    ],
    'NextToken': 'string'
}
```

**Response Structure**

- **(dict)** – 
  DescribeTapeArchivesOutput
– **TapeArchives (list)**

An array of virtual tape objects in the virtual tape shelf (VTS). The description includes the Amazon Resource Name (ARN) of the virtual tapes. The information returned includes the Amazon Resource Names (ARNs) of the tapes, size of the tapes, status of the tapes, progress of the description and tape barcode.

* (dict) –

Represents a virtual tape that is archived in the virtual tape shelf (VTS).

- **TapeARN (string)** –
  
The Amazon Resource Name (ARN) of an archived virtual tape.

- **TapeBarcode (string)** –
  
The barcode that identifies the archived virtual tape.

- **TapeSizeInBytes (integer)** –
  
The size, in bytes, of the archived virtual tape.

- **CompletionTime (datetime)** –
  
The time that the archiving of the virtual tape was completed.

  The string format of the completion time is in the ISO8601 extended YYYY-MM-DD'T'HH:MM:SS'Z' format.

- **RetrievedTo (string)** –
  
The Amazon Resource Name (ARN) of the gateway-VTL that the virtual tape is being retrieved to.

  The virtual tape is retrieved from the virtual tape shelf (VTS).

- **TapeStatus (string)** –
  
The current state of the archived virtual tape.

– **NextToken (string)** –

A token to resume pagination.

```python
class StorageGateway.Paginator.DescribeTapeRecoveryPoints
```

```python
paginator = client.get_paginator('describe_tape_recovery_points')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `StorageGateway.Client.describe_tape_recovery_points()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    GatewayARN='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**
• **GatewayARN** (*string*) — [REQUIRED]
  
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

• **PaginationConfig** (*dict*) — A dictionary that provides parameters to control pagination.
  
  – **MaxItems** (*integer*) —
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a **NextToken** will be provided in the output that you can use to resume pagination.
  
  – **PageSize** (*integer*) —
    
    The size of each page.
  
  – **StartingToken** (*string*) —
    
    A token to specify where to start paginating. This is the **NextToken** from a previous response.

**Return type**  
dict

**Returns**

**Response Syntax**

```
{
  'GatewayARN': 'string',
  'TapeRecoveryPointInfos': [ 
  {
    'TapeARN': 'string',
    'TapeRecoveryPointTime': datetime(2015, 1, 1),
    'TapeSizeInBytes': 123,
    'TapeStatus': 'string'
  },
  ],
  'NextToken': 'string'
}
```

**Response Structure**

• (*dict*) —

  DescribeTapeRecoveryPointsOutput

  – **GatewayARN** (*string*) —
    
    The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

  – **TapeRecoveryPointInfos** (*list*) —
    
    An array of **TapeRecoveryPointInfos** that are available for the specified gateway.

    * (*dict*) —

      Describes a recovery point.

      * **TapeARN** (*string*) —
        
        The Amazon Resource Name (ARN) of the virtual tape.

      * **TapeRecoveryPointTime** (*datetime*) —
        
        The time when the point-in-time view of the virtual tape was replicated for later recovery.
The string format of the tape recovery point time is in the ISO8601 extended YYYY-MM-DD’T’HH:MM:SS’Z’ format.

- **TapeSizeInBytes (integer)** –
  The size, in bytes, of the virtual tapes to recover.

- **TapeStatus (string)** –
  A token to resume pagination.

```python
class StorageGateway.Paginator.DescribeTapes

paginator = client.get_paginator('describe_tapes')

paginate(**kwargs)

Creates an iterator that will paginate through responses from StorageGateway.Client.describe_tapes().

Request Syntax

response_iterator = paginator.paginate(
    GatewayARN='string',
    TapeARNs=[
        'string',
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **GatewayARN (string)** – [REQUIRED]
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

- **TapeARNs (list)** – Specifies one or more unique Amazon Resource Names (ARNs) that represent the virtual tapes you want to describe. If this parameter is not specified, AWS Storage Gateway returns a description of all virtual tapes associated with the specified gateway.
  - **(string)** –

- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize (integer)** –
    The size of each page.
  - **StartingToken (string)** –
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict
Returns

Response Syntax

```
{
  'Tapes': [
    {
      'TapeARN': 'string',
      'TapeBarcode': 'string',
      'TapeSizeInBytes': 123,
      'TapeStatus': 'string',
      'VTLDevice': 'string',
      'Progress': 123.0
    },
  ],
  'NextToken': 'string'
}
```

Response Structure

- (dict) –  
  DescribeTapesOutput
  - Tapes (list) –  
    An array of virtual tape descriptions.
    * (dict) –  
      Describes a virtual tape object.
      - TapeARN (string) –  
        The Amazon Resource Name (ARN) of the virtual tape.
      - TapeBarcode (string) –  
        The barcode that identifies a specific virtual tape.
      - TapeSizeInBytes (integer) –  
        The size, in bytes, of the virtual tape.
      - TapeStatus (string) –  
        The current state of the virtual tape.
      - VTLDevice (string) –  
        The virtual tape library (VTL) device that the virtual tape is associated with.
      - Progress (float) –  
        For archiving virtual tapes, indicates how much data remains to be uploaded before archiving is complete.
        Range: 0 (not started) to 100 (complete).
    - NextToken (string) –  
      A token to resume pagination.

```
class StorageGateway.Paginator.DescribeVTLDevices

    paginator = client.get_paginator('describe_vtl_devices')
    
    paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `StorageGateway.Client.describe_vtl_devices()`.
Request Syntax

```python
response_iterator = paginator.paginate(
    GatewayARN='string',
    VTLDeviceARNs=[
        'string',
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **GatewayARN (string)** – [REQUIRED]
  
  The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

- **VTLDeviceARNs (list)** – An array of strings, where each string represents the Amazon Resource Name (ARN) of a VTL device.

  Note: All of the specified VTL devices must be from the same gateway. If no VTL devices are specified, the result will contain all devices on the specified gateway.

- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  
  - **MaxItems (integer)** –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  
  - **PageSize (integer)** –
    
    The size of each page.
  
  - **StartingToken (string)** –
    
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict

Returns

Response Syntax

```json
{
    'GatewayARN': 'string',
    'VTLDevices': [
        {
            'VTLDeviceARN': 'string',
            'VTLDeviceType': 'string',
            'VTLDeviceVendor': 'string',
            'VTLDeviceProductIdentifier': 'string',
            'DeviceiSCSIAttributes': {
                'TargetARN': 'string',
                'NetworkInterfaceId': 'string',
                'NetworkInterfacePort': 123,
            }
        }
    ]
}
```
'ChapEnabled': True|False
}
},
],
'NextToken': 'string'
}

Response Structure
• (dict) –
    DescribeVTLDevicesOutput
    – GatewayARN (string) –
        The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
    – VTLDevices (list) –
        An array of VTL device objects composed of the Amazon Resource Name(ARN) of the VTL devices.
        * (dict) –
            Represents a device object associated with a gateway-VTL.
            · VTLDeviceARN (string) –
                Specifies the unique Amazon Resource Name (ARN) of the device (tape drive or media changer).
            · VTLDeviceType (string) –
            · VTLDeviceVendor (string) –
            · VTLDeviceProductIdentifier (string) –
            · DeviceiSCSIAttributes (dict) –
                A list of iSCSI information about a VTL device.
            · TargetARN (string) –
                Specifies the unique Amazon Resource Name(ARN) that encodes the iSCSI qualified name(iqn) of a tape drive or media changer target.
            · NetworkInterfaceId (string) –
                The network interface identifier of the VTL device.
            · NetworkInterfacePort (integer) –
                The port used to communicate with iSCSI VTL device targets.
            · ChapEnabled (boolean) –
                Indicates whether mutual CHAP is enabled for the iSCSI target.
    – NextToken (string) –
        A token to resume pagination.

class StorageGateway.Paginator.ListGateways

paginator = client.get_paginator('list_gateways')

paginate(**kwargs)
Creates an iterator that will paginate through responses from StorageGateway.Client.list_gateways().

Request Syntax
response_iterator = paginator.paginate(
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters  
PaginationConfig (dict) – A dictionary that provides parameters to control pagination.

- **MaxItems** (integer) –
  The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

- **PageSize** (integer) –
  The size of each page.

- **StartingToken** (string) –
  A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  
dict

Returns

Response Syntax

```python
{
    'Gateways': [
    
    
    
    ],
    
    
    
    
    'NextToken': 'string'
}
```

Response Structure

- (dict) –
  - Gateways (list) –
    * (dict) –
      - GatewayARN (string) –
        The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
      - GatewayType (string) –
      - GatewayOperationalState (string) –
      - GatewayName (string) –
  - NextToken (string) –
    A token to resume pagination.

class StorageGateway.Paginator.ListVolumes
paginator = client.get_paginator('list_volumes')

**paginate(**kwargs**)

Creates an iterator that will paginate through responses from `StorageGateway.Client.list_volumes()`.

Request Syntax

```python
response_iterator = paginator.paginate(
    GatewayARN='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **GatewayARN** *(string)* – [REQUIRED]
  
The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  - **MaxItems** *(integer)* –
    
The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.

  - **PageSize** *(integer)* –
    
The size of each page.

  - **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

Return type  
dict

Returns

Response Syntax

```json
{
    'GatewayARN': 'string',
    'VolumeInfos': [
        {
            'VolumeARN': 'string',
            'VolumeType': 'string'
        },
    ],
    'NextToken': 'string'
}
```

Response Structure

- *(dict)* –
  
  - **GatewayARN** *(string)* –
    
The Amazon Resource Name (ARN) of the gateway. Use the ListGateways operation to return a list of gateways for your account and region.
STS

Table of Contents

- STS
  - Client

Client

class STS.Client

A low-level client representing AWS Security Token Service (STS):

```python
import boto3

client = boto3.client('sts')
```

These are the available methods:

- `assume_role(**kwargs)`
- `assume_role_with_saml()`
- `assume_role_with_web_identity()`
- `can_paginate()`
- `decode_authorization_message()`
- `generate_presigned_url()`
- `get_federation_token()`
- `get_paginators()`
- `get_session_token()`
- `get_waiter()`

`.assume_role(**kwargs)`

Returns a set of temporary security credentials (consisting of an access key ID, a secret access key, and a security token) that you can use to access AWS resources that you might not normally have access to. Typically, you use `AssumeRole` for cross-account access or federation.

**Important:** You cannot call `AssumeRole` by using AWS account credentials; access will be denied. You must use IAM user credentials or temporary security credentials to call `AssumeRole`.

For cross-account access, imagine that you own multiple accounts and need to access resources in each account. You could create long-term credentials in each account to access those resources. However, managing all those credentials and remembering which one can access which account can be time consuming. Instead, you can create one set of long-term credentials in one account and then use temporary security credentials to access all the other accounts by assuming roles in those accounts. For more information about roles, see IAM Roles (Delegation and Federation) in Using IAM.

For federation, you can, for example, grant single sign-on access to the AWS Management Console. If you already have an identity and authentication system in your corporate network, you don’t have to recreate user identities in AWS in order to grant those user identities access to AWS. Instead, after a user...
has been authenticated, you call AssumeRole (and specify the role with the appropriate permissions) to
get temporary security credentials for that user. With those temporary security credentials, you construct
a sign-in URL that users can use to access the console. For more information, see Scenarios for Granting

The temporary security credentials are valid for the duration that you specified when calling
AssumeRole, which can be from 900 seconds (15 minutes) to 3600 seconds (1 hour). The default
is 1 hour.

Optionally, you can pass an IAM access policy to this operation. If you choose not to pass a policy, the
temporary security credentials that are returned by the operation have the permissions that are defined in
the access policy of the role that is being assumed. If you pass a policy to this operation, the temporary
security credentials that are returned by the operation have the permissions that are allowed by both the
access policy of the role that is being assumed, *and* the policy that you pass. This gives you a way
to further restrict the permissions for the resulting temporary security credentials. You cannot use the
passed policy to grant permissions that are in excess of those allowed by the access policy of the role that
is being assumed. For more information, see Permissions for AssumeRole, AssumeRoleWithSAML, and
AssumeRoleWithWebIdentity in Using Temporary Security Credentials.

To assume a role, your AWS account must be trusted by the role. The trust relationship is defined in
the role’s trust policy when the role is created. You must also have a policy that allows you to call
sts:AssumeRole.

Using MFA with AssumeRole
You can optionally include multi-factor authentication (MFA) information when you call AssumeRole.
This is useful for cross-account scenarios in which you want to make sure that the user who is assuming
the role has been authenticated using an AWS MFA device. In that scenario, the trust policy of the role
being assumed includes a condition that tests for MFA authentication; if the caller does not include valid
MFA information, the request to assume the role is denied. The condition in a trust policy that tests for
MFA authentication might look like the following example.

"Condition": {"Bool": {"aws:MultiFactorAuthPresent": true}}

For more information, see Configuring MFA-Protected API Access in Using IAM guide.

To use MFA with AssumeRole, you pass values for the SerialNumber and TokenCode parameters. The SerialNumber value identifies the user’s hardware or virtual MFA device. The TokenCode is the time-based one-time password (TOTP) that the MFA devices produces.

Request Syntax

```python
response = client.assume_role(
    RoleArn='string',
    RoleSessionName='string',
    Policy='string',
    DurationSeconds=123,
    ExternalId='string',
    SerialNumber='string',
    TokenCode='string'
)
```

Parameters
- **RoleArn** *(string) – [REQUIRED]*
  The Amazon Resource Name (ARN) of the role to assume.
- **RoleSessionName** *(string) – [REQUIRED]*
  An identifier for the assumed role session.

Use the role session name to uniquely identify a session when the same role is
assumed by different principals or for different reasons. In cross-account sce-
narios, the role session name is visible to, and can be logged by the account that owns the role. The role session name is also used in the ARN of the assumed role principal. This means that subsequent cross-account API requests using the temporary security credentials will expose the role session name to the external account in their CloudTrail logs.

- **Policy** *(string)* – An IAM policy in JSON format.

  This parameter is optional. If you pass a policy, the temporary security credentials that are returned by the operation have the permissions that are allowed by both (the intersection of) the access policy of the role that is being assumed, and the policy that you pass. This gives you a way to further restrict the permissions for the resulting temporary security credentials. You cannot use the passed policy to grant permissions that are in excess of those allowed by the access policy of the role that is being assumed. For more information, see Permissions for AssumeRole, AssumeRoleWithSAML, and AssumeRoleWithWebIdentity in Using Temporary Security Credentials.

  **Note:** The policy plain text must be 2048 bytes or shorter. However, an internal conversion compresses it into a packed binary format with a separate limit. The PackedPolicySize response element indicates by percentage how close to the upper size limit the policy is, with 100% equaling the maximum allowed size.

- **DurationSeconds** *(integer)* – The duration, in seconds, of the role session. The value can range from 900 seconds (15 minutes) to 3600 seconds (1 hour). By default, the value is set to 3600 seconds.

- **ExternalId** *(string)* – A unique identifier that is used by third parties when assuming roles in their customers’ accounts. For each role that the third party can assume, they should instruct their customers to ensure the role’s trust policy checks for the external ID that the third party generated. Each time the third party assumes the role, they should pass the customer’s external ID. The external ID is useful in order to help third parties bind a role to the customer who created it. For more information about the external ID, see How to Use External ID When Granting Access to Your AWS Resources in Using Temporary Security Credentials.

- **SerialNumber** *(string)* – The identification number of the MFA device that is associated with the user who is making the AssumeRole call. Specify this value if the trust policy of the role being assumed includes a condition that requires MFA authentication. The value is either the serial number for a hardware device (such as GAHT12345678) or an Amazon Resource Name (ARN) for a virtual device (such as arn:aws:iam::123456789012:mfa/user).

- **TokenCode** *(string)* – The value provided by the MFA device, if the trust policy of the role being assumed requires MFA (that is, if the policy includes a condition that tests for MFA). If the role being assumed requires MFA and if the TokenCode value is missing or expired, the AssumeRole call returns an “access denied” error.

Return type  dict

Returns

Response Syntax

```json
{
    'Credentials': {
        'AccessKeyId': 'string',
        'SecretAccessKey': 'string',
        'SessionToken': 'string',
    }
}
```
Response Structure
- **(dict)** –
  Contains the response to a successful AssumeRole request, including temporary AWS credentials that can be used to make AWS requests.
  - **Credentials (dict)** –
    The temporary security credentials, which include an access key ID, a secret access key, and a security (or session) token.
    - **AccessKeyId (string)** –
      The access key ID that identifies the temporary security credentials.
    - **SecretAccessKey (string)** –
      The secret access key that can be used to sign requests.
    - **SessionToken (string)** –
      The token that users must pass to the service API to use the temporary credentials.
    - **Expiration (datetime)** –
      The date on which the current credentials expire.
  - **AssumedRoleUser (dict)** –
    The Amazon Resource Name (ARN) and the assumed role ID, which are identifiers that you can use to refer to the resulting temporary security credentials. For example, you can reference these credentials as a principal in a resource-based policy by using the ARN or assumed role ID. The ARN and ID include the RoleSessionName that you specified when you called AssumeRole.
    - **AssumedRoleId (string)** –
      A unique identifier that contains the role ID and the role session name of the role that is being assumed. The role ID is generated by AWS when the role is created.
    - **Arn (string)** –
      The ARN of the temporary security credentials that are returned from the AssumeRole action. For more information about ARNs and how to use them in policies, see IAM Identifiers in Using IAM.
  - **PackedPolicySize (integer)** –
    A percentage value that indicates the size of the policy in packed form. The service rejects any policy with a packed size greater than 100 percent, which means the policy exceeded the allowed space.

**assume_role_with_saml (**kwargs**)**
Returns a set of temporary security credentials for users who have been authenticated via a SAML authentication response. This operation provides a mechanism for tying an enterprise identity store or directory to role-based AWS access without user-specific credentials or configuration.
The temporary security credentials returned by this operation consist of an access key ID, a secret access key, and a security token. Applications can use these temporary security credentials to sign calls to AWS services. The credentials are valid for the duration that you specified when calling AssumeRoleWithSAML, which can be up to 3600 seconds (1 hour) or until the time specified in the SAML authentication response’s `SessionNotOnOrAfter` value, whichever is shorter.

**Note:** The maximum duration for a session is 1 hour, and the minimum duration is 15 minutes, even if values outside this range are specified.

Optionally, you can pass an IAM access policy to this operation. If you choose not to pass a policy, the temporary security credentials that are returned by the operation have the permissions that are defined in the access policy of the role that is being assumed. If you pass a policy to this operation, the temporary security credentials that are returned by the operation have the permissions that are allowed by both the access policy of the role that is being assumed, *and* the policy that you pass. This gives you a way to further restrict the permissions for the resulting temporary security credentials. You cannot use the passed policy to grant permissions that are in excess of those allowed by the access policy of the role that is being assumed. For more information, see Permissions for AssumeRoleWithSAML in Using Temporary Security Credentials.

Before your application can call AssumeRoleWithSAML, you must configure your SAML identity provider (IdP) to issue the claims required by AWS. Additionally, you must use AWS Identity and Access Management (IAM) to create a SAML provider entity in your AWS account that represents your identity provider, and create an IAM role that specifies this SAML provider in its trust policy.

Calling AssumeRoleWithSAML does not require the use of AWS security credentials. The identity of the caller is validated by using keys in the metadata document that is uploaded for the SAML provider entity for your identity provider.

For more information, see the following resources:

- Creating Temporary Security Credentials for SAML Federation.
- SAML Providers in Using IAM.
- Configuring a Relying Party and Claims in Using IAM.
- Creating a Role for SAML-Based Federation in Using IAM.

**Request Syntax**

```python
response = client.assume_role_with_saml(
    RoleArn='string',
    PrincipalArn='string',
    SAMLAssertion='string',
    Policy='string',
    DurationSeconds=123
)
```

**Parameters**

- **RoleArn** (string) – [REQUIRED]
  
The Amazon Resource Name (ARN) of the role that the caller is assuming.

- **PrincipalArn** (string) – [REQUIRED]
  
The Amazon Resource Name (ARN) of the SAML provider in IAM that describes the IdP.

- **SAMLAssertion** (string) – [REQUIRED]
  
The base-64 encoded SAML authentication response provided by the IdP.

For more information, see Configuring a Relying Party and Adding Claims in the Using IAM guide.
• **Policy** (*string*) – An IAM policy in JSON format.

The policy parameter is optional. If you pass a policy, the temporary security credentials that are returned by the operation have the permissions that are allowed by both the access policy of the role that is being assumed, *and* the policy that you pass. This gives you a way to further restrict the permissions for the resulting temporary security credentials. You cannot use the passed policy to grant permissions that are in excess of those allowed by the access policy of the role that is being assumed. For more information, see Permissions for AssumeRoleWithSAML in Using Temporary Security Credentials.

**Note:** The policy plain text must be 2048 bytes or shorter. However, an internal conversion compresses it into a packed binary format with a separate limit. The PackedPolicySize response element indicates by percentage how close to the upper size limit the policy is, with 100% equaling the maximum allowed size.

• **DurationSeconds** (*integer*) – The duration, in seconds, of the role session. The value can range from 900 seconds (15 minutes) to 3600 seconds (1 hour). By default, the value is set to 3600 seconds. An expiration can also be specified in the SAML authentication response's `SessionNotOnOrAfter` value. The actual expiration time is whichever value is shorter.

**Note:** The maximum duration for a session is 1 hour, and the minimum duration is 15 minutes, even if values outside this range are specified.

Return type: *dict*

Returns

**Response Syntax**

```json
{
    'Credentials': {
        'AccessKeyId': 'string',
        'SecretAccessKey': 'string',
        'SessionToken': 'string',
        'Expiration': datetime(2015, 1, 1)
    },
    'AssumedRoleUser': {
        'AssumedRoleId': 'string',
        'Arn': 'string'
    },
    'PackedPolicySize': 123,
    'Subject': 'string',
    'SubjectType': 'string',
    'Issuer': 'string',
    'Audience': 'string',
    'NameQualifier': 'string'
}
```

**Response Structure**

• (*dict*) –

Contains the response to a successful AssumeRoleWithSAML request, including temporary AWS credentials that can be used to make AWS requests.

  • **Credentials** (*dict*) –

    AWS credentials for API authentication.

      • **AccessKeyId** (*string*) –
The access key ID that identifies the temporary security credentials.

* **SecretAccessKey** *(string)* –
  The secret access key that can be used to sign requests.

* **SessionToken** *(string)* –
  The token that users must pass to the service API to use the temporary credentials.

* **Expiration** *(datetime)* –
  The date on which the current credentials expire.

- **AssumedRoleUser** *(dict)* –
  The identifiers for the temporary security credentials that the operation returns.

  * **AssumedRoleId** *(string)* –
    A unique identifier that contains the role ID and the role session name of the role that is being assumed. The role ID is generated by AWS when the role is created.

  * **Arn** *(string)* –
    The ARN of the temporary security credentials that are returned from the AssumeRole action. For more information about ARNs and how to use them in policies, see IAM Identifiers in *Using IAM*.

- **PackedPolicySize** *(integer)* –
  A percentage value that indicates the size of the policy in packed form. The service rejects any policy with a packed size greater than 100 percent, which means the policy exceeded the allowed space.

- **Subject** *(string)* –
  The value of the NameID element in the Subject element of the SAML assertion.

- **SubjectType** *(string)* –
  The format of the name ID, as defined by the Format attribute in the NameID element of the SAML assertion. Typical examples of the format are transient or persistent.

  If the format includes the prefix `urn:oasis:names:tc:SAML:2.0:nameid-format`, that prefix is removed. For example, `urn:oasis:names:tc:SAML:2.0:nameid-format:transient` is returned as `transient`. If the format includes any other prefix, the format is returned with no modifications.

- **Issuer** *(string)* –
  The value of the Issuer element of the SAML assertion.

- **Audience** *(string)* –
  The value of the Recipient attribute of the SubjectConfirmationData element of the SAML assertion.

- **NameQualifier** *(string)* –
  A hash value based on the concatenation of the Issuer response value, the AWS account ID, and the friendly name (the last part of the ARN) of the SAML provider in IAM. The combination of NameQualifier and Subject can be used to uniquely identify a federated user.

  The following pseudocode shows how the hash value is calculated:
**assume_role_with_web_identity(**kwargs**)

Returns a set of temporary security credentials for users who have been authenticated in a mobile or web application with a web identity provider, such as Amazon Cognito, Login with Amazon, Facebook, Google, or any OpenID Connect-compatible identity provider.

**Note:** For mobile applications, we recommend that you use Amazon Cognito. You can use Amazon Cognito with the AWS SDK for iOS and the AWS SDK for Android to uniquely identify a user and supply the user with a consistent identity throughout the lifetime of an application.

To learn more about Amazon Cognito, see Amazon Cognito Overview in the AWS SDK for Android Developer Guide guide and Amazon Cognito Overview in the AWS SDK for iOS Developer Guide.

Calling AssumeRoleWithWebIdentity does not require the use of AWS security credentials. Therefore, you can distribute an application (for example, on mobile devices) that requests temporary security credentials without including long-term AWS credentials in the application, and without deploying server-based proxy services that use long-term AWS credentials. Instead, the identity of the caller is validated by using a token from the web identity provider.

The temporary security credentials returned by this API consist of an access key ID, a secret access key, and a security token. Applications can use these temporary security credentials to sign calls to AWS service APIs. The credentials are valid for the duration that you specified when calling AssumeRoleWithWebIdentity, which can be from 900 seconds (15 minutes) to 3600 seconds (1 hour). By default, the temporary security credentials are valid for 1 hour.

Optionally, you can pass an IAM access policy to this operation. If you choose not to pass a policy, the temporary security credentials that are returned by the operation have the permissions that are defined in the access policy of the role that is being assumed. If you pass a policy to this operation, the temporary security credentials that are returned by the operation have the permissions that are allowed by both the access policy of the role that is being assumed, and the policy that you pass. This gives you a way to further restrict the permissions for the resulting temporary security credentials. You cannot use the passed policy to grant permissions that are in excess of those allowed by the access policy of the role that is being assumed. For more information, see Permissions for AssumeRoleWithWebIdentity.

Before your application can call AssumeRoleWithWebIdentity, you must have an identity token from a supported identity provider and create a role that the application can assume. The role that your application assumes must trust the identity provider that is associated with the identity token. In other words, the identity provider must be specified in the role's trust policy.

For more information about how to use web identity federation and the AssumeRoleWithWebIdentity API, see the following resources:

- Web Identity Federation Playground. This interactive website lets you walk through the process of authenticating via Login with Amazon, Facebook, or Google, getting temporary security credentials, and then using those credentials to make a request to AWS.
- AWS SDK for iOS and AWS SDK for Android. These toolkits contain sample apps that show how to invoke the identity providers, and then how to use the information from these providers to get and use temporary security credentials.
- Web Identity Federation with Mobile Applications. This article discusses web identity federation and shows an example of how to use web identity federation to get access to content in Amazon S3.

**Request Syntax**

```python
response = client.assume_role_with_web_identity(
    RoleArn='string',
)```

```bash
BASE64 ( SHA1 ( "https://example.com/saml" + "123456789012" + "/MySAMLIdP" ) )
```
Parameters

- **RoleArn** *(string)* – [REQUIRED]
  
  The Amazon Resource Name (ARN) of the role that the caller is assuming.

- **RoleSessionName** *(string)* – [REQUIRED]
  
  An identifier for the assumed role session. Typically, you pass the name or identifier that is associated with the user who is using your application. That way, the temporary security credentials that your application will use are associated with that user. This session name is included as part of the ARN and assumed role ID in the **AssumedRoleUser** response element.

- **WebIdentityToken** *(string)* – [REQUIRED]
  
  The OAuth 2.0 access token or OpenID Connect ID token that is provided by the identity provider. Your application must get this token by authenticating the user who is using your application with a web identity provider before the application makes an **AssumeRoleWithWebIdentity** call.

- **ProviderId** *(string)* – The fully qualified host component of the domain name of the identity provider.
  
  Specify this value only for OAuth 2.0 access tokens. Currently www.amazon.com and graph.facebook.com are the only supported identity providers for OAuth 2.0 access tokens. Do not include URL schemes and port numbers.
  
  Do not specify this value for OpenID Connect tokens.

- **Policy** *(string)* – An IAM policy in JSON format.
  
  The policy parameter is optional. If you pass a policy, the temporary security credentials that are returned by the operation have the permissions that are allowed by both the access policy of the role that is being assumed, *and* the policy that you pass. This gives you a way to further restrict the permissions for the resulting temporary security credentials. You cannot use the passed policy to grant permissions that are in excess of those allowed by the access policy of the role that is being assumed. For more information, see Permissions for **AssumeRoleWithWebIdentity**.

  **Note:** The policy plain text must be 2048 bytes or shorter. However, an internal conversion compresses it into a packed binary format with a separate limit. The **PackedPolicySize** response element indicates by percentage how close to the upper size limit the policy is, with 100% equaling the maximum allowed size.

- **DurationSeconds** *(integer)* – The duration, in seconds, of the role session. The value can range from 900 seconds (15 minutes) to 3600 seconds (1 hour). By default, the value is set to 3600 seconds.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'Credentials': {
        'AccessKeyId': 'string',
        'SecretAccessKey': 'string',
        'SessionToken': 'string',
        'Expiration': datetime(2015, 1, 1)
    },
    'SubjectFromWebIdentityToken': 'string',
    'AssumedRoleUser': {
        'AssumedRoleId': 'string',
        'Arn': 'string'
    },
    'PackedPolicySize': 123,
    'Provider': 'string',
    'Audience': 'string'
}
```

**Response Structure**

- **(dict)** – Contains the response to a successful AssumeRoleWithWebIdentity request, including temporary AWS credentials that can be used to make AWS requests.

  - **Credentials (dict)** – The temporary security credentials, which include an access key ID, a secret access key, and a security token.
    - **AccessKeyId (string)** – The access key ID that identifies the temporary security credentials.
    - **SecretAccessKey (string)** – The secret access key that can be used to sign requests.
    - **SessionToken (string)** – The token that users must pass to the service API to use the temporary credentials.
    - **Expiration (datetime)** – The date on which the current credentials expire.

  - **SubjectFromWebIdentityToken (string)** – The unique user identifier that is returned by the identity provider. This identifier is associated with the WebIdentityToken that was submitted with the AssumeRoleWithWebIdentity call. The identifier is typically unique to the user and the application that acquired the WebIdentityToken (pairwise identifier). For OpenID Connect ID tokens, this field contains the value returned by the identity provider as the token’s `sub` (Subject) claim.

  - **AssumedRoleUser (dict)** – The Amazon Resource Name (ARN) and the assumed role ID, which are identifiers that you can use to refer to the resulting temporary security credentials. For example, you can reference these credentials as a principal in a resource-based policy by using the ARN or assumed role ID. The ARN and ID include the RoleSessionName that you specified when you called AssumeRole.
    - **AssumedRoleId (string)** – A unique identifier that contains the role ID and the role session
name of the role that is being assumed. The role ID is generated by
AWS when the role is created.

* Arn (string) –

The ARN of the temporary security credentials that are returned
from the AssumeRole action. For more information about ARNs
and how to use them in policies, see IAM Identifiers in Using IAM.

– PackedPolicySize (integer) –

A percentage value that indicates the size of the policy in packed form.
The service rejects any policy with a packed size greater than 100 percent,
which means the policy exceeded the allowed space.

– Provider (string) –

The issuing authority of the web identity token presented. For OpenID
Connect ID Tokens this contains the value of the iss field. For OAuth
2.0 access tokens, this contains the value of the ProviderId parameter
that was passed in the AssumeRoleWithWebIdentity request.

– Audience (string) –

The intended audience (also known as client ID) of the web identity to-
ken. This is traditionally the client identifier issued to the application that
requested the web identity token.

can_paginate (operation_name)

Check if an operation can be paginated.

Parameters operation_name (string) – The operation name. This is the same name as
the method name on the client. For example, if the method name is create_foo,
and you’d normally invoke the operation as client.create_foo(**kwargs),
if the create_foo operation can be paginated, you can use the call
client.get_paginatosr("create_foo").

Returns True if the operation can be paginated, False otherwise.

decode_authorization_message (**kwargs)

Decodes additional information about the authorization status of a request from an encoded message
returned in response to an AWS request.

For example, if a user is not authorized to perform an action that he or she has requested, the request re-
turns a Client.UnauthorizedOperation response (an HTTP 403 response). Some AWS actions
additionally return an encoded message that can provide details about this authorization failure.

Note: Only certain AWS actions return an encoded authorization message. The documentation for an
individual action indicates whether that action returns an encoded message in addition to returning an
HTTP code.

The message is encoded because the details of the authorization status can constitute privileged informa-
tion that the user who requested the action should not see. To decode an authorization status message, a
user must be granted permissions via an IAM policy to request the DecodeAuthorizationMessage
(sts:DecodeAuthorizationMessage) action.

The decoded message includes the following type of information:

• Whether the request was denied due to an explicit deny or due to the absence of an explicit allow.
For more information, see Determining Whether a Request is Allowed or Denied in Using IAM.
• The principal who made the request.
• The requested action.
• The requested resource.
• The values of condition keys in the context of the user’s request.

Request Syntax
response = client.decode_authorization_message(
    EncodedMessage='string'
)

Parameters  EncodedMessage (string) – [REQUIRED]

The encoded message that was returned with the response.

Return type  dict

Returns  

Response Syntax

{
    'DecodedMessage': 'string'
}

Response Structure

• (dict) –
  A document that contains additional information about the authorization status of a request from an encoded message that is returned in response to an AWS request.
  • DecodedMessage (string) –
    An XML document that contains the decoded message. For more information, see DecodeAuthorizationMessage.

generate_presigned_url (ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)

Generate a presigned url given a client, its method, and arguments

Parameters

• ClientMethod (string) – The client method to presign for
• Params (dict) – The parameters normally passed to ClientMethod.
• ExpiresIn (int) – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
• HttpMethod (string) – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns  The presigned url

get_federation_token (**kwargs)

Returns a set of temporary security credentials (consisting of an access key ID, a secret access key, and a security token) for a federated user. A typical use is in a proxy application that gets temporary security credentials on behalf of distributed applications inside a corporate network. Because you must call the GetFederationToken action using the long-term security credentials of an IAM user, this call is appropriate in contexts where those credentials can be safely stored, usually in a server-based application.

Note: If you are creating a mobile-based or browser-based app that can authenticate users using a web identity provider like Login with Amazon, Facebook, Google, or an OpenID Connect-compatible identity provider, we recommend that you use Amazon Cognito or AssumeRoleWithWebIdentity. For more information, see Creating Temporary Security Credentials for Mobile Apps Using Identity Providers.

The GetFederationToken action must be called by using the long-term AWS security credentials of an IAM user. You can also call GetFederationToken using the security credentials of an AWS account (root), but this is not recommended. Instead, we recommend that you create an IAM user for the purpose of the proxy application and then attach a policy to the IAM user that limits federated users to only the actions and resources they need access to. For more information, see IAM Best Practices in Using IAM.
The temporary security credentials that are obtained by using the long-term credentials of an IAM user are valid for the specified duration, between 900 seconds (15 minutes) and 129600 seconds (36 hours). Temporary credentials that are obtained by using AWS account (root) credentials have a maximum duration of 3600 seconds (1 hour).

Permissions

The permissions for the temporary security credentials returned by GetFederationToken are determined by a combination of the following:

- The policy or policies that are attached to the IAM user whose credentials are used to call GetFederationToken.
- The policy that is passed as a parameter in the call.

The passed policy is attached to the temporary security credentials that result from the GetFederationToken API call—that is, to the federated user. When the federated user makes an AWS request, AWS evaluates the policy attached to the federated user in combination with the policy or policies attached to the IAM user whose credentials were used to call GetFederationToken. AWS allows the federated user’s request only when both the federated user *and* the IAM user are explicitly allowed to perform the requested action. The passed policy cannot grant more permissions than those that are defined in the IAM user policy.

A typical use case is that the permissions of the IAM user whose credentials are used to call GetFederationToken are designed to allow access to all the actions and resources that any federated user will need. Then, for individual users, you pass a policy to the operation that scopes down the permissions to a level that’s appropriate to that individual user, using a policy that allows only a subset of permissions that are granted to the IAM user.

If you do not pass a policy, the resulting temporary security credentials have no effective permissions. The only exception is when the temporary security credentials are used to access a resource that has a resource-based policy that specifically allows the federated user to access the resource.

For more information about how permissions work, see Permissions for GetFederationToken. For information about using GetFederationToken to create temporary security credentials, see Creating Temporary Credentials to Enable Access for Federated Users.

Request Syntax

```python
response = client.get_federationToken(
    Name='string',
    Policy='string',
    DurationSeconds=123
)
```

Parameters

- **Name (string) – [REQUIRED]**
  
The name of the federated user. The name is used as an identifier for the temporary security credentials (such as Bob). For example, you can reference the federated user name in a resource-based policy, such as in an Amazon S3 bucket policy.
- **Policy (string) –** An IAM policy in JSON format that is passed with the GetFederationToken call and evaluated along with the policy or policies that are attached to the IAM user whose credentials are used to call GetFederationToken. The passed policy is used to scope down the permissions that are available to the IAM user, by allowing only a subset of the permissions that are granted to the IAM user. The passed policy cannot grant more permissions than those granted to the IAM user. The final permissions for the federated user are the most restrictive set based on the intersection of the passed policy and the IAM user policy.
If you do not pass a policy, the resulting temporary security credentials have no effective permissions. The only exception is when the temporary security credentials are used to access a resource that has a resource-based policy that specifically allows the federated user to access the resource.

**Note:** The policy plain text must be 2048 bytes or shorter. However, an internal conversion compresses it into a packed binary format with a separate limit. The PackedPolicySize response element indicates by percentage how close to the upper size limit the policy is, with 100% equating the maximum allowed size.

For more information about how permissions work, see Permissions for GetFederationToken.

- **DurationSeconds** (integer) – The duration, in seconds, that the session should last. Acceptable durations for federation sessions range from 900 seconds (15 minutes) to 129600 seconds (36 hours), with 43200 seconds (12 hours) as the default. Sessions obtained using AWS account (root) credentials are restricted to a maximum of 3600 seconds (one hour). If the specified duration is longer than one hour, the session obtained by using AWS account (root) credentials defaults to one hour.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'Credentials': {
        'AccessKeyId': 'string',
        'SecretAccessKey': 'string',
        'SessionToken': 'string',
        'Expiration': datetime(2015, 1, 1)
    },
    'FederatedUser': {
        'FederatedUserId': 'string',
        'Arn': 'string'
    },
    'PackedPolicySize': 123
}
```

**Response Structure**

- (dict) –
  
  Contains the response to a successful GetFederationToken request, including temporary AWS credentials that can be used to make AWS requests.

  - **Credentials** (dict) –
    
    Credentials for the service API authentication.

      - **AccessKeyId** (string) –
        
        The access key ID that identifies the temporary security credentials.

      - **SecretAccessKey** (string) –
        
        The secret access key that can be used to sign requests.

      - **SessionToken** (string) –
        
        The token that users must pass to the service API to use the temporary credentials.

      - **Expiration** (datetime) –
The date on which the current credentials expire.

- **FederatedUser (dict)** –

  Identifiers for the federated user associated with the credentials (such as `arn:aws:sts::123456789012:federated-user/Bob` or `123456789012:Bob`). You can use the federated user’s ARN in your resource-based policies, such as an Amazon S3 bucket policy.

  - **FederatedUserId (string)** –

    The string that identifies the federated user associated with the credentials, similar to the unique ID of an IAM user.

  - **Arn (string)** –

    The ARN that specifies the federated user that is associated with the credentials. For more information about ARNs and how to use them in policies, see [IAM Identifiers in Using IAM](#).

- **PackedPolicySize (integer)** –

  A percentage value indicating the size of the policy in packed form. The service rejects policies for which the packed size is greater than 100 percent of the allowed value.

### get_paginator (operation_name)

Create a paginator for an operation.

**Parameters operation_name (string)** – The operation name. This is the same name as the method name on the client. For example, if the method name is `createFoo`, and you’d normally invoke the operation as `client.createFoo(**kwargs)`, if the `createFoo` operation can be paginated, you can use the call `client.get_paginator("createFoo")`.

**Raises** `OperationNotPageableError` Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

**Return type** `botocore.paginate.Paginator`

**Returns** A paginator object.

### get_session_token (**kwargs)**

Returns a set of temporary credentials for an AWS account or IAM user. The credentials consist of an access key ID, a secret access key, and a security token. Typically, you use `GetSessionToken` if you want to use MFA to protect programmatic calls to specific AWS APIs like Amazon EC2 `StopInstances`. MFA-enabled IAM users would need to call `GetSessionToken` and submit an MFA code that is associated with their MFA device. Using the temporary security credentials that are returned from the call, IAM users can then make programmatic calls to APIs that require MFA authentication.

The `GetSessionToken` action must be called by using the long-term AWS security credentials of the AWS account or an IAM user. Credentials that are created by IAM users are valid for the duration that you specify, between 900 seconds (15 minutes) and 129600 seconds (36 hours); credentials that are created by using account credentials have a maximum duration of 3600 seconds (1 hour).

**Note:** We recommend that you do not call `GetSessionToken` with root account credentials. Instead, follow our best practices by creating one or more IAM users, giving them the necessary permissions, and using IAM users for everyday interaction with AWS.

The permissions associated with the temporary security credentials returned by `GetSessionToken` are based on the permissions associated with account or IAM user whose credentials are used to call the action. If `GetSessionToken` is called using root account credentials, the temporary credentials have root account permissions. Similarly, if `GetSessionToken` is called using the credentials of an IAM user, the temporary credentials have the same permissions as the IAM user.
For more information about using GetSessionToken to create temporary credentials, go to Creating Temporary Credentials to Enable Access for IAM Users.

Request Syntax

```python
response = client.get_session_token(
    DurationSeconds=123,
    SerialNumber='string',
    TokenCode='string'
)
```

Parameters

- **DurationSeconds** *(integer)* – The duration, in seconds, that the credentials should remain valid. Acceptable durations for IAM user sessions range from 900 seconds (15 minutes) to 129600 seconds (36 hours), with 43200 seconds (12 hours) as the default. Sessions for AWS account owners are restricted to a maximum of 3600 seconds (one hour). If the duration is longer than one hour, the session for AWS account owners defaults to one hour.

- **SerialNumber** *(string)* – The identification number of the MFA device that is associated with the IAM user who is making the GetSessionToken call. Specify this value if the IAM user has a policy that requires MFA authentication. The value is either the serial number for a hardware device (such as GAHT12345678) or an Amazon Resource Name (ARN) for a virtual device (such as arn:aws:iam::123456789012:mfa/user). You can find the device for an IAM user by going to the AWS Management Console and viewing the user’s security credentials.

- **TokenCode** *(string)* – The value provided by the MFA device, if MFA is required. If any policy requires the IAM user to submit an MFA code, specify this value. If MFA authentication is required, and the user does not provide a code when requesting a set of temporary security credentials, the user will receive an “access denied” response when requesting resources that require MFA authentication.

Return type **dict**

Returns

**Response Syntax**

```json
{
    'Credentials': {
        'AccessKeyId': 'string',
        'SecretAccessKey': 'string',
        'SessionToken': 'string',
        'Expiration': datetime(2015, 1, 1)
    }
}
```

**Response Structure**

- *(dict)* – Contains the response to a successful GetSessionToken request, including temporary AWS credentials that can be used to make AWS requests.

  - **Credentials**(dict) –

    The session credentials for API authentication.

    - **AccessKeyId**(string) –

      The access key ID that identifies the temporary security credentials.
SecretAccessKey (string) –
The secret access key that can be used to sign requests.

SessionToken (string) –
The token that users must pass to the service API to use the temporary credentials.

Expiration (datetime) –
The date on which the current credentials expire.

get_waiter (waiter_name)

Support

Table of Contents

- Support
  - Client
  - Paginators

Client

class Support.Client
A low-level client representing AWS Support:

import boto3

client = boto3.client('support')

These are the available methods:

- add_attachments_to_set(**kwargs)
- add_communication_to_case()
- can_paginate()
- create_case()
- describe_attachment()
- describe_cases()
- describe_communications()
- describe_services()
- describe_severity_levels()
- describe_trusted_advisor_check_refresh_statuses()
- describe_trusted_advisor_check_result()
- describe_trusted_advisor_check_summaries()
- describe_trusted_advisor_checks()
- generate_presigned_url()
- getaginator()
- get_waiter()
- refresh_trusted_advisor_check()
- resolve_case()

add_attachments_to_set (**kwargs)
Adds one or more attachments to an attachment set. If an AttachmentSetId is not specified, a new attachment set is created, and the ID of the set is returned in the response. If an AttachmentSetId is specified, the attachments are added to the specified set, if it exists.

3.1. Services
An attachment set is a temporary container for attachments that are to be added to a case or case communication. The set is available for one hour after it is created; the `ExpiryTime` returned in the response indicates when the set expires. The maximum number of attachments in a set is 3, and the maximum size of any attachment in the set is 5 MB.

**Request Syntax**

```python
response = client.add_attachments_to_set(
    attachmentSetId='string',
    attachments=[
        {
            'fileName': 'string',
            'data': b'bytes'
        },
    ]
)
```

**Parameters**

- **attachmentSetId** *(string)* – The ID of the attachment set. If an `AttachmentSetId` is not specified, a new attachment set is created, and the ID of the set is returned in the response. If an `AttachmentSetId` is specified, the attachments are added to the specified set, if it exists.

- **attachments** *(list)* – [REQUIRED] One or more attachments to add to the set. The limit is 3 attachments per set, and the size limit is 5 MB per attachment.
  
  - *(dict)* – An attachment to a case communication. The attachment consists of the file name and the content of the file.
    
    - **fileName** *(string)* – The name of the attachment file.
    - **data** *(bytes)* – The content of the attachment file.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'attachmentSetId': 'string',
    'expiryTime': 'string'
}
```

**Response Structure**

- *(dict)* – The ID and expiry time of the attachment set returned by the `AddAttachmentsToSet` operation.
  
  - **attachmentSetId** *(string)* – The ID of the attachment set. If an `AttachmentSetId` was not specified, a new attachment set is created, and the ID of the set is returned in the response. If an `AttachmentSetId` was specified, the attachments are added to the specified set, if it exists.
  
  - **expiryTime** *(string)* – The time and date when the attachment set expires.
**add_communication_to_case(**kwargs)**

Adds additional customer communication to an AWS Support case. You use the `CaseId` value to identify the case to add communication to. You can list a set of email addresses to copy on the communication using the `CcEmailAddresses` value. The `CommunicationBody` value contains the text of the communication.

The response indicates the success or failure of the request.

This operation implements a subset of the features of the AWS Support Center.

**Request Syntax**

```python
response = client.add_communication_to_case(
    caseId='string',
    communicationBody='string',
    ccEmailAddresses=[
        'string',
    ],
    attachmentSetId='string'
)
```

**Parameters**

- **caseId** ([string](https://docs.amazonaws.cn/en/latest/region/latest/directoryservice/what-is-a-case-id.html)) – The AWS Support case ID requested or returned in the call. The case ID is an alphanumeric string formatted as shown in this example: case-12345678910-2013-c4c1d2bf33c5cf47
- **communicationBody** ([string](https://docs.amazonaws.cn/en/latest/region/latest/directoryservice/what-is-a-case-id.html)) – [REQUIRED] The body of an email communication to add to the support case.
- **CcEmailAddresses** ([list](https://docs.amazonaws.cn/en/latest/region/latest/directoryservice/what-is-a-case-id.html)) – The email addresses in the CC line of an email to be added to the support case.
  - ([string](https://docs.amazonaws.cn/en/latest/region/latest/directoryservice/what-is-a-case-id.html))
- **attachmentSetId** ([string](https://docs.amazonaws.cn/en/latest/region/latest/directoryservice/what-is-a-case-id.html)) – The ID of a set of one or more attachments for the communication to add to the case. Create the set by calling `AddAttachmentsToSet`

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'result': True|False
}
```

**Response Structure**

- ([dict](https://docs.amazonaws.cn/en/latest/region/latest/directoryservice/what-is-a-case-id.html))
  - The result of the `AddCommunicationToCase` operation.
  - **result** ([boolean](https://docs.amazonaws.cn/en/latest/region/latest/directoryservice/what-is-a-case-id.html)) – True if `AddCommunicationToCase` succeeds. Otherwise, returns an error.

**can_paginate**(operation_name)

Check if an operation can be paginated.

**Parameters operation_name** (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

**Returns** True if the operation can be paginated, False otherwise.
create_case(**kwargs)

Creates a new case in the AWS Support Center. This operation is modeled on the behavior of the AWS Support Center Create Case page. Its parameters require you to specify the following information:

• **IssueType.** The type of issue for the case. You can specify either “customer-service” or “technical.” If you do not indicate a value, the default is “technical.”
• **ServiceCode.** The code for an AWS service. You obtain the ServiceCode by calling DescribeServices.
• **CategoryCode.** The category for the service defined for the ServiceCode value. You also obtain the category code for a service by calling DescribeServices. Each AWS service defines its own set of category codes.
• **SeverityCode.** A value that indicates the urgency of the case, which in turn determines the response time according to your service level agreement with AWS Support. You obtain the SeverityCode by calling DescribeSeverityLevels.
• **Subject.** The Subject field on the AWS Support Center Create Case page.
• **CommunicationBody.** The Description field on the AWS Support Center Create Case page.
• **AttachmentSetId.** The ID of a set of attachments that has been created by using AddAttachmentsToSet.
• **Language.** The human language in which AWS Support handles the case. English and Japanese are currently supported.
• **CcEmailAddresses.** The AWS Support Center CC field on the Create Case page. You can list email addresses to be copied on any correspondence about the case. The account that opens the case is already identified by passing the AWS Credentials in the HTTP POST method or in a method or function call from one of the programming languages supported by an AWS SDK.

**Note:** To add additional communication or attachments to an existing case, use AddCommunicationToCase.

A successful CreateCase request returns a case number. Case numbers are used by the DescribeCases operation to retrieve existing AWS Support cases.

**Request Syntax**

```python
response = client.create_case(
    subject='string',
    serviceCode='string',
    severityCode='string',
    categoryCode='string',
    communicationBody='string',
    ccEmailAddresses=[
        'string',
    ],
    language='string',
    issueType='string',
    attachmentSetId='string'
)
```

**Parameters**

- **subject (string)** – [REQUIRED]
  The title of the AWS Support case.
- **serviceCode (string)** – The code for the AWS service returned by the call to DescribeServices.
- **severityCode (string)** – The code for the severity level returned by the call to DescribeSeverityLevels.

**Note:** The availability of severity levels depends on each customer’s support...
subscription. In other words, your subscription may not necessarily require the urgent level of response time.

- **categoryCode (string)** – The category of problem for the AWS Support case.
- **communicationBody (string)** – [REQUIRED]

The communication body text when you create an AWS Support case by calling CreateCase.

- **ccEmailAddresses (list)** – A list of email addresses that AWS Support copies on case correspondence.
  - (string)

- **language (string)** – The ISO 639-1 code for the language in which AWS provides support. AWS Support currently supports English ("en") and Japanese ("ja"). Language parameters must be passed explicitly for operations that take them.

- **issueType (string)** – The type of issue for the case. You can specify either “customer-service” or “technical.” If you do not indicate a value, the default is “technical.”

- **attachmentSetId (string)** – The ID of a set of one or more attachments for the case. Create the set by using AddAttachmentsToSet.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'caseId': 'string'
}
```

**Response Structure**

- (dict) –

The AWS Support case ID returned by a successful completion of the CreateCase operation.

- **caseId (string)** –

The AWS Support case ID requested or returned in the call. The case ID is an alphanumeric string formatted as shown in this example: `case-12345678910-2013-c4c1d2df33c5cf47`

**describe_attachment (**)kwargs

Returns the attachment that has the specified ID. Attachment IDs are generated by the case management system when you add an attachment to a case or case communication. Attachment IDs are returned in the AttachmentDetails objects that are returned by the DescribeCommunications operation.

**Request Syntax**

```python
response = client.describe_attachment(
    attachmentId='string'
)
```

**Parameters**

**attachmentId (string)** – [REQUIRED]

The ID of the attachment to return. Attachment IDs are returned by the DescribeCommunications operation.

**Return type** dict

**Returns**

**Response Syntax**
Boto3 Documentation, Release 1.1.4

```json
{
    'attachment': {
        'fileName': 'string',
        'data': b'bytes'
    }
}
```

**Response Structure**
- *(dict)* – The content and file name of the attachment returned by the DescribeAttachment operation.
  - **attachment (dict)** – The attachment content and file name.
    - *fileName (string)* – The name of the attachment file.
    - *data (bytes)* – The content of the attachment file.

**describe_cases (**kwargs**)**
Returns a list of cases that you specify by passing one or more case IDs. In addition, you can filter the cases by date by setting values for the AfterTime and BeforeTime request parameters. You can set values for the IncludeResolvedCases and IncludeCommunications request parameters to control how much information is returned.

Case data is available for 12 months after creation. If a case was created more than 12 months ago, a request for data might cause an error.

The response returns the following in JSON format:
- One or more CaseDetails data types.
- One or more NextToken values, which specify where to paginate the returned records represented by the CaseDetails objects.

**Request Syntax**

```python
response = client.describe_cases(
    caseIdList=['string'],
    displayId='string',
    afterTime='string',
    beforeTime='string',
    includeResolvedCases=True|False,
    nextToken='string',
    maxResults=123,
    language='string',
    includeCommunications=True|False
)
```

**Parameters**
- **caseIdList (list)** – A list of ID numbers of the support cases you want returned. The maximum number of cases is 100.
- **displayId (string)** – The ID displayed for a case in the AWS Support Center user interface.
- **afterTime** *(string)* – The start date for a filtered date search on support case communications. Case communications are available for 12 months after creation.
- **beforeTime** *(string)* – The end date for a filtered date search on support case communications. Case communications are available for 12 months after creation.
- **includeResolvedCases** *(boolean)* – Specifies whether resolved support cases should be included in the DescribeCases results. The default is `false`.
- **nextToken** *(string)* – A resumption point for pagination.
- **maxResults** *(integer)* – The maximum number of results to return before paginating.
- **language** *(string)* – The ISO 639-1 code for the language in which AWS provides support. AWS Support currently supports English (“en”) and Japanese (“ja”). Language parameters must be passed explicitly for operations that take them.
- **includeCommunications** *(boolean)* – Specifies whether communications should be included in the DescribeCases results. The default is `true`.

### Returns

**Response Syntax**

```json
{
    'cases': [
        {
            'caseId': 'string',
            'displayId': 'string',
            'subject': 'string',
            'status': 'string',
            'serviceCode': 'string',
            'categoryCode': 'string',
            'severityCode': 'string',
            'submittedBy': 'string',
            'timeCreated': 'string',
            'recentCommunications': {
                'communications': [
                    {
                        'caseId': 'string',
                        'body': 'string',
                        'submittedBy': 'string',
                        'timeCreated': 'string',
                        'attachmentSet': [
                            {
                                'attachmentId': 'string',
                                'fileName': 'string'
                            }
                        ],
                    }
                ],
            },
            'nextToken': 'string'
        },
        {
            'ccEmailAddresses': [ 'string' ],
            'language': 'string'
        },
    ],
    'nextToken': 'string'
}
```
Response Structure

- (dict) –
  Returns an array of CaseDetails objects and a NextToken that defines a point for pagination in the result set.

  - cases (list) –
    The details for the cases that match the request.

      * (dict) –
        A JSON-formatted object that contains the metadata for a support case. It is contained the response from a DescribeCases request.

        CaseDetails contains the following fields:

          - CaseID. The AWS Support case ID requested or returned in the call. The case ID is an alphanumeric string formatted as shown in this example: case-12345678910-2013-c4c1d2bf33c5cf47.
          - CategoryCode. The category of problem for the AWS Support case. Corresponds to the CategoryCode values returned by a call to DescribeServices.
          - DisplayId. The identifier for the case on pages in the AWS Support Center.
          - Language. The ISO 639-1 code for the language in which AWS provides support. AWS Support currently supports English ("en") and Japanese ("ja"). Language parameters must be passed explicitly for operations that take them.
          - RecentCommunications. One or more Communication objects. Fields of these objects are Attachments, Body, CaseId, SubmittedBy, and TimeCreated.
          - NextToken. A resumption point for pagination.
          - ServiceCode. The identifier for the AWS service that corresponds to the service code defined in the call to DescribeServices.
          - SeverityCode. The severity code assigned to the case. Contains one of the values returned by the call to DescribeSeverityLevels.
          - Status. The status of the case in the AWS Support Center.
          - Subject. The subject line of the case.
          - SubmittedBy. The email address of the account that submitted the case.
          - TimeCreated. The time the case was created, in ISO-8601 format.

        - caseId (string) –
          The AWS Support case ID requested or returned in the call. The case ID is an alphanumeric string formatted as shown in this example: case-12345678910-2013-c4c1d2bf33c5cf47

        - displayId (string) –
          The ID displayed for the case in the AWS Support Center. This is a numeric string.

        - subject (string) –
          The subject line for the case in the AWS Support Center.

        - status (string) –
          The status of the case.
· **serviceCode** *(string)* –
  The code for the AWS service returned by the call to DescribeServices.
· **categoryCode** *(string)* –
  The category of problem for the AWS Support case.
· **severityCode** *(string)* –
  The code for the severity level returned by the call to DescribeSeverityLevels.
· **submittedBy** *(string)* –
  The email address of the account that submitted the case.
· **timeCreated** *(string)* –
  The time that the case was created in the AWS Support Center.
· **recentCommunications** *(dict)* –
  The five most recent communications between you and AWS Support Center, including the IDs of any attachments to the communications. Also includes a *nextToken* that you can use to retrieve earlier communications.
· **communications** *(list)* –
  The five most recent communications associated with the case.
  · *(dict)* –
    A communication associated with an AWS Support case. The communication consists of the case ID, the message body, attachment information, the account email address, and the date and time of the communication.
· **caseId** *(string)* –
  The AWS Support case ID requested or returned in the call. The case ID is an alphanumeric string formatted as shown in this example: case-12345678910-2013-c4c1d2bf33c5cf47
· **body** *(string)* –
  The text of the communication between the customer and AWS Support.
· **submittedBy** *(string)* –
  The email address of the account that submitted the AWS Support case.
· **timeCreated** *(string)* –
  The time the communication was created.
· **attachmentSet** *(list)* –
  Information about the attachments to the case communication.
  · *(dict)* –
    The file name and ID of an attachment to a case communication. You can use the ID to retrieve the attachment with the DescribeAttachment operation.
The ID of the attachment.

· **fileName** *(string)* –
  
  The file name of the attachment.

· **nextToken** *(string)* –
  
  A resumption point for pagination.

· **ccEmailAddresses** *(list)* –
  
  The email addresses that receive copies of communication about the case.

· **language** *(string)* –
  
  The ISO 639-1 code for the language in which AWS provides support. AWS Support currently supports English (“en”) and Japanese (“ja”). Language parameters must be passed explicitly for operations that take them.

· **nextToken** *(string)* –
  
  A resumption point for pagination.

**describe_communications** (**kwargs**)

Returns communications (and attachments) for one or more support cases. You can use the `AfterTime` and `BeforeTime` parameters to filter by date. You can use the `CaseId` parameter to restrict the results to a particular case.

Case data is available for 12 months after creation. If a case was created more than 12 months ago, a request for data might cause an error.

You can use the `MaxResults` and `NextToken` parameters to control the pagination of the result set. Set `MaxResults` to the number of cases you want displayed on each page, and use `NextToken` to specify the resumption of pagination.

**Request Syntax**

```python
response = client.describe_communications(
    caseId='string',
    beforeTime='string',
    afterTime='string',
    nextToken='string',
    maxResults=123
)
```

**Parameters**

- **caseId** *(string)* – [REQUIRED]
  
  The AWS Support case ID requested or returned in the call. The case ID is an alphanumeric string formatted as shown in this example: case-12345678910-2013-c4c1d2bf33c5cf47

- **beforeTime** *(string)* – The end date for a filtered date search on support case communications. Case communications are available for 12 months after creation.

- **afterTime** *(string)* – The start date for a filtered date search on support case communications. Case communications are available for 12 months after creation.

- **nextToken** *(string)* – A resumption point for pagination.

- **maxResults** *(integer)* – The maximum number of results to return before paginating.

**Return type** dict
Returns

Response Syntax

{
  'communications': [
    {
      'caseId': 'string',
      'body': 'string',
      'submittedBy': 'string',
      'timeCreated': 'string',
      'attachmentSet': [
        {
          'attachmentId': 'string',
          'fileName': 'string'
        }
      ]
    },
  ],
  'nextToken': 'string'
}

Response Structure

* (dict) –

The communications returned by the DescribeCommunications operation.

  communications (list) –

  The communications for the case.

    * (dict) –

    A communication associated with an AWS Support case. The com-
    munication consists of the case ID, the message body, attachment
    information, the account email address, and the date and time of
    the communication.

      · caseId (string) –

        The AWS Support case ID requested or returned in the call.
        The case ID is an alphanumeric string formatted as shown in
        this example: case-J2345678910-2013-c4c1d2bf33c5cf47

      · body (string) –

        The text of the communication between the customer and
        AWS Support.

      · submittedBy (string) –

        The email address of the account that submitted the AWS
        Support case.

      · timeCreated (string) –

        The time the communication was created.

      · attachmentSet (list) –

        Information about the attachments to the case communica-
        tion.

        · (dict) –

        The file name and ID of an attachment to a case communica-
        tion. You can use the ID to retrieve the attachment with the
        DescribeAttachment operation.
The ID of the attachment.

- **fileName (string)** –

The file name of the attachment.

- **nextToken (string)** –

A resumption point for pagination.

describe_services(**kwargs)**

Returns the current list of AWS services and a list of service categories that applies to each one. You then use service names and categories in your CreateCase requests. Each AWS service has its own set of categories.

The service codes and category codes correspond to the values that are displayed in the Service and Category drop-down lists on the AWS Support Center Create Case page. The values in those fields, however, do not necessarily match the service codes and categories returned by the `DescribeServices` request. Always use the service codes and categories obtained programmatically. This practice ensures that you always have the most recent set of service and category codes.

Request Syntax

```python
response = client.describe_services(
    serviceCodeList=[
        'string',
    ],
    language='string'
)
```

Parameters

- **serviceCodeList (list)** – A JSON-formatted list of service codes available for AWS services.
  - **(string)** –

- **language (string)** – The ISO 639-1 code for the language in which AWS provides support. AWS Support currently supports English (“en”) and Japanese (“ja”). Language parameters must be passed explicitly for operations that take them.

Return type  **dict**

Response Syntax

```json
{
    'services': [
        {
            'code': 'string',
            'name': 'string',
            'categories': [
                {
                    'code': 'string',
                    'name': 'string'
                }
            ]
        }
    ]
}
```

Response Structure
• (dict) –
  The list of AWS services returned by the DescribeServices operation.
  
  • services (list) –
    A JSON-formatted list of AWS services.
    
    • (dict) –
      Information about an AWS service returned by the DescribeServices operation.
      
      • code (string) –
        The code for an AWS service returned by the DescribeServices response. The Name element contains the corresponding friendly name.
      
      • name (string) –
        The friendly name for an AWS service. The Code element contains the corresponding code.
      
      • categories (list) –
        A list of categories that describe the type of support issue a case describes. Categories consist of a category name and a category code. Category names and codes are passed to AWS Support when you call CreateCase.
      
    • (dict) –
      A JSON-formatted name/value pair that represents the category name and category code of the problem, selected from the DescribeServices response for each AWS service.
      
      • code (string) –
        The category code for the support case.
      
      • name (string) –
        The category name for the support case.

describe_severity_levels(**kwargs)

Returns the list of severity levels that you can assign to an AWS Support case. The severity level for a case is also a field in the CaseDetails data type included in any CreateCase request.

Request Syntax

```python
response = client.describe_severity_levels(
    language='string'
)
```

Parameters

- language (string) – The ISO 639-1 code for the language in which AWS provides support. AWS Support currently supports English (“en”) and Japanese (“ja”). Language parameters must be passed explicitly for operations that take them.

Return type

dict

Returns

Response Syntax

```json
{
    'severityLevels': [
        {
            'code': 'string',
            'name': 'string'
        }
    ]
}
```
Response Structure

- *(dict)* –
  
  The list of severity levels returned by the DescribeSeverityLevels operation.
  
  - **severityLevels** *(list)* –
    
    The available severity levels for the support case. Available severity levels are defined by your service level agreement with AWS.
    
    - *(dict)* –
      
      A code and name pair that represent a severity level that can be applied to a support case.
      
      - **code** *(string)* –
        
        One of four values: “low,” “medium,” “high,” and “urgent”. These values correspond to response times returned to the caller in SeverityLevel.name.
      
      - **name** *(string)* –
        
        The name of the severity level that corresponds to the severity level code.

**describe_trusted_advisor_check_refresh_statuses**(**kwargs**)

Returns the refresh status of the Trusted Advisor checks that have the specified check IDs. Check IDs can be obtained by calling DescribeTrustedAdvisorChecks.

**Request Syntax**

```python
response = client.describe_trusted_advisor_check_refresh_statuses(
    checkIds=[
        'string',
    ]
)
```

**Parameters**  
**checkIds** *(list)* – [REQUIRED]

The IDs of the Trusted Advisor checks.

- *(string)* –

**Return type**  
**dict**

**Returns**

**Response Syntax**

```python
{
    'statuses': [
        {
            'checkId': 'string',
            'status': 'string',
            'millisUntilNextRefreshable': 123
        },
    ]
}
```

**Response Structure**
• (dict) –
  The statuses of the Trusted Advisor checks returned by the DescribeTrustedAdvisorCheckRefreshStatuses operation.
  
  statuses (list) –
  The refresh status of the specified Trusted Advisor checks.

* (dict) –
  The refresh status of a Trusted Advisor check.

  · checkId (string) –
    The unique identifier for the Trusted Advisor check.

  · status (string) –
    The status of the Trusted Advisor check for which a refresh has been requested: “none”, “enqueued”, “processing”, “success”, or “abandoned”.

  · millisUntilNextRefreshable (integer) –
    The amount of time, in milliseconds, until the Trusted Advisor check is eligible for refresh.

describe_trusted_advisor_check_result (**kwargs)

Returns the results of the Trusted Advisor check that has the specified check ID. Check IDs can be obtained by calling DescribeTrustedAdvisorChecks.

The response contains a TrustedAdvisorCheckResult object, which contains these three objects:
• TrustedAdvisorCategorySpecificSummary
• TrustedAdvisorResourceDetail
• TrustedAdvisorResourcesSummary

In addition, the response contains these fields:
• Status. The alert status of the check: “ok” (green), “warning” (yellow), “error” (red), or “not_available”.
• Timestamp. The time of the last refresh of the check.
• CheckId. The unique identifier for the check.

Request Syntax

response = client.describe_trusted_advisor_check_result(
  checkId='string',
  language='string'
)

Parameters

  • checkId (string) – [REQUIRED]
    The unique identifier for the Trusted Advisor check.

  • language (string) – The ISO 639-1 code for the language in which AWS provides support. AWS Support currently supports English (“en”) and Japanese (“ja”). Language parameters must be passed explicitly for operations that take them.

Return type: dict

Returns

Response Syntax

```python
{
  'result': {
    'checkId': 'string',
    'timestamp': 'string',
```

3.1. Services
'status': 'string',
'resourcesSummary': {
    'resourcesProcessed': 123,
    'resourcesFlagged': 123,
    'resourcesIgnored': 123,
    'resourcesSuppressed': 123
},
'categorySpecificSummary': {
    'costOptimizing': {
        'estimatedMonthlySavings': 123.0,
        'estimatedPercentMonthlySavings': 123.0
    }
},
'flaggedResources': [
    {
        'status': 'string',
        'region': 'string',
        'resourceId': 'string',
        'isSuppressed': True|False,
        'metadata': ['string',
                     ]
    }
]
}

Response Structure
• (dict) –
  The result of the Trusted Advisor check returned by the DescribeTrustedAdvisorCheckResult operation.
    – result (dict) –
      The detailed results of the Trusted Advisor check.
        * checkId (string) –
          The unique identifier for the Trusted Advisor check.
        * timestamp (string) –
          The time of the last refresh of the check.
        * status (string) –
          The alert status of the check: “ok” (green), “warning” (yellow), “error” (red), or “not_available”.
        * resourcesSummary (dict) –
          Details about AWS resources that were analyzed in a call to Trusted Advisor DescribeTrustedAdvisorCheckSummaries.
            • resourcesProcessed (integer) –
              The number of AWS resources that were analyzed by the Trusted Advisor check.
            • resourcesFlagged (integer) –
              The number of AWS resources that were flagged (listed) by the Trusted Advisor check.
            • resourcesIgnored (integer) –
              The number of AWS resources ignored by Trusted Advisor
because information was unavailable.

- **resourcesSuppressed** (integer) –
  The number of AWS resources ignored by Trusted Advisor because they were marked as suppressed by the user.

- **categorySpecificSummary** (dict) –
  Summary information that relates to the category of the check. Cost Optimizing is the only category that is currently supported.

  - **costOptimizing** (dict) –
    The summary information about cost savings for a Trusted Advisor check that is in the Cost Optimizing category.
  
  - **estimatedMonthlySavings** (float) –
    The estimated monthly savings that might be realized if the recommended actions are taken.
  
  - **estimatedPercentMonthlySavings** (float) –
    The estimated percentage of savings that might be realized if the recommended actions are taken.

- **flaggedResources** (list) –
  The details about each resource listed in the check result.

  - (dict) –
    Contains information about a resource identified by a Trusted Advisor check.
  
  - **status** (string) –
    The status code for the resource identified in the Trusted Advisor check.
  
  - **region** (string) –
    The AWS region in which the identified resource is located.
  
  - **resourceId** (string) –
    The unique identifier for the identified resource.
  
  - **isSuppressed** (boolean) –
    Specifies whether the AWS resource was ignored by Trusted Advisor because it was marked as suppressed by the user.
  
  - **metadata** (list) –
    Additional information about the identified resource. The exact metadata and its order can be obtained by inspecting the TrustedAdvisorCheckDescription object returned by the call to DescribeTrustedAdvisorChecks. Metadata contains all the data that is shown in the Excel download, even in those cases where the UI shows just summary data.

**describe_trusted_advisor_check_summaries(** **kwargs**)

Returns the summaries of the results of the Trusted Advisor checks that have the specified check IDs. Check IDs can be obtained by calling DescribeTrustedAdvisorChecks.

The response contains an array of TrustedAdvisorCheckSummary objects.

**Request Syntax**
response = client.describe_trusted_advisor_check_summaries(
    checkIds=[
        'string',
    ]
)

**Parameters**  
**checkIds** *(list)* – [REQUIRED]

The IDs of the Trusted Advisor checks.

- *(string)* –

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'summaries': [
        {
            'checkId': 'string',
            'timestamp': 'string',
            'status': 'string',
            'hasFlaggedResources': True|False,
            'resourcesSummary': {
                'resourcesProcessed': 123,
                'resourcesFlagged': 123,
                'resourcesIgnored': 123,
                'resourcesSuppressed': 123
            },
            'categorySpecificSummary': {
                'costOptimizing': {
                    'estimatedMonthlySavings': 123.0,
                    'estimatedPercentMonthlySavings': 123.0
                }
            }
        },
    ],
}
```

**Response Structure**

- *(dict)* –

The summaries of the Trusted Advisor checks returned by the DescribeTrustedAdvisorCheckSummaries operation.

- **summaries** *(list)* –

The summary information for the requested Trusted Advisor checks.

- *(dict)* –

A summary of a Trusted Advisor check result, including the alert status, last refresh, and number of resources examined.

- **checkId** *(string)* –

The unique identifier for the Trusted Advisor check.

- **timestamp** *(string)* –

The time of the last refresh of the check.

- **status** *(string)* –

The alert status of the check: “ok” (green), “warning” (yellow), “error” (red), or “not_available”.

---

4364 Chapter 3. API Reference
- **hasFlaggedResources** *(boolean)* –
  Specifies whether the Trusted Advisor check has flagged resources.
- **resourcesSummary** *(dict)* –
  Details about AWS resources that were analyzed in a call to Trusted Advisor DescribeTrustedAdvisorCheckSummaries.
- **resourcesProcessed** *(integer)* –
  The number of AWS resources that were analyzed by the Trusted Advisor check.
- **resourcesFlagged** *(integer)* –
  The number of AWS resources that were flagged (listed) by the Trusted Advisor check.
- **resourcesIgnored** *(integer)* –
  The number of AWS resources ignored by Trusted Advisor because information was unavailable.
- **resourcesSuppressed** *(integer)* –
  The number of AWS resources ignored by Trusted Advisor because they were marked as suppressed by the user.
- **categorySpecificSummary** *(dict)* –
  Summary information that relates to the category of the check. Cost Optimizing is the only category that is currently supported.
- **costOptimizing** *(dict)* –
  The summary information about cost savings for a Trusted Advisor check that is in the Cost Optimizing category.
- **estimatedMonthlySavings** *(float)* –
  The estimated monthly savings that might be realized if the recommended actions are taken.
- **estimatedPercentMonthlySavings** *(float)* –
  The estimated percentage of savings that might be realized if the recommended actions are taken.

**describe_trusted_advisor_checks** (**kwargs)**

Returns information about all available Trusted Advisor checks, including name, ID, category, description, and metadata. You must specify a language code: English (“en”) and Japanese (“ja”) are currently supported. The response contains a TrustedAdvisorCheckDescription for each check.

**Request Syntax**

```python
response = client.describe_trusted_advisor_checks(
    language='string'
)
```

**Parameters**

- **language** *(string)* – [REQUIRED]
  The ISO 639-1 code for the language in which AWS provides support. AWS Support currently supports English (“en”) and Japanese (“ja”). Language parameters must be passed explicitly for operations that take them.

**Return type** *dict*
Returns

Response Syntax

```
{
  'checks': [
    {
      'id': 'string',
      'name': 'string',
      'description': 'string',
      'category': 'string',
      'metadata': [
        'string',
      ],
    },
  ],
}
```

Response Structure

- `(dict)` — Information about the Trusted Advisor checks returned by the DescribeTrustedAdvisorChecks operation.
  - `checks` *(list)* — Information about all available Trusted Advisor checks.
    * `(dict)` — The description and metadata for a Trusted Advisor check.
      - `id` *(string)* — The unique identifier for the Trusted Advisor check.
      - `name` *(string)* — The display name for the Trusted Advisor check.
      - `description` *(string)* — The description of the Trusted Advisor check, which includes the alert criteria and recommended actions (contains HTML markup).
      - `category` *(string)* — The category of the Trusted Advisor check.
      - `metadata` *(list)* — The column headings for the data returned by the Trusted Advisor check. The order of the headings corresponds to the order of the data in the `Metadata` element of the `TrustedAdvisorResourceDetail` for the check. `Metadata` contains all the data that is shown in the Excel download, even in those cases where the UI shows just summary data.

    `generate_presigned_url` *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*
    Generate a presigned url given a client, its method, and arguments

Parameters

- `ClientMethod` *(string)* — The client method to presign for
- `Params` *(dict)* — The parameters normally passed to `ClientMethod`
- `ExpiresIn` *(int)* — The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
• **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns**

The presigned url

**get_paginator** *(operation_name)*

Create a paginator for an operation.

**Parameters**

operation_name *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is *create_foo*, and you’d normally invoke the operation as *client.create_foo(**kwargs)**, if the *create_foo* operation can be paginated, you can use the call *client.get_paginator("create_foo").*

**Raises OperationNotPageableError**

Raised if the operation is not pageable. You can use the *client.can_paginate* method to check if an operation is pageable.

**Return type**

*L{botocore.paginate.Paginator}*

**Returns**

A paginator object.

**get_waiter** *(waiter_name)*

**refresh_trusted_advisor_check** *(**kwargs)**

Requests a refresh of the Trusted Advisor check that has the specified check ID. Check IDs can be obtained by calling *DescribeTrustedAdvisorChecks*.

The response contains a TrustedAdvisorCheckRefreshStatus object, which contains these fields:

• **Status**. The refresh status of the check: “none”, “enqueued”, “processing”, “success”, or “abandoned”.

• **MillisUntilNextRefreshable**. The amount of time, in milliseconds, until the check is eligible for refresh.

• **CheckId**. The unique identifier for the check.

**Request Syntax**

```python
response = client.refresh_trusted_advisor_check(
    checkId='string'
)
```

**Parameters**

checkId *(string)* – [REQUIRED]

The unique identifier for the Trusted Advisor check.

**Return type**

dict

**Returns**

**Response Syntax**

```python
{
    'status': {
        'checkId': 'string',
        'status': 'string',
        'millisUntilNextRefreshable': 123
    }
}
```

**Response Structure**

• *(dict)* –

The current refresh status of a Trusted Advisor check.

  • **status** *(dict)* –

    The current refresh status for a check, including the amount of time until the check is eligible for refresh.
* checkId (string) –
  The unique identifier for the Trusted Advisor check.
* status (string) –
  The status of the Trusted Advisor check for which a refresh has
  been requested: “none”, “enqueued”, “processing”, “success”, or
  “abandoned”.
* millisUntilNextRefreshable (integer) –
  The amount of time, in milliseconds, until the Trusted Advisor
  check is eligible for refresh.

resolve_case(**kwargs)
  Takes a CaseId and returns the initial state of the case along with the state of the case after the call to
  ResolveCase completed.

Request Syntax

response = client.resolve_case(
    caseId='string'
)

Parameters caseId (string) – The AWS Support case ID requested or returned in the call.
  The case ID is an alphanumeric string formatted as shown in this example: case-
  12345678910-2013-c4c1d2bf33c5cf47

Returns dict

Response Syntax

{
    'initialCaseStatus': 'string',
    'finalCaseStatus': 'string'
}

Response Structure

• (dict) –
  The status of the case returned by the ResolveCase operation.
  – initialCaseStatus (string) –
  The status of the case when the ResolveCase request was sent.
  – finalCaseStatus (string) –
  The status of the case after the ResolveCase request was processed.

Paginators

The available paginators are:

• Support.Paginator.DescribeCases
• Support.Paginator.DescribeCommunications

class Support.Paginator.DescribeCases

    paginator = client.get_paginator('describe_cases')
paginate(**kwargs)

Creates an iterator that will paginate through responses from Support.Client.describe_cases().

Request Syntax

```python
response_iterator = paginator.paginate(
    caseIdList=[
        'string',
    ],
    displayId='string',
    afterTime='string',
    beforeTime='string',
    includeResolvedCases=True|False,
    language='string',
    includeCommunications=True|False,
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **caseIdList** (list) – A list of ID numbers of the support cases you want returned. The maximum number of cases is 100.
  - (string) –
- **displayId** (string) – The ID displayed for a case in the AWS Support Center user interface.
- **afterTime** (string) – The start date for a filtered date search on support case communications. Case communications are available for 12 months after creation.
- **beforeTime** (string) – The end date for a filtered date search on support case communications. Case communications are available for 12 months after creation.
- **includeResolvedCases** (boolean) – Specifies whether resolved support cases should be included in the DescribeCases results. The default is False.
- **language** (string) – The ISO 639-1 code for the language in which AWS provides support. AWS Support currently supports English (“en”) and Japanese (“ja”). Language parameters must be passed explicitly for operations that take them.
- **includeCommunications** (boolean) – Specifies whether communications should be included in the DescribeCases results. The default is True.
- **PaginationConfig** (dict) – A dictionary that provides parameters to control pagination.
  - **MaxItems** (integer) –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** (integer) –
    The size of each page.
  - **StartingToken** (string) –
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type
dict

Returns
Response Syntax

```json
{
    'cases': [
        {
            'caseId': 'string',
            'displayId': 'string',
            'subject': 'string',
            'status': 'string',
            'serviceCode': 'string',
            'categoryCode': 'string',
            'severityCode': 'string',
            'submittedBy': 'string',
            'timeCreated': 'string',
            'recentCommunications': {
                'communications': [
                    {
                        'caseId': 'string',
                        'body': 'string',
                        'submittedBy': 'string',
                        'timeCreated': 'string',
                        'attachmentSet': [
                            {
                                'attachmentId': 'string',
                                'fileName': 'string'
                            }
                        ],
                    },
                ],
                'nextToken': 'string'
            },
            'ccEmailAddresses': [ 'string' ],
            'language': 'string'
        }
    ],
    'NextToken': 'string'
}
```

Response Structure

- *(dict)* –

Returns an array of CaseDetails objects and a NextToken that defines a point for pagination in the result set.

- **cases** *(list)* –

  The details for the cases that match the request.

  - *(dict)* –

    A JSON-formatted object that contains the metadata for a support case. It is contained the response from a DescribeCases request.

    **CaseDetails** contains the following fields:

    - **CaseID.** The AWS Support case ID requested or returned in the call. The case ID is an alphanumeric string formatted as shown in this example: case-12345678910-2013-c4c1d2b3c5cf47.
    - **CategoryCode.** The category of problem for the AWS Support case. Corresponds to the CategoryCode values returned
by a call to DescribeServices.

- **DisplayId.** The identifier for the case on pages in the AWS Support Center.
- **Language.** The ISO 639-1 code for the language in which AWS provides support. AWS Support currently supports English (“en”) and Japanese (“ja”). Language parameters must be passed explicitly for operations that take them.
- **RecentCommunications.** One or more Communication objects. Fields of these objects are `Attachments`, `Body`, `CaseId`, `SubmittedBy`, and `TimeCreated`.
- **NextToken.** A resumption point for pagination.
- **ServiceCode.** The identifier for the AWS service that corresponds to the service code defined in the call to DescribeServices.
- **SeverityCode.** The severity code assigned to the case. Contains one of the values returned by the call to DescribeSeverityLevels.
- **Status.** The status of the case in the AWS Support Center.
- **Subject.** The subject line of the case.
- **SubmittedBy.** The email address of the account that submitted the case.
- **TimeCreated.** The time the case was created, in ISO-8601 format.

- **caseId (string) –**
  The AWS Support case ID requested or returned in the call. The case ID is an alphanumeric string formatted as shown in this example: case-J2345678910-2013-c4c1d2bf33c5cf47

- **displayId (string) –**
  The ID displayed for the case in the AWS Support Center. This is a numeric string.

- **subject (string) –**
  The subject line for the case in the AWS Support Center.

- **status (string) –**
  The status of the case.

- **serviceCode (string) –**
  The code for the AWS service returned by the call to DescribeServices.

- **categoryCode (string) –**
  The category of problem for the AWS Support case.

- **severityCode (string) –**
  The code for the severity level returned by the call to DescribeSeverityLevels.

- **submittedBy (string) –**
  The email address of the account that submitted the case.

- **timeCreated (string) –**
  The time that the case was case created in the AWS Support Center.

- **recentCommunications (dict) –**
The five most recent communications between you and AWS Support Center, including the IDs of any attachments to the communications. Also includes a nextToken that you can use to retrieve earlier communications.

- **communications** *(list)* –
  
  The five most recent communications associated with the case.

  - *(dict)* –

    A communication associated with an AWS Support case. The communication consists of the case ID, the message body, attachment information, the account email address, and the date and time of the communication.

- **caseId** *(string)* –
  
  The AWS Support case ID requested or returned in the call. The case ID is an alphanumeric string formatted as shown in this example: case-j2345678910-2013-c4c1d2bf33c5cf47

- **body** *(string)* –
  
  The text of the communication between the customer and AWS Support.

- **submittedBy** *(string)* –
  
  The email address of the account that submitted the AWS Support case.

- **timeCreated** *(string)* –
  
  The time the communication was created.

- **attachmentSet** *(list)* –
  
  Information about the attachments to the case communication.

  - *(dict)* –

    The file name and ID of an attachment to a case communication. You can use the ID to retrieve the attachment with the DescribeAttachment operation.

- **attachmentId** *(string)* –
  
  The ID of the attachment.

- **fileName** *(string)* –
  
  The file name of the attachment.

- **nextToken** *(string)* –
  
  A resumption point for pagination.

- **ccEmailAddresses** *(list)* –
  
  The email addresses that receive copies of communication about the case.

- **language** *(string)* –
  
  The ISO 639-1 code for the language in which AWS provides support. AWS Support currently supports English (“en”) and Japanese (“ja”). Language parameters must be passed explicitly for operations that take them.
– NextToken (string) –
A token to resume pagination.

class Support.Paginator.DescribeCommunications

    paginator = client.get_paginator('describe_communications')

    paginate (**kwargs)
    Creates an iterator that will paginate through responses from
    Support.Client.describe_communications().

    Request Syntax

    response_iterator = paginator.paginate(
        caseId='string',
        beforeTime='string',
        afterTime='string',
        PaginationConfig={
            'MaxItems': 123,
            'PageSize': 123,
            'StartingToken': 'string'
        }
    )

    Parameters
    • caseId (string) – [REQUIRED]
        The AWS Support case ID requested or returned in the call. The case ID is an
        alphanumeric string formatted as shown in this example: case-12345678910-
        2013-c4c1d2bf33c5cf47
    • beforeTime (string) – The end date for a filtered date search on support case
        communications. Case communications are available for 12 months after cre-
        ation.
    • afterTime (string) – The start date for a filtered date search on support case com-
        munications. Case communications are available for 12 months after creation.
    • PaginationConfig (dict) – A dictionary that provides parameters to control pag-
        ination.
        – MaxItems (integer) –
            The total number of items to return. If the total number of items available
            is more than the value specified in max-items then a NextToken will be
            provided in the output that you can use to resume pagination.
        – PageSize (integer) –
            The size of each page.
        – StartingToken (string) –
            A token to specify where to start paginating. This is the NextToken
            from a previous response.

    Return type  dict
    Returns

    Response Syntax

    {
        'communications': [
        ]
    }
'caseId': 'string',
'body': 'string',
'submittedBy': 'string',
'timeCreated': 'string',
'attachmentSet': [
    {
        'attachmentId': 'string',
        'fileName': 'string'
    },
    
},
],

'NextToken': 'string'
}

Response Structure

• (dict) –
  
  The communications returned by the DescribeCommunications operation.

  – communications (list) –
    
    The communications for the case.

    • (dict) –
      
      A communication associated with an AWS Support case. The communication consists of the case ID, the message body, attachment information, the account email address, and the date and time of the communication.

      • caseId (string) –
        
        The AWS Support case ID requested or returned in the call. The case ID is an alphanumeric string formatted as shown in this example: case-12345678910-2013-c4c1d2bf33c5cf47

      • body (string) –
        
        The text of the communication between the customer and AWS Support.

      • submittedBy (string) –
        
        The email address of the account that submitted the AWS Support case.

      • timeCreated (string) –
        
        The time the communication was created.

      • attachmentSet (list) –
        
        Information about the attachments to the case communication.

      • (dict) –
        
        The file name and ID of an attachment to a case communication. You can use the ID to retrieve the attachment with the DescribeAttachment operation.

      • attachmentId (string) –
        
        The ID of the attachment.

      • fileName (string) –
        
        The file name of the attachment.

    – NextToken (string) –
A token to resume pagination.

**SWF**

- `request_cancel_workflow_execution()`
- `respond_activity_task_canceled()`
- `respond_activity_task_completed()`
- `respond_activity_task_failed()`

---

**3.1. Services**
Boto3 Documentation, Release 1.1.4

- respond_decision_task_completed()
- signal_workflow_execution()
- start_workflow_execution()
- terminate_workflow_execution()

**can_paginate**(operation_name)

Check if an operation can be paginated.

**Parameters** operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

**Returns** True if the operation can be paginated, False otherwise.

**count_closed_workflow_executions**(**kwargs)

Returns the number of closed workflow executions within the given domain that meet the specified filtering criteria.

**Note:** This operation is eventually consistent. The results are best effort and may not exactly reflect recent updates and changes.

---

**Access Control**

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a Resource element with the domain name to limit the action to only specified domains.
- Use an Action element to allow or deny permission to call this action.
- Constrain the following parameters by using a Condition element with the appropriate keys. *
  - tagFilter.tag: String constraint. The key is swf:tagFilter.tag.
  - typeFilter.name: String constraint. The key is swf:typeFilter.name.
  - typeFilter.version: String constraint. The key is swf:typeFilter.version.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s cause parameter will be set to OPERATION_NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

**Request Syntax**

```python
response = client.count_closed_workflow_executions(
    domain='string',
    startTimeFilter={
        'oldestDate': datetime(2015, 1, 1),
        'latestDate': datetime(2015, 1, 1)
    },
    closeTimeFilter={
        'oldestDate': datetime(2015, 1, 1),
        'latestDate': datetime(2015, 1, 1)
    },
    executionFilter={
        'workflowId': 'string'
    },
    typeFilter={
        'name': 'string',
        'version': 'string'
    },
    tagFilter={
        'tag': 'string'
    },
    closeStatusFilter={
```
'status': 'COMPLETED'|'FAILED'|'CANCELED'|'TERMINATED'|'CONTINUED_AS_NEW'|'TIMED_OUT'
}
}

Parameters

- **domain** *(string)* – [REQUIRED]
The name of the domain containing the workflow executions to count.

- **startTimeFilter** *(dict)* – If specified, only workflow executions that meet the start time criteria of the filter are counted.

  **Note:** startTimeFilter and closeTimeFilter are mutually exclusive. You must specify one of these in a request but not both.

  - **oldestDate** *(datetime)* – [REQUIRED]
    Specifies the oldest start or close date and time to return.
  - **latestDate** *(datetime)* –
    Specifies the latest start or close date and time to return.

- **closeTimeFilter** *(dict)* – If specified, only workflow executions that meet the close time criteria of the filter are counted.

  **Note:** startTimeFilter and closeTimeFilter are mutually exclusive. You must specify one of these in a request but not both.

  - **oldestDate** *(datetime)* – [REQUIRED]
    Specifies the oldest start or close date and time to return.
  - **latestDate** *(datetime)* –
    Specifies the latest start or close date and time to return.

- **executionFilter** *(dict)* – If specified, only workflow executions matching the WorkflowId in the filter are counted.

  **Note:** closeStatusFilter, executionFilter, typeFilter and tagFilter are mutually exclusive. You can specify at most one of these in a request.

  - **workflowId** *(string)* – [REQUIRED]
    The workflowId to pass of match the criteria of this filter.

- **typeFilter** *(dict)* – If specified, indicates the type of the workflow executions to be counted.

  **Note:** closeStatusFilter, executionFilter, typeFilter and tagFilter are mutually exclusive. You can specify at most one of these in a request.

  - **name** *(string)* – [REQUIRED]
    Required. Name of the workflow type.
  - **version** *(string)* –
    Version of the workflow type.

- **tagFilter** *(dict)* – If specified, only executions that have a tag that matches the filter are counted.
**tag** *(string)* — [REQUIRED]

Required. Specifies the tag that must be associated with the execution for it to meet the filter criteria.

• **closeStatusFilter** *(dict)* — If specified, only workflow executions that match this close status are counted. This filter has an affect only if **executionStatus** is specified as **CLOSED**.

**status** *(string)* — [REQUIRED]

Required. The close status that must match the close status of an execution for it to meet the criteria of this filter.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'count': 123,
    'truncated': True|False
}
```

**Response Structure**

• *(dict)* —

Contains the count of workflow executions returned from CountOpenWorkflowExecutions or CountClosedWorkflowExecutions

• **count** *(integer)* —

The number of workflow executions.

• **truncated** *(boolean)* —

If set to true, indicates that the actual count was more than the maximum supported by this API and the count returned is the truncated value.

**count_open_workflow_executions** (**kwargs**)

Returns the number of open workflow executions within the given domain that meet the specified filtering criteria.

**Note:** This operation is eventually consistent. The results are best effort and may not exactly reflect recent updates and changes.

**Access Control**

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

• Use a **Resource** element with the domain name to limit the action to only specified domains.

• Use an **Action** element to allow or deny permission to call this action.

• Constrain the following parameters by using a **Condition** element with the appropriate keys. *

  • **tagFilter.tag**: String constraint. The key is `swf:tagFilter.tag`.
If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s cause parameter will be set to OPERATION NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

Request Syntax

```python
response = client.count_open_workflow_executions(
    domain='string',
    startTimeFilter={
        'oldestDate': datetime(2015, 1, 1),
        'latestDate': datetime(2015, 1, 1)
    },
    typeFilter={
        'name': 'string',
        'version': 'string'
    },
    tagFilter={
        'tag': 'string'
    },
    executionFilter={
        'workflowId': 'string'
    }
)
```

Parameters

- **domain (string) – [REQUIRED]**
  
  The name of the domain containing the workflow executions to count.

- **startTimeFilter (dict) – [REQUIRED]**
  
  Specifies the start time criteria that workflow executions must meet in order to be counted.
  
  - **oldestDate (datetime) – [REQUIRED]**
    
    Specifies the oldest start or close date and time to return.
  
  - **latestDate (datetime)**
    
    Specifies the latest start or close date and time to return.

- **typeFilter (dict) –** Specifies the type of the workflow executions to be counted.

  - **name (string) – [REQUIRED]**
    
    Required. Name of the workflow type.
  
  - **version (string)**
    
    Version of the workflow type.

- **tagFilter (dict) –** If specified, only executions that have a tag that matches the filter are counted.

  - **tag (string)**
    
    You can specify at most one of these in a request.

  - **name (string) – [REQUIRED]**
    
    Required. Name of the workflow type.
  
  - **version (string)**
    
    Version of the workflow type.
- `tag (string)` – [REQUIRED]

  **Required.** Specifies the tag that must be associated with the execution for it to meet the filter criteria.

- `executionFilter (dict)` – If specified, only workflow executions matching the WorkflowId in the filter are counted.

**Note:** `executionFilter`, `typeFilter` and `tagFilter` are mutually exclusive. You can specify at most one of these in a request.

- `workflowId (string)` – [REQUIRED]

  The workflowId to pass of match the criteria of this filter.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'count': 123,
    'truncated': True|False
}
```

**Response Structure**

- `(dict)` –

  Contains the count of workflow executions returned from CountOpenWorkflowExecutions or CountClosedWorkflowExecutions

  - `count (integer)` –

    The number of workflow executions.

  - `truncated (boolean)` –

    If set to true, indicates that the actual count was more than the maximum supported by this API and the count returned is the truncated value.

**count_pending_activity_tasks(**kwargs)**

Returns the estimated number of activity tasks in the specified task list. The count returned is an approximation and is not guaranteed to be exact. If you specify a task list that no activity task was ever scheduled in then 0 will be returned.

**Access Control**

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a Resource element with the domain name to limit the action to only specified domains.
- Use an Action element to allow or deny permission to call this action.
- Constrain the `taskList.name` parameter by using a Condition element with the `swf:taskList.name` key to allow the action to access only certain task lists.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s `cause` parameter will be set to `OPERATION_NOT_PERMITTED`. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

**Request Syntax**

```python
response = client.count_pending_activity_tasks(
    domain='string',
    taskList={
        'name': 'string'
    }
)```
Parameters

- **domain** *(string)* – [REQUIRED]
  The name of the domain that contains the task list.
- **taskList** *(dict)* – [REQUIRED]
  The name of the task list.
  - **name** *(string)* – [REQUIRED]
    The name of the task list.

Return type  dict

Returns

Response Syntax

```python
{
    'count': 123,
    'truncated': True|False
}
```

Response Structure

- *(dict)* –
  Contains the count of tasks in a task list.
  - **count** *(integer)* –
    The number of tasks in the task list.
  - **truncated** *(boolean)* –
    If set to true, indicates that the actual count was more than the maximum supported by this API and the count returned is the truncated value.

count_pending_decision_tasks(**kwargs)**

Returns the estimated number of decision tasks in the specified task list. The count returned is an approximation and is not guaranteed to be exact. If you specify a task list that no decision task was ever scheduled in then 0 will be returned.

Access Control

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a Resource element with the domain name to limit the action to only specified domains.
- Use an Action element to allow or deny permission to call this action.
- Constrain the taskList.name parameter by using a Condition element with the swf:taskList.name key to allow the action to access only certain task lists.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s cause parameter will be set to OPERATION_NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

Request Syntax

```python
response = client.count_pending_decision_tasks(
    domain='string',
    taskList={
        'name': 'string'
    }
)
```
Parameters

• domain (string) – [REQUIRED]
  The name of the domain that contains the task list.

• taskList (dict) – [REQUIRED]
  The name of the task list.
  – name (string) – [REQUIRED]
    The name of the task list.

Return type  dict

Returns

Response Syntax

{
  'count': 123,
  'truncated': True|False
}

Response Structure

• (dict) –
  Contains the count of tasks in a task list.
  – count (integer) –
    The number of tasks in the task list.
  – truncated (boolean) –
    If set to true, indicates that the actual count was more than the maximum supported by this API and the count returned is the truncated value.

def deprecate_activity_type(**kwargs)
Deprecates the specified activity type. After an activity type has been deprecated, you cannot create new tasks of that activity type. Tasks of this type that were scheduled before the type was deprecated will continue to run.

Note:  This operation is eventually consistent. The results are best effort and may not exactly reflect recent updates and changes.

Access Control

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:
  • Use a Resource element with the domain name to limit the action to only specified domains.
  • Use an Action element to allow or deny permission to call this action.
  • Constrain the following parameters by using a Condition element with the appropriate keys. *
    activityType.name: String constraint. The key is swf:activityType.name.
    activityType.version: String constraint. The key is swf:activityType.version.
If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s cause parameter will be set to OPERATION_NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

Request Syntax

response = client.deprecate_activity_type(
  domain='string',
  activityType={
    'name': 'string',
  })
Parameters

- **domain** *(string)* – [REQUIRED]
  The name of the domain in which the activity type is registered.

- **activityType** *(dict)* – [REQUIRED]
  The activity type to deprecate.
  - **name** *(string)* – [REQUIRED]
    The name of this activity.
  
  **Note:** The combination of activity type name and version must be unique within a domain.

  - **version** *(string)* – [REQUIRED]
    The version of this activity.

  **Note:** The combination of activity type name and version must be unique with in a domain.

Returns None

def deprecate_domain(**kwargs)
Deprecates the specified domain. After a domain has been deprecated it cannot be used to create new workflow executions or register new types. However, you can still use visibility actions on this domain. Deprecating a domain also deprecates all activity and workflow types registered in the domain. Executions that were started before the domain was deprecated will continue to run.

**Note:** This operation is eventually consistent. The results are best effort and may not exactly reflect recent updates and changes.

Access Control

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a Resource element with the domain name to limit the action to only specified domains.
- Use an Action element to allow or deny permission to call this action.
- You cannot use an IAM policy to constrain this action’s parameters.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s cause parameter will be set to OPERATION_NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

Request Syntax

```python
response = client.deprecate_domain(
    name='string'
)
```

Parameters **name** *(string)* – [REQUIRED]

  The name of the domain to deprecate.

Returns None
deprecate_workflow_type(**kwargs)

Deprecates the specified workflow type. After a workflow type has been deprecated, you cannot create new executions of that type. Executions that were started before the type was deprecated will continue to run. A deprecated workflow type may still be used when calling visibility actions.

**Note:** This operation is eventually consistent. The results are best effort and may not exactly reflect recent updates and changes.

Access Control

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a Resource element with the domain name to limit the action to only specified domains.
- Use an Action element to allow or deny permission to call this action.
- Constrain the following parameters by using a Condition element with the appropriate keys. *
  * workflowType.name: String constraint. The key is swf:workflowType.name.
  * workflowType.version: String constraint. The key is swf:workflowType.version.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s cause parameter will be set to OPERATION_NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

Request Syntax

```python
response = client.deprecate_workflow_type(
    domain='string',
    workflowType={
        'name': 'string',
        'version': 'string'
    }
)
```

**Parameters**

- **domain (string)** – [REQUIRED]
  
The name of the domain in which the workflow type is registered.

- **workflowType (dict)** – [REQUIRED]
  
The workflow type to deprecate.
  - **name (string)** – [REQUIRED]
    
    Required. The name of the workflow type.

    **Note:** The combination of workflow type name and version must be unique with in a domain.

  - **version (string)** – [REQUIRED]
    
    Required. The version of the workflow type.

    **Note:** The combination of workflow type name and version must be unique with in a domain.

**Returns** None

describe_activity_type(**kwargs)

Returns information about the specified activity type. This includes configuration settings provided when the type was registered and other general information about the type.

Access Control
You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a **Resource** element with the domain name to limit the action to only specified domains.
- Use an **Action** element to allow or deny permission to call this action.
- Constrain the following parameters by using a **Condition** element with the appropriate keys. *activityType.name* is a **String constraint**. The key is *swf:activityType.name*.
- activityType.version: **String constraint**. The key is *swf:activityType.version*.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s **cause** parameter will be set to **OPERATION_NOT_PERMITTED**. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

**Request Syntax**

```python
response = client.describe_activity_type(
    domain='string',
    activityType={
        'name': 'string',
        'version': 'string'
    }
)
```

**Parameters**

- **domain** (*string*) – [REQUIRED]
The name of the domain in which the activity type is registered.
- **activityType** (*dict*) – [REQUIRED]
The activity type to get information about. Activity types are identified by the **name** and **version** that were supplied when the activity was registered.
  - **name** (*string*) – [REQUIRED]
The name of this activity.
  
  **Note**: The combination of activity type name and version must be unique within a domain.

  - **version** (*string*) – [REQUIRED]
The version of this activity.

  **Note**: The combination of activity type name and version must be unique within a domain.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'typeInfo': {
        'activityType': {
            'name': 'string',
            'version': 'string'
        },
        'status': 'REGISTERED'|'DEPRECATED',
        'description': 'string',
        'creationDate': datetime(2015, 1, 1),
        'deprecationDate': datetime(2015, 1, 1)
    },
```

**3.1. Services**

4385
'configuration': {
    'defaultTaskStartToCloseTimeout': 'string',
    'defaultTaskHeartbeatTimeout': 'string',
    'defaultTaskList': {
        'name': 'string'
    },
    'defaultTaskPriority': 'string',
    'defaultTaskScheduleToStartTimeout': 'string',
    'defaultTaskScheduleToCloseTimeout': 'string'
}

Response Structure

* (dict) – Detailed information about an activity type.

  – typeInfo (dict) – General information about the activity type.

  The status of activity type (returned in the ActivityTypeInfo structure) can be one of the following.
  * **REGISTERED**: The type is registered and available. Workers supporting this type should be running.
  * **DEPRECATED**: The type was deprecated using DeprecateActivityType, but is still in use. You should keep workers supporting this type running. You cannot create new tasks of this type.
  * **activityType** (dict) – The ActivityType type structure representing the activity type.
    * **name** (string) – The name of this activity.
      
      Note: The combination of activity type name and version must be unique within a domain.
      
      * **version** (string) – The version of this activity.
      
      Note: The combination of activity type name and version must be unique within a domain.
      
      * **status** (string) – The current status of the activity type.
      * **description** (string) – The description of the activity type provided in RegisterActivityType.
      * **creationDate** (datetime) – The date and time this activity type was created through RegisterActivityType.
      * **deprecationDate** (datetime) – If DEPRECATED, the date and time DeprecateActivityType was called.
The configuration settings registered with the activity type.

* **defaultTaskStartToCloseTimeout (string)** –

  *Optional.* The default maximum duration for tasks of an activity type specified when registering the activity type. You can override this default when scheduling a task through the ScheduleActivityTask decision.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

* **defaultTaskHeartbeatTimeout (string)** –

  *Optional.* The default maximum time, in seconds, before which a worker processing a task must report progress by calling RecordActivityTaskHeartbeat.

  You can specify this value only when registering an activity type. The registered default value can be overridden when you schedule a task through the ScheduleActivityTask decision. If the activity worker subsequently attempts to record a heartbeat or returns a result, the activity worker receives an UnknownResource fault. In this case, Amazon SWF no longer considers the activity task to be valid; the activity worker should clean up the activity task.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

* **defaultTaskList (dict)** –

  *Optional.* The default task list specified for this activity type at registration. This default is used if a task list is not provided when a task is scheduled through the ScheduleActivityTask decision. You can override the default registered task list when scheduling a task through the ScheduleActivityTask decision.

    · **name (string)** –

      The name of the task list.

* **defaultTaskPriority (string)** –

  *Optional.* The default task priority for tasks of this activity type, specified at registration. If not set, then “0” will be used as the default priority. This default can be overridden when scheduling an activity task.

  Valid values are integers that range from Java’s `Integer.MIN_VALUE` (-2147483648) to `Integer.MAX_VALUE` (2147483647). Higher numbers indicate higher priority.

  For more information about setting task priority, see Setting Task Priority in the *Amazon Simple Workflow Developer Guide*.

* **defaultTaskScheduleToStartTimeout (string)** –

  *Optional.* The default maximum duration, specified when registering the activity type, that a task of an activity type can wait before being assigned to a worker. You can override this default when scheduling a task through the ScheduleActivityTask decision.
The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

* `defaultTaskScheduleToCloseTimeout (string)` –

  *Optional.* The default maximum duration, specified when registering the activity type, for tasks of this activity type. You can override this default when scheduling a task through the `ScheduleActivityTask` decision.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

`describe_domain(**kwargs)`

Returns information about the specified domain, including description and status.

**Access Control**

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

* Use a `Resource` element with the domain name to limit the action to only specified domains.
* Use an `Action` element to allow or deny permission to call this action.
* You cannot use an IAM policy to constrain this action’s parameters.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s `cause` parameter will be set to `OPERATION_NOT_PERMITTED`. For details and example IAM policies, see [Using IAM to Manage Access to Amazon SWF Workflows](https://docs.aws.amazon.com/AmazonSWF/latest/apireference/using-iam-to-manage-access-to-amazon-swf-workflows.html).

**Request Syntax**

```python
response = client.describe_domain(
    name='string'
)
```

- **Parameters**
  - `name (string)` – [REQUIRED]

  The name of the domain to describe.

- **Return type**
  - dict

**Returns**

**Response Syntax**

```python
{
    'domainInfo': {
        'name': 'string',
        'status': 'REGISTERED'|'DEPRECATED',
        'description': 'string'
    },
    'configuration': {
        'workflowExecutionRetentionPeriodInDays': 'string'
    }
}
```

- **Response Structure**
  - (dict) –

  Contains details of a domain.

  - `domainInfo (dict)` –

    Contains general information about a domain.

    - `name (string)` –

      The name of the domain. This name is unique within the account.
* status (string) –

The status of the domain:
- **REGISTERED**: The domain is properly registered and available. You can use this domain for registering types and creating new workflow executions.
- **DEPRECATED**: The domain was deprecated using DeprecateDomain, but is still in use. You should not create new workflow executions in this domain.

* description (string) –

The description of the domain provided through RegisterDomain.

- configuration (dict) –

Contains the configuration settings of a domain.

* workflowExecutionRetentionPeriodInDays (string) –

The retention period for workflow executions in this domain.

```python
describe_workflow_execution(**kwargs)
```

Returns information about the specified workflow execution including its type and some statistics.

**Note:** This operation is eventually consistent. The results are best effort and may not exactly reflect recent updates and changes.

**Access Control**

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:
- Use a Resource element with the domain name to limit the action to only specified domains.
- Use an Action element to allow or deny permission to call this action.
- You cannot use an IAM policy to constrain this action’s parameters.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s cause parameter will be set to OPERATION_NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

```python
response = client.describe_workflow_execution(
    domain='string',
    execution={
        'workflowId': 'string',
        'runId': 'string'
    }
)
```

**Parameters**

- **domain (string)** – [REQUIRED]

  The name of the domain containing the workflow execution.

- **execution (dict)** – [REQUIRED]

  The workflow execution to describe.
  - **workflowId (string)** – [REQUIRED]

    The user defined identifier associated with the workflow execution.
  - **runId (string)** – [REQUIRED]

    A system-generated unique identifier for the workflow execution.

**Return type** dict
Returns

Response Syntax

```json
{
   'executionInfo': {
      'execution': {
         'workflowId': 'string',
         'runId': 'string'
      },
      'workflowType': {
         'name': 'string',
         'version': 'string'
      },
      'startTimestamp': datetime(2015, 1, 1),
      'closeTimestamp': datetime(2015, 1, 1),
      'executionStatus': 'OPEN'|'CLOSED',
      'closeStatus': 'COMPLETED'|'FAILED'|'CANCELED'|'TERMINATED'|'CONTINUED_AS新京',
      'parent': {
         'workflowId': 'string',
         'runId': 'string'
      },
      'tagList': [ 'string',
      ],
      'cancelRequested': True|False
   },
   'executionConfiguration': {
      'taskStartToCloseTimeout': 'string',
      'executionStartToCloseTimeout': 'string',
      'taskList': {
         'name': 'string'
      },
      'taskPriority': 'string',
      'childPolicy': 'TERMINATE'|'REQUEST_CANCEL'|'ABANDON',
      'lambdaRole': 'string'
   },
   'openCounts': {
      'openActivityTasks': 123,
      'openDecisionTasks': 123,
      'openTimers': 123,
      'openChildWorkflowExecutions': 123,
      'openLambdaFunctions': 123
   },
   'latestActivityTaskTimestamp': datetime(2015, 1, 1),
   'latestExecutionContext': 'string'
}
```

Response Structure

* (dict) –

Contains details about a workflow execution.

  – **executionInfo** (dict) –

     Information about the workflow execution.

       * **execution** (dict) –

          The workflow execution this information is about.

         · **workflowId** (string) –
The user defined identifier associated with the workflow execution.

- **runId** (*string*) –
  
  A system-generated unique identifier for the workflow execution.

- **workflowType** (*dict*) –
  
  The type of the workflow execution.
  
  - **name** (*string*) –
    
    Required. The name of the workflow type.
  
  - **version** (*string*) –
    
    Required. The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- **startTime** (*datetime*) –
  
  The time when the execution was started.

- **closeTime** (*datetime*) –
  
  The time when the workflow execution was closed. Set only if the execution status is CLOSED.

- **executionStatus** (*string*) –
  
  The current status of the execution.

- **closeStatus** (*string*) –
  
  If the execution status is closed then this specifies how the execution was closed:
  
  - **COMPLETED**: the execution was successfully completed.
  - **CANCELED**: the execution was canceled. Cancellation allows the implementation to gracefully clean up before the execution is closed.
  - **TERMINATED**: the execution was force terminated.
  - **FAILED**: the execution failed to complete.
  - **TIMED_OUT**: the execution did not complete in the allotted time and was automatically timed out.
  - **CONTINUED_AS_NEW**: the execution is logically continued. This means the current execution was completed and a new execution was started to carry on the workflow.

- **parent** (*dict*) –
  
  If this workflow execution is a child of another execution then contains the workflow execution that started this execution.

  - **workflowId** (*string*) –
    
    The user defined identifier associated with the workflow execution.

  - **runId** (*string*) –
    
    A system-generated unique identifier for the workflow execution.
- **tagList** *(list)* –
  The list of tags associated with the workflow execution. Tags can be used to identify and list workflow executions of interest through the visibility APIs. A workflow execution can have a maximum of 5 tags.
  - `(string)` –
- **cancelRequested** *(boolean)* –
  Set to true if a cancellation is requested for this workflow execution.

- **executionConfiguration** *(dict)* –
  The configuration settings for this workflow execution including timeout values, tasklist etc.
  - **taskStartToCloseTimeout** *(string)* –
    The maximum duration allowed for decision tasks for this workflow execution.
    The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.
  - **executionStartToCloseTimeout** *(string)* –
    The total duration for this workflow execution.
    The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.
  - **taskList** *(dict)* –
    The task list used for the decision tasks generated for this workflow execution.
    - **name** *(string)* –
      The name of the task list.
  - **taskPriority** *(string)* –
    The priority assigned to decision tasks for this workflow execution. Valid values are integers that range from Java’s `Integer.MIN_VALUE` (-2147483648) to `Integer.MAX_VALUE` (2147483647). Higher numbers indicate higher priority.
    For more information about setting task priority, see Setting Task Priority in the Amazon Simple Workflow Developer Guide.
  - **childPolicy** *(string)* –
    The policy to use for the child workflow executions if this workflow execution is terminated, by calling the TerminateWorkflowExecution action explicitly or due to an expired timeout.
    The supported child policies are:
    - **TERMINATE**: the child executions will be terminated.
    - **REQUEST_CANCEL**: a request to cancel will be attempted for each child execution by recording a `WorkflowExecutionCancelRequested` event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
    - **ABANDON**: no action will be taken. The child executions will continue to run.
  - **lambdaRole** *(string)* –
The IAM role used by this workflow execution when invoking AWS Lambda functions.

- `openCounts (dict)` –
  The number of tasks for this workflow execution. This includes open and closed tasks of all types.
  * `openActivityTasks (integer)` –
    The count of activity tasks whose status is OPEN.
  * `openDecisionTasks (integer)` –
    The count of decision tasks whose status is OPEN. A workflow execution can have at most one open decision task.
  * `openTimers (integer)` –
    The count of timers started by this workflow execution that have not fired yet.
  * `openChildWorkflowExecutions (integer)` –
    The count of child workflow executions whose status is OPEN.
  * `openLambdaFunctions (integer)` –
    The count of AWS Lambda functions that are currently executing.

- `latestActivityTaskTimestamp (datetime)` –
  The time when the last activity task was scheduled for this workflow execution. You can use this information to determine if the workflow has not made progress for an unusually long period of time and might require a corrective action.

- `latestExecutionContext (string)` –
  The latest executionContext provided by the decider for this workflow execution. A decider can provide an executionContext (a free-form string) when closing a decision task using RespondDecisionTaskCompleted.

`describe_workflow_type (**kwargs)`

Returns information about the specified `workflow type`. This includes configuration settings specified when the type was registered and other information such as creation date, current status, and so on.

Access Control

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a `Resource` element with the domain name to limit the action to only specified domains.
- Use an `Action` element to allow or deny permission to call this action.
- Constrain the following parameters by using a `Condition` element with the appropriate keys. * workflowType.name : String constraint. The key is `swf:workflowType.name`.
  * workflowType.version : String constraint. The key is `swf:workflowType.version`.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s `cause` parameter will be set to `OPERATION_NOT_PERMITTED`. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

Request Syntax

```python
response = client.describe_workflow_type(
    domain='string',
    workflowType={
        'name': 'string',
        'version': 'string'
    })
```
Parameters

- **domain** *(string) – [REQUIRED]*
  The name of the domain in which this workflow type is registered.

- **workflowType** *(dict) – [REQUIRED]*
  The workflow type to describe.
  - **name** *(string) – [REQUIRED]*
    Required. The name of the workflow type.
    
    **Note:** The combination of workflow type name and version must be unique within a domain.
  
  - **version** *(string) – [REQUIRED]*
    Required. The version of the workflow type.
    
    **Note:** The combination of workflow type name and version must be unique within a domain.

Return type: **dict**

Returns

Response Syntax

```python
{
    'typeInfo': {
        'workflowType': {
            'name': 'string',
            'version': 'string'
        },
        'status': 'REGISTERED'|'DEPRECATED',
        'description': 'string',
        'creationDate': datetime(2015, 1, 1),
        'deprecationDate': datetime(2015, 1, 1)
    },
    'configuration': {
        'defaultTaskStartToCloseTimeout': 'string',
        'defaultExecutionStartToCloseTimeout': 'string',
        'defaultTaskList': {
            'name': 'string'
        },
        'defaultTaskPriority': 'string',
        'defaultChildPolicy': 'TERMINATE'|'REQUEST_CANCEL'|'ABANDON',
        'defaultLambdaRole': 'string'
    }
}
```

Response Structure

- *(dict)*
  Contains details about a workflow type.
  
  - **typeInfo** *(dict)*
    General information about the workflow type.
The status of the workflow type (returned in the WorkflowTypeInfo structure) can be one of the following.

- **REGISTERED**: The type is registered and available. Workers supporting this type should be running.
- **DEPRECATED**: The type was deprecated using DeprecateWorkflowType, but is still in use. You should keep workers supporting this type running. You cannot create new workflow executions of this type.

- **workflowType (dict)** –
  The workflow type this information is about.
  - **name (string)** –
    Required. The name of the workflow type.
    
    **Note**: The combination of workflow type name and version must be unique within a domain.

  - **version (string)** –
    Required. The version of the workflow type.
    
    **Note**: The combination of workflow type name and version must be unique within a domain.

- **status (string)** –
  The current status of the workflow type.

- **description (string)** –
  The description of the type registered through RegisterWorkflowType.

- **creationDate (datetime)** –
  The date when this type was registered.

- **deprecationDate (datetime)** –
  If the type is in deprecated state, then it is set to the date when the type was deprecated.

- **configuration (dict)** –
  Configuration settings of the workflow type registered through RegisterWorkflowType.

- **defaultTaskStartToCloseTimeout (string)** –
  *Optional*. The default maximum duration, specified when registering the workflow type, that a decision task for executions of this workflow type might take before returning completion or failure. If the task does not close in the specified time then the task is automatically timed out and rescheduled. If the decider eventually reports a completion or failure, it is ignored. This default can be overridden when starting a workflow execution using the StartWorkflowExecution action or the StartChildWorkflowExecution decision.
  
  The duration is specified in seconds; an integer greater than or equal to 0. The value "NONE" can be used to specify unlimited duration.

- **defaultExecutionStartToCloseTimeout (string)** –
  *Optional*. The default maximum duration, specified when registering the workflow type, for executions of this workflow
type. This default can be overridden when starting a workflow execution using the StartWorkflowExecution action or the StartChildWorkflowExecution decision.

The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

* defaultTaskList (dict) –

Optional. The default task list, specified when registering the workflow type, for decisions tasks scheduled for workflow executions of this type. This default can be overridden when starting a workflow execution using the StartWorkflowExecution action or the StartChildWorkflowExecution decision.

- name (string) –

The name of the task list.

* defaultTaskPriority (string) –

Optional. The default task priority, specified when registering the workflow type, for all decision tasks of this workflow type. This default can be overridden when starting a workflow execution using the StartWorkflowExecution action or the StartChildWorkflowExecution decision.

Valid values are integers that range from Java’s `Integer.MIN_VALUE` (-2147483648) to `Integer.MAX_VALUE` (2147483647). Higher numbers indicate higher priority.

For more information about setting task priority, see Setting Task Priority in the Amazon Simple Workflow Developer Guide.

* defaultChildPolicy (string) –

Optional. The default policy to use for the child workflow executions when a workflow execution of this type is terminated, by calling the TerminateWorkflowExecution action explicitly or due to an expired timeout. This default can be overridden when starting a workflow execution using the StartWorkflowExecution action or the StartChildWorkflowExecution decision.

The supported child policies are:

- TERMINATE: the child executions will be terminated.
- REQUEST_CANCEL: a request to cancel will be attempted for each child execution by recording a WorkflowExecutionCancelRequested event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
- ABANDON: no action will be taken. The child executions will continue to run.

* defaultLambdaRole (string) –

The default IAM role to use when a workflow execution invokes a AWS Lambda function.

generate_presigned_url (ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None) Generate a presigned url given a client, its method, and arguments

Parameters

- ClientMethod (string) – The client method to presign for
- Params (dict) – The parameters normally passed to ClientMethod.
ExpiresIn (int) – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)

HttpMethod (string) – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns The presigned url

get_paginator (operation_name)
Create a paginator for an operation.

Parameters operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

Raises OperationNotPageableError Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

Return type L{botocore.paginate.Paginator}

Returns A paginator object.

get_waiter (waiter_name)

get_workflow_execution_history (**kwargs)
Returns the history of the specified workflow execution. The results may be split into multiple pages. To retrieve subsequent pages, make the call again using the nextPageToken returned by the initial call.

Note: This operation is eventually consistent. The results are best effort and may not exactly reflect recent updates and changes.

Access Control
You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

• Use a Resource element with the domain name to limit the action to only specified domains.
• Use an Action element to allow or deny permission to call this action.
• You cannot use an IAM policy to constrain this action’s parameters.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s cause parameter will be set to OPERATION_NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

Request Syntax

response = client.get_workflow_execution_history(
    domain='string',
    execution={
        'workflowId': 'string',
        'runId': 'string'
    },
    nextPageToken='string',
    maximumPageSize=123,
    reverseOrder=True|False
)

Parameters

• domain (string) – [REQUIRED]
  The name of the domain containing the workflow execution.

• execution (dict) – [REQUIRED]
  Specifies the workflow execution for which to return the history.
- **workflowId** *(string)* – [REQUIRED]
  The user defined identifier associated with the workflow execution.
- **runId** *(string)* – [REQUIRED]
  A system-generated unique identifier for the workflow execution.

- **nextPageToken** *(string)* – If a NextPageToken was returned by a previous call, there are more results available. To retrieve the next page of results, make the call again using the returned token in nextPageToken. Keep all other arguments unchanged.

  The configured `maximumPageSize` determines how many results can be returned in a single call.

- **maximumPageSize** *(integer)* – The maximum number of results that will be returned per call. `nextPageToken` can be used to obtain further pages of results. The default is 1000, which is the maximum allowed page size. You can, however, specify a page size smaller than the maximum.

  This is an upper limit only; the actual number of results returned per call may be fewer than the specified maximum.

- **reverseOrder** *(boolean)* – When set to true, returns the events in reverse order. By default, the results are returned in ascending order of the `eventTimeStamp` of the events.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'events': [
        {

Response Structure

- (dict) –

Paginated representation of a workflow history for a workflow execution. This is the up to date, complete and authoritative record of the events related to all tasks and events in the life of the workflow execution.

- events (list) –

The list of history events.

* (dict) –

Event within a workflow execution. A history event can be one of these types:

- **WorkflowExecutionStarted** : The workflow execution was started.
- **WorkflowExecutionCompleted** : The workflow execution was closed due to successful completion.
- **WorkflowExecutionFailed** : The workflow execution closed
due to a failure.

- **WorkflowExecutionTimedOut**: The workflow execution was closed because a time out was exceeded.
- **WorkflowExecutionCanceled**: The workflow execution was successfully canceled and closed.
- **WorkflowExecutionTerminated**: The workflow execution was terminated.
- **WorkflowExecutionContinuedAsNew**: The workflow execution was closed and a new execution of the same type was created with the same workflowId.
- **WorkflowExecutionCancelRequested**: A request to cancel this workflow execution was made.
- **DecisionTaskScheduled**: A decision task was scheduled for the workflow execution.
- **DecisionTaskStarted**: The decision task was dispatched to a decider.
- **DecisionTaskCompleted**: The decider successfully completed a decision task by calling RespondDecisionTaskCompleted.
- **DecisionTaskTimedOut**: The decision task timed out.
- **ActivityTaskScheduled**: An activity task was scheduled for execution.
- **ScheduleActivityTaskFailed**: Failed to process ScheduleActivityTask decision. This happens when the decision is not configured properly, for example the activity type specified is not registered.
- **ActivityTaskStarted**: The scheduled activity task was dispatched to a worker.
- **ActivityTaskCompleted**: An activity worker successfully completed an activity task by calling RespondActivityTaskCompleted.
- **ActivityTaskFailed**: An activity worker failed an activity task by calling RespondActivityTaskFailed.
- **ActivityTaskTimedOut**: The activity task timed out.
- **ActivityTaskCanceled**: The activity task was successfully canceled.
- **ActivityTaskCancelRequested**: A RequestCancelActivityTask decision was received by the system.
- **RequestCancelActivityTaskFailed**: Failed to process RequestCancelActivityTask decision. This happens when the decision is not configured properly.
- **WorkflowExecutionSignaled**: An external signal was received for the workflow execution.
- **MarkerRecorded**: A marker was recorded in the workflow history as the result of a RecordMarker decision.
- **TimerStarted**: A timer was started for the workflow execution due to a StartTimer decision.
- **StartTimerFailed**: Failed to process StartTimer decision. This happens when the decision is not configured properly, for example a timer already exists with the specified timer ID.
- **TimerFired**: A timer, previously started for this workflow execution, fired.
- **TimerCanceled**: A timer, previously started for this work-
flow execution, was successfully canceled.
- **CancelTimerFailed** : Failed to process CancelTimer decision. This happens when the decision is not configured properly, for example no timer exists with the specified timer ID.
- **StartChildWorkflowExecutionInitiated** : A request was made to start a child workflow execution.
- **StartChildWorkflowExecutionFailed** : Failed to process StartChildWorkflowExecution decision. This happens when the decision is not configured properly, for example the workflow type specified is not registered.
- **ChildWorkflowExecutionStarted** : A child workflow execution was successfully started.
- **ChildWorkflowExecutionCompleted** : A child workflow execution, started by this workflow execution, completed successfully and was closed.
- **ChildWorkflowExecutionFailed** : A child workflow execution, started by this workflow execution, failed to complete successfully and was closed.
- **ChildWorkflowExecutionTimedOut** : A child workflow execution, started by this workflow execution, timed out and was closed.
- **ChildWorkflowExecutionCanceled** : A child workflow execution, started by this workflow execution, was canceled and closed.
- **ChildWorkflowExecutionTerminated** : A child workflow execution, started by this workflow execution, was terminated.
- **SignalExternalWorkflowExecutionInitiated** : A request to signal an external workflow was made.
- **ExternalWorkflowExecutionSignaled** : A signal, requested by this workflow execution, was successfully delivered to the target external workflow execution.
- **SignalExternalWorkflowExecutionFailed** : The request to signal an external workflow execution failed.
- **RequestCancelExternalWorkflowExecutionInitiated** : A request was made to request the cancellation of an external workflow execution.
- **ExternalWorkflowExecutionCancelRequested** : Request to cancel an external workflow execution was successfully delivered to the target execution.
- **RequestCancelExternalWorkflowExecutionFailed** : Request to cancel an external workflow execution failed.
- **LambdaFunctionScheduled** : An AWS Lambda function was scheduled for execution.
- **LambdaFunctionStarted** : The scheduled function was invoked in the AWS Lambda service.
- **LambdaFunctionCompleted** : The AWS Lambda function successfully completed.
- **LambdaFunctionFailed** : The AWS Lambda function execution failed.
- **LambdaFunctionTimedOut** : The AWS Lambda function execution timed out.
- **ScheduleLambdaFunctionFailed** : Failed to process ScheduleLambdaFunction decision. This happens when the work-
flow execution does not have the proper IAM role attached to
invoke AWS Lambda functions.

- **StartLambdaFunctionFailed**: Failed to invoke the scheduled function in the AWS Lambda service. This happens when the AWS Lambda service is not available in the current region, or received too many requests.

- **eventTimestamp** *(datetime)* –
  The date and time when the event occurred.

- **eventType** *(string)* –
  The type of the history event.

- **eventId** *(integer)* –
  The system generated ID of the event. This ID uniquely identifies the event within the workflow execution history.

- **workflowExecutionStartedEventAttributes** *(dict)* –
  If the event is of type `WorkflowExecutionStarted` then this member is set and provides detailed information about the event. It is not set for other event types.

- **input** *(string)* –
  The input provided to the workflow execution (if any).

- **executionStartToCloseTimeout** *(string)* –
  The maximum duration for this workflow execution.
  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **taskStartToCloseTimeout** *(string)* –
  The maximum duration of decision tasks for this workflow type.
  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **childPolicy** *(string)* –
  The policy to use for the child workflow executions if this workflow execution is terminated, by calling the TerminateWorkflowExecution action explicitly or due to an expired timeout.

  The supported child policies are:
  - **TERMINATE**: the child executions will be terminated.
  - **REQUEST_CANCEL**: a request to cancel will be attempted for each child execution by recording a `WorkflowExecutionCancelRequested` event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
  - **ABANDON**: no action will be taken. The child executions will continue to run.

- **taskList** *(dict)* –
  The name of the task list for scheduling the decision tasks for this workflow execution.
· **name** *(string)* –
  The name of the task list.

· **workflowType** *(dict)* –
  The workflow type of this execution.

· **name** *(string)* –
  **Required.** The name of the workflow type.

  **Note:** The combination of workflow type name and version must be unique with in a domain.

· **version** *(string)* –
  **Required.** The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique with in a domain.

· **tagList** *(list)* –
  The list of tags associated with this workflow execution. An execution can have up to 5 tags.

· **taskPriority** *(string)* –

· **continuedExecutionRunId** *(string)* –
  If this workflow execution was started due to a `ContinueAsNewWorkflowExecution` decision, then it contains the `runId` of the previous workflow execution that was closed and continued as this execution.

· **parentWorkflowExecution** *(dict)* –
  The source workflow execution that started this workflow execution. The member is not set if the workflow execution was not started by a workflow.

· **workflowId** *(string)* –
  The user defined identifier associated with the workflow execution.

· **runId** *(string)* –
  A system-generated unique identifier for the workflow execution.

· **parentInitiatedEventId** *(integer)* –
  The ID of the `StartChildWorkflowExecutionInitiated` event corresponding to the `StartChildWorkflowExecution` decision to start this workflow execution. The source event with this ID can be found in the history of the source workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· **lambdaRole** *(string)* –
  The IAM role attached to this workflow execution to use when invoking AWS Lambda functions.

· **workflowExecutionCompletedEventAttributes** *(dict)* –
If the event is of type `WorkflowExecutionCompleted` then this member is set and provides detailed information about the event. It is not set for other event types.

- **result (string)** –
  The result produced by the workflow execution upon successful completion.

- **decisionTaskCompletedEventId (integer)** –
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `CompleteWorkflowExecution` decision to complete this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **completeWorkflowExecutionFailedEventAttributes (dict)** –
  If the event is of type `CompleteWorkflowExecutionFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

  - **cause (string)** –
    The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  Note: If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId (integer)** –
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `CompleteWorkflowExecution` decision to complete this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **workflowExecutionFailedEventAttributes (dict)** –
  If the event is of type `WorkflowExecutionFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

  - **reason (string)** –
    The descriptive reason provided for the failure (if any).

  - **details (string)** –
    The details of the failure (if any).

- **decisionTaskCompletedEventId (integer)** –
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `FailWorkflowExecution` decision to fail this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
· **failWorkflowExecutionFailedEventAttributes** *(dict)* –
  
  If the event is of type `FailWorkflowExecutionFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

· **cause** *(string)* –
  
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

· **decisionTaskCompletedEventId** *(integer)* –
  
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `FailWorkflowExecution` decision to fail this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· **workflowExecutionTimedOutEventAttributes** *(dict)* –
  
  If the event is of type `WorkflowExecutionTimedOut` then this member is set and provides detailed information about the event. It is not set for other event types.

· **timeoutType** *(string)* –
  
  The type of timeout that caused this event.

· **childPolicy** *(string)* –
  
  The policy used for the child workflow executions of this workflow execution.

  The supported child policies are:

  - **TERMINATE**: the child executions will be terminated.
  - **REQUEST_CANCEL**: a request to cancel will be attempted for each child execution by recording a `WorkflowExecutionCancelRequested` event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
  - **ABANDON**: no action will be taken. The child executions will continue to run.

· **workflowExecutionCanceledEventAttributes** *(dict)* –
  
  If the event is of type `WorkflowExecutionCanceled` then this member is set and provides detailed information about the event. It is not set for other event types.

· **details** *(string)* –
  
  Details for the cancellation (if any).

· **decisionTaskCompletedEventId** *(integer)* –
  
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `CancelWorkflowExecution` decision for this cancellation request. This information can be useful for diagnosing
problems by tracing back the chain of events leading up to this event.

· **cancelWorkflowExecutionFailedEventAttributes (dict)** –

  If the event is of type `CancelWorkflowExecutionFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

· **cause (string)** –

  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see [Using IAM to Manage Access to Amazon SWF Workflows](#).

· **decisionTaskCompletedEventId (integer)** –

  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `CancelWorkflowExecution` decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· **workflowExecutionContinuedAsNewEventAttributes (dict)** –

  If the event is of type `WorkflowExecutionContinuedAsNew` then this member is set and provides detailed information about the event. It is not set for other event types.

· **input (string)** –

  The input provided to the new workflow execution.

· **decisionTaskCompletedEventId (integer)** –

  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `ContinueAsNewWorkflowExecution` decision that started this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· **newExecutionRunId (string)** –

  The `runId` of the new workflow execution.

· **executionStartToCloseTimeout (string)** –

  The total duration allowed for the new workflow execution. The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

· **taskList (dict)** –

  Represents a task list.

· **name (string)** –

  The name of the task list.
· taskPriority (string) –
· taskStartToCloseTimeout (string) –

The maximum duration of decision tasks for the new workflow execution.

The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

· childPolicy (string) –

The policy to use for the child workflow executions of the new execution if it is terminated by calling the TerminateWorkflowExecution action explicitly or due to an expired timeout.

The supported child policies are:
· TERMINATE: the child executions will be terminated.
· REQUESTCANCEL: a request to cancel will be attempted for each child execution by recording a WorkflowExecutionCancelRequested event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
· ABANDON: no action will be taken. The child executions will continue to run.
· tagList (list) –

The list of tags associated with the new workflow execution.

· workflowType (dict) –

Represents a workflow type.
· name (string) –

Required. The name of the workflow type.

Note: The combination of workflow type name and version must be unique within a domain.

· version (string) –

Required. The version of the workflow type.

Note: The combination of workflow type name and version must be unique within a domain.

· lambdaRole (string) –

The IAM role attached to this workflow execution to use when invoking AWS Lambda functions.

· continueAsNewWorkflowExecutionFailedEventAttributes (dict) –

If the event is of type ContinueAsNewWorkflowExecutionFailed then this member is set and provides detailed information about the event. It is not set for other event types.
· cause (string) –

The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.
Note: If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId (integer)**
  
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `ContinueAsNewWorkflowExecution` decision that started this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **workflowExecutionTerminatedEventAttributes (dict)**
  
  If the event is of type `WorkflowExecutionTerminated` then this member is set and provides detailed information about the event. It is not set for other event types.

  - **reason (string)**
    
    The reason provided for the termination (if any).

  - **details (string)**
    
    The details provided for the termination (if any).

  - **childPolicy (string)**
    
    The policy used for the child workflow executions of this workflow execution.

    The supported child policies are:

    - **TERMINATE**: the child executions will be terminated.
    - **REQUEST_CANCEL**: a request to cancel will be attempted for each child execution by recording a `WorkflowExecutionCancelRequested` event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
    - **ABANDON**: no action will be taken. The child executions will continue to run.

  - **cause (string)**
    
    If set, indicates that the workflow execution was automatically terminated, and specifies the cause. This happens if the parent workflow execution times out or is terminated and the child policy is set to terminate child executions.

- **workflowExecutionCancelRequestedEventAttributes (dict)**
  
  If the event is of type `WorkflowExecutionCancelRequested` then this member is set and provides detailed information about the event. It is not set for other event types.

  - **externalWorkflowExecution (dict)**
    
    The external workflow execution for which the cancellation was requested.

  - **workflowId (string)**
    
    The ID of the workflow execution.
The user defined identifier associated with the workflow execution.

- **runId (string)** –

  A system-generated unique identifier for the workflow execution.

- **externalInitiatedEventId (integer)** –

  The ID of the RequestCancelExternalWorkflowExecutionInitiated event corresponding to the RequestCancelExternalWorkflowExecution decision to cancel this workflow execution. The source event with this ID can be found in the history of the source workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **cause (string)** –

  If set, indicates that the request to cancel the workflow execution was automatically generated, and specifies the cause. This happens if the parent workflow execution times out or is terminated, and the child policy is set to cancel child executions.

- **decisionTaskScheduledEventAttributes (dict)** –

  If the event is of type DecisionTaskScheduled then this member is set and provides detailed information about the event. It is not set for other event types.

- **taskList (dict)** –

  The name of the task list in which the decision task was scheduled.

- **name (string)** –

  The name of the task list.

- **taskPriority (string)** –

  Optional. A task priority that, if set, specifies the priority for this decision task. Valid values are integers that range from Java’s `Integer.MIN_VALUE` (-2147483648) to `Integer.MAX_VALUE` (2147483647). Higher numbers indicate higher priority.

  For more information about setting task priority, see Setting Task Priority in the Amazon Simple Workflow Developer Guide.

- **startToCloseTimeout (string)** –

  The maximum duration for this decision task. The task is considered timed out if it does not completed within this duration.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **decisionTaskStartedEventAttributes (dict)** –

  If the event is of type DecisionTaskStarted then this member is set and provides detailed information about the event. It is not set for other event types.
- **identity** (*string*) –
  Identity of the decider making the request. This enables diagnostic tracing when problems arise. The form of this identity is user defined.

- **scheduledEventId** (*integer*) –
  The ID of the `DecisionTaskScheduled` event that was recorded when this decision task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **decisionTaskCompletedEventAttributes** (*dict*) –
  If the event is of type `DecisionTaskCompleted` then this member is set and provides detailed information about the event. It is not set for other event types.

- **executionContext** (*string*) –
  User defined context for the workflow execution.

- **scheduledEventId** (*integer*) –
  The ID of the `DecisionTaskScheduled` event that was recorded when this decision task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId** (*integer*) –
  The ID of the `DecisionTaskStarted` event recorded when this decision task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **decisionTaskTimedOutEventAttributes** (*dict*) –
  If the event is of type `DecisionTaskTimedOut` then this member is set and provides detailed information about the event. It is not set for other event types.

- **timeoutType** (*string*) –
  The type of timeout that expired before the decision task could be completed.

- **scheduledEventId** (*integer*) –
  The ID of the `DecisionTaskScheduled` event that was recorded when this decision task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId** (*integer*) –
  The ID of the `DecisionTaskStarted` event recorded when this decision task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityTaskScheduledEventAttributes** (*dict*) –
  If the event is of type `ActivityTaskScheduled` then this member is set and provides detailed information about the event. It is not set for other event types.

- **activityType** (*dict*) –
  The type of the activity task.
· **name** *(string)* –

The name of this activity.

**Note:** The combination of activity type name and version must be unique within a domain.

· **version** *(string)* –

The version of this activity.

**Note:** The combination of activity type name and version must be unique within a domain.

· **activityId** *(string)* –

The unique ID of the activity task.

· **input** *(string)* –

The input provided to the activity task.

· **control** *(string)* –

*Optional.* Data attached to the event that can be used by the decider in subsequent workflow tasks. This data is not sent to the activity.

· **scheduleToStartTimeout** *(string)* –

The maximum amount of time the activity task can wait to be assigned to a worker.

· **scheduleToCloseTimeout** *(string)* –

The maximum amount of time for this activity task.

· **startToCloseTimeout** *(string)* –

The maximum amount of time a worker may take to process the activity task.

· **taskList** *(dict)* –

The task list in which the activity task has been scheduled.

· **name** *(string)* –

The name of the task list.

· **taskPriority** *(string)* –

*Optional.* The priority to assign to the scheduled activity task. If set, this will override any default priority value that was assigned when the activity type was registered.

Valid values are integers that range from Java’s `Integer.MIN_VALUE` (-2147483648) to `Integer.MAX_VALUE` (2147483647). Higher numbers indicate higher priority.

For more information about setting task priority, see Setting Task Priority in the Amazon Simple Workflow Developer Guide.

· **decisionTaskCompletedEventId** *(integer)* –

The ID of the DecisionTaskCompleted event corresponding to the decision that resulted in the scheduling of this activity task. This information can be useful for diagnosing
problems by tracing back the chain of events leading up to
this event.

- **heartbeatTimeout (string)**

  The maximum time before which the worker processing this
task must report progress by calling RecordActivityTask-
Heartbeat. If the timeout is exceeded, the activity task is
automatically timed out. If the worker subsequently attempts
to record a heartbeat or return a result, it will be ignored.

- **activityTaskStartedEventAttributes (dict)**

  If the event is of type ActivityTaskStarted then this
member is set and provides detailed information about the
event. It is not set for other event types.

- **identity (string)**

  Identity of the worker that was assigned this task. This aids
diagnostics when problems arise. The form of this identity is
user defined.

- **scheduledEventId (integer)**

  The ID of the ActivityTaskScheduled event that was
recorded when this activity task was scheduled. This infor-
mation can be useful for diagnosing problems by tracing back
the chain of events leading up to this event.

- **activityTaskCompletedEventAttributes (dict)**

  If the event is of type ActivityTaskCompleted then this
member is set and provides detailed information about the
event. It is not set for other event types.

- **result (string)**

  The results of the activity task (if any).

- **scheduledEventId (integer)**

  The ID of the ActivityTaskScheduled event that was
recorded when this activity task was scheduled. This infor-
mation can be useful for diagnosing problems by tracing back
the chain of events leading up to this event.

- **startedEventId (integer)**

  The ID of the ActivityTaskStarted event recorded
when this activity task was started. This information can be
useful for diagnosing problems by tracing back the chain of
events leading up to this event.

- **activityTaskFailedEventAttributes (dict)**

  If the event is of type ActivityTaskFailed then this
member is set and provides detailed information about the
event. It is not set for other event types.

- **reason (string)**

  The reason provided for the failure (if any).

- **details (string)**

  The details of the failure (if any).

- **scheduledEventId (integer)**

  The ID of the ActivityTaskScheduled event that was
recorded when this activity task was scheduled. This infor-
mation can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –
  The ID of the ActivityTaskStarted event recorded when this activity task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityTaskTimedOutEventAttributes (dict)** –
  If the event is of type ActivityTaskTimedOut then this member is set and provides detailed information about the event. It is not set for other event types.

- **timeoutType (string)** –
  The type of the timeout that caused this event.

- **scheduledEventId (integer)** –
  The ID of the ActivityTaskScheduled event that was recorded when this activity task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –
  The ID of the ActivityTaskStarted event recorded when this activity task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **details (string)** –
  Contains the content of the details parameter for the last call made by the activity to RecordActivityTaskHeartbeat.

- **activityTaskCanceledEventAttributes (dict)** –
  If the event is of type ActivityTaskCanceled then this member is set and provides detailed information about the event. It is not set for other event types.

- **details (string)** –
  Details of the cancellation (if any).

- **scheduledEventId (integer)** –
  The ID of the ActivityTaskScheduled event that was recorded when this activity task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –
  The ID of the ActivityTaskStarted event recorded when this activity task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **latestCancelRequestedEventId (integer)** –
  If set, contains the ID of the last ActivityTaskCancelRequested event recorded for this activity task. This information can be useful for
diagnosing problems by tracing back the chain of events leading up to this event.

- **activityTaskCancelRequestedEventAttributes (dict)** –
  
  If the event is of type `ActivityTaskCancelRequested` then this member is set and provides detailed information about the event. It is not set for other event types.

- **decisionTaskCompletedEventId (integer)** –
  
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `RequestCancelActivityTask` decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityId (string)** –
  
  The unique ID of the task.

- **workflowExecutionSignaledEventAttributes (dict)** –
  
  If the event is of type `WorkflowExecutionSignaled` then this member is set and provides detailed information about the event. It is not set for other event types.

- **signalName (string)** –
  
  The name of the signal received. The decider can use the signal name and inputs to determine how to process the signal.

- **input (string)** –
  
  Inputs provided with the signal (if any). The decider can use the signal name and inputs to determine how to process the signal.

- **externalWorkflowExecution (dict)** –
  
  The workflow execution that sent the signal. This is set only if the signal was sent by another workflow execution.

- **workflowId (string)** –
  
  The user defined identifier associated with the workflow execution.

- **runId (string)** –
  
  A system-generated unique identifier for the workflow execution.

- **externalInitiatedEventId (integer)** –
  
  The ID of the `SignalExternalWorkflowExecutionInitiated` event corresponding to the `SignalExternalWorkflow` decision to signal this workflow execution. The source event with this ID can be found in the history of the source workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event. This field is set only if the signal was initiated by another workflow execution.

- **markerRecordedEventAttributes (dict)** –
  
  If the event is of type `MarkerRecorded` then this member
is set and provides detailed information about the event. It is not set for other event types.

- **markerName (string)** –
  The name of the marker.
- **details (string)** –
  Details of the marker (if any).
- **decisionTaskCompletedEventId (integer)** –
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the RecordMarker decision that requested this marker. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
- **recordMarkerFailedEventAttributes (dict)** –
  If the event is of type DecisionTaskFailed then this member is set and provides detailed information about the event. It is not set for other event types.
  - **markerName (string)** –
    The marker’s name.
  - **cause (string)** –
    The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If cause is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId (integer)** –
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the RecordMarkerFailed decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
- **timerStartedEventAttributes (dict)** –
  If the event is of type TimerStarted then this member is set and provides detailed information about the event. It is not set for other event types.
  - **timerId (string)** –
    The unique ID of the timer that was started.
  - **control (string)** –
    Optional. Data attached to the event that can be used by the decider in subsequent workflow tasks.
  - **startToFireTimeout (string)** –
    The duration of time after which the timer will fire.
    The duration is specified in seconds; an integer greater than or equal to 0.
- **decisionTaskCompletedEventId (integer)** –
The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `StartTimer` decision for this activity task. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- `timerFiredEventAttributes (dict)` –
  
  If the event is of type `TimerFired` then this member is set and provides detailed information about the event. It is not set for other event types.

- `timerId (string)` –
  
  The unique ID of the timer that fired.

- `startedEventId (integer)` –
  
  The ID of the `TimerStarted` event that was recorded when this timer was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- `timerCanceledEventAttributes (dict)` –
  
  If the event is of type `TimerCanceled` then this member is set and provides detailed information about the event. It is not set for other event types.

- `timerId (string)` –
  
  The unique ID of the timer that was canceled.

- `startedEventId (integer)` –
  
  The ID of the `TimerStarted` event that was recorded when this timer was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- `decisionTaskCompletedEventId (integer)` –
  
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `CancelTimer` decision to cancel this timer. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- `startChildWorkflowExecutionInitiatedEventAttributes (dict)` –
  
  If the event is of type `StartChildWorkflowExecutionInitiated` then this member is set and provides detailed information about the event. It is not set for other event types.

- `workflowId (string)` –
  
  The `workflowId` of the child workflow execution.

- `workflowType (dict)` –
  
  The type of the child workflow execution.

- `name (string)` –
  
  Required. The name of the workflow type.

Note: The combination of workflow type name and version must be unique within a domain.
- **version** *(string)* –

  Required. The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- **control** *(string)* –

  Optional. Data attached to the event that can be used by the decider in subsequent decision tasks. This data is not sent to the activity.

- **input** *(string)* –

  The inputs provided to the child workflow execution (if any).

- **executionStartToCloseTimeout** *(string)* –

  The maximum duration for the child workflow execution. If the workflow execution is not closed within this duration, it will be timed out and force terminated.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **taskList** *(dict)* –

  The name of the task list used for the decision tasks of the child workflow execution.

- **name** *(string)* –

  The name of the task list.

- **taskPriority** *(string)* –

  Optional. The priority assigned for the decision tasks for this workflow execution. Valid values are integers that range from Java’s `Integer.MIN_VALUE` (-2147483648) to `Integer.MAX_VALUE` (2147483647). Higher numbers indicate higher priority.

  For more information about setting task priority, see Setting Task Priority in the Amazon Simple Workflow Developer Guide.

- **decisionTaskCompletedEventId** *(integer)* –

  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `StartChildWorkflowExecution` decision to request this child workflow execution. This information can be useful for diagnosing problems by tracing back the cause of events.

- **childPolicy** *(string)* –

  The policy to use for the child workflow executions if this execution gets terminated by explicitly calling the TerminateWorkflowExecution action or due to an expired timeout.

  The supported child policies are:
  - **TERMINATE:** the child executions will be terminated.
  - **REQUEST_CANCEL:** a request to cancel will be attempted for each child execution by recording a `WorkflowExecutionCancelRequested` event in
its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.

- **ABANDON**: no action will be taken. The child executions will continue to run.
- **taskStartToCloseTimeout** *(string)* —
  The maximum duration allowed for the decision tasks for this workflow execution.
  
  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.
- **tagList** *(list)* —
  The list of tags to associated with the child workflow execution.
- **(string)** —
  **lambdaRole** *(string)* —
  The IAM role attached to this workflow execution to use when invoking AWS Lambda functions.
- **childWorkflowExecutionStartedEventAttributes** *(dict)* —
  If the event is of type `ChildWorkflowExecutionStarted` then this member is set and provides detailed information about the event. It is not set for other event types.
- **workflowExecution** *(dict)* —
  The child workflow execution that was started.
- **workflowId** *(string)* —
  The user defined identifier associated with the workflow execution.
- **runId** *(string)* —
  A system-generated unique identifier for the workflow execution.
- **workflowType** *(dict)* —
  The type of the child workflow execution.
- **name** *(string)* —
  **Required.** The name of the workflow type.

  **Note:** The combination of workflow type name and version must be unique with in a domain.

- **version** *(string)* —
  **Required.** The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique with in a domain.

- **initiatedEventId** *(integer)* —
  The ID of the `StartChildWorkflowExecutionInitiated` event corresponding to the `StartChildWorkflowExecution` decision to start this child workflow execution. This information can be useful
for diagnosing problems by tracing back the chain of events leading up to this event.

- **childWorkflowExecutionCompletedEventAttributes** *(dict)* –

  If the event is of type ChildWorkflowExecutionCompleted then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowExecution** *(dict)* –

  The child workflow execution that was completed.

- **workflowId** *(string)* –

  The user defined identifier associated with the workflow execution.

- **runId** *(string)* –

  A system-generated unique identifier for the workflow execution.

- **workflowType** *(dict)* –

  The type of the child workflow execution.

  - **name** *(string)* –

    **Required.** The name of the workflow type.

    **Note:** The combination of workflow type name and version must be unique with in a domain.

- **version** *(string)* –

  **Required.** The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique with in a domain.

- **result** *(string)* –

  The result of the child workflow execution (if any).

- **initiatedEventId** *(integer)* –

  The ID of the `StartChildWorkflowExecutionInitiated` event corresponding to the `StartChildWorkflowExecution` decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId** *(integer)* –

  The ID of the `ChildWorkflowExecutionStarted` event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **childWorkflowExecutionFailedEventAttributes** *(dict)* –

  If the event is of type ChildWorkflowExecutionFailed then this member
is set and provides detailed information about the event. It is not set for other event types.

- ** workflowExecution (dict) –**
  
The child workflow execution that failed.

- ** workflowId (string) –**
  
The user defined identifier associated with the workflow execution.

- ** runId (string) –**
  
A system-generated unique identifier for the workflow execution.

- ** workflowType (dict) –**
  
The type of the child workflow execution.

  - ** name (string) –**
    
  **Required.** The name of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- ** version (string) –**
  
**Required.** The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- ** reason (string) –**
  
The reason for the failure (if provided).

- ** details (string) –**
  
The details of the failure (if provided).

- ** initiatedEventId (integer) –**
  
The ID of the StartChildWorkflowExecutionInitiated event corresponding to the StartChildWorkflowExecution decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- ** startedEventId (integer) –**
  
The ID of the ChildWorkflowExecutionStarted event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- ** childWorkflowExecutionTimedOutEventAttributes (dict) –**
  
  If the event is of type ChildWorkflowExecutionTimedOut then this member is set and provides detailed information about the event. It is not set for other event types.

- ** workflowExecution (dict) –**
  
The child workflow execution that timed out.
- **workflowId** *(string)* –
  The user defined identifier associated with the workflow execution.
- **runId** *(string)* –
  A system-generated unique identifier for the workflow execution.
- **workflowType** *(dict)* –
  The type of the child workflow execution.
  - **name** *(string)* –
    Required. The name of the workflow type.
  - **version** *(string)* –
    Required. The version of the workflow type.
    - **Note:** The combination of workflow type name and version must be unique with in a domain.
- **timeoutType** *(string)* –
  The type of the timeout that caused the child workflow execution to time out.
- **initiatedEventId** *(integer)* –
  The ID of the `StartChildWorkflowExecutionInitiated` event corresponding to the `StartChildWorkflowExecution` decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
- **startedEventId** *(integer)* –
  The ID of the `ChildWorkflowExecutionStarted` event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
- **childWorkflowExecutionCanceledEventAttributes** *(dict)* –
  If the event is of type `ChildWorkflowExecutionCanceled` then this member is set and provides detailed information about the event. It is not set for other event types.
- **workflowExecution** *(dict)* –
  The child workflow execution that was canceled.
  - **workflowId** *(string)* –
    The user defined identifier associated with the workflow execution.
  - **runId** *(string)* –
    A system-generated unique identifier for the workflow execution.
- **workflowType** *(dict)* –
  The type of the child workflow execution.
- **name** *(string)* –
  **Required.** The name of the workflow type.

  **Note:** The combination of workflow type name and version
  must be unique with in a domain.

- **version** *(string)* –
  **Required.** The version of the workflow type.

  **Note:** The combination of workflow type name and version
  must be unique with in a domain.

- **details** *(string)* –
  Details of the cancellation (if provided).
- **initiatedEventId** *(integer)* –
  The ID of the `StartChildWorkflowExecutionInitiated`
  event corresponding to the `StartChildWorkflowExecution`
decision to start this child workflow execution. This information can be useful
for diagnosing problems by tracing back the chain of events
leading up to this event.
- **startedEventId** *(integer)* –
  The ID of the `ChildWorkflowExecutionStarted`
  event recorded when this child workflow execution was
  started. This information can be useful for diagnosing prob-
  lems by tracing back the chain of events leading up to this
  event.
- **childWorkflowExecutionTerminatedEventAttributes** *(dict)* –
  If the event is of type `ChildWorkflowExecutionTerminated`
  then this member is set and provides detailed information about the
  event. It is not set for other event types.
- **workflowExecution** *(dict)* –
  The child workflow execution that was terminated.
- **workflowId** *(string)* –
  The user defined identifier associated with the workflow exe-
  cution.
- **runId** *(string)* –
  A system-generated unique identifier for the workflow execu-
  tion.
- **workflowType** *(dict)* –
  The type of the child workflow execution.
- **name** *(string)* –
  **Required.** The name of the workflow type.

  **Note:** The combination of workflow type name and version
must be unique with in a domain.

- **version** *(string)* –

  **Required.** The version of the workflow type.

**Note:** The combination of workflow type name and version must be unique with in a domain.

- **initiatedEventId** *(integer)* –

  The ID of the `StartChildWorkflowExecutionInitiated` event corresponding to the `StartChildWorkflowExecution` decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId** *(integer)* –

  The ID of the `ChildWorkflowExecutionStarted` event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **signalExternalWorkflowExecutionInitiatedEventAttributes** *(dict)* –

  If the event is of type `SignalExternalWorkflowExecutionInitiated` then this member is set and provides detailed information about the event. It is not set for other event types.

  - **workflowId** *(string)* –

    The `workflowId` of the external workflow execution.

  - **runId** *(string)* –

    The `runId` of the external workflow execution to send the signal to.

  - **signalName** *(string)* –

    The name of the signal.

  - **input** *(string)* –

    Input provided to the signal (if any).

  - **decisionTaskCompletedEventId** *(integer)* –

    The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `SignalExternalWorkflowExecution` decision for this signal. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

  - **control** *(string)* –

    **Optional.** data attached to the event that can be used by the decider in subsequent decision tasks.

- **externalWorkflowExecutionSignaledEventAttributes** *(dict)* –

  If the event is of type
**ExternalWorkflowExecutionSignaled**

then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowExecution** *(dict)* —
  
The external workflow execution that the signal was delivered to.

- **workflowId** *(string)* —
  
The user defined identifier associated with the workflow execution.

- **runId** *(string)* —
  
A system-generated unique identifier for the workflow execution.

- **initiatedEventId** *(integer)* —
  
The ID of the `SignalExternalWorkflowExecutionInitiated` event corresponding to the `SignalExternalWorkflowExecution` decision to request this signal. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **signalExternalWorkflowExecutionFailedEventAttributes** *(dict)* —
  
  If the event is of type `SignalExternalWorkflowExecutionFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

  - **workflowId** *(string)* —
    
    The `workflowId` of the external workflow execution that the signal was being delivered to.

  - **runId** *(string)* —
    
    The `runId` of the external workflow execution that the signal was being delivered to.

  - **cause** *(string)* —
    
    The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

    **Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **initiatedEventId** *(integer)* —
  
The ID of the `SignalExternalWorkflowExecutionInitiated` event corresponding to the `SignalExternalWorkflowExecution` decision to request this signal. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **decisionTaskCompletedEventId** *(integer)* —
  
The ID of the `DecisionTaskCompleted` event corresponding to the `SignalExternalWorkflowExecution` decision to request this signal. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
responding to the decision task that resulted in the `SignalExternalWorkflowExecution` decision for this signal. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **control (string)** –
- **externalWorkflowExecutionCancelRequestedEventAttributes (dict)** –

  If the event is of type `ExternalWorkflowExecutionCancelRequested` then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowExecution (dict)** –

  The external workflow execution to which the cancellation request was delivered.

- **workflowId (string)** –

  The user defined identifier associated with the workflow execution.

- **runId (string)** –

  A system-generated unique identifier for the workflow execution.

- **initiatedEventId (integer)** –

  The ID of the `RequestCancelExternalWorkflowExecutionInitiated` event corresponding to the `RequestCancelExternalWorkflowExecution` decision to cancel this external workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **requestCancelExternalWorkflowExecutionInitiatedEventAttributes (dict)** –

  If the event is of type `RequestCancelExternalWorkflowExecutionInitiated` then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowId (string)** –

  The `workflowId` of the external workflow execution to be canceled.

- **runId (string)** –

  The `runId` of the external workflow execution to be canceled.

- **decisionTaskCompletedEventId (integer)** –

  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `RequestCancelExternalWorkflowExecution` decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **control (string)** –
Optional. Data attached to the event that can be used by the
decider in subsequent workflow tasks.

- **requestCancelExternalWorkflowExecutionFailedEventAttributes**
  - (dict) –

  If the event is of type RequestCancelExternalWorkflowExecutionFailed then this member is set and provides detailed information about the event. It is not set for other event types.

  - **workflowId** (string) –

    The workflowId of the external workflow to which the cancel request was to be delivered.

  - **runId** (string) –

    The runId of the external workflow execution.

  - **cause** (string) –

    The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  Note: If cause is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **initiatedEventId** (integer) –

  The ID of the RequestCancelExternalWorkflowExecutionInitiated event corresponding to the RequestCancelExternalWorkflowExecution decision to cancel this external workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **decisionTaskCompletedEventId** (integer) –

  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the RequestCancelExternalWorkflowExecution decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **control** (string) –

- **scheduleActivityTaskFailedEventAttributes** (dict) –

  If the event is of type ScheduleActivityTaskFailed then this member is set and provides detailed information about the event. It is not set for other event types.

  - **activityType** (dict) –

    The activity type provided in the ScheduleActivityTask decision that failed.

  - **name** (string) –

    The name of this activity.

  Note: The combination of activity type name and version must be unique within a domain.
· **version** *(string)* –
  The version of this activity.

  **Note:** The combination of activity type name and version must be unique with in a domain.

· **activityId** *(string)* –
  The activityId provided in the ScheduleActivityTask decision that failed.

· **cause** *(string)* –
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

· **decisionTaskCompletedEventId** *(integer)* –
  The ID of the DecisionTaskCompleted event corresponding to the decision that resulted in the scheduling of this activity task. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· **requestCancelActivityTaskFailedEventAttributes** *(dict)* –
  If the event is of type RequestCancelActivityTaskFailed then this member is set and provides detailed information about the event. It is not set for other event types.

  · **activityId** *(string)* –
    The activityId provided in the RequestCancelActivityTask decision that failed.

  · **cause** *(string)* –
    The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

· **decisionTaskCompletedEventId** *(integer)* –
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the RequestCancelActivityTask decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· **startTimerFailedEventAttributes** *(dict)* –
  If the event is of type StartTimerFailed then this mem-
ber is set and provides detailed information about the event. It is not set for other event types.

- **timerId (string)** –
  
  The timerId provided in the `StartTimer` decision that failed.

- **cause (string)** –

  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see [Using IAM to Manage Access to Amazon SWF Workflows](#).

- **decisionTaskCompletedEventId (integer)** –

  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `StartTimer` decision for this activity task. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **cancelTimerFailedEventAttributes (dict)** –

  If the event is of type `CancelTimerFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

  - **timerId (string)** –

    The timerId provided in the `CancelTimer` decision that failed.

  - **cause (string)** –

    The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see [Using IAM to Manage Access to Amazon SWF Workflows](#).

- **decisionTaskCompletedEventId (integer)** –

  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `CancelTimer` decision to cancel this timer. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startChildWorkflowExecutionFailedEventAttributes (dict)** –

  If the event is of type `StartChildWorkflowExecutionFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

  - **workflowType (dict)** –

    The workflow type provided in the
StartChildWorkflowExecution decision that failed.

- **name (string)** –
  
  Required. The name of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- **version (string)** –
  
  Required. The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- **cause (string)** –
  
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If cause is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **workflowId (string)** –
  
  The workflowId of the child workflow execution.

- **initiatedEventId (integer)** –
  
  The ID of the StartChildWorkflowExecutionInitiated event corresponding to the StartChildWorkflowExecution decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **decisionTaskCompletedEventId (integer)** –
  
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the StartChildWorkflowExecution decision to request this child workflow execution. This information can be useful for diagnosing problems by tracing back the cause of events.

- **control (string)** –

- **lambdaFunctionScheduledEventAttributes (dict)** –
  
  Provides details for the LambdaFunctionScheduled event.

  - **id (string)** –
    
    The unique Amazon SWF ID for the AWS Lambda task.

  - **name (string)** –
    
    The name of the scheduled AWS Lambda function.

  - **input (string)** –
    
    Input provided to the AWS Lambda function.

  - **startToCloseTimeout (string)** –
The maximum time, in seconds, that the AWS Lambda function can take to execute from start to close before it is marked as failed.

- **decisionTaskCompletedEventId (integer)** –
  
The ID of the DecisionTaskCompleted event for the decision that resulted in the scheduling of this AWS Lambda function. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **lambdaFunctionStartedEventAttributes (dict)** –
  
  Provides details for the LambdaFunctionStarted event.

- **scheduledEventId (integer)** –
  
The ID of the LambdaFunctionScheduled event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **lambdaFunctionCompletedEventAttributes (dict)** –
  
  Provides details for the LambdaFunctionCompleted event.

- **scheduledEventId (integer)** –
  
The ID of the LambdaFunctionScheduled event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **result (string)** –
  
The result of the function execution (if any).

- **lambdaFunctionFailedEventAttributes (dict)** –
  
  Provides details for the LambdaFunctionFailed event.

- **scheduledEventId (integer)** –
  
The ID of the LambdaFunctionScheduled event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –
  
The ID of the LambdaFunctionStarted event recorded in the history.

- **reason (string)** –
  
The reason provided for the failure (if any).

- **details (string)** –
  
The details of the failure (if any).

- **lambdaFunctionTimedOutEventAttributes (dict)** –
  
  Provides details for the LambdaFunctionTimedOut event.

- **scheduledEventId (integer)** –
The ID of the LambdaFunctionScheduled event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –
  The ID of the LambdaFunctionStarted event recorded in the history.

- **timeoutType (string)** –
  The type of the timeout that caused this event.

- **scheduleLambdaFunctionFailedEventAttributes (dict)** –
  Provides details for the ScheduleLambdaFunctionFailed event.
  - **id (string)** –
    The unique Amazon SWF ID of the AWS Lambda task.
  - **name (string)** –
    The name of the scheduled AWS Lambda function.
  - **cause (string)** –
    The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

**Note:** If **cause** is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId (integer)** –
  The ID of the DecisionTaskCompleted event corresponding to the decision that resulted in the scheduling of this AWS Lambda function. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startLambdaFunctionFailedEventAttributes (dict)** –
  Provides details for the StartLambdaFunctionFailed event.

- **scheduledEventId (integer)** –
  The ID of the LambdaFunctionScheduled event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **cause (string)** –
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

**Note:** If **cause** is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **message (string)** –
The error message (if any).

- **nextPageToken** *(string)* –
  If a `nextPageToken` was returned by a previous call, there are more results available. To retrieve the next page of results, make the call again using the returned token in `nextPageToken`. Keep all other arguments unchanged.

The configured `maximumPageSize` determines how many results can be returned in a single call.

`list_activity_types(**kwargs)`

Returns information about all activities registered in the specified domain that match the specified name and registration status. The result includes information like creation date, current status of the activity, etc. The results may be split into multiple pages. To retrieve subsequent pages, make the call again using the `nextPageToken` returned by the initial call.

**Access Control**

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a `Resource` element with the domain name to limit the action to only specified domains.
- Use an `Action` element to allow or deny permission to call this action.
- You cannot use an IAM policy to constrain this action’s parameters.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s `cause` parameter will be set to `OPERATION_NOT_PERMITTED`. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

**Request Syntax**

```python
response = client.list_activity_types(
    domain='string',
    name='string',
    registrationStatus='REGISTERED' | 'DEPRECATED',
    nextPageToken='string',
    maximumPageSize=123,
    reverseOrder=True | False
)
```

**Parameters**

- **domain** *(string)* – [REQUIRED]
  The name of the domain in which the activity types have been registered.
- **name** *(string)* – If specified, only lists the activity types that have this name.
- **registrationStatus** *(string)* – [REQUIRED]
  Specifies the registration status of the activity types to list.
- **nextPageToken** *(string)* – If a `nextPageToken` was returned by a previous call, there are more results available. To retrieve the next page of results, make the call again using the returned token in `nextPageToken`. Keep all other arguments unchanged.

The configured `maximumPageSize` determines how many results can be returned in a single call.

- **maximumPageSize** *(integer)* – The maximum number of results that will be returned per call. `nextPageToken` can be used to obtain further pages of results. The default is 1000, which is the maximum allowed page size. You can, however, specify a page size smaller than the maximum.
This is an upper limit only; the actual number of results returned per call may be fewer than the specified maximum.

- **reverseOrder** *(boolean)* – When set to `true`, returns the results in reverse order. By default, the results are returned in ascending alphabetical order by `name` of the activity types.

**Return type** `dict`

**Response Syntax**

```python
{
    'typeInfos': [
        {
            'activityType': {
                'name': 'string',
                'version': 'string'
            },
            'status': 'REGISTERED'|'DEPRECATED',
            'description': 'string',
            'creationDate': datetime(2015, 1, 1),
            'deprecationDate': datetime(2015, 1, 1)
        },
        
        'nextPageToken': 'string'
    }
}
```

**Response Structure**

- *(dict)* –
  Contains a paginated list of activity type information structures.
  - **typeInfos (list)** –
    List of activity type information.
    - *(dict)* –
      Detailed information about an activity type.
      - **activityType (dict)** –
        The ActivityType type structure representing the activity type.
      - **name (string)** –
        The name of this activity.
      - **version (string)** –
        The version of this activity.
      - **status (string)** –
        The current status of the activity type.
      - **description (string)** –
        The description of the activity type provided in RegisterActivityType.

**Note:** The combination of activity type name and version must be unique within a domain.

**Note:** The combination of activity type name and version must be unique within a domain.
creationDate (datetime) –
The date and time this activity type was created through RegisterActivityType.

deprecationDate (datetime) –
If DEPRECATED, the date and time DeprecateActivityType was called.

nextPageToken (string) –
If a nextPageToken was returned by a previous call, there are more results available. To retrieve the next page of results, make the call again using the returned token in nextPageToken. Keep all other arguments unchanged.

The configured maximumPageSize determines how many results can be returned in a single call.

list_closed_workflow_executions (**kwargs)
Returns a list of closed workflow executions in the specified domain that meet the filtering criteria. The results may be split into multiple pages. To retrieve subsequent pages, make the call again using the nextPageToken returned by the initial call.

**Note:** This operation is eventually consistent. The results are best effort and may not exactly reflect recent updates and changes.

### Access Control

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a Resource element with the domain name to limit the action to only specified domains.
- Use an Action element to allow or deny permission to call this action.
- Constrain the following parameters by using a Condition element with the appropriate keys. *
  
  - `tagFilter.tag`: String constraint. The key is `swf:tagFilter.tag`.
  - `typeFilter.name`: String constraint. The key is `swf:typeFilter.name`.
  - `typeFilter.version`: String constraint. The key is `swf:typeFilter.version`.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s cause parameter will be set to OPERATION_NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

### Request Syntax

```python
response = client.list_closed_workflow_executions(
    domain='string',
    startTimeFilter={
        'oldestDate': datetime(2015, 1, 1),
        'latestDate': datetime(2015, 1, 1)
    },
    closeTimeFilter={
        'oldestDate': datetime(2015, 1, 1),
        'latestDate': datetime(2015, 1, 1)
    },
    executionFilter={
        'workflowId': 'string'
    },
    closeStatusFilter={
        'status': 'COMPLETED'|'FAILED'|'CANCELED'|'TERMINATED'|'CONTINUED_AS_NEW'|'TIMED_OUT'
    },
```
Parameters

- **domain** *(string)* – [REQUIRED]
  
The name of the domain that contains the workflow executions to list.

- **startTimeFilter** *(dict)* – If specified, the workflow executions are included in the returned results based on whether their start times are within the range specified by this filter. Also, if this parameter is specified, the returned results are ordered by their start times.
  
  **Note:** startTimeFilter and closeTimeFilter are mutually exclusive. You must specify one of these in a request but not both.

  - **oldestDate** *(datetime)* – [REQUIRED]
    
    Specifies the oldest start or close date and time to return.
  
  - **latestDate** *(datetime)* –
    
    Specifies the latest start or close date and time to return.

- **closeTimeFilter** *(dict)* – If specified, the workflow executions are included in the returned results based on whether their close times are within the range specified by this filter. Also, if this parameter is specified, the returned results are ordered by their close times.
  
  **Note:** startTimeFilter and closeTimeFilter are mutually exclusive. You must specify one of these in a request but not both.

  - **oldestDate** *(datetime)* – [REQUIRED]
    
    Specifies the oldest start or close date and time to return.
  
  - **latestDate** *(datetime)* –
    
    Specifies the latest start or close date and time to return.

- **executionFilter** *(dict)* – If specified, only workflow executions matching the workflow ID specified in the filter are returned.
  
  **Note:** closeStatusFilter, executionFilter, typeFilter and tagFilter are mutually exclusive. You can specify at most one of these in a request.

  - **workflowId** *(string)* – [REQUIRED]
    
    The workflowId to pass of match the criteria of this filter.

- **closeStatusFilter** *(dict)* – If specified, only workflow executions that match this close status are listed. For example, if TERMINATED is specified, then only TERMINATED workflow executions are listed.
Note: closeStatusFilter, executionFilter, typeFilter and tagFilter are mutually exclusive. You can specify at most one of these in a request.

- **status**(string) – [REQUIRED]
  
  Required. The close status that must match the close status of an execution for it to meet the criteria of this filter.

- **typeFilter**(dict) – If specified, only executions of the type specified in the filter are returned.

Note: closeStatusFilter, executionFilter, typeFilter and tagFilter are mutually exclusive. You can specify at most one of these in a request.

- **name**(string) – [REQUIRED]
  
  Required. Name of the workflow type.

- **version**(string) –
  
  Version of the workflow type.

- **tagFilter**(dict) – If specified, only executions that have the matching tag are listed.

Note: closeStatusFilter, executionFilter, typeFilter and tagFilter are mutually exclusive. You can specify at most one of these in a request.

- **tag**(string) – [REQUIRED]
  
  Required. Specifies the tag that must be associated with the execution for it to meet the filter criteria.

- **nextPageToken**(string) – If a NextPageToken was returned by a previous call, there are more results available. To retrieve the next page of results, make the call again using the returned token in nextPageToken. Keep all other arguments unchanged.

The configured maximumPageSize determines how many results can be returned in a single call.

- **maximumPageSize**(integer) – The maximum number of results that will be returned per call. nextPageToken can be used to obtain further pages of results. The default is 1000, which is the maximum allowed page size. You can, however, specify a page size smaller than the maximum.

  This is an upper limit only; the actual number of results returned per call may be fewer than the specified maximum.

- **reverseOrder**(boolean) – When set to true, returns the results in reverse order. By default the results are returned in descending order of the start or the close time of the executions.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'executionInfos': [
```
```json
{
  'execution': {
    'workflowId': 'string',
    'runId': 'string'
  },
  'workflowType': {
    'name': 'string',
    'version': 'string'
  },
  'startTimestamp': datetime(2015, 1, 1),
  'closeTimestamp': datetime(2015, 1, 1),
  'executionStatus': 'OPEN'|'CLOSED',
  'closeStatus': 'COMPLETED'|'FAILED'|'CANCELED'|'TERMINATED'|'CONTINUED_AS_NEW'|'TIMED_OUT',
  'parent': {
    'workflowId': 'string',
    'runId': 'string'
  },
  'tagList': [
    'string',
  ],
  'cancelRequested': True|False
},
'nextPageToken': 'string'
}
```

**Response Structure**

- *(dict)* –
  Contains a paginated list of information about workflow executions.

  - `executionInfos` *(list)* –
    The list of workflow information structures.

    - *(dict)* –
      Contains information about a workflow execution.

      - `execution` *(dict)* –
        The workflow execution this information is about.

      - `workflowId` *(string)* –
        The user defined identifier associated with the workflow execution.

      - `runId` *(string)* –
        A system-generated unique identifier for the workflow execution.

      - `workflowType` *(dict)* –
        The type of the workflow execution.

      - `name` *(string)* –
        Required. The name of the workflow type.

      - `version` *(string)* –
        Required. The version of the workflow type.

      **Note:** The combination of workflow type name and version must be unique within a domain.
Note: The combination of workflow type name and version must be unique with in a domain.

- `startTimestamp (datetime)` –
  The time when the execution was started.

- `closeTimestamp (datetime)` –
  The time when the workflow execution was closed. Set only if the execution status is CLOSED.

- `executionStatus (string)` –
  The current status of the execution.

- `closeStatus (string)` –
  If the execution status is closed then this specifies how the execution was closed:
  - `COMPLETED`: the execution was successfully completed.
  - `CANCELED`: the execution was canceled. Cancellation allows the implementation to gracefully clean up before the execution is closed.
  - `TERMINATED`: the execution was force terminated.
  - `FAILED`: the execution failed to complete.
  - `TIMED_OUT`: the execution did not complete in the allotted time and was automatically timed out.
  - `CONTINUED_AS_NEW`: the execution is logically continued. This means the current execution was completed and a new execution was started to carry on the workflow.

- `parent (dict)` –
  If this workflow execution is a child of another execution then contains the workflow execution that started this execution.

- `workflowId (string)` –
  The user defined identifier associated with the workflow execution.

- `runId (string)` –
  A system-generated unique identifier for the workflow execution.

- `tagList (list)` –
  The list of tags associated with the workflow execution. Tags can be used to identify and list workflow executions of interest through the visibility APIs. A workflow execution can have a maximum of 5 tags.

- `(string)` –
  - `cancelRequested (boolean)` –
    Set to true if a cancellation is requested for this workflow execution.

- `nextPageToken (string)` –
  If a `nextPageToken` was returned by a previous call, there are more results available. To retrieve the next page of results, make the call again using the returned token in `nextPageToken`. Keep all other arguments unchanged.

  The configured `maximumPageSize` determines how many results can be returned in a single call.
**list_domains(**kwargs)**

Returns the list of domains registered in the account. The results may be split into multiple pages. To retrieve subsequent pages, make the call again using the nextPageToken returned by the initial call.

**Note:** This operation is eventually consistent. The results are best effort and may not exactly reflect recent updates and changes.

**Access Control**

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a Resource element with the domain name to limit the action to only specified domains. The element must be set to `arn:aws:swf::AccountID:domain/*`, where `AccountID` is the account ID, with no dashes.
- Use an Action element to allow or deny permission to call this action.
- You cannot use an IAM policy to constrain this action’s parameters.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s cause parameter will be set to OPERATION_NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

**Request Syntax**

```python
response = client.list_domains(
    nextPageToken='string',
    registrationStatus='REGISTERED'|'DEPRECATED',
    maximumPageSize=123,
    reverseOrder=True|False
)
```

**Parameters**

- **nextPageToken** *(string)* – If a NextPageToken was returned by a previous call, there are more results available. To retrieve the next page of results, make the call again using the returned token in nextPageToken. Keep all other arguments unchanged.

  The configured maximumPageSize determines how many results can be returned in a single call.

- **registrationStatus** *(string)* – [REQUIRED]

  Specifies the registration status of the domains to list.

- **maximumPageSize** *(integer)* – The maximum number of results that will be returned per call. nextPageToken can be used to obtain further pages of results. The default is 1000, which is the maximum allowed page size. You can, however, specify a page size smaller than the maximum.

  This is an upper limit only; the actual number of results returned per call may be fewer than the specified maximum.

- **reverseOrder** *(boolean)* – When set to true, returns the results in reverse order. By default, the results are returned in ascending alphabetical order by name of the domains.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'domainInfos': [
```
Response Structure

- (dict) –
  Contains a paginated collection of DomainInfo structures.
  - domainInfos (list) –
    A list of DomainInfo structures.
      * (dict) –
        Contains general information about a domain.
          - name (string) –
            The name of the domain. This name is unique within the
            account.
          - status (string) –
            The status of the domain:
            - REGISTERED: The domain is properly registered and
              available. You can use this domain for registering types
              and creating new workflow executions.
            - DEPRECATED: The domain was deprecated using Depre-
              cateDomain, but is still in use. You should not create
              new workflow executions in this domain.
          - description (string) –
            The description of the domain provided through RegisterDo-
            main.
  - nextPageToken (string) –
    If a nextPageToken was returned by a previous call, there are more
    results available. To retrieve the next page of results, make the call again
    using the returned token in nextPageToken. Keep all other arguments
    unchanged.

The configured maximumPageSize determines how many results can
be returned in a single call.

list_open_workflow_executions(**kwargs)

Returns a list of open workflow executions in the specified domain that meet the filtering criteria. The
results may be split into multiple pages. To retrieve subsequent pages, make the call again using the
nextPageToken returned by the initial call.

**Note:** This operation is eventually consistent. The results are best effort and may not exactly reflect
recent updates and changes.

Access Control

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:
- Use a Resource element with the domain name to limit the action to only specified domains.
- Use an Action element to allow or deny permission to call this action.
Constrain the following parameters by using a `Condition` element with the appropriate keys.

- `tagFilter.tag`: String constraint. The key is `swf:tagFilter.tag`.
- `typeFilter.name`: String constraint. The key is `swf:typeFilter.name`.
- `typeFilter.version`: String constraint. The key is `swf:typeFilter.version`.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s `cause` parameter will be set to `OPERATION_NOT_PERMITTED`. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

Request Syntax

```python
response = client.list_open_workflow_executions(
    domain='string',
    startTimeFilter={
        'oldestDate': datetime(2015, 1, 1),
        'latestDate': datetime(2015, 1, 1)
    },
    typeFilter={
        'name': 'string',
        'version': 'string'
    },
    tagFilter={
        'tag': 'string'
    },
    nextPageToken='string',
    maximumPageSize=123,
    reverseOrder=True|False,
    executionFilter={
        'workflowId': 'string'
    } )
```

### Parameters

- **domain (string)** – [REQUIRED]
  The name of the domain that contains the workflow executions to list.

- **startTimeFilter (dict)** – [REQUIRED]
  Workflow executions are included in the returned results based on whether their start times are within the range specified by this filter.
  - **oldestDate (datetime)** – [REQUIRED]
    Specifies the oldest start or close date and time to return.
  - **latestDate (datetime)** –
    Specifies the latest start or close date and time to return.

- **typeFilter (dict)** – If specified, only executions of the type specified in the filter are returned.
  - **name (string)** – [REQUIRED]
    Required. Name of the workflow type.
  - **version (string)** –
    Version of the workflow type.
• **tagFilter** (*dict*) – If specified, only executions that have the matching tag are listed.

**Note:** `executionFilter`, `typeFilter` and `tagFilter` are mutually exclusive. You can specify at most one of these in a request.

  - **tag** (*string*) – [REQUIRED]
    
    **Required.** Specifies the tag that must be associated with the execution for it to meet the filter criteria.

• **nextPageToken** (*string*) – If a `NextPageToken` was returned by a previous call, there are more results available. To retrieve the next page of results, make the call again using the returned token in `nextPageToken`. Keep all other arguments unchanged.

The configured `maximumPageSize` determines how many results can be returned in a single call.

• **maximumPageSize** (*integer*) – The maximum number of results that will be returned per call. `nextPageToken` can be used to obtain further pages of results. The default is 1000, which is the maximum allowed page size. You can, however, specify a page size smaller than the maximum.

  This is an upper limit only; the actual number of results returned per call may be fewer than the specified maximum.

• **reverseOrder** (*boolean*) – When set to `true`, returns the results in reverse order. By default the results are returned in descending order of the start time of the executions.

• **executionFilter** (*dict*) – If specified, only workflow executions matching the workflow ID specified in the filter are returned.

  **Note:** `executionFilter`, `typeFilter` and `tagFilter` are mutually exclusive. You can specify at most one of these in a request.

  - **workflowId** (*string*) – [REQUIRED]
    
    The workflowId to pass of match the criteria of this filter.
Response Structure

* **(dict)** –
  Contains a paginated list of information about workflow executions.
    * **executionInfos (list)** –
      The list of workflow information structures.
        * **(dict)** –
          Contains information about a workflow execution.
            * **execution (dict)** –
              The workflow execution this information is about.
            * **workflowId (string)** –
              The user defined identifier associated with the workflow execution.
            * **runId (string)** –
              A system-generated unique identifier for the workflow execution.
            * **workflowType (dict)** –
              The type of the workflow execution.
              * **name (string)** –
                Required. The name of the workflow type.
              * **version (string)** –
                Required. The version of the workflow type.
              Note: The combination of workflow type name and version must be unique with in a domain.
            * **startTime (datetime)** –
              The time when the execution was started.
            * **closeTime (datetime)** –
              The time when the workflow execution was closed. Set only if the execution status is CLOSED.
If the execution status is closed then this specifies how the execution was closed:

- **COMPLETED**: the execution was successfully completed.
- **CANCELED**: the execution was canceled. Cancellation allows the implementation to gracefully clean up before the execution is closed.
- **TERMINATED**: the execution was force terminated.
- **FAILED**: the execution failed to complete.
- **TIMED_OUT**: the execution did not complete in the allotted time and was automatically timed out.
- **CONTINUED_AS_NEW**: the execution is logically continued. This means the current execution was completed and a new execution was started to carry on the workflow.

- **parent (dict)** –
  If this workflow execution is a child of another execution then contains the workflow execution that started this execution.

- **workflowId (string)** –
  The user defined identifier associated with the workflow execution.

- **runId (string)** –
  A system-generated unique identifier for the workflow execution.

- **tagList (list)** –
  The list of tags associated with the workflow execution. Tags can be used to identify and list workflow executions of interest through the visibility APIs. A workflow execution can have a maximum of 5 tags.

- **cancelRequested (boolean)** –
  Set to true if a cancellation is requested for this workflow execution.

- **nextPageToken (string)** –
  If a nextPageToken was returned by a previous call, there are more results available. To retrieve the next page of results, make the call again using the returned token in nextPageToken. Keep all other arguments unchanged.

  The configured maximumPageSize determines how many results can be returned in a single call.

### list_workflow_types (**kwargs)**

Returns information about workflow types in the specified domain. The results may be split into multiple pages that can be retrieved by making the call repeatedly.

#### Access Control

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a **Resource** element with the domain name to limit the action to only specified domains.
- Use an **Action** element to allow or deny permission to call this action.
- You cannot use an IAM policy to constrain this action’s parameters.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s **cause** parameter will be set to
OPERATION_NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

Request Syntax

```python
response = client.list_workflow_types(
    domain='string',
    name='string',
    registrationStatus='REGISTERED'|'DEPRECATED',
    nextPageToken='string',
    maximumPageSize=123,
    reverseOrder=True|False
)
```

Parameters

- **domain** *(string)* – [REQUIRED]
  The name of the domain in which the workflow types have been registered.
- **name** *(string)* – If specified, lists the workflow type with this name.
- **registrationStatus** *(string)* – [REQUIRED]
  Specifies the registration status of the workflow types to list.
- **nextPageToken** *(string)* – If a `NextPageToken` was returned by a previous call, there are more results available. To retrieve the next page of results, make the call again using the returned token in `nextPageToken`. Keep all other arguments unchanged.
  The configured `maximumPageSize` determines how many results can be returned in a single call.
- **maximumPageSize** *(integer)* – The maximum number of results that will be returned per call. `nextPageToken` can be used to obtain further pages of results. The default is 1000, which is the maximum allowed page size. You can, however, specify a page size smaller than the maximum.
  This is an upper limit only; the actual number of results returned per call may be fewer than the specified maximum.
- **reverseOrder** *(boolean)* – When set to `true`, returns the results in reverse order. By default the results are returned in ascending alphabetical order of the name of the workflow types.

Return type **dict**

Returns

Response Syntax

```json
{
    'typeInfos': [  
        {
            'workflowType': {
                'name': 'string',
                'version': 'string'
            },
            'status': 'REGISTERED'|'DEPRECATED',
            'description': 'string',
            'creationDate': datetime(2015, 1, 1),
            'deprecationDate': datetime(2015, 1, 1)
        },
        {
            'nextPageToken': 'string'
        }
    ]
}
```
Response Structure
  • (dict) –
    Contains a paginated list of information structures about workflow types.
      – typeInfos (list) –
        The list of workflow type information.
          • (dict) –
            Contains information about a workflow type.
              • workflowType (dict) –
                The workflow type this information is about.
              • name (string) –
                Required. The name of the workflow type.
                Note: The combination of workflow type name and version
                must be unique within a domain.
              • version (string) –
                Required. The version of the workflow type.
                Note: The combination of workflow type name and version
                must be unique within a domain.
              • status (string) –
                The current status of the workflow type.
              • description (string) –
                The description of the type registered through RegisterWork-
                flowType.
              • creationDate (datetime) –
                The date when this type was registered.
              • deprecationDate (datetime) –
                If the type is in deprecated state, then it is set to the date when
                the type was deprecated.
            – nextPageToken (string) –
              If a nextPageToken was returned by a previous call, there are more
              results available. To retrieve the next page of results, make the call again
              using the returned token in nextPageToken. Keep all other arguments
              unchanged.
              The configured maximumPageSize determines how many results can
              be returned in a single call.

poll_for_activity_task (***kwargs)
  Used by workers to get an ActivityTask from the specified activity taskList. This initiates a long poll,
  where the service holds the HTTP connection open and responds as soon as a task becomes available.
  The maximum time the service holds on to the request before responding is 60 seconds. If no task is
  available within 60 seconds, the poll will return an empty result. An empty result, in this context, means
  that an ActivityTask is returned, but that the value of taskToken is an empty string. If a task is returned,
  the worker should use its type to identify and process it correctly.
**Warning:** Workers should set their client side socket timeout to at least 70 seconds (10 seconds higher than the maximum time service may hold the poll request).

**Access Control**

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a **Resource** element with the domain name to limit the action to only specified domains.
- Use an **Action** element to allow or deny permission to call this action.
- Constrain the **taskList.name** parameter by using a **Condition** element with the **swf:taskList.name** key to allow the action to access only certain task lists.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s **cause** parameter will be set to **OPERATION_NOT_PERMITTED**. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

**Request Syntax**

```python
response = client.poll_for_activity_task(
    domain='string',
    taskList={
        'name': 'string'
    },
    identity='string'
)
```

**Parameters**

- **domain (string)** – [REQUIRED]
  
  The name of the domain that contains the task lists being polled.

- **taskList (dict)** – [REQUIRED]
  
  Specifies the task list to poll for activity tasks.
  
  The specified string must not start or end with whitespace. It must not contain a : (colon), / (slash), | (vertical bar), or any control characters (u0000-u001f | u007f - u009f). Also, it must not contain the literal string quotarnquot.
  
  - **name (string)** – [REQUIRED]
    
    The name of the task list.

- **identity (string)** – Identity of the worker making the request, recorded in the **ActivityTaskStarted** event in the workflow history. This enables diagnostic tracing when problems arise. The form of this identity is user defined.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'taskToken': 'string',
    'activityId': 'string',
    'startedEventId': 123,
    'workflowExecution': {
        'workflowId': 'string',
        'runId': 'string'
    },
    'activityType': {
        'name': 'string',
        'version': 'string'
    }
}
```
Response Structure

- (dict) –
  Unit of work sent to an activity worker.

  - taskToken (string) –
    The opaque string used as a handle on the task. This token is used by
    workers to communicate progress and response information back to the
    system about the task.

  - activityId (string) –
    The unique ID of the task.

  - startedEventId (integer) –
    The ID of the ActivityTaskStarted event recorded in the history.

  - workflowExecution (dict) –
    The workflow execution that started this activity task.
    - workflowId (string) –
      The user defined identifier associated with the workflow execution.
    - runId (string) –
      A system-generated unique identifier for the workflow execution.

  - activityType (dict) –
    The type of this activity task.
    - name (string) –
      The name of this activity.

    Note: The combination of activity type name and version must be
    unique within a domain.

    - version (string) –
      The version of this activity.

    Note: The combination of activity type name and version must be
    unique within a domain.

  - input (string) –
    The inputs provided when the activity task was scheduled. The form of
    the input is user defined and should be meaningful to the activity imple-
    mentation.

poll_for_decision_task (**kwargs)

Used by deciders to get a DecisionTask from the specified decision taskList. A decision task may
be returned for any open workflow execution that is using the specified task list. The task includes a
paginated view of the history of the workflow execution. The decider should use the workflow type and
the history to determine how to properly handle the task.

This action initiates a long poll, where the service holds the HTTP connection open and responds as soon
a task becomes available. If no decision task is available in the specified task list before the timeout of 60
seconds expires, an empty result is returned. An empty result, in this context, means that a DecisionTask
is returned, but that the value of taskToken is an empty string.
Warning: Deciders should set their client-side socket timeout to at least 70 seconds (10 seconds higher than the timeout).

Warning: Because the number of workflow history events for a single workflow execution might be very large, the result returned might be split up across a number of pages. To retrieve subsequent pages, make additional calls to `PollForDecisionTask` using the `nextPageToken` returned by the initial call. Note that you do not call `GetWorkflowExecutionHistory` with this `nextPageToken`. Instead, call `PollForDecisionTask` again.

Access Control

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a `Resource` element with the domain name to limit the action to only specified domains.
- Use an `Action` element to allow or deny permission to call this action.
- Constrain the `taskList.name` parameter by using a `Condition` element with the `swf:taskList.name` key to allow the action to access only certain task lists.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s `cause` parameter will be set to `OPERATION_NOT_PERMITTED`. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

Request Syntax

```python
response = client.poll_for_decision_task(
    domain='string',
    taskList={
        'name': 'string'
    },
    identity='string',
    nextPageToken='string',
    maximumPageSize=123,
    reverseOrder=True|False
)
```

Parameters

- **domain (string)** – [REQUIRED]
  
The name of the domain containing the task lists to poll.

- **taskList (dict)** – [REQUIRED]
  
  Specifies the task list to poll for decision tasks.
  
The specified string must not start or end with whitespace. It must not contain a : (colon), / (slash), | (vertical bar), or any control characters (u0000-u001f | u007f - u009f). Also, it must not contain the literal string quotarnquot.
  - **name (string)** – [REQUIRED]
    
    The name of the task list.

- **identity (string)** – Identity of the decider making the request, which is recorded in the DecisionTaskStarted event in the workflow history. This enables diagnostic tracing when problems arise. The form of this identity is user defined.

- **nextPageToken (string)** – If a `NextPageToken` was returned by a previous call, there are more results available. To retrieve the next page of results, make the call again using the returned token in `nextPageToken`. Keep all other arguments unchanged.
The configured `maximumPageSize` determines how many results can be returned in a single call.

**Note:** The `nextPageToken` returned by this action cannot be used with `GetWorkflowExecutionHistory` to get the next page. You must call `PollForDecisionTask` again (with the `nextPageToken`) to retrieve the next page of history records. Calling `PollForDecisionTask` with a `nextPageToken` will not return a new decision task.

- **maximumPageSize** *(integer)* – The maximum number of results that will be returned per call. `nextPageToken` can be used to obtain further pages of results. The default is 1000, which is the maximum allowed page size. You can, however, specify a page size smaller than the maximum.

  This is an upper limit only; the actual number of results returned per call may be fewer than the specified maximum.

- **reverseOrder** *(boolean)* – When set to `true`, returns the events in reverse order. By default the results are returned in ascending order of the `eventTimestamp` of the events.

**Return type** `dict`

**Returns**

**Response Syntax**

```
Response Structure

A structure that represents a decision task. Decision tasks are sent to deciders in order for them to make decisions.

- **taskToken** *(string)*

  The opaque string used as a handle on the task. This token is used by workers to communicate progress and response information back to the
system about the task.

- **startedEventId** (*integer*)
  
  The ID of the `DecisionTaskStarted` event recorded in the history.

- **workflowExecution** (*dict*)
  
  The workflow execution for which this decision task was created.
    - **workflowId** (*string*)
      
      The user defined identifier associated with the workflow execution.
    - **runId** (*string*)
      
      A system-generated unique identifier for the workflow execution.

- **workflowType** (*dict*)
  
  The type of the workflow execution for which this decision task was created.
    - **name** (*string*)
      
      Required. The name of the workflow type.

      **Note:** The combination of workflow type name and version must be unique within a domain.
    - **version** (*string*)
      
      Required. The version of the workflow type.

      **Note:** The combination of workflow type name and version must be unique within a domain.

- **events** (*list*)
  
  A paginated list of history events of the workflow execution. The decider uses this during the processing of the decision task.
    - (*dict*)

      Event within a workflow execution. A history event can be one of these types:
        - **WorkflowExecutionStarted**: The workflow execution was started.
        - **WorkflowExecutionCompleted**: The workflow execution was closed due to successful completion.
        - **WorkflowExecutionFailed**: The workflow execution closed due to a failure.
        - **WorkflowExecutionTimedOut**: The workflow execution was closed because a time out was exceeded.
        - **WorkflowExecutionCanceled**: The workflow execution was successfully canceled and closed.
        - **WorkflowExecutionTerminated**: The workflow execution was terminated.
        - **WorkflowExecutionContinuedAsNew**: The workflow execution was closed and a new execution of the same type was created with the same workflowId.
        - **WorkflowExecutionCancelRequested**: A request to cancel this workflow execution was made.
        - **DecisionTaskScheduled**: A decision task was scheduled for the workflow execution.
- **DecisionTaskStarted**: The decision task was dispatched to a decider.
- **DecisionTaskCompleted**: The decider successfully completed a decision task by calling `RespondDecisionTaskCompleted`.
- **DecisionTaskTimedOut**: The decision task timed out.
- **ActivityTaskScheduled**: An activity task was scheduled for execution.
- **ScheduleActivityTaskFailed**: Failed to process `ScheduleActivityTask` decision. This happens when the decision is not configured properly, for example the activity type specified is not registered.
- **ActivityTaskStarted**: The scheduled activity task was dispatched to a worker.
- **ActivityTaskCompleted**: An activity worker successfully completed an activity task by calling `RespondActivityTaskCompleted`.
- **ActivityTaskFailed**: An activity worker failed an activity task by calling `RespondActivityTaskFailed`.
- **ActivityTaskTimedOut**: The activity task timed out.
- **ActivityTaskCanceled**: The activity task was successfully canceled.
- **ActivityTaskCancelRequested**: A `RequestCancelActivityTask` decision was received by the system.
- **RequestCancelActivityTaskFailed**: Failed to process `RequestCancelActivityTask` decision. This happens when the decision is not configured properly.
- **WorkflowExecutionSignaled**: An external signal was received for the workflow execution.
- **MarkerRecorded**: A marker was recorded in the workflow history as the result of a `RecordMarker` decision.
- **TimerStarted**: A timer was started for the workflow execution due to a `StartTimer` decision.
- **StartTimerFailed**: Failed to process `StartTimer` decision. This happens when the decision is not configured properly, for example a timer already exists with the specified timer ID.
- **TimerFired**: A timer, previously started for this workflow execution, fired.
- **TimerCanceled**: A timer, previously started for this workflow execution, was successfully canceled.
- **CancelTimerFailed**: Failed to process `CancelTimer` decision. This happens when the decision is not configured properly, for example no timer exists with the specified timer ID.
- **StartChildWorkflowExecutionInitiated**: A request was made to start a child workflow execution.
- **StartChildWorkflowExecutionFailed**: Failed to process `StartChildWorkflowExecution` decision. This happens when the decision is not configured properly, for example the workflow type specified is not registered.
- **ChildWorkflowExecutionStarted**: A child workflow execution was successfully started.
- **ChildWorkflowExecutionCompleted**: A child workflow execution, started by this workflow execution, completed suc-
cessfully and was closed.

- **ChildWorkflowExecutionFailed**: A child workflow execution, started by this workflow execution, failed to complete successfully and was closed.

- **ChildWorkflowExecutionTimedOut**: A child workflow execution, started by this workflow execution, timed out and was closed.

- **ChildWorkflowExecutionCanceled**: A child workflow execution, started by this workflow execution, was canceled and closed.

- **ChildWorkflowExecutionTerminated**: A child workflow execution, started by this workflow execution, was terminated.

- **SignalExternalWorkflowExecutionInitiated**: A request to signal an external workflow was made.

- **ExternalWorkflowExecutionSignaled**: A signal, requested by this workflow execution, was successfully delivered to the target external workflow execution.

- **SignalExternalWorkflowExecutionFailed**: The request to signal an external workflow execution failed.

- **RequestCancelExternalWorkflowExecutionInitiated**: A request was made to request the cancellation of an external workflow execution.

- **ExternalWorkflowExecutionCancelRequested**: Request to cancel an external workflow execution was successfully delivered to the target execution.

- **RequestCancelExternalWorkflowExecutionFailed**: Request to cancel an external workflow execution failed.

- **LambdaFunctionScheduled**: An AWS Lambda function was scheduled for execution.

- **LambdaFunctionStarted**: The scheduled function was invoked in the AWS Lambda service.

- **LambdaFunctionCompleted**: The AWS Lambda function successfully completed.

- **LambdaFunctionFailed**: The AWS Lambda function execution failed.

- **LambdaFunctionTimedOut**: The AWS Lambda function execution timed out.

- **ScheduleLambdaFunctionFailed**: Failed to process ScheduleLambdaFunction decision. This happens when the workflow execution does not have the proper IAM role attached to invoke AWS Lambda functions.

- **StartLambdaFunctionFailed**: Failed to invoke the scheduled function in the AWS Lambda service. This happens when the AWS Lambda service is not available in the current region, or received too many requests.

- **eventTimestamp (datetime)** –

  The date and time when the event occurred.

- **eventType (string)** –

  The type of the history event.

- **eventId (integer)** –

  The system generated ID of the event. This ID uniquely iden-
tifies the event with in the workflow execution history.
• `workflowExecutionStartedEventAttributes (dict)` –
  If the event is of type `WorkflowExecutionStarted` then this member is set and provides detailed information about the event. It is not set for other event types.
• `input (string)` –
  The input provided to the workflow execution (if any).
• `executionStartToCloseTimeout (string)` –
  The maximum duration for this workflow execution.
  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.
• `taskStartToCloseTimeout (string)` –
  The maximum duration of decision tasks for this workflow type.
  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.
• `childPolicy (string)` –
  The policy to use for the child workflow executions if this workflow execution is terminated, by calling the Terminate-WorkflowExecution action explicitly or due to an expired timeout.
  The supported child policies are:
  • `TERMINATE`: the child executions will be terminated.
  • `REQUEST_CANCEL`: a request to cancel will be attempted for each child execution by recording a `WorkflowExecutionCancelRequested` event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
  • `ABANDON`: no action will be taken. The child executions will continue to run.
• `taskList (dict)` –
  The name of the task list for scheduling the decision tasks for this workflow execution.
  • `name (string)` –
  The name of the task list.
• `workflowType (dict)` –
  The workflow type of this execution.
  • `name (string)` –
    Required. The name of the workflow type.

**Note:** The combination of workflow type name and version must be unique with in a domain.

• `version (string)` –
  Required. The version of the workflow type.
**Note:** The combination of workflow type name and version must be unique with in a domain.

- **tagList (list)** –
  
The list of tags associated with this workflow execution. An execution can have up to 5 tags.
  - **(string)** –
    - **taskPriority (string)** –
    - **continuedExecutionRunId (string)** –
      
      If this workflow execution was started due to a `ContinueAsNewWorkflowExecution` decision, then it contains the `runId` of the previous workflow execution that was closed and continued as this execution.

- **parentWorkflowExecution (dict)** –
  
The source workflow execution that started this workflow execution. The member is not set if the workflow execution was not started by a workflow.

- ** workflowId (string)** –
  
The user defined identifier associated with the workflow execution.

- **runId (string)** –
  
  A system-generated unique identifier for the workflow execution.

- **parentInitiatedEventId (integer)** –
  
  The ID of the `StartChildWorkflowExecutionInitiated` event corresponding to the `StartChildWorkflowExecution` decision to start this workflow execution. The source event with this ID can be found in the history of the source workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **lambdaRole (string)** –
  
  The IAM role attached to this workflow execution to use when invoking AWS Lambda functions.

- **workflowExecutionCompletedEventAttributes (dict)** –
  
  If the event is of type `WorkflowExecutionCompleted` then this member is set and provides detailed information about the event. It is not set for other event types.

- **result (string)** –
  
  The result produced by the workflow execution upon successful completion.

- **decisionTaskCompletedEventId (integer)** –
  
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `CompleteWorkflowExecution` decision to complete this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
• **completeWorkflowExecutionFailedEventAttributes** *(dict)*
  
  If the event is of type `CompleteWorkflowExecutionFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

• **cause** *(string)* –

  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

**Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

• **decisionTaskCompletedEventId** *(integer)* –

  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `CompleteWorkflowExecution` decision to complete this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

• **workflowExecutionFailedEventAttributes** *(dict)* –

  If the event is of type `WorkflowExecutionFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

• **reason** *(string)* –

  The descriptive reason provided for the failure (if any).

• **details** *(string)* –

  The details of the failure (if any).

• **decisionTaskCompletedEventId** *(integer)* –

  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `FailWorkflowExecution` decision to fail this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

• **failWorkflowExecutionFailedEventAttributes** *(dict)* –

  If the event is of type `FailWorkflowExecutionFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

• **cause** *(string)* –

  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

**Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.
· decisionTaskCompletedEventId (integer) –

The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the FailWorkflowExecution decision to fail this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· workflowExecutionTimedOutEventAttributes (dict) –

If the event is of type WorkflowExecutionTimedOut then this member is set and provides detailed information about the event. It is not set for other event types.

· timeoutType (string) –

The type of timeout that caused this event.

· childPolicy (string) –

The policy used for the child workflow executions of this workflow execution.

    The supported child policies are:
    · TERMINATE: the child executions will be terminated.
    · REQUEST_CANCEL: a request to cancel will be attempted for each child execution by recording a WorkflowExecutionCancelRequested event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
    · ABANDON: no action will be taken. The child executions will continue to run.

· workflowExecutionCanceledEventAttributes (dict) –

If the event is of type WorkflowExecutionCanceled then this member is set and provides detailed information about the event. It is not set for other event types.

· details (string) –

Details for the cancellation (if any).

· decisionTaskCompletedEventId (integer) –

The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the CancelWorkflowExecution decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· cancelWorkflowExecutionFailedEventAttributes (dict) –

If the event is of type CancelWorkflowExecutionFailed then this member is set and provides detailed information about the event. It is not set for other event types.

· cause (string) –

The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

Note: If cause is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions.
For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- `decisionTaskCompletedEventId (integer)`
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the CancelWorkflowExecution decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- `workflowExecutionContinuedAsNewEventAttributes (dict)`
  If the event is of type WorkflowExecutionContinuedAsNew then this member is set and provides detailed information about the event. It is not set for other event types.
- `input (string)`
  The input provided to the new workflow execution.
- `decisionTaskCompletedEventId (integer)`
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the ContinueAsNewWorkflowExecution decision that started this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
- `newExecutionRunId (string)`
  The runId of the new workflow execution.
- `executionStartToCloseTimeout (string)`
  The total duration allowed for the new workflow execution.
  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.
- `taskList (dict)`
  Represents a task list.
- `name (string)`
  The name of the task list.
- `taskPriority (string)`
- `taskStartToCloseTimeout (string)`
  The maximum duration of decision tasks for the new workflow execution.
  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.
- `childPolicy (string)`
  The policy to use for the child workflow executions of the new execution if it is terminated by calling the TerminateWorkflowExecution action explicitly or due to an expired timeout.

The supported child policies are:

---

3.1. Services
- **TERMINATE**: the child executions will be terminated.
- **REQUEST_CANCEL**: a request to cancel will be attempted for each child execution by recording a `WorkflowExecutionCancelRequested` event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
- **ABANDON**: no action will be taken. The child executions will continue to run.
- **tagList** *(list)* –
  The list of tags associated with the new workflow execution.
  - *(string)* –
  - **workflowType** *(dict)* –
    Represents a workflow type.
    - **name** *(string)* –
      Required. The name of the workflow type.

  **Note**: The combination of workflow type name and version must be unique within a domain.

- **version** *(string)* –
  Required. The version of the workflow type.

  **Note**: The combination of workflow type name and version must be unique within a domain.

- **lambdaRole** *(string)* –
  The IAM role attached to this workflow execution to use when invoking AWS Lambda functions.
- **continueAsNewWorkflowExecutionFailedEventAttributes** *(dict)* –
  If the event is of type `ContinueAsNewWorkflowExecutionFailed` then this member is set and provides detailed information about the event. It is not set for other event types.
  - **cause** *(string)* –
    The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note**: If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId** *(integer)* –
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `ContinueAsNewWorkflowExecution` decision that started this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
- **workflowExecutionTerminatedEventAttributes** *(dict)* –
If the event is of type WorkflowExecutionTerminated then this member is set and provides detailed information about the event. It is not set for other event types.
- **reason** *(string)* –
  The reason provided for the termination (if any).
- **details** *(string)* –
  The details provided for the termination (if any).
- **childPolicy** *(string)* –
  The policy used for the child workflow executions of this workflow execution.
  The supported child policies are:
- **TERMINATE**: the child executions will be terminated.
- **REQUEST_CANCEL**: a request to cancel will be attempted for each child execution by recording a WorkflowExecutionCancelRequested event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
- **ABANDON**: no action will be taken. The child executions will continue to run.
- **cause** *(string)* –
  If set, indicates that the workflow execution was automatically terminated, and specifies the cause. This happens if the parent workflow execution times out or is terminated and the child policy is set to terminate child executions.
- **workflowExecutionCancelRequestedEventAttributes** *(dict)* –
  If the event is of type WorkflowExecutionCancelRequested then this member is set and provides detailed information about the event. It is not set for other event types.
- **externalWorkflowExecution** *(dict)* –
  The external workflow execution for which the cancellation was requested.
- **workflowId** *(string)* –
  The user defined identifier associated with the workflow execution.
- **runId** *(string)* –
  A system-generated unique identifier for the workflow execution.
- **externalInitiatedEventId** *(integer)* –
  The ID of the RequestCancelExternalWorkflowExecutionInitiated event corresponding to the RequestCancelExternalWorkflowExecution decision to cancel this workflow execution. The source event with this ID can be found in the history of the source workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
· cause (string) –
If set, indicates that the request to cancel the workflow execution was automatically generated, and specifies the cause. This happens if the parent workflow execution times out or is terminated, and the child policy is set to cancel child executions.

· decisionTaskScheduledEventAttributes (dict) –
If the event is of type DecisionTaskScheduled then this member is set and provides detailed information about the event. It is not set for other event types.

· taskList (dict) –
The name of the task list in which the decision task was scheduled.

· name (string) –
The name of the task list.

· taskPriority (string) –
Optional. A task priority that, if set, specifies the priority for this decision task. Valid values are integers that range from Java's `Integer.MIN_VALUE` (-2147483648) to `Integer.MAX_VALUE` (2147483647). Higher numbers indicate higher priority.

For more information about setting task priority, see Setting Task Priority in the Amazon Simple Workflow Developer Guide.

· startToCloseTimeout (string) –
The maximum duration for this decision task. The task is considered timed out if it does not completed within this duration.

The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

· decisionTaskStartedEventAttributes (dict) –
If the event is of type DecisionTaskStarted then this member is set and provides detailed information about the event. It is not set for other event types.

· identity (string) –
Identity of the decider making the request. This enables diagnostic tracing when problems arise. The form of this identity is user defined.

· scheduledEventId (integer) –
The ID of the DecisionTaskScheduled event that was recorded when this decision task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· decisionTaskCompletedEventAttributes (dict) –
If the event is of type DecisionTaskCompleted then this member is set and provides detailed information about the event. It is not set for other event types.
- **executionContext** *(string)* –
  User defined context for the workflow execution.

- **scheduledEventId** *(integer)* –
  The ID of the DecisionTaskScheduled event that was recorded when this decision task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId** *(integer)* –
  The ID of the DecisionTaskStarted event recorded when this decision task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **decisionTaskTimedOutEventAttributes** *(dict)* –
  If the event is of type DecisionTaskTimedOut then this member is set and provides detailed information about the event. It is not set for other event types.

- **timeoutType** *(string)* –
  The type of timeout that expired before the decision task could be completed.

- **scheduledEventId** *(integer)* –
  The ID of the DecisionTaskScheduled event that was recorded when this decision task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId** *(integer)* –
  The ID of the DecisionTaskStarted event recorded when this decision task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityTaskScheduledEventAttributes** *(dict)* –
  If the event is of type ActivityTaskScheduled then this member is set and provides detailed information about the event. It is not set for other event types.

- **activityType** *(dict)* –
  The type of the activity task.

- **name** *(string)* –
  The name of this activity.

  **Note:** The combination of activity type name and version must be unique within a domain.

- **version** *(string)* –
  The version of this activity.

  **Note:** The combination of activity type name and version must be unique within a domain.

- **activityId** *(string)* –
  The unique ID of the activity task.
· **input** *(string)* –
  The input provided to the activity task.

· **control** *(string)* –
  *Optional.* Data attached to the event that can be used by the decider in subsequent workflow tasks. This data is not sent to the activity.

· **scheduleToStartTimeout** *(string)* –
  The maximum amount of time the activity task can wait to be assigned to a worker.

· **scheduleToCloseTimeout** *(string)* –
  The maximum amount of time for this activity task.

· **startToCloseTimeout** *(string)* –
  The maximum amount of time a worker may take to process the activity task.

· **taskList** *(dict)* –
  The task list in which the activity task has been scheduled.

· **name** *(string)* –
  The name of the task list.

· **taskPriority** *(string)* –
  *Optional.* The priority to assign to the scheduled activity task. If set, this will override any default priority value that was assigned when the activity type was registered.

  Valid values are integers that range from Java’s `Integer.MIN_VALUE` (-2147483648) to `Integer.MAX_VALUE` (2147483647). Higher numbers indicate higher priority.

  For more information about setting task priority, see Setting Task Priority in the Amazon Simple Workflow Developer Guide.

· **decisionTaskCompletedEventId** *(integer)* –
  The ID of the DecisionTaskCompleted event corresponding to the decision that resulted in the scheduling of this activity task. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· **heartbeatTimeout** *(string)* –
  The maximum time before which the worker processing this task must report progress by calling RecordActivityTaskHeartbeat. If the timeout is exceeded, the activity task is automatically timed out. If the worker subsequently attempts to record a heartbeat or return a result, it will be ignored.

· **activityTaskStartedEventAttributes** *(dict)* –
  If the event is of type `ActivityTaskStarted` then this member is set and provides detailed information about the event. It is not set for other event types.

· **identity** *(string)* –
Identity of the worker that was assigned this task. This aids diagnostics when problems arise. The form of this identity is user defined.

- **scheduledEventId (integer)** –
  
The ID of the `ActivityTaskScheduled` event that was recorded when this activity task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityTaskCompletedEventAttributes (dict)** –
  
  If the event is of type `ActivityTaskCompleted` then this member is set and provides detailed information about the event. It is not set for other event types.

- **result (string)** –
  
  The results of the activity task (if any).

- **scheduledEventId (integer)** –
  
  The ID of the `ActivityTaskScheduled` event that was recorded when this activity task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –
  
  The ID of the `ActivityTaskStarted` event recorded when this activity task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityTaskFailedEventAttributes (dict)** –
  
  If the event is of type `ActivityTaskFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

- **reason (string)** –
  
  The reason provided for the failure (if any).

- **details (string)** –
  
  The details of the failure (if any).

- **scheduledEventId (integer)** –
  
  The ID of the `ActivityTaskScheduled` event that was recorded when this activity task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –
  
  The ID of the `ActivityTaskStarted` event recorded when this activity task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityTaskTimedOutEventAttributes (dict)** –
  
  If the event is of type `ActivityTaskTimedOut` then this member is set and provides detailed information about the event. It is not set for other event types.

- **timeoutType (string)** –
  
  The type of the timeout that caused this event.
· scheduledEventId (integer) –

The ID of the ActivityTaskScheduled event that was recorded when this activity task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· startedEventId (integer) –

The ID of the ActivityTaskStarted event recorded when this activity task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· details (string) –

Contains the content of the details parameter for the last call made by the activity to RecordActivityTaskHeartbeat.

· activityTaskCanceledEventAttributes (dict) –

If the event is of type ActivityTaskCanceled then this member is set and provides detailed information about the event. It is not set for other event types.

· details (string) –

Details of the cancellation (if any).

· scheduledEventId (integer) –

The ID of the ActivityTaskScheduled event that was recorded when this activity task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· startedEventId (integer) –

The ID of the ActivityTaskStarted event recorded when this activity task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· latestCancelRequestedEventId (integer) –

If set, contains the ID of the last ActivityTaskCancelRequested event recorded for this activity task. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· activityTaskCancelRequestedEventAttributes (dict) –

If the event is of type ActivityTaskCancelRequested then this member is set and provides detailed information about the event. It is not set for other event types.

· decisionTaskCompletedEventId (integer) –

The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the RequestCancelActivityTask decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· activityId (string) –
The unique ID of the task.

- `workflowExecutionSignaledEventAttributes (dict)` –
  If the event is of type `WorkflowExecutionSignaled` then this member is set and provides detailed information about the event. It is not set for other event types.

- `signalName (string)` –
  The name of the signal received. The decider can use the signal name and inputs to determine how to process the signal.

- `input (string)` –
  Inputs provided with the signal (if any). The decider can use the signal name and inputs to determine how to process the signal.

- `externalWorkflowExecution (dict)` –
  The workflow execution that sent the signal. This is set only of the signal was sent by another workflow execution.

- `workflowId (string)` –
  The user defined identifier associated with the workflow execution.

- `runId (string)` –
  A system-generated unique identifier for the workflow execution.

- `externalInitiatedEventId (integer)` –
  The ID of the `SignalExternalWorkflowExecutionInitiated` event corresponding to the `SignalExternalWorkflowExecutionInitiated` decision to signal this workflow execution. The source event with this ID can be found in the history of the source workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event. This field is set only if the signal was initiated by another workflow execution.

- `markerRecordedEventAttributes (dict)` –
  If the event is of type `MarkerRecorded` then this member is set and provides detailed information about the event. It is not set for other event types.

- `markerName (string)` –
  The name of the marker.

- `details (string)` –
  Details of the marker (if any).

- `decisionTaskCompletedEventId (integer)` –
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `RecordMarker` decision that requested this marker. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- `recordMarkerFailedEventAttributes (dict)` –
  If the event is of type `DecisionTaskFailed` then this member is set and provides detailed information about the
event. It is not set for other event types.

- **markerName (string)** –
  
The marker’s name.

- **cause (string)** –
  
The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

**Note:** If cause is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId (integer)** –
  
The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the RecordMarkerFailed decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **timerStartedEventAttributes (dict)** –
  
If the event is of type TimerStarted then this member is set and provides detailed information about the event. It is not set for other event types.

- **timerId (string)** –
  
The unique ID of the timer that was started.

- **control (string)** –
  
*Optional.* Data attached to the event that can be used by the decider in subsequent workflow tasks.

- **startToFireTimeout (string)** –
  
The duration of time after which the timer will fire.
  
The duration is specified in seconds; an integer greater than or equal to 0.

- **decisionTaskCompletedEventId (integer)** –
  
The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the StartTimer decision for this activity task. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **timerFiredEventAttributes (dict)** –
  
If the event is of type TimerFired then this member is set and provides detailed information about the event. It is not set for other event types.

- **timerId (string)** –
  
The unique ID of the timer that fired.

- **startedEventId (integer)** –
  
The ID of the TimerStarted event that was recorded when this timer was started. This information can be useful for diagnosing problems by tracing back the chain of events leading
up to this event.

- **timerCanceledEventAttributes (dict)**
  
  If the event is of type `TimerCanceled` then this member is set and provides detailed information about the event. It is not set for other event types.

- **timerId (string)**
  
  The unique ID of the timer that was canceled.

- **startedEventId (integer)**
  
  The ID of the `TimerStarted` event that was recorded when this timer was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **decisionTaskCompletedEventId (integer)**
  
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `CancelTimer` decision to cancel this timer. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startChildWorkflowExecutionInitiatedEventAttributes (dict)**
  
  If the event is of type `StartChildWorkflowExecutionInitiated` then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowId (string)**
  
  The `workflowId` of the child workflow execution.

- **workflowType (dict)**
  
  The type of the child workflow execution.

- **name (string)**
  
  Required. The name of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- **version (string)**
  
  Required. The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- **control (string)**
  
  Optional. Data attached to the event that can be used by the decider in subsequent decision tasks. This data is not sent to the activity.

- **input (string)**
  
  The inputs provided to the child workflow execution (if any).

- **executionStartToCloseTimeout (string)**
  
  The maximum duration for the child workflow execution. If the workflow execution is not closed within this duration, it
will be timed out and force terminated.

The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **taskList (dict)** –

  The name of the task list used for the decision tasks of the child workflow execution.

- **name (string)** –

  The name of the task list.

- **taskPriority (string)** –

  *Optional.* The priority assigned for the decision tasks for this workflow execution. Valid values are integers that range from Java’s `Integer.MIN_VALUE (-2147483648)` to `Integer.MAX_VALUE (2147483647)`. Higher numbers indicate higher priority.

  For more information about setting task priority, see Setting Task Priority in the Amazon Simple Workflow Developer Guide.

- **decisionTaskCompletedEventId (integer)** –

  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `StartChildWorkflowExecution` decision to request this child workflow execution. This information can be useful for diagnosing problems by tracing back the cause of events.

- **childPolicy (string)** –

  The policy to use for the child workflow executions if this execution gets terminated by explicitly calling the TerminateWorkflowExecution action or due to an expired timeout.

  The supported child policies are:

  - **TERMINATE**: the child executions will be terminated.
  - **REQUEST_CANCEL**: a request to cancel will be attempted for each child execution by recording a `WorkflowExecutionCancelRequested` event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
  - **ABANDON**: no action will be taken. The child executions will continue to run.
  - **taskStartToCloseTimeout (string)** –

  The maximum duration allowed for the decision tasks for this workflow execution.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **tagList (list)** –

  The list of tags to associated with the child workflow execution.

  - **(string)** –
  - **lambdaRole (string)** –
The IAM role attached to this workflow execution to use when invoking AWS Lambda functions.

- **childWorkflowExecutionStartedEventAttributes** (`dict`) –
  
  If the event is of type `ChildWorkflowExecutionStarted` then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowExecution** (`dict`) –

  The child workflow execution that was started.

- **workflowId** (`string`) –

  The user defined identifier associated with the workflow execution.

- **runId** (`string`) –

  A system-generated unique identifier for the workflow execution.

- **workflowType** (`dict`) –

  The type of the child workflow execution.

  - **name** (`string`) –

    Required. The name of the workflow type.

    **Note:** The combination of workflow type name and version must be unique within a domain.

- **version** (`string`) –

  Required. The version of the workflow type.

    **Note:** The combination of workflow type name and version must be unique within a domain.

- **initiatedEventId** (`integer`) –

  The ID of the `StartChildWorkflowExecutionInitiated` event corresponding to the `StartChildWorkflowExecution` decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **childWorkflowExecutionCompletedEventAttributes** (`dict`) –

  If the event is of type `ChildWorkflowExecutionCompleted` then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowExecution** (`dict`) –

  The child workflow execution that was completed.

- **workflowId** (`string`) –

  The user defined identifier associated with the workflow execution.

- **runId** (`string`) –
A system-generated unique identifier for the workflow execution.

- **workflowType (dict)** –

  The type of the child workflow execution.

- **name (string)** –

  **Required.** The name of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- **version (string)** –

  **Required.** The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- **result (string)** –

  The result of the child workflow execution (if any).

- **initiatedEventId (integer)** –

  The ID of the `StartChildWorkflowExecutionInitiated` event corresponding to the `StartChildWorkflowExecution` decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –

  The ID of the `ChildWorkflowExecutionStarted` event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **childWorkflowExecutionFailedEventAttributes (dict)** –

  If the event is of type `ChildWorkflowExecutionFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowExecution (dict)** –

  The child workflow execution that failed.

- **workflowId (string)** –

  The user-defined identifier associated with the workflow execution.

- **runId (string)** –

  A system-generated unique identifier for the workflow execution.

- **workflowType (dict)** –

  The type of the child workflow execution.

- **name (string)** –

  **Required.** The name of the workflow type.
Note: The combination of workflow type name and version must be unique with in a domain.

- **version** *(string)* – Required. The version of the workflow type.

Note: The combination of workflow type name and version must be unique with in a domain.

- **reason** *(string)* –
  The reason for the failure (if provided).

- **details** *(string)* –
  The details of the failure (if provided).

- **initiatedEventId** *(integer)* –
  The ID of the StartChildWorkflowExecutionInitiated event corresponding to the StartChildWorkflowExecution decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId** *(integer)* –
  The ID of the ChildWorkflowExecutionStarted event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **childWorkflowExecutionTimedOutEventAttributes** *(dict)* –
  If the event is of type ChildWorkflowExecutionTimedOut then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowExecution** *(dict)* –
  The child workflow execution that timed out.

- **workflowId** *(string)* –
  The user defined identifier associated with the workflow execution.

- **runId** *(string)* –
  A system-generated unique identifier for the workflow execution.

- **workflowType** *(dict)* –
  The type of the child workflow execution.

- **name** *(string)* – Required. The name of the workflow type.

  Note: The combination of workflow type name and version must be unique with in a domain.

- **version** *(string)* –
Required. The version of the workflow type.

Note: The combination of workflow type name and version must be unique with in a domain.

- `timeoutType (string)` –
  The type of the timeout that caused the child workflow execution to time out.

- `initiatedEventId (integer)` –
  The ID of the StartChildWorkflowExecutionInitiated event corresponding to the StartChildWorkflowExecution decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- `startedEventId (integer)` –
  The ID of the ChildWorkflowExecutionStarted event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- `childWorkflowExecutionCanceledEventAttributes (dict)` –
  If the event is of type ChildWorkflowExecutionCanceled then this member is set and provides detailed information about the event. It is not set for other event types.

- `workflowExecution (dict)` –
  The child workflow execution that was canceled.

  - `workflowId (string)` –
    The user defined identifier associated with the workflow execution.

  - `runId (string)` –
    A system-generated unique identifier for the workflow execution.

  - `workflowType (dict)` –
    The type of the child workflow execution.

  - `name (string)` –
    Required. The name of the workflow type.

Note: The combination of workflow type name and version must be unique with in a domain.

- `version (string)` –
  Required. The version of the workflow type.

Note: The combination of workflow type name and version must be unique with in a domain.

- `details (string)` –
Details of the cancellation (if provided).

- **initiatedEventId** *(integer)* –

  The ID of the `StartChildWorkflowExecutionInitiated` event corresponding to the `StartChildWorkflowExecution` decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId** *(integer)* –

  The ID of the `ChildWorkflowExecutionStarted` event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **childWorkflowExecutionTerminatedEventAttributes** *(dict)* –

  If the event is of type `ChildWorkflowExecutionTerminated` then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowExecution** *(dict)* –

  The child workflow execution that was terminated.

  - **workflowId** *(string)* –

    The user defined identifier associated with the workflow execution.

  - **runId** *(string)* –

    A system-generated unique identifier for the workflow execution.

  - **workflowType** *(dict)* –

    The type of the child workflow execution.

    - **name** *(string)* –

      Required. The name of the workflow type.

      **Note:** The combination of workflow type name and version must be unique with in a domain.

    - **version** *(string)* –

      Required. The version of the workflow type.

      **Note:** The combination of workflow type name and version must be unique with in a domain.

- **initiatedEventId** *(integer)* –

  The ID of the `StartChildWorkflowExecutionInitiated` event corresponding to the `StartChildWorkflowExecution` decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
- startedEventId (integer) –

The ID of the ChildWorkflowExecutionStarted event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- signalExternalWorkflowExecutionInitiatedEventAttributes (dict) –

If the event is of type SignalExternalWorkflowExecutionInitiated then this member is set and provides detailed information about the event. It is not set for other event types.

- workflowId (string) –

The workflowId of the external workflow execution.

- runId (string) –

The runId of the external workflow execution to send the signal to.

- signalName (string) –

The name of the signal.

- input (string) –

Input provided to the signal (if any).

- decisionTaskCompletedEventId (integer) –

The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the SignalExternalWorkflowExecution decision for this signal. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- control (string) –

Optional. data attached to the event that can be used by the decider in subsequent decision tasks.

- externalWorkflowExecutionSignaledEventAttributes (dict) –

If the event is of type ExternalWorkflowExecutionSignaled then this member is set and provides detailed information about the event. It is not set for other event types.

- workflowExecution (dict) –

The external workflow execution that the signal was delivered to.

- workflowId (string) –

The user defined identifier associated with the workflow execution.

- runId (string) –

A system-generated unique identifier for the workflow execution.

- initiatedEventId (integer) –
The ID of the `SignalExternalWorkflowExecutionInitiated` event corresponding to the `SignalExternalWorkflowExecution` decision to request this signal. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- `signalExternalWorkflowExecutionFailedEventAttributes (dict)`

  If the event is of type `SignalExternalWorkflowExecutionFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

  - `workflowId (string)`

    The `workflowId` of the external workflow execution that the signal was being delivered to.

  - `runId (string)`

    The `runId` of the external workflow execution that the signal was being delivered to.

  - `cause (string)`

    The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

    **Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see [Using IAM to Manage Access to Amazon SWF Workflows](#).

- `initiatedEventId (integer)`

  The ID of the `SignalExternalWorkflowExecutionInitiated` event corresponding to the `SignalExternalWorkflowExecution` decision to request this signal. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- `decisionTaskCompletedEventId (integer)`

  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `SignalExternalWorkflowExecution` decision for this signal. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

  - `control (string)`

  - `externalWorkflowExecutionCancelRequestedEventAttributes (dict)`

    If the event is of type `ExternalWorkflowExecutionCancelRequested` then this member is set and provides detailed information about the event. It is not set for other event types.

  - `workflowExecution (dict)`

    The external workflow execution to which the cancellation
request was delivered.

- **workflowId (string)** –

  The user defined identifier associated with the workflow execution.

- **runId (string)** –

  A system-generated unique identifier for the workflow execution.

- **initiatedEventId (integer)** –

  The ID of the RequestCancelExternalWorkflowExecutionInitiated event corresponding to the RequestCancelExternalWorkflowExecution decision to cancel this external workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **requestCancelExternalWorkflowExecutionInitiatedEventAttributes (dict)** –

  If the event is of type RequestCancelExternalWorkflowExecutionInitiated then this member is set and provides detailed information about the event. It is not set for other event types.

  - **workflowId (string)** –

    The workflowId of the external workflow execution to be canceled.

  - **runId (string)** –

    The runId of the external workflow execution to be canceled.

  - **decisionTaskCompletedEventId (integer)** –

    The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the RequestCancelExternalWorkflowExecution decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

  - **control (string)** –

    Optional. Data attached to the event that can be used by the decider in subsequent workflow tasks.

- **requestCancelExternalWorkflowExecutionFailedEventAttributes (dict)** –

  If the event is of type RequestCancelExternalWorkflowExecutionFailed then this member is set and provides detailed information about the event. It is not set for other event types.

  - **workflowId (string)** –

    The workflowId of the external workflow to which the cancel request was to be delivered.

  - **runId (string)** –

    The runId of the external workflow execution.

  - **cause (string)** –
The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

**Note**: If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **initiatedEventId (integer)** –
  The ID of the `RequestCancelExternalWorkflowExecutionInitiated` event corresponding to the `RequestCancelExternalWorkflowExecution` decision to cancel this external workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **decisionTaskCompletedEventId (integer)** –
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `RequestCancelExternalWorkflowExecution` decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **control (string)** –

- **scheduleActivityTaskFailedEventAttributes (dict)** –
  If the event is of type `ScheduleActivityTaskFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

- **activityType (dict)** –
  The activity type provided in the `ScheduleActivityTask` decision that failed.

- **name (string)** –
  The name of this activity.

**Note**: The combination of activity type name and version must be unique within a domain.

- **version (string)** –
  The version of this activity.

**Note**: The combination of activity type name and version must be unique within a domain.

- **activityId (string)** –
  The activityId provided in the `ScheduleActivityTask` decision that failed.

- **cause (string)** –
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

**Note**: If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions.
For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId (integer)** –
  The ID of the DecisionTaskCompleted event corresponding to the decision that resulted in the scheduling of this activity task. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **requestCancelActivityTaskFailedEventAttributes (dict)** –
  If the event is of type RequestCancelActivityTaskFailed then this member is set and provides detailed information about the event. It is not set for other event types.

  - **activityId (string)** –
    The activityId provided in the RequestCancelActivityTask decision that failed.

  - **cause (string)** –
    The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If cause is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId (integer)** –
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the RequestCancelActivityTask decision for this cancelation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startTimerFailedEventAttributes (dict)** –
  If the event is of type StartTimerFailed then this member is set and provides detailed information about the event. It is not set for other event types.

  - **timerId (string)** –
    The timerId provided in the StartTimer decision that failed.

  - **cause (string)** –
    The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If cause is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId (integer)** –
The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the StartTimer decision for this activity task. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- `cancelTimerFailedEventAttributes (dict)` –
  
  If the event is of type CancelTimerFailed then this member is set and provides detailed information about the event. It is not set for other event types.

- `timerId (string)` –
  
  The timerId provided in the CancelTimer decision that failed.

- `cause (string)` –
  
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

**Note:** If `cause` is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- `decisionTaskCompletedEventId (integer)` –
  
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the CancelTimer decision to cancel this timer. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- `startChildWorkflowExecutionFailedEventAttributes (dict)` –
  
  If the event is of type StartChildWorkflowExecutionFailed then this member is set and provides detailed information about the event. It is not set for other event types.

- `workflowType (dict)` –
  
  The workflow type provided in the StartChildWorkflowExecution decision that failed.

  - `name (string)` –
    
    Required. The name of the workflow type.

**Note:** The combination of workflow type name and version must be unique within a domain.

- `version (string)` –
  
  Required. The version of the workflow type.

**Note:** The combination of workflow type name and version must be unique within a domain.
The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

**Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see [Using IAM to Manage Access to Amazon SWF Workflows](#).

- `workflowId (string)` – The `workflowId` of the child workflow execution.
- `initiatedEventId (integer)` – The ID of the `StartChildWorkflowExecutionInitiated` event corresponding to the `StartChildWorkflowExecution` decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
- `decisionTaskCompletedEventId (integer)` – The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `StartChildWorkflowExecution` decision to request this child workflow execution. This information can be useful for diagnosing problems by tracing back the cause of events.
- `control (string)` –
- `lambdaFunctionScheduledEventAttributes (dict)` – Provides details for the `LambdaFunctionScheduled` event.
  - `id (string)` – The unique Amazon SWF ID for the AWS Lambda task.
  - `name (string)` – The name of the scheduled AWS Lambda function.
  - `input (string)` – Input provided to the AWS Lambda function.
  - `startToCloseTimeout (string)` – The maximum time, in seconds, that the AWS Lambda function can take to execute from start to close before it is marked as failed.
- `decisionTaskCompletedEventId (integer)` – The ID of the `DecisionTaskCompleted` event for the decision that resulted in the scheduling of this AWS Lambda function. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
- `lambdaFunctionStartedEventAttributes (dict)` – Provides details for the `LambdaFunctionStarted` event.
- `scheduledEventId (integer)` – The ID of the `LambdaFunctionScheduled` event that was recorded when this AWS Lambda function was sched-
uled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **lambdaFunctionCompletedEventAttributes (dict)** –
  
  Provides details for the LambdaFunctionCompleted event.
  
  - **scheduledEventId (integer)** –
    
    The ID of the LambdaFunctionScheduled event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
  
  - **startedEventId (integer)** –
    
    The ID of the LambdaFunctionStarted event recorded in the history.
  
  - **result (string)** –
    
    The result of the function execution (if any).

- **lambdaFunctionFailedEventAttributes (dict)** –
  
  Provides details for the LambdaFunctionFailed event.
  
  - **scheduledEventId (integer)** –
    
    The ID of the LambdaFunctionScheduled event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
  
  - **startedEventId (integer)** –
    
    The ID of the LambdaFunctionStarted event recorded in the history.
  
  - **reason (string)** –
    
    The reason provided for the failure (if any).
  
  - **details (string)** –
    
    The details of the failure (if any).

- **lambdaFunctionTimedOutEventAttributes (dict)** –
  
  Provides details for the LambdaFunctionTimedOut event.
  
  - **scheduledEventId (integer)** –
    
    The ID of the LambdaFunctionScheduled event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
  
  - **startedEventId (integer)** –
    
    The ID of the LambdaFunctionStarted event recorded in the history.
  
  - **timeoutType (string)** –
    
    The type of the timeout that caused this event.

- **scheduleLambdaFunctionFailedEventAttributes (dict)** –
  
  Provides details for the ScheduleLambdaFunctionFailed event.
  
  - **id (string)** –
The unique Amazon SWF ID of the AWS Lambda task.

- **name (string)** –
  The name of the scheduled AWS Lambda function.

- **cause (string)** –
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If **cause** is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId (integer)** –
  The ID of the DecisionTaskCompleted event corresponding to the decision that resulted in the scheduling of this AWS Lambda function. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startLambdaFunctionFailedEventAttributes (dict)** –
  Provides details for the StartLambdaFunctionFailed event.

- **scheduledEventId (integer)** –
  The ID of the LambdaFunctionScheduled event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **cause (string)** –
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If **cause** is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **message (string)** –
  The error message (if any).

- **nextPageToken (string)** –
  If a nextPageToken was returned by a previous call, there are more results available. To retrieve the next page of results, make the call again using the returned token in nextPageToken. Keep all other arguments unchanged.

  The configured maximumPageSize determines how many results can be returned in a single call.

- **previousStartedEventId (integer)** –
  The ID of the DecisionTaskStarted event of the previous decision task of this workflow execution that was processed by the decider. This can be used to determine the events in the history new since the last decision task received by the decider.
record_activity_task_heartbeat(**kwargs)

Used by activity workers to report to the service that the ActivityTask represented by the specified taskToken is still making progress. The worker can also (optionally) specify details of the progress, for example percent complete, using the details parameter. This action can also be used by the worker as a mechanism to check if cancellation is being requested for the activity task. If a cancellation is being attempted for the specified task, then the boolean cancelRequested flag returned by the service is set to true.

This action resets the taskHeartbeatTimeout clock. The taskHeartbeatTimeout is specified in RegisterActivityType.

This action does not in itself create an event in the workflow execution history. However, if the task times out, the workflow execution history will contain a ActivityTaskTimedOut event that contains the information from the last heartbeat generated by the activity worker.

**Note:** The taskStartToCloseTimeout of an activity type is the maximum duration of an activity task, regardless of the number of RecordActivityTaskHeartbeat requests received. The taskStartToCloseTimeout is also specified in RegisterActivityType.

**Note:** This operation is only useful for long-lived activities to report liveliness of the task and to determine if a cancellation is being attempted.

**Warning:** If the cancelRequested flag returns true, a cancellation is being attempted. If the worker can cancel the activity, it should respond with RespondActivityTaskCanceled. Otherwise, it should ignore the cancellation request.

**Access Control**

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a Resource element with the domain name to limit the action to only specified domains.
- Use an Action element to allow or deny permission to call this action.
- You cannot use an IAM policy to constrain this action’s parameters.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s cause parameter will be set to OPERATION_NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

**Request Syntax**

```python
response = client.record_activity_task_heartbeat(
    taskToken='string',
    details='string'
)
```

**Parameters**

- **taskToken (string)** – [REQUIRED]
  
The taskToken of the ActivityTask.

  **Warning:** taskToken is generated by the service and should be treated as an opaque value. If the task is passed to another process, its taskToken must also be passed. This enables it to provide its progress and respond with results.

- **details (string)** – If specified, contains details about the progress of the task.

**Return type** dict
Returns

Response Syntax

{  
   'cancelRequested': True|False
}

Response Structure

- (dict) – Status information about an activity task.
  - cancelRequested (boolean) – Set to true if cancellation of the task is requested.

```
def register_activity_type(**kwargs)
    Registers a new activity type along with its configuration settings in the specified domain.
    
    Warning: A TypeAlreadyExists fault is returned if the type already exists in the domain. You cannot change any configuration settings of the type after its registration, and it must be registered as a new version.
```

Access Control

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a Resource element with the domain name to limit the action to only specified domains.
- Use an Action element to allow or deny permission to call this action.
- Constrain the following parameters by using a Condition element with the appropriate keys. *
  - defaultTaskList.name: String constraint. The key is swf:defaultTaskList.name.
  - name: String constraint. The key is swf:name.
  - version: String constraint. The key is swf:version.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s cause parameter will be set to OPERATION_NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

Request Syntax

```
response = client.register_activity_type(
    domain='string',
    name='string',
    version='string',
    description='string',
    defaultTaskStartToCloseTimeout='string',
    defaultTaskHeartbeatTimeout='string',
    defaultTaskList={'
        'name': 'string'
    },
    defaultTaskPriority='string',
    defaultTaskScheduleToStartTimeout='string',
    defaultTaskScheduleToCloseTimeout='string'
)
```

Parameters

- domain (string) – [REQUIRED]
  
  The name of the domain in which this activity is to be registered.
• **name (string)** – [REQUIRED]

The name of the activity type within the domain.

The specified string must not start or end with whitespace. It must not contain a : (colon), / (slash), | (vertical bar), or any control characters (u0000-u001f | u007f - u009f). Also, it must not contain the literal string quotarnquot.

• **version (string)** – [REQUIRED]

The version of the activity type.

**Note:** The activity type consists of the name and version, the combination of which must be unique within the domain.

The specified string must not start or end with whitespace. It must not contain a : (colon), / (slash), | (vertical bar), or any control characters (u0000-u001f | u007f - u009f). Also, it must not contain the literal string quotarnquot.

• **description (string)** – A textual description of the activity type.

• **defaultTaskStartToCloseTimeout (string)** – If set, specifies the default maximum duration that a worker can take to process tasks of this activity type. This default can be overridden when scheduling an activity task using the ScheduleActivityTask decision.

The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

• **defaultTaskHeartbeatTimeout (string)** – If set, specifies the default maximum time before which a worker processing a task of this type must report progress by calling RecordActivityTaskHeartbeat. If the timeout is exceeded, the activity task is automatically timed out. This default can be overridden when scheduling an activity task using the ScheduleActivityTask decision. If the activity worker subsequently attempts to record a heartbeat or returns a result, the activity worker receives an UnknownResource fault. In this case, Amazon SWF no longer considers the activity task to be valid; the activity worker should clean up the activity task.

The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

• **defaultTaskList (dict)** – If set, specifies the default task list to use for scheduling tasks of this activity type. This default task list is used if a task list is not provided when a task is scheduled through the ScheduleActivityTask decision.

  – **name (string)** – [REQUIRED]

The name of the task list.

• **defaultTaskPriority (string)** – The default task priority to assign to the activity type. If not assigned, then “0” will be used. Valid values are integers that range from Java’s `Integer.MIN_VALUE (-2147483648)` to `Integer.MAX_VALUE (2147483647)`. Higher numbers indicate higher priority.

For more information about setting task priority, see Setting Task Priority in the Amazon Simple Workflow Developer Guide.

• **defaultTaskScheduleToStartTimeout (string)** – If set, specifies the default maximum duration that a task of this activity type can wait before being assigned to a worker. This default can be overridden when scheduling an activity task using the ScheduleActivityTask decision.

The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.
• defaultTaskScheduleToCloseTimeout (string) – If set, specifies the default maximum duration for a task of this activity type. This default can be overridden when scheduling an activity task using the ScheduleActivityTask decision.

The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

Returns None

register_domain(**kwargs)
Registers a new domain.

Access Control
You can use IAM policies to control this action's access to Amazon SWF resources as follows:
• You cannot use an IAM policy to control domain access for this action. The name of the domain being registered is available as the resource of this action.
• Use an Action element to allow or deny permission to call this action.
• You cannot use an IAM policy to constrain this action's parameters.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute's cause parameter will be set to OPERATION_NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

Request Syntax
response = client.register_domain(
  name='string',
  description='string',
  workflowExecutionRetentionPeriodInDays='string'
)

Parameters
• name (string) – [REQUIRED]
  Name of the domain to register. The name must be unique in the region that the domain is registered in.

  The specified string must not start or end with whitespace. It must not contain a : (colon), / (slash), | (vertical bar), or any control characters (u0000-u001f | u007f - u009f). Also, it must not contain the literal string quotarnquot.

• description (string) – A text description of the domain.
• workflowExecutionRetentionPeriodInDays (string) – [REQUIRED]
  The duration (in days) that records and histories of workflow executions on the domain should be kept by the service. After the retention period, the workflow execution is not available in the results of visibility calls.

  If you pass the value NONE or 0 (zero), then the workflow execution history will not be retained. As soon as the workflow execution completes, the execution record and its history are deleted.

  The maximum workflow execution retention period is 90 days. For more information about Amazon SWF service limits, see: Amazon SWF Service Limits in the Amazon SWF Developer Guide.

Returns None

register_workflow_type(**kwargs)
Registers a new workflow type and its configuration settings in the specified domain.
The retention period for the workflow history is set by the RegisterDomain action.

Warning: If the type already exists, then a TypeAlreadyExists fault is returned. You cannot change the configuration settings of a workflow type once it is registered and it must be registered as a new version.

Access Control

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

• Use a Resource element with the domain name to limit the action to only specified domains.
• Use an Action element to allow or deny permission to call this action.
• Constrain the following parameters by using a Condition element with the appropriate keys. *
  defaultTaskList.name: String constraint. The key is swf:defaultTaskList.name.
  *name: String constraint. The key is swf:name.
  *version: String constraint. The key is swf:version.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s cause parameter will be set to OPERATION_NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

Request Syntax

response = client.register_workflow_type(
    domain='string',
    name='string',
    version='string',
    description='string',
    defaultTaskStartToCloseTimeout='string',
    defaultExecutionStartToCloseTimeout='string',
    defaultTaskList={
        'name': 'string'
    },
    defaultTaskPriority='string',
    defaultChildPolicy='TERMINATE'|'REQUEST_CANCEL'|'ABANDON',
    defaultLambdaRole='string'
)

Parameters

• domain (string) – [REQUIRED]

    The name of the domain in which to register the workflow type.

• name (string) – [REQUIRED]

    The name of the workflow type.

    The specified string must not start or end with whitespace. It must not contain a : (colon), / (slash), | (vertical bar), or any control characters (\u0000-\u001f | \u007f - \u009f). Also, it must not contain the literal string quotarnquot.

• version (string) – [REQUIRED]

    The version of the workflow type.

    The specified string must not start or end with whitespace. It must not contain a : (colon), / (slash), | (vertical bar), or any control characters (\u0000-\u001f | \u007f - \u009f). Also, it must not contain the literal string quotarnquot.

Note: The workflow type consists of the name and version, the combination of which must be unique within the domain. To get a list of all currently registered workflow types, use the ListWorkflowTypes action.
• \textbf{description} (\textit{string}) – Textual description of the workflow type.

• \textbf{default\_Task\_Start\_To\_Close\_Timeout} (\textit{string}) – If set, specifies the default maximum duration of decision tasks for this workflow type. This default can be overridden when starting a workflow execution using the \texttt{StartWorkflowExecution} action or the \texttt{StartChildWorkflowExecution} decision.

The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

• \textbf{default\_Execution\_Start\_To\_Close\_Timeout} (\textit{string}) – If set, specifies the default maximum duration for executions of this workflow type. You can override this default when starting an execution through the \texttt{StartWorkflowExecution} action or \texttt{StartChildWorkflowExecution} decision.

The duration is specified in seconds; an integer greater than or equal to 0. Unlike some of the other timeout parameters in Amazon SWF, you cannot specify a value of “NONE” for \texttt{default\_Execution\_Start\_To\_Close\_Timeout}; there is a one-year max limit on the time that a workflow execution can run. Exceeding this limit will always cause the workflow execution to time out.

• \textbf{default\_Task\_List} (\textit{dict}) – If set, specifies the default task list to use for scheduling decision tasks for executions of this workflow type. This default is used only if a task list is not provided when starting the execution through the \texttt{StartWorkflowExecution} action or \texttt{StartChildWorkflowExecution} decision.

  – \textbf{name} (\textit{string}) – [REQURED]

  The name of the task list.

• \textbf{default\_Task\_Priority} (\textit{string}) – The default task priority to assign to the workflow type. If not assigned, then “0” will be used. Valid values are integers that range from Java’s \texttt{Integer.MIN\_VALUE} (-2147483648) to \texttt{Integer.MAX\_VALUE} (2147483647). Higher numbers indicate higher priority.

For more information about setting task priority, see Setting Task Priority in the Amazon Simple Workflow Developer Guide.

• \textbf{default\_Child\_Policy} (\textit{string}) – If set, specifies the default policy to use for the child workflow executions when a workflow execution of this type is terminated, by calling the \texttt{TerminateWorkflowExecution} action explicitly or due to an expired timeout. This default can be overridden when starting a workflow execution using the \texttt{StartWorkflowExecution} action or the \texttt{StartChildWorkflowExecution} decision.

The supported child policies are:

  – \textbf{TERMINATE}: the child executions will be terminated.

  – \textbf{REQUEST\_CANCEL}: a request to cancel will be attempted for each child execution by recording a \texttt{WorkflowExecutionCancelRequested} event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.

  – \textbf{ABANDON}: no action will be taken. The child executions will continue to run.

• \textbf{default\_Lambda\_Role} (\textit{string}) – The ARN of the default IAM role to use when a workflow execution of this type invokes AWS Lambda functions.

This default can be overridden when starting a workflow execution using the \texttt{StartWorkflowExecution} action or the \texttt{StartChildWorkflowExecution} and \texttt{ContinueAsNewWorkflowExecution} decision.

\textbf{Returns}: None
request_cancel_workflow_execution(**kwargs)

Records a WorkflowExecutionCancelRequested event in the currently running workflow execution identified by the given domain, workflowId, and runId. This logically requests the cancellation of the workflow execution as a whole. It is up to the decider to take appropriate actions when it receives an execution history with this event.

**Note:** If the runId is not specified, the WorkflowExecutionCancelRequested event is recorded in the history of the current open workflow execution with the specified workflowId in the domain.

**Note:** Because this action allows the workflow to properly clean up and gracefully close, it should be used instead of TerminateWorkflowExecution when possible.

**Access Control**

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a `Resource` element with the domain name to limit the action to only specified domains.
- Use an `Action` element to allow or deny permission to call this action.
- You cannot use an IAM policy to constrain this action’s parameters.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s `cause` parameter will be set to `OPERATION_NOT_PERMITTED`. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

**Request Syntax**

```python
response = client.request_cancel_workflow_execution(
    domain='string',
    workflowId='string',
    runId='string'
)
```

**Parameters**

- **domain (string)** – [REQUIRED]
  
The name of the domain containing the workflow execution to cancel.

- **workflowId (string)** – [REQUIRED]
  
The workflowId of the workflow execution to cancel.

- **runId (string)** – The runId of the workflow execution to cancel.

**Returns**

None

respond_activity_task_canceled(**kwargs)

Used by workers to tell the service that the ActivityTask identified by the taskToken was successfully canceled. Additional details can be optionally provided using the `details` argument.

These details (if provided) appear in the ActivityTaskCanceled event added to the workflow history.

**Warning:** Only use this operation if the `canceled` flag of a RecordActivityTaskHeartbeat request returns `true` and if the activity can be safely undone or abandoned.

A task is considered open from the time that it is scheduled until it is closed. Therefore a task is reported as open while a worker is processing it. A task is closed after it has been specified in a call to RespondActivityTaskCompleted, RespondActivityTaskCanceled, RespondActivityTaskFailed, or the task has timed out.

**Access Control**
You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a `Resource` element with the domain name to limit the action to only specified domains.
- Use an `Action` element to allow or deny permission to call this action.
- You cannot use an IAM policy to constrain this action’s parameters.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s `cause` parameter will be set to `OPERATION_NOT_PERMITTED`. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

Request Syntax

```python
response = client.respond_activity_task_canceled(
    taskToken='string',
    details='string'
)
```

**Parameters**

- **taskToken** (`string`) – [REQUIRED]
  The `taskToken` of the ActivityTask.

  Warning: `taskToken` is generated by the service and should be treated as an opaque value. If the task is passed to another process, its `taskToken` must also be passed. This enables it to provide its progress and respond with results.

- **details** (`string`) – Optional. Information about the cancellation.

Returns None

```python
respond_activity_task_completed(**kwargs)
```

Used by workers to tell the service that the ActivityTask identified by the `taskToken` completed successfully with a result (if provided). The result appears in the `ActivityTaskCompleted` event in the workflow history.

Warning: If the requested task does not complete successfully, use `RespondActivityTaskFailed` instead. If the worker finds that the task is canceled through the `canceled` flag returned by `RecordActivityTaskHeartbeat`, it should cancel the task, clean up and then call `RespondActivityTaskCanceled`.

A task is considered open from the time that it is scheduled until it is closed. Therefore a task is reported as open while a worker is processing it. A task is closed after it has been specified in a call to `RespondActivityTaskCompleted`, `RespondActivityTaskCanceled`, `RespondActivityTaskFailed`, or the task has timed out.

**Access Control**

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a `Resource` element with the domain name to limit the action to only specified domains.
- Use an `Action` element to allow or deny permission to call this action.
- You cannot use an IAM policy to constrain this action’s parameters.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s `cause` parameter will be set to `OPERATION_NOT_PERMITTED`. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

**Request Syntax**
response = client.respond_activity_task_completed(
    taskToken='string',
    result='string'
)

Parameters

- **taskToken (string)** – [REQUIRED]
  
The `taskToken` of the ActivityTask.

  **Warning:** `taskToken` is generated by the service and should be treated as an opaque value. If the task is passed to another process, its `taskToken` must also be passed. This enables it to provide its progress and respond with results.

- **result (string)** – The result of the activity task. It is a free form string that is implementation specific.

Returns None

**respond_activity_task_failed(**kwargs)

Used by workers to tell the service that the ActivityTask identified by the `taskToken` has failed with `reason` (if specified). The `reason` and `details` appear in the `ActivityTaskFailed` event added to the workflow history.

A task is considered open from the time that it is scheduled until it is closed. Therefore a task is reported as open while a worker is processing it. A task is closed after it has been specified in a call to `RespondActivityTaskCompleted`, `RespondActivityTaskCanceled`, `RespondActivityTaskFailed`, or the task has timed out.

Access Control

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

- Use a `Resource` element with the domain name to limit the action to only specified domains.
- Use an `Action` element to allow or deny permission to call this action.
- You cannot use an IAM policy to constrain this action’s parameters.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s `cause` parameter will be set to `OPERATION_NOT_PERMITTED`. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

Request Syntax

response = client.respond_activity_task_failed(
    taskToken='string',
    reason='string',
    details='string'
)

Parameters

- **taskToken (string)** – [REQUIRED]
  
The `taskToken` of the ActivityTask.

  **Warning:** `taskToken` is generated by the service and should be treated as an opaque value. If the task is passed to another process, its `taskToken` must also be passed. This enables it to provide its progress and respond with results.
**reason (string)** – Description of the error that may assist in diagnostics.

**details (string)** – Optional. Detailed information about the failure.

**Returns** None

`respond_decision_task_completed(**kwargs)`

Used by deciders to tell the service that the DecisionTask identified by the `taskToken` has successfully completed. The `decisions` argument specifies the list of decisions made while processing the task.

A `DecisionTaskCompleted` event is added to the workflow history. The `executionContext` specified is attached to the event in the workflow execution history.

**Access Control**

If an IAM policy grants permission to use `RespondDecisionTaskCompleted`, it can express permissions for the list of decisions in the `decisions` parameter. Each of the decisions has one or more parameters, much like a regular API call. To allow for policies to be as readable as possible, you can express permissions on decisions as if they were actual API calls, including applying conditions to some parameters. For more information, see Using IAM to Manage Access to Amazon SWF Workflows.

**Request Syntax**

```python
response = client.respond_decision_task_completed(
    taskToken='string',
    decisions=[
        {
            'decisionType': 'ScheduleActivityTask'|'RequestCancelActivityTask'|'StartChildWorkflowExecution'|'ScheduleLambdaFunction',
            'scheduleActivityTaskDecisionAttributes': {
                'activityType': {
                    'name': 'string',
                    'version': 'string'
                },
                'activityId': 'string',
                'control': 'string',
                'input': 'string',
                'scheduleToCloseTimeout': 'string',
                'taskList': {
                    'name': 'string'
                },
                'taskPriority': 'string',
                'scheduleToStartTimeout': 'string',
                'startToCloseTimeout': 'string',
                'heartbeatTimeout': 'string'
            },
            'requestCancelActivityTaskDecisionAttributes': {
                'activityId': 'string'
            },
            'completeWorkflowExecutionDecisionAttributes': {
                'result': 'string'
            },
            'failWorkflowExecutionDecisionAttributes': {
                'reason': 'string',
                'details': 'string'
            },
            'cancelWorkflowExecutionDecisionAttributes': {
                'details': 'string'
            },
            'continueAsNewWorkflowExecutionDecisionAttributes': {
                'input': 'string',
                'executionStartToCloseTimeout': 'string',
                '...'
            }
        },
        ...
    ]
)
```
'taskList': { 
  'name': 'string' 
},

  'childPolicy': 'TERMINATE'|'REQUESTCANCEL'|'ABANDON',
  'tagList': [ 
    'string', 
  ],
  'lambdaRole': 'string'
},
'scheduleLambdaFunctionDecisionAttributes': { 
  'id': 'string', 
}
Parameters

- **taskToken** *(string)* – [REQUIRED]

  The *taskToken* from the DecisionTask.

  **Warning:** *taskToken* is generated by the service and should be treated as an opaque value. If the task is passed to another process, its *taskToken* must also be passed. This enables it to provide its progress and respond with results.

- **decisions** *(list)* – The list of decisions (possibly empty) made by the decider while processing this decision task. See the docs for the decision structure for details.
  
  - *(dict)* –

    Specifies a decision made by the decider. A decision can be one of these types:
    
    - **CancelTimer**: cancels a previously started timer and records a *TimerCanceled* event in the history.
    - **CancelWorkflowExecution**: closes the workflow execution and records a *WorkflowExecutionCanceled* event in the history.
    - **CompleteWorkflowExecution**: closes the workflow execution and records a *WorkflowExecutionCompleted* event in the history.
    - **ContinueAsNewWorkflowExecution**: closes the workflow execution and starts a new workflow execution of the same type using the same workflow ID and a unique run ID. A *WorkflowExecutionContinuedAsNew* event is recorded in the history.
    - **FailWorkflowExecution**: closes the workflow execution and records a *WorkflowExecutionFailed* event in the history.
    - **RecordMarker**: records a *MarkerRecorded* event in the history. Markers can be used for adding custom information in the history for instance to let deciders know that they do not need to look at the history beyond the marker event.
    - **RequestCancelActivityTask**: attempts to cancel a previously scheduled activity task. If the activity task was scheduled but has not been assigned to a worker, then it will be canceled. If the activity task was already assigned to a worker, then the worker will be informed that cancellation has been requested in the response to *RecordActivityTaskHeartbeat*.
    - **RequestCancelExternalWorkflowExecution**: requests that a request be made to cancel the specified external workflow execution and records a *RequestCancelExternalWorkflowExecutionInitiated* event in the history.
    - **ScheduleActivityTask**: schedules an activity task.
* **ScheduleLambdaFunction**: schedules a AWS Lambda function.
* **SignalExternalWorkflowExecution**: requests a signal to be delivered to the specified external workflow execution and records a `SignalExternalWorkflowExecutionInitiated` event in the history.
* **StartChildWorkflowExecution**: requests that a child workflow execution be started and records a `StartChildWorkflowExecutionInitiated` event in the history. The child workflow execution is a separate workflow execution with its own history.
* **StartTimer**: starts a timer for this workflow execution and records a `TimerStarted` event in the history. This timer will fire after the specified delay and record a `TimerFired` event.

**Access Control**

If you grant permission to use `RespondDecisionTaskCompleted`, you can use IAM policies to express permissions for the list of decisions returned by this action as if they were members of the API. Treating decisions as a pseudo API maintains a uniform conceptual model and helps keep policies readable. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

**Decision Failure**

Decisions can fail for several reasons:
- The ordering of decisions should follow a logical flow. Some decisions might not make sense in the current context of the workflow execution and will therefore fail.
- A limit on your account was reached.
- The decision lacks sufficient permissions.

One of the following events might be added to the history to indicate an error. The event attribute’s `cause` parameter indicates the cause. If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

* **ScheduleActivityTaskFailed**: a ScheduleActivityTask decision failed. This could happen if the activity type specified in the decision is not registered, is in a deprecated state, or the decision is not properly configured.
* **ScheduleLambdaFunctionFailed**: a ScheduleLambdaFunctionFailed decision failed. This could happen if the AWS Lambda function specified in the decision does not exist, or the AWS Lambda service’s limits are exceeded.
* **RequestCancelActivityTaskFailed**: a RequestCancelActivityTask decision failed. This could happen if there is no open activity task with the specified activityId.
* **StartTimerFailed**: a StartTimer decision failed. This could happen if there is another open timer with the same timerId.
* **CancelTimerFailed**: a CancelTimer decision failed. This could happen if there is no open timer with the specified timerId.
* **StartChildWorkflowExecutionFailed**: a StartChildWorkflowExecution decision failed. This could happen if the workflow type specified is not registered, is deprecated, or the decision is not properly configured.
* **SignalExternalWorkflowExecutionFailed**: a SignalExternal-
WorkflowExecution decision failed. This could happen if the workflowID specified in the decision was incorrect.

- **RequestCancelExternalWorkflowExecutionFailed**: a RequestCancelExternalWorkflowExecution decision failed. This could happen if the workflowID specified in the decision was incorrect.

- **CancelWorkflowExecutionFailed**: a CancelWorkflowExecution decision failed. This could happen if there is an unhandled decision task pending in the workflow execution.

- **CompleteWorkflowExecutionFailed**: a CompleteWorkflowExecution decision failed. This could happen if there is an unhandled decision task pending in the workflow execution.

- **ContinueAsNewWorkflowExecutionFailed**: a ContinueAsNewWorkflowExecution decision failed. This could happen if there is an unhandled decision task pending in the workflow execution or the ContinueAsNewWorkflowExecution decision was not configured correctly.

- **FailWorkflowExecutionFailed**: a FailWorkflowExecution decision failed. This could happen if there is an unhandled decision task pending in the workflow execution.

The preceding error events might occur due to an error in the decider logic, which might put the workflow execution in an unstable state. The cause field in the event structure for the error event indicates the cause of the error.

**Note:** A workflow execution may be closed by the decider by returning one of the following decisions when completing a decision task: CompleteWorkflowExecution, FailWorkflowExecution, CancelWorkflowExecution and ContinueAsNewWorkflowExecution. An UnhandledDecisionFault will be returned if a workflow closing decision is specified and a signal or activity event had been added to the history while the decision task was being performed by the decider. Unlike the above situations which are logic issues, this fault is always possible because of race conditions in a distributed system. The right action here is to call RespondDecisionTaskCompleted without any decisions. This would result in another decision task with these new events included in the history. The decider should handle the new events and may decide to close the workflow execution.

**How to code a decision**

You code a decision by first setting the decision type field to one of the above decision values, and then set the corresponding attributes field shown below:

- ScheduleActivityTaskDecisionAttributes
- ScheduleLambdaFunctionDecisionAttributes
- RequestCancelActivityTaskDecisionAttributes
- CompleteWorkflowExecutionDecisionAttributes
- FailWorkflowExecutionDecisionAttributes
- CancelWorkflowExecutionDecisionAttributes
- ContinueAsNewWorkflowExecutionDecisionAttributes
- RecordMarkerDecisionAttributes
- StartTimerDecisionAttributes
- CancelTimerDecisionAttributes
* SignalExternalWorkflowExecutionDecisionAttributes
* RequestCancelExternalWorkflowExecutionDecisionAttributes
* StartChildWorkflowExecutionDecisionAttributes

* decisionType (string) – [REQUIRED]
  
  Specifies the type of the decision.

* scheduleActivityTaskDecisionAttributes (dict) –
  
  Provides details of the ScheduleActivityTask decision. It is not set for other decision types.
  
  · activityType (dict) – [REQUIRED]
    
    Required. The type of the activity task to schedule.

  · name (string) – [REQUIRED]
    
    The name of this activity.

  **Note:** The combination of activity type name and version must be unique within a domain.

  · version (string) – [REQUIRED]
    
    The version of this activity.

  **Note:** The combination of activity type name and version must be unique with in a domain.

  · activityId (string) – [REQUIRED]
    
    Required. The activityId of the activity task.
    
    The specified string must not start or end with whitespace. It must not contain a : (colon), / (slash), | (vertical bar), or any control characters (u0000-u001f | u007f - u009f). Also, it must not contain the literal string quotarnquot.

  · control (string) –
    
    Optional. Data attached to the event that can be used by the decider in subsequent workflow tasks. This data is not sent to the activity.

  · input (string) –
    
    The input provided to the activity task.

  · scheduleToCloseTimeout (string) –
    
    The maximum duration for this activity task.
    
    The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

  **Note:** A schedule-to-close timeout for this activity task must be specified either as a default for the activity type or through this field. If neither this field is set nor a default schedule-to-close timeout was specified at registration time then a fault will be returned.

  · taskList (dict) –
    
    If set, specifies the name of the task list in which to schedule
the activity task. If not specified, the `defaultTaskList` registered with the activity type will be used.

**Note:** A task list for this activity task must be specified either as a default for the activity type or through this field. If neither this field is set nor a default task list was specified at registration time then a fault will be returned.

The specified string must not start or end with whitespace. It must not contain a : (colon), / (slash), | (vertical bar), or any control characters (u0000-u001f | u007f - u009f). Also, it must not contain the literal string `quotarnquot`. Also, it must not contain the literal string `quotarnquot`.

- **name (string)** – [REQUIRED]
  
The name of the task list.

- **taskPriority (string)** –
  
  *Optional.* If set, specifies the priority with which the activity task is to be assigned to a worker. This overrides the `defaultTaskPriority` specified when registering the activity type using `RegisterActivityType` . Valid values are integers that range from Java's `Integer.MIN_VALUE` (-2147483648) to `Integer.MAX_VALUE` (2147483647). Higher numbers indicate higher priority.

  For more information about setting task priority, see `Setting Task Priority` in the *Amazon Simple Workflow Developer Guide* .

- **scheduleToStartTimeout (string)** –
  
  *Optional.* If set, specifies the maximum duration the activity task can wait to be assigned to a worker. This overrides the default schedule-to-start timeout specified when registering the activity type using `RegisterActivityType` .

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

  **Note:** A schedule-to-start timeout for this activity task must be specified either as a default for the activity type or through this field. If neither this field is set nor a default schedule-to-start timeout was specified at registration time then a fault will be returned.

- **startToCloseTimeout (string)** –
  
  If set, specifies the maximum duration a worker may take to process this activity task. This overrides the default start-to-close timeout specified when registering the activity type using `RegisterActivityType` .

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

  **Note:** A start-to-close timeout for this activity task must be specified either as a default for the activity type or through
this field. If neither this field is set nor a default start-to-close timeout was specified at registration time then a fault will be returned.

- **heartbeatTimeout (string)** –

  If set, specifies the maximum time before which a worker processing a task of this type must report progress by calling RecordActivityTaskHeartbeat. If the timeout is exceeded, the activity task is automatically timed out. If the worker subsequently attempts to record a heartbeat or returns a result, it will be ignored. This overrides the default heartbeat timeout specified when registering the activity type using RegisterActivityType.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **requestCancelActivityTaskDecisionAttributes (dict)** –

  Provides details of the RequestCancelActivityTask decision. It is not set for other decision types.
  - **activityId (string)** – [REQUIRED]

    The activityId of the activity task to be canceled.

- **completeWorkflowExecutionDecisionAttributes (dict)** –

  Provides details of the CompleteWorkflowExecution decision. It is not set for other decision types.
  - **result (string)** –

    The result of the workflow execution. The form of the result is implementation defined.

- **failWorkflowExecutionDecisionAttributes (dict)** –

  Provides details of the FailWorkflowExecution decision. It is not set for other decision types.
  - **reason (string)** –

    A descriptive reason for the failure that may help in diagnostics.
  - **details (string)** –

    Optional. Details of the failure.

- **cancelWorkflowExecutionDecisionAttributes (dict)** –

  Provides details of the CancelWorkflowExecution decision. It is not set for other decision types.
  - **details (string)** –

    Optional. Details of the cancellation.

- **continueAsNewWorkflowExecutionDecisionAttributes (dict)** –

  Provides details of the ContinueAsNewWorkflowExecution decision. It is not set for other decision types.
  - **input (string)** –

    The input provided to the new workflow execution.
  - **executionStartToCloseTimeout (string)** –
If set, specifies the total duration for this workflow execution. This overrides the defaultExecutionStartToCloseTimeout specified when registering the workflow type.

The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

**Note:** An execution start-to-close timeout for this workflow execution must be specified either as a default for the workflow type or through this field. If neither this field is set nor a default execution start-to-close timeout was specified at registration time then a fault will be returned.

- **taskList (dict)** –
  
  Represents a task list.

- **name (string)** – [REQUIRED]
  
  The name of the task list.

- **taskPriority (string)** –
  
  Optional. The task priority that, if set, specifies the priority for the decision tasks for this workflow execution. This overrides the defaultTaskPriority specified when registering the workflow type. Valid values are integers that range from Java’s `Integer.MIN_VALUE (-2147483648)` to `Integer.MAX_VALUE (2147483647)`. Higher numbers indicate higher priority.

For more information about setting task priority, see Setting Task Priority in the Amazon Simple Workflow Developer Guide.

- **taskStartToCloseTimeout (string)** –
  
  Specifies the maximum duration of decision tasks for the new workflow execution. This parameter overrides the defaultTaskStartToCloseTimeout specified when registering the workflow type using RegisterWorkflowType.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

**Note:** A task start-to-close timeout for the new workflow execution must be specified either as a default for the workflow type or through this parameter. If neither this parameter is set nor a default task start-to-close timeout was specified at registration time then a fault will be returned.

- **childPolicy (string)** –
  
  If set, specifies the policy to use for the child workflow executions of the new execution if it is terminated by calling the TerminateWorkflowExecution action explicitly or due to an expired timeout. This policy overrides the default child policy specified when registering the workflow type using RegisterWorkflowType.
The supported child policies are:

- **TERMINATE**: the child executions will be terminated.
- **REQUEST_CANCEL**: a request to cancel will be attempted for each child execution by recording a `WorkflowExecutionCancelRequested` event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
- **ABANDON**: no action will be taken. The child executions will continue to run.

**Note:** A child policy for this workflow execution must be specified either as a default for the workflow type or through this parameter. If neither this parameter is set nor a default child policy was specified at registration time then a fault will be returned.

- **tagList (list)** –
  The list of tags to associate with the new workflow execution. A maximum of 5 tags can be specified. You can list workflow executions with a specific tag by calling `ListOpenWorkflowExecutions` or `ListClosedWorkflowExecutions` and specifying a TagFilter.

- **(string)** –
- **workflowTypeVersion (string)** –
- **lambdaRole (string)** –
  The ARN of an IAM role that authorizes Amazon SWF to invoke AWS Lambda functions.

**Note:** In order for this workflow execution to invoke AWS Lambda functions, an appropriate IAM role must be specified either as a default for the workflow type or through this field.

* **recordMarkerDecisionAttributes (dict)** –
  Provides details of the `RecordMarker` decision. It is not set for other decision types.
  - **markerName (string)** – [REQUIRED]
    - **Required.** The name of the marker.
  - **details (string)** –
    - **Optional.** details of the marker.

* **startTimerDecisionAttributes (dict)** –
  Provides details of the `StartTimer` decision. It is not set for other decision types.
  - **timerId (string)** – [REQUIRED]
    - **Required.** The unique ID of the timer.
    
    The specified string must not start or end with whitespace. It must not contain a : (colon), / (slash), | (vertical bar), or any control characters (u0000-u001f | u007f - u009f). Also, it must not contain the literal string quotarnquot.
  - **control (string)** –
    - **Optional.** Data attached to the event that can be used by the decider in subsequent workflow tasks.
· **startToFireTimeout** *(string)* – [REQUIRED]

  Required. The duration to wait before firing the timer.

  The duration is specified in seconds; an integer greater than or equal to 0.

  * **cancelTimerDecisionAttributes** *(dict)* –

    Provides details of the CancelTimer decision. It is not set for other decision types.

    · **timerId** *(string)* – [REQUIRED]

      Required. The unique ID of the timer to cancel.

  * **signalExternalWorkflowExecutionDecisionAttributes** *(dict)* –

    Provides details of the SignalExternalWorkflowExecution decision. It is not set for other decision types.

    · **workflowId** *(string)* – [REQUIRED]

      Required. The workflowId of the workflow execution to be signaled.

    · **runId** *(string)* –

      The runId of the workflow execution to be signaled.

    · **signalName** *(string)* – [REQUIRED]

      Required. The name of the signal. The target workflow execution will use the signal name and input to process the signal.

    · **input** *(string)* –

      Optional. Input data to be provided with the signal. The target workflow execution will use the signal name and input data to process the signal.

    · **control** *(string)* –

      Optional. Data attached to the event that can be used by the decider in subsequent decision tasks.

  * **requestCancelExternalWorkflowExecutionDecisionAttributes** *(dict)* –

    Provides details of the RequestCancelExternalWorkflowExecution decision. It is not set for other decision types.

    · **workflowId** *(string)* – [REQUIRED]

      Required. The workflowId of the external workflow execution to cancel.

    · **runId** *(string)* –

      The runId of the external workflow execution to cancel.

    · **control** *(string)* –

      Optional. Data attached to the event that can be used by the decider in subsequent workflow tasks.

  * **startChildWorkflowExecutionDecisionAttributes** *(dict)* –

    Provides details of the StartChildWorkflowExecution decision. It is not set for other decision types.

    · **workflowType** *(dict)* – [REQUIRED]

      Required. The type of the workflow execution to be started.

    · **name** *(string)* – [REQUIRED]
Required. The name of the workflow type.

Note: The combination of workflow type name and version must be unique within a domain.

- **version (string) – [REQUIRED]**

  Required. The version of the workflow type.

  Note: The combination of workflow type name and version must be unique within a domain.

- **workflowId (string) – [REQUIRED]**

  Required. The workflowId of the workflow execution.

  The specified string must not start or end with whitespace. It must not contain a : (colon), / (slash), | (vertical bar), or any control characters (u0000-u001f u007f - u009f). Also, it must not contain the literal string quotarnquot.

- **control (string) –**

  Optional. Data attached to the event that can be used by the decider in subsequent workflow tasks. This data is not sent to the child workflow execution.

- **input (string) –**

  The input to be provided to the workflow execution.

- **executionStartToCloseTimeout (string) –**

  The total duration for this workflow execution. This overrides the defaultExecutionStartToCloseTimeout specified when registering the workflow type.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

  Note: An execution start-to-close timeout for this workflow execution must be specified either as a default for the workflow type or through this parameter. If neither this parameter is set nor a default execution start-to-close timeout was specified at registration time then a fault will be returned.

- **taskList (dict) –**

  The name of the task list to be used for decision tasks of the child workflow execution.

  Note: A task list for this workflow execution must be specified either as a default for the workflow type or through this parameter. If neither this parameter is set nor a default task list was specified at registration time then a fault will be returned.

  The specified string must not start or end with whitespace. It must not contain a : (colon), / (slash), | (vertical bar), or any control characters (u0000-u001f u007f - u009f). Also, it must not contain the literal string quotarnquot.

- **name (string) – [REQUIRED]**
The name of the task list.

- **taskPriority** *(string)* –
  
  *Optional.* A task priority that, if set, specifies the priority for a decision task of this workflow execution. This overrides the defaultTaskPriority specified when registering the workflow type. Valid values are integers that range from Java's `Integer.MIN_VALUE` (-2147483648) to `Integer.MAX_VALUE` (2147483647). Higher numbers indicate higher priority.

  For more information about setting task priority, see *Setting Task Priority* in the *Amazon Simple Workflow Developer Guide*.

- **taskStartToCloseTimeout** *(string)* –
  
  Specifies the maximum duration of decision tasks for this workflow execution. This parameter overrides the defaultTaskStartToCloseTimeout specified when registering the workflow type using `RegisterWorkflowType`.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

  **Note:** A task start-to-close timeout for this workflow execution must be specified either as a default for the workflow type or through this parameter. If neither this parameter is set nor a default task start-to-close timeout was specified at registration time then a fault will be returned.

- **childPolicy** *(string)* –
  
  *Optional.* If set, specifies the policy to use for the child workflow executions if the workflow execution being started is terminated by calling the TerminateWorkflowExecution action explicitly or due to an expired timeout. This policy overrides the default child policy specified when registering the workflow type using `RegisterWorkflowType`.

  The supported child policies are:
  - **TERMINATE:** the child executions will be terminated.
  - **REQUEST_CANCEL:** a request to cancel will be attempted for each child execution by recording a `WorkflowExecutionCancelRequested` event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
  - **ABANDON:** no action will be taken. The child executions will continue to run.

  **Note:** A child policy for this workflow execution must be specified either as a default for the workflow type or through this parameter. If neither this parameter is set nor a default child policy was specified at registration time then a fault will be returned.

- **tagList** *(list)* –
  
  The list of tags to associate with the child workflow execu-
A maximum of 5 tags can be specified. You can list workflow executions with a specific tag by calling ListOpenWorkflowExecutions or ListClosedWorkflowExecutions and specifying a TagFilter.

- *(string)*
  - **lambdaRole (string)*–

  The ARN of an IAM role that authorizes Amazon SWF to invoke AWS Lambda functions.

**Note:** In order for this workflow execution to invoke AWS Lambda functions, an appropriate IAM role must be specified either as a default for the workflow type or through this field.

**scheduleLambdaFunctionDecisionAttributes (dict)*–

Provides details of the ScheduleLambdaFunction decision.

**Access Control**

You can use IAM policies to control this decision’s access to Amazon SWF resources as follows:

- Use a Resource element with the domain name to limit the action to only specified domains.
- Use an Action element to allow or deny permission to call this action.
- Constrain the following parameters by using a Condition element with the appropriate keys. *
  - **activityType.name**: String constraint. The key is swf:activityType.name.
  - **activityType.version**: String constraint. The key is swf:activityType.version.
  - **taskList**: String constraint. The key is swf:taskList.name.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s cause parameter will be set to OPERATION_NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **id (string)* – [REQUIRED]

  Required. The SWF id of the AWS Lambda task.

  The specified string must not start or end with whitespace. It must not contain a : (colon), / (slash), | (vertical bar), or any control characters (u0000-u001f | u007f - u009f). Also, it must not contain the literal string quotarnquot.

- **name (string)* – [REQUIRED]

  Required. The name of the AWS Lambda function to invoke.

- **input (string)* –

  The input provided to the AWS Lambda function.

- **startToCloseTimeout (string)* –

  If set, specifies the maximum duration the function may take to execute.

- **ExecutionContext (string)* – User defined context to add to workflow execution.
Returns None

**signal_workflow_execution(**kwargs)**

Records a WorkflowExecutionSignaled event in the workflow execution history and creates a decision task for the workflow execution identified by the given domain, workflowId and runId. The event is recorded with the specified user defined signalName and input (if provided).

**Note:** If a runId is not specified, then the WorkflowExecutionSignaled event is recorded in the history of the current open workflow with the matching workflowId in the domain.

**Note:** If the specified workflow execution is not open, this method fails with UnknownResource.

Access Control

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

• Use a Resource element with the domain name to limit the action to only specified domains.
• Use an Action element to allow or deny permission to call this action.
• You cannot use an IAM policy to constrain this action’s parameters.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s cause parameter will be set to OPERATION_NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

Request Syntax

```python
response = client.signal_workflow_execution(
    domain='string',
    workflowId='string',
    runId='string',
    signalName='string',
    input='string'
)
```

Parameters

• **domain** (*string*) – [REQUIRED]
  The name of the domain containing the workflow execution to signal.

• **workflowId** (*string*) – [REQUIRED]
  The workflowId of the workflow execution to signal.

• **runId** (*string*) – The runId of the workflow execution to signal.

• **signalName** (*string*) – [REQUIRED]
  The name of the signal. This name must be meaningful to the target workflow.

• **input** (*string*) – Data to attach to the WorkflowExecutionSignaled event in the target workflow execution’s history.

Returns None

**start_workflow_execution(**kwargs)**

Starts an execution of the workflow type in the specified domain using the provided workflowId and input data.

This action returns the newly started workflow execution.

Access Control

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

• Use a Resource element with the domain name to limit the action to only specified domains.
• Use an Action element to allow or deny permission to call this action.
• Constrain the following parameters by using a `Condition` element with the appropriate keys.
  * `tagList.member.0`: The key is `swf:tagList.member.0`.
  * `tagList.member.1`: The key is `swf:tagList.member.1`.
  * `tagList.member.2`: The key is `swf:tagList.member.2`.
  * `tagList.member.3`: The key is `swf:tagList.member.3`.
  * `tagList.member.4`: The key is `swf:tagList.member.4`.
  * `taskList`: String constraint. The key is `swf:taskList.name`.
  * `workflowType.name`: String constraint. The key is `swf:workflowType.name`.
  * `workflowType.version`: String constraint. The key is `swf:workflowType.version`.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s `cause` parameter will be set to `OPERATION_NOT_PERMITTED`. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

**Request Syntax**

```python
response = client.start_workflow_execution(
    domain='string',
    workflowId='string',
    workflowType={
        'name': 'string',
        'version': 'string'
    },
    taskList={
        'name': 'string'
    },
    taskPriority='string',
    input='string',
    executionStartToCloseTimeout='string',
    tagList=[
        'string',
    ],
    taskStartToCloseTimeout='string',
    childPolicy='TERMINATE'|'REQUEST_CANCEL'|'ABANDON',
    lambdaRole='string'
)
```

**Parameters**

- **domain (string)** – [REQUIRED]
  The name of the domain in which the workflow execution is created.

- **workflowId (string)** – [REQUIRED]
  The user defined identifier associated with the workflow execution. You can use this to associate a custom identifier with the workflow execution. You may specify the same identifier if a workflow execution is logically a `restart` of a previous execution. You cannot have two open workflow executions with the same workflowId at the same time.

  The specified string must not start or end with whitespace. It must not contain a : (colon), / (slash), | (vertical bar), or any control characters (u0000-u001f | u007f - u009f). Also, it must not contain the literal string `quotarnquot.`

- **workflowType (dict)** – [REQUIRED]
  The type of the workflow to start.
  ```
  - name (string) – [REQUIRED]
    Required. The name of the workflow type.
  ```

---

**3.1. Services** 4521
- **Note:** The combination of workflow type name and version must be unique with in a domain.

  - **version (string) – [REQUIRED]**

  **Required.** The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique with in a domain.

- **taskList (dict) –** The task list to use for the decision tasks generated for this workflow execution. This overrides the `defaultTaskList` specified when registering the workflow type.

  **Note:** A task list for this workflow execution must be specified either as a default for the workflow type or through this parameter. If neither this parameter is set nor a default task list was specified at registration time then a fault will be returned.

  The specified string must not start or end with whitespace. It must not contain a: (colon), / (slash), | (vertical bar), or any control characters (u0000-u001f | u007f - u009f). Also, it must not contain the literal string `quotarnquot`.  

  - **name (string) – [REQUIRED]**

    The name of the task list.

- **taskPriority (string) –** The task priority to use for this workflow execution. This will override any default priority that was assigned when the workflow type was registered. If not set, then the default task priority for the workflow type will be used. Valid values are integers that range from Java's `Integer.MIN_VALUE` (-2147483648) to `Integer.MAX_VALUE` (2147483647). Higher numbers indicate higher priority.

  For more information about setting task priority, see Setting Task Priority in the Amazon Simple Workflow Developer Guide.

- **input (string) –** The input for the workflow execution. This is a free form string which should be meaningful to the workflow you are starting. This input is made available to the new workflow execution in the `WorkflowExecutionStarted` history event.

- **executionStartToCloseTimeout (string) –** The total duration for this workflow execution. This overrides the default `ExecutionStartToCloseTimeout` specified when registering the workflow type.

  The duration is specified in seconds; an integer greater than or equal to 0. Exceeding this limit will cause the workflow execution to time out. Unlike some of the other timeout parameters in Amazon SWF, you cannot specify a value of “NONE” for this timeout; there is a one-year max limit on the time that a workflow execution can run.

  **Note:** An execution start-to-close timeout must be specified either through this parameter or as a default when the workflow type is registered. If neither this parameter nor a default execution start-to-close timeout is specified, a fault is returned.

- **tagList (list) –** The list of tags to associate with the workflow execution. You can specify a maximum of 5 tags. You can list workflow executions with a specific tag by calling `ListOpenWorkflowExecutions` or `ListClosedWorkflowExecutions` and specifying a TagFilter.
• taskStartToCloseTimeout \((\text{string})\) – Specifies the maximum duration of decision tasks for this workflow execution. This parameter overrides the defaultTaskStartToCloseTimeout specified when registering the workflow type using RegisterWorkflowType.

The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

**Note:** A task start-to-close timeout for this workflow execution must be specified either as a default for the workflow type or through this parameter. If neither this parameter is set nor a default task start-to-close timeout was specified at registration time then a fault will be returned.

• childPolicy \((\text{string})\) – If set, specifies the policy to use for the child workflow executions of this workflow execution if it is terminated, by calling the TerminateWorkflowExecution action explicitly or due to an expired timeout. This policy overrides the default child policy specified when registering the workflow type using RegisterWorkflowType.

The supported child policies are:

- **TERMINATE**: the child executions will be terminated.
- **REQUEST_CANCEL**: a request to cancel will be attempted for each child execution by recording a WorkflowExecutionCancelRequested event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
- **ABANDON**: no action will be taken. The child executions will continue to run.

**Note:** A child policy for this workflow execution must be specified either as a default for the workflow type or through this parameter. If neither this parameter is set nor a default child policy was specified at registration time then a fault will be returned.

• lambdaRole \((\text{string})\) – The ARN of an IAM role that authorizes Amazon SWF to invoke AWS Lambda functions.

**Note:** In order for this workflow execution to invoke AWS Lambda functions, an appropriate IAM role must be specified either as a default for the workflow type or through this field.

**Return type** \(\text{dict}\)

**Returns**

**Response Syntax**

```
{
    'runId': 'string'
}
```

**Response Structure**

- \((\text{dict})\) –

  Specifies the runId of a workflow execution.

  - **runId \((\text{string})\) –**

    The runId of a workflow execution. This ID is generated by the ser-
vice and can be used to uniquely identify the workflow execution within a domain.

**terminate_workflow_execution(**kwargs\)**

Records a WorkflowExecutionTerminated event and forces closure of the workflow execution identified by the given domain, runId, and workflowId. The child policy, registered with the workflow type or specified when starting this execution, is applied to any open child workflow executions of this workflow execution.

**Warning:** If the identified workflow execution was in progress, it is terminated immediately.

**Note:** If a runId is not specified, then the WorkflowExecutionTerminated event is recorded in the history of the current open workflow with the matching workflowId in the domain.

**Note:** You should consider using RequestCancelWorkflowExecution action instead because it allows the workflow to gracefully close while TerminateWorkflowExecution does not.

**Access Control**

You can use IAM policies to control this action’s access to Amazon SWF resources as follows:

• Use a Resource element with the domain name to limit the action to only specified domains.
• Use an Action element to allow or deny permission to call this action.
• You cannot use an IAM policy to constrain this action’s parameters.

If the caller does not have sufficient permissions to invoke the action, or the parameter values fall outside the specified constraints, the action fails. The associated event attribute’s cause parameter will be set to OPERATION_NOT_PERMITTED. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

**Request Syntax**

```python
response = client.terminate_workflow_execution(
    domain='string',
    workflowId='string',
    runId='string',
    reason='string',
    details='string',
    childPolicy='TERMINATE'|'REQUEST_CANCEL'|'ABANDON'
)
```

**Parameters**

- **domain (string)** – [REQUIRED]
  The domain of the workflow execution to terminate.
- **workflowId (string)** – [REQUIRED]
  The workflowId of the workflow execution to terminate.
- **runId (string)** – The runId of the workflow execution to terminate.
- **reason (string)** – Optional. A descriptive reason for terminating the workflow execution.
- **details (string)** – Optional. Details for terminating the workflow execution.
- **childPolicy (string)** – If set, specifies the policy to use for the child workflow executions of the workflow execution being terminated. This policy overrides the child policy specified for the workflow execution at registration time or when starting the execution.

The supported child policies are:
- **TERMINATE**: the child executions will be terminated.
- **REQUEST_CANCEL**: a request to cancel will be attempted for each child execution by recording a WorkflowExecutionCancelRequested event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
- **ABANDON**: no action will be taken. The child executions will continue to run.

Note: A child policy for this workflow execution must be specified either as a default for the workflow type or through this parameter. If neither this parameter is set nor a default child policy was specified at registration time then a fault will be returned.

**Returns** None

**Paginators**

The available paginators are:

- SWFPaginator.GetWorkflowExecutionHistory
- SWFPaginator.ListActivityTypes
- SWFPaginator.ListClosedWorkflowExecutions
- SWFPaginator.ListDomains
- SWFPaginator.ListOpenWorkflowExecutions
- SWFPaginator.ListWorkflowTypes
- SWFPaginator.PollForDecisionTask

```python
class SWFPaginator.GetWorkflowExecutionHistory

paginator = client.get_paginator('get_workflow_execution_history')
paginate(**kwargs)
```

Creates an iterator that will paginate through responses from SWF.Client.get_workflow_execution_history().

**Request Syntax**

```python
response_iterator = paginator.paginate(
    domain='string',
    execution={
        'workflowId': 'string',
        'runId': 'string'
    },
    reverseOrder=True|False,
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**
• **domain** *(string)* – [REQUIRED]

The name of the domain containing the workflow execution.

• **execution** *(dict)* – [REQUIRED]

Specifies the workflow execution for which to return the history.

  – **workflowId** *(string)* – [REQUIRED]

    The user defined identifier associated with the workflow execution.

  – **runId** *(string)* – [REQUIRED]

    A system-generated unique identifier for the workflow execution.

• **reverseOrder** *(boolean)* – When set to `true`, returns the events in reverse order.

By default the results are returned in ascending order of the `eventTimestamp` of the events.

• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

  – **MaxItems** *(integer)* –

    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.

  – **PageSize** *(integer)* –

    The size of each page.

  – **StartingToken** *(string)* –

    A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** *dict*

**Returns**

**Response Syntax**

```
{
    'events': [
        {
            'eventTimestamp': datetime(2015, 1, 1),
            'eventType': 'WorkflowExecutionStarted'|'WorkflowExecutionCancelRequested'|'WorkflowExecutionTerminated',
            'eventId': 123,
            'workflowExecutionStartedEventAttributes': {
                'input': 'string',
                'executionStartToCloseTimeout': 'string',
                'taskStartToCloseTimeout': 'string',
                'childPolicy': 'TERMINATE'|'REQUEST_CANCEL'|'ABANDON',
                'taskList': {
                    'name': 'string'
                },
                'workflowType': {
                    'name': 'string',
                    'version': 'string'
                },
                'tagList': [
                    'string',
                ],
                'taskPriority': 'string',
                'continuedExecutionRunId': 'string',
                'parentWorkflowExecution': {
                    'workflowId': 'string',
                    'runId': 'string'
                }
            }
        }
    ]
}

Response Structure

- (dict) –

Paginated representation of a workflow history for a workflow execution. This is
the up to date, complete and authoritative record of the events related to all tasks
and events in the life of the workflow execution.

- events (list) –

The list of history events.

- * (dict) –

Event within a workflow execution. A history event can be one of
these types:

- WorkflowExecutionStarted : The workflow execution was
· WorkflowExecutionStarted : The workflow execution was started.
· WorkflowExecutionCompleted : The workflow execution was closed due to successful completion.
· WorkflowExecutionFailed : The workflow execution closed due to a failure.
· WorkflowExecutionTimedOut : The workflow execution was closed because a time out was exceeded.
· WorkflowExecutionCanceled : The workflow execution was successfully canceled and closed.
· WorkflowExecutionTerminated : The workflow execution was terminated.
· WorkflowExecutionContinuedAsNew : The workflow execution was closed and a new execution of the same type was created with the same workflowId.
· WorkflowExecutionCancelRequested : A request to cancel this workflow execution was made.
· DecisionTaskScheduled : A decision task was scheduled for the workflow execution.
· DecisionTaskStarted : The decision task was dispatched to a decider.
· DecisionTaskCompleted : The decider successfully completed a decision task by calling RespondDecisionTaskCompleted.
· DecisionTaskTimedOut : The decision task timed out.
· ActivityTaskScheduled : An activity task was scheduled for execution.
· ScheduleActivityTaskFailed : Failed to process ScheduleActivityTask decision. This happens when the decision is not configured properly, for example the activity type specified is not registered.
· ActivityTaskStarted : The scheduled activity task was dispatched to a worker.
· ActivityTaskCompleted : An activity worker successfully completed an activity task by calling RespondActivityTaskCompleted.
· ActivityTaskFailed : An activity worker failed an activity task by calling RespondActivityTaskFailed.
· ActivityTaskTimedOut : The activity task timed out.
· ActivityTaskCanceled : The activity task was successfully canceled.
· ActivityTaskCancelRequested : A RequestCancelActivityTask decision was received by the system.
· RequestCancelActivityTaskFailed : Failed to process RequestCancelActivityTask decision. This happens when the decision is not configured properly.
· WorkflowExecutionSignaled : An external signal was received for the workflow execution.
· MarkerRecorded : A marker was recorded in the workflow history as the result of a RecordMarker decision.
· TimerStarted : A timer was started for the workflow execution due to a StartTimer decision.
· StartTimerFailed : Failed to process StartTimer decision. This happens when the decision is not configured properly,
for example a timer already exists with the specified timer ID.

- **TimerFired**: A timer, previously started for this workflow execution, fired.
- **TimerCanceled**: A timer, previously started for this workflow execution, was successfully canceled.
- **CancelTimerFailed**: Failed to process CancelTimer decision. This happens when the decision is not configured properly, for example no timer exists with the specified timer ID.
- **StartChildWorkflowExecutionInitiated**: A request was made to start a child workflow execution.
- **StartChildWorkflowExecutionFailed**: Failed to process StartChildWorkflowExecution decision. This happens when the decision is not configured properly, for example the workflow type specified is not registered.
- **ChildWorkflowExecutionStarted**: A child workflow execution was successfully started.
- **ChildWorkflowExecutionCompleted**: A child workflow execution, started by this workflow execution, completed successfully and was closed.
- **ChildWorkflowExecutionFailed**: A child workflow execution, started by this workflow execution, failed to complete successfully and was closed.
- **ChildWorkflowExecutionTimedOut**: A child workflow execution, started by this workflow execution, timed out and was closed.
- **ChildWorkflowExecutionCanceled**: A child workflow execution, started by this workflow execution, was canceled and closed.
- **ChildWorkflowExecutionTerminated**: A child workflow execution, started by this workflow execution, was terminated.
- **SignalExternalWorkflowExecutionInitiated**: A request to signal an external workflow was made.
- **ExternalWorkflowExecutionSignaled**: A signal, requested by this workflow execution, was successfully delivered to the target external workflow execution.
- **SignalExternalWorkflowExecutionFailed**: The request to signal an external workflow execution failed.
- **RequestCancelExternalWorkflowExecutionInitiated**: A request was made to request the cancellation of an external workflow execution.
- **ExternalWorkflowExecutionCancelRequested**: Request to cancel an external workflow execution was successfully delivered to the target execution.
- **RequestCancelExternalWorkflowExecutionFailed**: Request to cancel an external workflow execution failed.
- **LambdaFunctionScheduled**: An AWS Lambda function was scheduled for execution.
- **LambdaFunctionStarted**: The scheduled function was invoked in the AWS Lambda service.
- **LambdaFunctionCompleted**: The AWS Lambda function successfully completed.
- **LambdaFunctionFailed**: The AWS Lambda function execution failed.
- **LambdaFunctionTimedOut**: The AWS Lambda function execution timed out.
- **ScheduleLambdaFunctionFailed**: Failed to process ScheduleLambdaFunction decision. This happens when the workflow execution does not have the proper IAM role attached to invoke AWS Lambda functions.
- **StartLambdaFunctionFailed**: Failed to invoke the scheduled function in the AWS Lambda service. This happens when the AWS Lambda service is not available in the current region, or received too many requests.

- **eventTimestamp** *(datetime)* –
  The date and time when the event occurred.

- **eventType** *(string)* –
  The type of the history event.

- **eventId** *(integer)* –
  The system generated ID of the event. This ID uniquely identifies the event within the workflow execution history.

- **workflowExecutionStartedEventAttributes** *(dict)* –
  If the event is of type `WorkflowExecutionStarted` then this member is set and provides detailed information about the event. It is not set for other event types.

- **input** *(string)* –
  The input provided to the workflow execution (if any).

- **executionStartToCloseTimeout** *(string)* –
  The maximum duration for this workflow execution. The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **taskStartToCloseTimeout** *(string)* –
  The maximum duration of decision tasks for this workflow type. The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **childPolicy** *(string)* –
  The policy to use for the child workflow executions if this workflow execution is terminated, by calling the TerminateWorkflowExecution action explicitly or due to an expired timeout.

  The supported child policies are:
  - **TERMINATE**: the child executions will be terminated.
  - **REQUEST_CANCEL**: a request to cancel will be attempted for each child execution by recording a `WorkflowExecutionCancelRequested` event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
  - **ABANDON**: no action will be taken. The child executions will continue to run.
· **taskList** *(dict)* –
  The name of the task list for scheduling the decision tasks for this workflow execution.

· **name** *(string)* –
  The name of the task list.

· **workflowType** *(dict)* –
  The workflow type of this execution.

· **name** *(string)* –
  **Required.** The name of the workflow type.

  **Note:** The combination of workflow type name and version must be unique with in a domain.

· **version** *(string)* –
  **Required.** The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique with in a domain.

· **tagList** *(list)* –
  The list of tags associated with this workflow execution. An execution can have up to 5 tags.

· **taskPriority** *(string)* –

· **continuedExecutionRunId** *(string)* –
  If this workflow execution was started due to a ContinueAsNewWorkflowExecution decision, then it contains the runId of the previous workflow execution that was closed and continued as this execution.

· **parentWorkflowExecution** *(dict)* –
  The source workflow execution that started this workflow execution. The member is not set if the workflow execution was not started by a workflow.

· **workflowId** *(string)* –
  The user defined identifier associated with the workflow execution.

· **runId** *(string)* –
  A system-generated unique identifier for the workflow execution.

· **parentInitiatedEventId** *(integer)* –
  The ID of the StartChildWorkflowExecutionInitiated event corresponding to the StartChildWorkflowExecution decision to start this workflow execution. The source event with this ID can be found in the history of the source workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· **lambdaRole** *(string)* –
The IAM role attached to this workflow execution to use when invoking AWS Lambda functions.

- **workflowExecutionCompletedEventAttributes (dict)** –
  
  If the event is of type `WorkflowExecutionCompleted` then this member is set and provides detailed information about the event. It is not set for other event types.

- **result (string)** –
  
  The result produced by the workflow execution upon successful completion.

- **decisionTaskCompletedEventId (integer)** –
  
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `CompleteWorkflowExecution` decision to complete this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **completeWorkflowExecutionFailedEventAttributes (dict)** –
  
  If the event is of type `CompleteWorkflowExecutionFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

- **cause (string)** –
  
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If **cause** is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId (integer)** –
  
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `CompleteWorkflowExecution` decision to complete this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **workflowExecutionFailedEventAttributes (dict)** –
  
  If the event is of type `WorkflowExecutionFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

- **reason (string)** –
  
  The descriptive reason provided for the failure (if any).

- **details (string)** –
  
  The details of the failure (if any).

- **decisionTaskCompletedEventId (integer)** –
  
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the
FailWorkflowExecution decision to fail this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **failWorkflowExecutionFailedEventAttributes (dict)** –

  If the event is of type FailWorkflowExecutionFailed then this member is set and provides detailed information about the event. It is not set for other event types.

- **cause (string)** –

  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If cause is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId (integer)** –

  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the FailWorkflowExecution decision to fail this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **workflowExecutionTimedOutEventAttributes (dict)** –

  If the event is of type WorkflowExecutionTimedOut then this member is set and provides detailed information about the event. It is not set for other event types.

- **timeoutType (string)** –

  The type of timeout that caused this event.

- **childPolicy (string)** –

  The policy used for the child workflow executions of this workflow execution.

  The supported child policies are:

  - **TERMINATE:** the child executions will be terminated.
  - **REQUESTCANCEL:** a request to cancel will be attempted for each child execution by recording a WorkflowExecutionCancelRequested event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
  - **ABANDON:** no action will be taken. The child executions will continue to run.

- **workflowExecutionCanceledEventAttributes (dict)** –

  If the event is of type WorkflowExecutionCanceled then this member is set and provides detailed information about the event. It is not set for other event types.

- **details (string)** –

  Details for the cancellation (if any).

- **decisionTaskCompletedEventId (integer)** –

  The ID of the DecisionTaskCompleted event cor-
responding to the decision task that resulted in the CancelWorkflowExecution decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **cancelWorkflowExecutionFailedEventAttributes (dict)** –
  If the event is of type CancelWorkflowExecutionFailed then this member is set and provides detailed information about the event. It is not set for other event types.

- **cause (string)** –
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If cause is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId (integer)** –
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the CancelWorkflowExecution decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **workflowExecutionContinuedAsNewEventAttributes (dict)** –
  If the event is of type WorkflowExecutionContinuedAsNew then this member is set and provides detailed information about the event. It is not set for other event types.

- **input (string)** –
  The input provided to the new workflow execution.

- **decisionTaskCompletedEventId (integer)** –
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the ContinueAsNewWorkflowExecution decision that started this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **newExecutionRunId (string)** –
  The runId of the new workflow execution.

- **executionStartToCloseTimeout (string)** –
  The total duration allowed for the new workflow execution.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **taskList (dict)** –
Represents a task list.

- **name (string)**

  The name of the task list.

- **taskPriority (string)**

- **taskStartToCloseTimeout (string)**

  The maximum duration of decision tasks for the new workflow execution.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **childPolicy (string)**

  The policy to use for the child workflow executions of the new execution if it is terminated by calling the TerminateWorkflowExecution action explicitly or due to an expired timeout.

  The supported child policies are:
  - **TERMINATE**: the child executions will be terminated.
  - **REQUEST_CANCEL**: a request to cancel will be attempted for each child execution by recording a WorkflowExecutionCancelRequested event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
  - **ABANDON**: no action will be taken. The child executions will continue to run.

- **tagList (list)**

  The list of tags associated with the new workflow execution.

- **workflowType (dict)**

  Represents a workflow type.

  - **name (string)**

    **Required.** The name of the workflow type.

    **Note:** The combination of workflow type name and version must be unique with in a domain.

- **version (string)**

  **Required.** The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique with in a domain.

- **lambdaRole (string)**

  The IAM role attached to this workflow execution to use when invoking AWS Lambda functions.

- **continueAsNewWorkflowExecutionFailedEventAttributes (dict)**

  If the event is of type ContinueAsNewWorkflowExecutionFailed then this member is set and provides detailed information about the event. It is not set for other event types.
• **cause (string)** –

  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If **cause** is set to **OPERATION_NOT_PERMITTED**, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

• **decisionTaskCompletedEventId (integer)** –

  The ID of the **DecisionTaskCompleted** event corresponding to the decision task that resulted in the **ContinueAsNewWorkflowExecution** decision that started this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

• **workflowExecutionTerminatedEventAttributes (dict)** –

  If the event is of type **WorkflowExecutionTerminated** then this member is set and provides detailed information about the event. It is not set for other event types.

  • **reason (string)** –

    The reason provided for the termination (if any).

  • **details (string)** –

    The details provided for the termination (if any).

  • **childPolicy (string)** –

    The policy used for the child workflow executions of this workflow execution.

    The supported child policies are:

    • **TERMINATE**: the child executions will be terminated.

    • **REQUEST_CANCEL**: a request to cancel will be attempted for each child execution by recording a **WorkflowExecutionCancelRequested** event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.

    • **ABANDON**: no action will be taken. The child executions will continue to run.

  • **cause (string)** –

    If set, indicates that the workflow execution was automatically terminated, and specifies the cause. This happens if the parent workflow execution times out or is terminated and the child policy is set to terminate child executions.

• **workflowExecutionCancelRequestedEventAttributes (dict)** –

  If the event is of type **WorkflowExecutionCancelRequested** then this member is set and provides detailed information about the event. It is not set for other event types.

• **externalWorkflowExecution (dict)** –
The external workflow execution for which the cancellation was requested.

- **workflowId** *(string)* –

  The user defined identifier associated with the workflow execution.

- **runId** *(string)* –

  A system-generated unique identifier for the workflow execution.

- **externalInitiatedEventId** *(integer)* –

  The ID of the `RequestCancelExternalWorkflowExecutionInitiated` event corresponding to the `RequestCancelExternalWorkflowExecution` decision to cancel this workflow execution. The source event with this ID can be found in the history of the source workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **cause** *(string)* –

  If set, indicates that the request to cancel the workflow execution was automatically generated, and specifies the cause. This happens if the parent workflow execution times out or is terminated, and the child policy is set to cancel child executions.

- **decisionTaskScheduledEventAttributes** *(dict)* –

  If the event is of type `DecisionTaskScheduled` then this member is set and provides detailed information about the event. It is not set for other event types.

- **taskList** *(dict)* –

  The name of the task list in which the decision task was scheduled.

  - **name** *(string)* –

    The name of the task list.

  - **taskPriority** *(string)* –

    *Optional.* A task priority that, if set, specifies the priority for this decision task. Valid values are integers that range from Java’s `Integer.MIN_VALUE` (`-2147483648`) to `Integer.MAX_VALUE` (`2147483647`). Higher numbers indicate higher priority.

    For more information about setting task priority, see Setting Task Priority in the Amazon Simple Workflow Developer Guide.

- **startToCloseTimeout** *(string)* –

  The maximum duration for this decision task. The task is considered timed out if it does not completed within this duration.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **decisionTaskStartedEventAttributes** *(dict)* –
If the event is of type `DecisionTaskStarted` then this member is set and provides detailed information about the event. It is not set for other event types.

- **identity (string)** –
  Identity of the decider making the request. This enables diagnostic tracing when problems arise. The form of this identity is user defined.

- **scheduledEventId (integer)** –
  The ID of the `DecisionTaskScheduled` event that was recorded when this decision task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **decisionTaskCompletedEventAttributes (dict)** –
  If the event is of type `DecisionTaskCompleted` then this member is set and provides detailed information about the event. It is not set for other event types.

- **executionContext (string)** –
  User defined context for the workflow execution.

- **scheduledEventId (integer)** –
  The ID of the `DecisionTaskScheduled` event that was recorded when this decision task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –
  The ID of the `DecisionTaskStarted` event recorded when this decision task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **decisionTaskTimedOutEventAttributes (dict)** –
  If the event is of type `DecisionTaskTimedOut` then this member is set and provides detailed information about the event. It is not set for other event types.

- **timeoutType (string)** –
  The type of timeout that expired before the decision task could be completed.

- **scheduledEventId (integer)** –
  The ID of the `DecisionTaskScheduled` event that was recorded when this decision task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –
  The ID of the `DecisionTaskStarted` event recorded when this decision task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityTaskScheduledEventAttributes (dict)** –
  If the event is of type `ActivityTaskScheduled` then this member is set and provides detailed information about
the event. It is not set for other event types.

- **activityType** *(dict)* –
  The type of the activity task.

- **name** *(string)* –
  The name of this activity.

**Note:** The combination of activity type name and version must be unique within a domain.

- **version** *(string)* –
  The version of this activity.

**Note:** The combination of activity type name and version must be unique within a domain.

- **activityId** *(string)* –
  The unique ID of the activity task.

- **input** *(string)* –
  The input provided to the activity task.

- **control** *(string)* –
  Optional. Data attached to the event that can be used by the decider in subsequent workflow tasks. This data is not sent to the activity.

- **scheduleToStartTimeout** *(string)* –
  The maximum amount of time the activity task can wait to be assigned to a worker.

- **scheduleToCloseTimeout** *(string)* –
  The maximum amount of time for this activity task.

- **startToCloseTimeout** *(string)* –
  The maximum amount of time a worker may take to process the activity task.

- **taskList** *(dict)* –
  The task list in which the activity task has been scheduled.

- **name** *(string)* –
  The name of the task list.

- **taskPriority** *(string)* –
  Optional. The priority to assign to the scheduled activity task. If set, this will override any default priority value that was assigned when the activity type was registered.

  Valid values are integers that range from Java’s `Integer.MIN_VALUE` (-2147483648) to `Integer.MAX_VALUE` (2147483647). Higher numbers indicate higher priority.

  For more information about setting task priority, see Setting Task Priority in the Amazon Simple Workflow Developer Guide.

- **decisionTaskCompletedEventId** *(integer)* –
The ID of the DecisionTaskCompleted event corresponding to the decision that resulted in the scheduling of this activity task. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **heartbeatTimeout (string)** –
  
The maximum time before which the worker processing this task must report progress by calling RecordActivityTaskHeartbeat. If the timeout is exceeded, the activity task is automatically timed out. If the worker subsequently attempts to record a heartbeat or return a result, it will be ignored.

- **activityTaskStartedEventAttributes (dict)** –
  
  If the event is of type ActivityTaskStarted then this member is set and provides detailed information about the event. It is not set for other event types.

- **identity (string)** –
  
  Identity of the worker that was assigned this task. This aids diagnostics when problems arise. The form of this identity is user defined.

- **scheduledEventId (integer)** –
  
  The ID of the ActivityTaskScheduled event that was recorded when this activity task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityTaskCompletedEventAttributes (dict)** –
  
  If the event is of type ActivityTaskCompleted then this member is set and provides detailed information about the event. It is not set for other event types.

- **result (string)** –
  
  The results of the activity task (if any).

- **scheduledEventId (integer)** –
  
  The ID of the ActivityTaskScheduled event that was recorded when this activity task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –
  
  The ID of the ActivityTaskStarted event recorded when this activity task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityTaskFailedEventAttributes (dict)** –
  
  If the event is of type ActivityTaskFailed then this member is set and provides detailed information about the event. It is not set for other event types.

- **reason (string)** –
  
  The reason provided for the failure (if any).

- **details (string)** –
  
  The details of the failure (if any).
• **scheduledEventId** *(integer)*

  The ID of the `ActivityTaskScheduled` event that was recorded when this activity task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

• **startedEventId** *(integer)*

  The ID of the `ActivityTaskStarted` event recorded when this activity task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

• **activityTaskTimedOutEventAttributes** *(dict)*

  If the event is of type `ActivityTaskTimedOut` then this member is set and provides detailed information about the event. It is not set for other event types.

  • **timeoutType** *(string)*

    The type of the timeout that caused this event.

  • **scheduledEventId** *(integer)*

    The ID of the `ActivityTaskScheduled` event that was recorded when this activity task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

  • **startedEventId** *(integer)*

    The ID of the `ActivityTaskStarted` event recorded when this activity task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

  • **details** *(string)*

    Contains the content of the `details` parameter for the last call made by the activity to `RecordActivityTaskHeartbeat`.

• **activityTaskCanceledEventAttributes** *(dict)*

  If the event is of type `ActivityTaskCanceled` then this member is set and provides detailed information about the event. It is not set for other event types.

  • **details** *(string)*

    Details of the cancellation (if any).

  • **scheduledEventId** *(integer)*

    The ID of the `ActivityTaskScheduled` event that was recorded when this activity task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

  • **startedEventId** *(integer)*

    The ID of the `ActivityTaskStarted` event recorded when this activity task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

• **latestCancelRequestedEventId** *(integer)*
If set, contains the ID of the last `ActivityTaskCancelRequested` event recorded for this activity task. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityTaskCancelRequestedEventAttributes (dict)** –
  
  If the event is of type `ActivityTaskCancelRequested` then this member is set and provides detailed information about the event. It is not set for other event types.

- **decisionTaskCompletedEventId (integer)** –
  
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `RequestCancelActivityTask` decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityId (string)** –
  
  The unique ID of the task.

- **workflowExecutionSignaledEventAttributes (dict)** –
  
  If the event is of type `WorkflowExecutionSignaled` then this member is set and provides detailed information about the event. It is not set for other event types.

  - **signalName (string)** –
    
    The name of the signal received. The decider can use the signal name and inputs to determine how to process the signal.

  - **input (string)** –
    
    Inputs provided with the signal (if any). The decider can use the signal name and inputs to determine how to process the signal.

  - **externalWorkflowExecution (dict)** –
    
    The workflow execution that sent the signal. This is set only if the signal was sent by another workflow execution.

  - **workflowId (string)** –
    
    The user defined identifier associated with the workflow execution.

  - **runId (string)** –
    
    A system-generated unique identifier for the workflow execution.

- **externalInitiatedEventId (integer)** –
  
  The ID of the `SignalExternalWorkflowExecutionInitiated` event corresponding to the `SignalExternalWorkflow` decision to signal this workflow execution. The source event with this ID can be found in the history of the source workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event. This field is set only if the signal was initiated by another workflow execution.
- **markerRecordedEventAttributes** *(dict)* –
  If the event is of type *MarkerRecorded* then this member is set and provides detailed information about the event. It is not set for other event types.
- **markerName** *(string)* –
  The name of the marker.
- **details** *(string)* –
  Details of the marker (if any).
- **decisionTaskCompletedEventId** *(integer)* –
  The ID of the *DecisionTaskCompleted* event corresponding to the decision task that resulted in the *RecordMarker* decision that requested this marker. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
- **recordMarkerFailedEventAttributes** *(dict)* –
  If the event is of type *DecisionTaskFailed* then this member is set and provides detailed information about the event. It is not set for other event types.
- **markerName** *(string)* –
  The marker’s name.
- **cause** *(string)* –
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

**Note:** If *cause* is set to *OPERATION_NOT_PERMITTED*, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId** *(integer)* –
  The ID of the *DecisionTaskCompleted* event corresponding to the decision task that resulted in the *RecordMarkerFailed* decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
- **timerStartedEventAttributes** *(dict)* –
  If the event is of type *TimerStarted* then this member is set and provides detailed information about the event. It is not set for other event types.
- **timerId** *(string)* –
  The unique ID of the timer that was started.
- **control** *(string)* –
  *Optional.* Data attached to the event that can be used by the decider in subsequent workflow tasks.
- **startToFireTimeout** *(string)* –
  The duration of time after which the timer will fire.
The duration is specified in seconds; an integer greater than or equal to 0.

- **decisionTaskCompletedEventId** (integer) –
  
The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the StartTimer decision for this activity task. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **timerFiredEventAttributes** (dict) –
  
  If the event is of type TimerFired then this member is set and provides detailed information about the event. It is not set for other event types.

  - **timerId** (string) –
    
The unique ID of the timer that fired.

- **startedEventId** (integer) –
  
The ID of the TimerStarted event that was recorded when this timer was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **timerCanceledEventAttributes** (dict) –
  
  If the event is of type TimerCanceled then this member is set and provides detailed information about the event. It is not set for other event types.

  - **timerId** (string) –
    
The unique ID of the timer that was canceled.

- **startedEventId** (integer) –
  
The ID of the TimerStarted event that was recorded when this timer was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **decisionTaskCompletedEventId** (integer) –
  
The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the CancelTimer decision to cancel this timer. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startChildWorkflowExecutionInitiatedEventAttributes** (dict) –
  
  If the event is of type StartChildWorkflowExecutionInitiated then this member is set and provides detailed information about the event. It is not set for other event types.

  - **workflowId** (string) –
    
The workflowId of the child workflow execution.

  - **workflowType** (dict) –
    
The type of the child workflow execution.

  - **name** (string) –
    
    Required. The name of the workflow type.
**Note:** The combination of workflow type name and version must be unique within a domain.

- **version (string)** –
  
  **Required.** The version of the workflow type.

**Note:** The combination of workflow type name and version must be unique within a domain.

- **control (string)** –
  
  **Optional.** Data attached to the event that can be used by the decider in subsequent decision tasks. This data is not sent to the activity.

- **input (string)** –
  
  The inputs provided to the child workflow execution (if any).

- **executionStartToCloseTimeout (string)** –
  
  The maximum duration for the child workflow execution. If the workflow execution is not closed within this duration, it will be timed out and force terminated.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **taskList (dict)** –
  
  The name of the task list used for the decision tasks of the child workflow execution.

- **name (string)** –
  
  The name of the task list.

- **taskPriority (string)** –
  
  **Optional.** The priority assigned for the decision tasks for this workflow execution. Valid values are integers that range from Java’s `Integer.MIN_VALUE` (-2147483648) to `Integer.MAX_VALUE` (2147483647). Higher numbers indicate higher priority.

  For more information about setting task priority, see Setting Task Priority in the Amazon Simple Workflow Developer Guide.

- **decisionTaskCompletedEventId (integer)** –
  
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `StartChildWorkflowExecution` decision to request this child workflow execution. This information can be useful for diagnosing problems by tracing back the cause of events.

- **childPolicy (string)** –
  
  The policy to use for the child workflow executions if this execution gets terminated by explicitly calling the `TerminateWorkflowExecution` action or due to an expired timeout.

  The supported child policies are:

  - **TERMINATE:** the child executions will be terminated.
· REQUEST_CANCEL: a request to cancel will be attempted for each child execution by recording a WorkflowExecutionCancelRequested event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
· ABANDON: no action will be taken. The child executions will continue to run.

· taskStartToCloseTimeout (string) –
  The maximum duration allowed for the decision tasks for this workflow execution.
  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

· tagList (list) –
  The list of tags to associate with the child workflow execution.

· lambdaRole (string) –
  The IAM role attached to this workflow execution to use when invoking AWS Lambda functions.

· childWorkflowExecutionStartedEventAttributes (dict) –
  If the event is of type ChildWorkflowExecutionStarted then this member is set and provides detailed information about the event. It is not set for other event types.

· workflowExecution (dict) –
  The child workflow execution that was started.

· workflowId (string) –
  The user-defined identifier associated with the workflow execution.

· runId (string) –
  A system-generated unique identifier for the workflow execution.

· workflowType (dict) –
  The type of the child workflow execution.

· name (string) –
  Required. The name of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

· version (string) –
  **Required.** The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

· initiatedEventId (integer) –
The ID of the StartChildWorkflowExecutionInitiated event corresponding to the StartChildWorkflowExecution decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **childWorkflowExecutionCompletedEventAttributes (dict)** –

  If the event is of type ChildWorkflowExecutionCompleted then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowExecution (dict)** –

  The child workflow execution that was completed.

  - **workflowId (string)** –

    The user defined identifier associated with the workflow execution.

  - **runId (string)** –

    A system-generated unique identifier for the workflow execution.

  - **workflowType (dict)** –

    The type of the child workflow execution.

    - **name (string)** –

      Required. The name of the workflow type.

      Note: The combination of workflow type name and version must be unique within a domain.

    - **version (string)** –

      Required. The version of the workflow type.

      Note: The combination of workflow type name and version must be unique within a domain.

  - **result (string)** –

    The result of the child workflow execution (if any).

  - **initiatedEventId (integer)** –

    The ID of the StartChildWorkflowExecutionInitiated event corresponding to the StartChildWorkflowExecution decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

  - **startedEventId (integer)** –

    The ID of the ChildWorkflowExecutionStarted event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
· **childWorkflowExecutionFailedEventAttributes (dict)** –
  If the event is of type ChildWorkflowExecutionFailed then this member is set and provides detailed information about the event. It is not set for other event types.

· **workflowExecution (dict)** –
  The child workflow execution that failed.

· **workflowId (string)** –
  The user defined identifier associated with the workflow execution.

· **runId (string)** –
  A system-generated unique identifier for the workflow execution.

· **workflowType (dict)** –
  The type of the child workflow execution.

  · **name (string)** –
    Required. The name of the workflow type.

    **Note:** The combination of workflow type name and version must be unique within a domain.

dict

· **version (string)** –
  Required. The version of the workflow type.

    **Note:** The combination of workflow type name and version must be unique within a domain.

· **reason (string)** –
  The reason for the failure (if provided).

· **details (string)** –
  The details of the failure (if provided).

· **initiatedEventId (integer)** –
  The ID of the StartChildWorkflowExecutionInitiated event corresponding to the StartChildWorkflowExecution decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· **startedEventId (integer)** –
  The ID of the ChildWorkflowExecutionStarted event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· **childWorkflowExecutionTimedOutEventAttributes (dict)** –
  If the event is of type ChildWorkflowExecutionTimedOut then this
member is set and provides detailed information about the event. It is not set for other event types.

- workflowExecution (dict) –
  The child workflow execution that timed out.
- workflowId (string) –
  The user defined identifier associated with the workflow execution.
- runId (string) –
  A system-generated unique identifier for the workflow execution.
- workflowType (dict) –
  The type of the child workflow execution.
  - name (string) –
    Required. The name of the workflow type.

  **Note:** The combination of workflow type name and version must be unique with in a domain.
- version (string) –
  Required. The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique with in a domain.
- timeoutType (string) –
  The type of the timeout that caused the child workflow execution to time out.
- initiatedEventId (integer) –
  The ID of the StartChildWorkflowExecutionInitiated event corresponding to the StartChildWorkflowExecution decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
- startedEventId (integer) –
  The ID of the ChildWorkflowExecutionStarted event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
- childWorkflowExecutionCanceledEventAttributes (dict) –
  If the event is of type ChildWorkflowExecutionCanceled then this member is set and provides detailed information about the event. It is not set for other event types.
- workflowExecution (dict) –
  The child workflow execution that was canceled.
- workflowId (string) –
The user defined identifier associated with the workflow execution.

- **runId** (string) –
  A system-generated unique identifier for the workflow execution.

- **workflowType** (dict) –
  The type of the child workflow execution.
  - **name** (string) –
    Required. The name of the workflow type.
  
  **Note:** The combination of workflow type name and version must be unique within a domain.

- **version** (string) –
  Required. The version of the workflow type.
  
  **Note:** The combination of workflow type name and version must be unique within a domain.

- **details** (string) –
  Details of the cancellation (if provided).

- **initiatedEventId** (integer) –
  The ID of the `StartChildWorkflowExecutionInitiated` event corresponding to the `StartChildWorkflowExecution` decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId** (integer) –
  The ID of the `ChildWorkflowExecutionStarted` event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **childWorkflowExecutionTerminatedEventAttributes** (dict) –
  If the event is of type `ChildWorkflowExecutionTerminated` then this member is set and provides detailed information about the event. It is not set for other event types.

  - **workflowExecution** (dict) –
    The child workflow execution that was terminated.

  - **workflowId** (string) –
    The user defined identifier associated with the workflow execution.

  - **runId** (string) –
    A system-generated unique identifier for the workflow execution.

  - **workflowType** (dict) –
      

The type of the child workflow execution.

- **name** *(string)* —
  
  **Required.** The name of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- **version** *(string)* —
  
  **Required.** The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- **initiatedEventId** *(integer)* —
  
  The ID of the StartChildWorkflowExecutionInitiated event corresponding to the StartChildWorkflowExecution decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId** *(integer)* —
  
  The ID of the ChildWorkflowExecutionStarted event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **signalExternalWorkflowExecutionInitiatedEventAttributes** *(dict)* —
  
  If the event is of type SignalExternalWorkflowExecutionInitiated then this member is set and provides detailed information about the event. It is not set for other event types.

  - **workflowId** *(string)* —
    
    The workflowId of the external workflow execution.

  - **runId** *(string)* —
    
    The runId of the external workflow execution to send the signal to.

  - **signalName** *(string)* —
    
    The name of the signal.

  - **input** *(string)* —
    
    Input provided to the signal (if any).

  - **decisionTaskCompletedEventId** *(integer)* —
    
    The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the SignalExternalWorkflowExecutionInitiated decision for this signal. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

  - **control** *(string)* —
Optional. data attached to the event that can be used by the
decider in subsequent decision tasks.

- **externalWorkflowExecutionSignaledEventAttributes**
  *(dict)*

  If the event is of type ExternalWorkflowExecutionSignaled then
  this member is set and provides detailed information about
  the event. It is not set for other event types.

- **workflowExecution** *(dict)*

  The external workflow execution that the signal was delivered
to.

- **workflowId** *(string)*

  The user defined identifier associated with the workflow exe-
cution.

- **runId** *(string)*

  A system-generated unique identifier for the workflow execu-
tion.

- **initiatedEventId** *(integer)*

  The ID of the SignalExternalWorkflowExecutionInitiated
event corresponding to the SignalExternalWorkflowExecution
decision to request this signal. This information can be useful for
diagnosing problems by tracing back the chain of events
leading up to this event.

- **signalExternalWorkflowExecutionFailedEventAttributes**
  *(dict)*

  If the event is of type SignalExternalWorkflowExecutionFailed
  then this member is set and provides detailed information
  about the event. It is not set for other event types.

- **workflowId** *(string)*

  The workflowId of the external workflow execution that
  the signal was being delivered to.

- **runId** *(string)*

  The runId of the external workflow execution that the signal
  was being delivered to.

- **cause** *(string)*

  The cause of the failure. This information is generated by the
  system and can be useful for diagnostic purposes.

**Note:** If **cause** is set to OPERATION_NOT_PERMITTED,
the decision failed because it lacked sufficient permissions.
For details and example IAM policies, see Using IAM to
Manage Access to Amazon SWF Workflows.

- **initiatedEventId** *(integer)*

  The ID of the SignalExternalWorkflowExecutionInitiated
event corresponding to the SignalExternalWorkflowExecution
decision
to request this signal. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **decisionTaskCompletedEventId (integer)** –
  
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the SignalExternalWorkflowExecution decision for this signal. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **control (string)** –

- **externalWorkflowExecutionCancelRequestedEventAttributes (dict)** –
  
  If the event is of type ExternalWorkflowExecutionCancelRequested then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowExecution (dict)** –
  
  The external workflow execution to which the cancellation request was delivered.

- **workflowId (string)** –
  
  The user defined identifier associated with the workflow execution.

- **runId (string)** –
  
  A system-generated unique identifier for the workflow execution.

- **initiatedEventId (integer)** –
  
  The ID of the RequestCancelExternalWorkflowExecutionInitiated event corresponding to the RequestCancelExternalWorkflowExecution decision to cancel this external workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **requestCancelExternalWorkflowExecutionInitiatedEventAttributes (dict)** –
  
  If the event is of type RequestCancelExternalWorkflowExecutionInitiated then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowId (string)** –
  
  The workflowId of the external workflow execution to be canceled.

- **runId (string)** –
  
  The runId of the external workflow execution to be canceled.

- **decisionTaskCompletedEventId (integer)** –
  
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the decision to cancel this external workflow execution.
RequestCancelExternalWorkflowExecution decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **control (string)** –

  Optional. Data attached to the event that can be used by the decider in subsequent workflow tasks.

- **requestCancelExternalWorkflowExecutionFailedEventAttributes (dict)** –

  If the event is of type RequestCancelExternalWorkflowExecutionFailed then this member is set and provides detailed information about the event. It is not set for other event types.

  - **workflowId (string)** –

    The workflowId of the external workflow to which the cancel request was to be delivered.

  - **runId (string)** –

    The runId of the external workflow execution.

  - **cause (string)** –

    The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

    **Note:** If cause is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

  - **initiatedEventId (integer)** –

    The ID of the RequestCancelExternalWorkflowExecutionInitiated event corresponding to the RequestCancelExternalWorkflowExecution decision to cancel this external workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

  - **decisionTaskCompletedEventId (integer)** –

    The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the RequestCancelExternalWorkflowExecution decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

  - **control (string)** –

  - **scheduleActivityTaskFailedEventAttributes (dict)** –

    If the event is of type ScheduleActivityTaskFailed then this member is set and provides detailed information about the event. It is not set for other event types.

  - **activityType (dict)** –

    The activity type provided in the ScheduleActivityTask decision that failed.

  - **name (string)** –
The name of this activity.

**Note:** The combination of activity type name and version must be unique within a domain.

- **version** *(string)* –
  The version of this activity.

**Note:** The combination of activity type name and version must be unique within a domain.

- **activityId** *(string)* –
  The activityId provided in the ScheduleActivityTask decision that failed.

- **cause** *(string)* –
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

**Note:** If **cause** is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId** *(integer)* –
  The ID of the DecisionTaskCompleted event corresponding to the decision that resulted in the scheduling of this activity task. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **requestCancelActivityTaskFailedEventAttributes** *(dict)* –
  If the event is of type RequestCancelActivityTaskFailed then this member is set and provides detailed information about the event. It is not set for other event types.

- **activityId** *(string)* –
  The activityId provided in the RequestCancelActivityTask decision that failed.

- **cause** *(string)* –
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

**Note:** If **cause** is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId** *(integer)* –
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the RequestCancelActivityTask decision for this cancellation request. This information can be useful for diag-
nosing problems by tracing back the chain of events leading up to this event.

- **startTimerFailedEventAttributes**(dict) –

  If the event is of type `StartTimerFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

- **timerId**(string) –

  The timerId provided in the `StartTimer` decision that failed.

- **cause**(string) –

  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId**(integer) –

  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `StartTimer` decision for this activity task. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **cancelTimerFailedEventAttributes**(dict) –

  If the event is of type `CancelTimerFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

- **timerId**(string) –

  The timerId provided in the `CancelTimer` decision that failed.

- **cause**(string) –

  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId**(integer) –

  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `CancelTimer` decision to cancel this timer. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startChildWorkflowExecutionFailedEventAttributes**(dict) –

  If the event is of type `StartChildWorkflowExecutionFailed` then
this member is set and provides detailed information about the event. It is not set for other event types.

- workflowType (dict) –

  The workflow type provided in the StartChildWorkflowExecution decision that failed.

- name (string) –

  Required. The name of the workflow type.

  Note: The combination of workflow type name and version must be unique with in a domain.

- version (string) –

  Required. The version of the workflow type.

  Note: The combination of workflow type name and version must be unique with in a domain.

- cause (string) –

  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  Note: If cause is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows .

- workflowId (string) –

  The workflowId of the child workflow execution.

- initiatedEventId (integer) –

  The ID of the StartChildWorkflowExecutionInitiated event corresponding to the StartChildWorkflowExecution decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- decisionTaskCompletedEventId (integer) –

  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the StartChildWorkflowExecution decision to request this child workflow execution. This information can be useful for diagnosing problems by tracing back the cause of events.

- control (string) –

- lambdaFunctionScheduledEventAttributes (dict) –

  Provides details for the LambdaFunctionScheduled event.

- id (string) –

  The unique Amazon SWF ID for the AWS Lambda task.

- name (string) –

  The name of the scheduled AWS Lambda function.
- **input (string)** –
  Input provided to the AWS Lambda function.

- **startToCloseTimeout (string)** –
  The maximum time, in seconds, that the AWS Lambda function can take to execute from start to close before it is marked as failed.

- **decisionTaskCompletedEventId (integer)** –
  The ID of the DecisionTaskCompleted event for the decision that resulted in the scheduling of this AWS Lambda function. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **lambdaFunctionStartedEventAttributes (dict)** –
  Provides details for the LambdaFunctionStarted event.

- **scheduledEventId (integer)** –
  The ID of the LambdaFunctionScheduled event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **lambdaFunctionCompletedEventAttributes (dict)** –
  Provides details for the LambdaFunctionCompleted event.

- **scheduledEventId (integer)** –
  The ID of the LambdaFunctionScheduled event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –
  The ID of the LambdaFunctionStarted event recorded in the history.

- **result (string)** –
  The result of the function execution (if any).

- **lambdaFunctionFailedEventAttributes (dict)** –
  Provides details for the LambdaFunctionFailed event.

- **scheduledEventId (integer)** –
  The ID of the LambdaFunctionScheduled event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –
  The ID of the LambdaFunctionStarted event recorded in the history.

- **reason (string)** –
  The reason provided for the failure (if any).

- **details (string)** –
  The details of the failure (if any).
· **lambdaFunctionTimedOutEventAttributes (dict)** –
  Provides details for the LambdaFunctionTimedOut event.

· **scheduledEventId (integer)** –
  The ID of the LambdaFunctionScheduled event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· **startedEventId (integer)** –
  The ID of the LambdaFunctionStarted event recorded in the history.

· **timeoutType (string)** –
  The type of the timeout that caused this event.

· **scheduleLambdaFunctionFailedEventAttributes (dict)** –
  Provides details for the ScheduleLambdaFunctionFailed event.

· **id (string)** –
  The unique Amazon SWF ID of the AWS Lambda task.

· **name (string)** –
  The name of the scheduled AWS Lambda function.

· **cause (string)** –
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

· **decisionTaskCompletedEventId (integer)** –
  The ID of the DecisionTaskCompleted event corresponding to the decision that resulted in the scheduling of this AWS Lambda function. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· **startLambdaFunctionFailedEventAttributes (dict)** –
  Provides details for the StartLambdaFunctionFailed event.

· **scheduledEventId (integer)** –
  The ID of the LambdaFunctionScheduled event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· **cause (string)** –
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`,...
the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **message (string)** – The error message (if any).
  - **NextToken (string)** – A token to resume pagination.

```python
class SWF.Paginator.ListActivityTypes

paginator = client.get_paginator('list_activity_types')

paginate(**kwargs)

Creates an iterator that will paginate through responses from SWF.Client.list_activity_types().

**Request Syntax**

```python
response_iterator = paginator.paginate(
    domain='string',
    name='string',
    registrationStatus='REGISTERED'|'DEPRECATED',
    reverseOrder=True|False,
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **domain (string)** – [REQUIRED]
  The name of the domain in which the activity types have been registered.
- **name (string)** – If specified, only lists the activity types that have this name.
- **registrationStatus (string)** – [REQUIRED]
  Specifies the registration status of the activity types to list.
- **reverseOrder (boolean)** – When set to true, returns the results in reverse order. By default, the results are returned in ascending alphabetical order by name of the activity types.
- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** – The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize (integer)** – The size of each page.
  - **StartingToken (string)** – A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** dict
Returns

Response Syntax

{
    'typeInfos': [
        {
            'activityType': {
                'name': 'string',
                'version': 'string'
            },
            'status': 'REGISTERED'|'DEPRECATED',
            'description': 'string',
            'creationDate': datetime(2015, 1, 1),
            'deprecationDate': datetime(2015, 1, 1)
        },
        {
            'NextToken': 'string'
        }
    ]
}

Response Structure

* (dict) –

Contains a paginated list of activity type information structures.

- typeInfos (list) –

List of activity type information.

* (dict) –

Detailed information about an activity type.

- activityType (dict) –

The ActivityType type structure representing the activity type.

- name (string) –

The name of this activity.

Note: The combination of activity type name and version must be unique within a domain.

- version (string) –

The version of this activity.

Note: The combination of activity type name and version must be unique within a domain.

- status (string) –

The current status of the activity type.

- description (string) –

The description of the activity type provided in RegisterActivityType.

- creationDate (datetime) –

The date and time this activity type was created through RegisterActivityType.

- deprecationDate (datetime) –
If DEPRECATED, the date and time DeprecateActivityType was called.

- **NextToken** *(string)* —
  
  A token to resume pagination.

```python
class SWF.Paginator.ListClosedWorkflowExecutions

paginator = client.get_paginator('list_closed_workflow_executions')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `SWF.Client.list_closed_workflow_executions()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    domain='string',
    startTimeFilter={
        'oldestDate': datetime(2015, 1, 1),
        'latestDate': datetime(2015, 1, 1)
    },
    closeTimeFilter={
        'oldestDate': datetime(2015, 1, 1),
        'latestDate': datetime(2015, 1, 1)
    },
    executionFilter={
        'workflowId': 'string'
    },
    closeStatusFilter={
        'status': 'COMPLETED'|'FAILED'|'CANCELED'|'TERMINATED'|'CONTINUED_AS_NEW'|'TIMED_OUT'
    },
    typeFilter={
        'name': 'string',
        'version': 'string'
    },
    tagFilter={
        'tag': 'string'
    },
    reverseOrder=True|False,
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    })
```

**Parameters**

- **domain** *(string)* – [REQUIRED]
  
  The name of the domain that contains the workflow executions to list.

- **startTimeFilter** *(dict)* – If specified, the workflow executions are included in the returned results based on whether their start times are within the range specified by this filter. Also, if this parameter is specified, the returned results are ordered by their start times.

**Note**: `startTimeFilter` and `closeTimeFilter` are mutually exclusive. You must specify one of these in a request but not both.
- **oldestDate** *(datetime) – [REQUIRED]*
  Specifies the oldest start or close date and time to return.
- **latestDate** *(datetime) –*
  Specifies the latest start or close date and time to return.

- **closeTimeFilter** *(dict) –* If specified, the workflow executions are included in the returned results based on whether their close times are within the range specified by this filter. Also, if this parameter is specified, the returned results are ordered by their close times.

  **Note:** `startTimeFilter` and `closeTimeFilter` are mutually exclusive. You must specify one of these in a request but not both.

- **oldestDate** *(datetime) – [REQUIRED]*
  Specifies the oldest start or close date and time to return.
- **latestDate** *(datetime) –*
  Specifies the latest start or close date and time to return.

- **executionFilter** *(dict) –* If specified, only workflow executions matching the workflow ID specified in the filter are returned.

  **Note:** `closeStatusFilter`, `executionFilter`, `typeFilter` and `tagFilter` are mutually exclusive. You can specify at most one of these in a request.

- **workflowId** *(string) – [REQUIRED]*
  The workflowId to pass of match the criteria of this filter.

- **closeStatusFilter** *(dict) –* If specified, only workflow executions that match this close status are listed. For example, if TERMINATED is specified, then only TERMINATED workflow executions are listed.

  **Note:** `closeStatusFilter`, `executionFilter`, `typeFilter` and `tagFilter` are mutually exclusive. You can specify at most one of these in a request.

- **status** *(string) – [REQUIRED]*
  Required. The close status that must match the close status of an execution for it to meet the criteria of this filter.

- **typeFilter** *(dict) –* If specified, only executions of the type specified in the filter are returned.

  **Note:** `closeStatusFilter`, `executionFilter`, `typeFilter` and `tagFilter` are mutually exclusive. You can specify at most one of these in a request.

- **name** *(string) – [REQUIRED]*
  Required. Name of the workflow type.
- **version** *(string) –*
  Version of the workflow type.
• **tagFilter** (*dict*) – If specified, only executions that have the matching tag are listed.

**Note:** closeStatusFilter, executionFilter, typeFilter and tagFilter are mutually exclusive. You can specify at most one of these in a request.

- **tag** (*string*) – [REQUIRED]
  
  Required. Specifies the tag that must be associated with the execution for it to meet the filter criteria.

- **reverseOrder** (*boolean*) – When set to `true`, returns the results in reverse order. By default the results are returned in descending order of the start or the close time of the executions.

- **PaginationConfig** (*dict*) – A dictionary that provides parameters to control pagination.
  - **MaxItems** (*integer*) –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize** (*integer*) –
    
    The size of each page.
  - **StartingToken** (*string*) –
    
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'executionInfos': [
        {
            'execution': {
                'workflowId': 'string',
                'runId': 'string'
            },
            'workflowType': {
                'name': 'string',
                'version': 'string'
            },
            'startTimestamp': datetime(2015, 1, 1),
            'closeTimestamp': datetime(2015, 1, 1),
            'executionStatus': 'OPEN'|'CLOSED',
            'closeStatus': 'COMPLETED'|'FAILED'|'CANCELLED'|'TERMINATED'|'CONTINUED
            'parent': {
                'workflowId': 'string',
                'runId': 'string'
            },
            'tagList': [
                'string',
            ],
            'cancelRequested': True|False
        },
    ]
}
```
Response Structure

- \( \text{dict} \) –
  Contains a paginated list of information about workflow executions.
  - \( \text{executionInfos} \) (list) –
    The list of workflow information structures.
    * \( \text{dict} \) –
      Contains information about a workflow execution.
      - \( \text{execution} \) (dict) –
        The workflow execution this information is about.
        - \( \text{workflowId} \) (string) –
          The user defined identifier associated with the workflow execution.
        - \( \text{runId} \) (string) –
          A system-generated unique identifier for the workflow execution.
        - \( \text{workflowType} \) (dict) –
          The type of the workflow execution.
        - \( \text{name} \) (string) –
          \text{Required}. The name of the workflow type.
        - \( \text{version} \) (string) –
          \text{Required}. The version of the workflow type.
      
      \text{Note}: The combination of workflow type name and version must be unique with in a domain.
    - \( \text{startTimestamp} \) (datetime) –
      The time when the execution was started.
    - \( \text{closeTimestamp} \) (datetime) –
      The time when the workflow execution was closed. Set only if the execution status is CLOSED.
    - \( \text{executionStatus} \) (string) –
      The current status of the execution.
    - \( \text{closeStatus} \) (string) –
      If the execution status is closed then this specifies how the execution was closed:
      - \text{COMPLETED}: the execution was successfully completed.
      - \text{CANCELED}: the execution was canceled. Cancellation allows the implementation to gracefully clean up before the execution is closed.
      - \text{TERMINATED}: the execution was force terminated.
      - \text{FAILED}: the execution failed to complete.
· TIMED_OUT: the execution did not complete in the allotted time and was automatically timed out.
· CONTINUED_AS_NEW: the execution is logically continued. This means the current execution was completed and a new execution was started to carry on the workflow.
· parent (dict) –
  If this workflow execution is a child of another execution then contains the workflow execution that started this execution.
· workflowId (string) –
  The user defined identifier associated with the workflow execution.
· runId (string) –
  A system-generated unique identifier for the workflow execution.
· tagList (list) –
  The list of tags associated with the workflow execution. Tags can be used to identify and list workflow executions of interest through the visibility APIs. A workflow execution can have a maximum of 5 tags.
· (string) –
· cancelRequested (boolean) –
  Set to true if a cancellation is requested for this workflow execution.
· NextToken (string) –
  A token to resume pagination.

class SWF.Paginator.ListDomains

   paginator = client.get_paginator('list_domains')

   paginate(**kwargs)
       Creates an iterator that will paginate through responses from SWF.Client.list_domains().

   Request Syntax

       response_iterator = paginator.paginate(
           registrationStatus='REGISTERED'|'DEPRECATED',
           reverseOrder=True|False,
           PaginationConfig={
                           'MaxItems': 123,
                           'PageSize': 123,
                           'StartingToken': 'string'
           })

   Parameters
       • registrationStatus (string) – [REQUIRED]
         Specifies the registration status of the domains to list.
       • reverseOrder (boolean) – When set to true, returns the results in reverse order. By default, the results are returned in ascending alphabetical order by name of the domains.
**PaginationConfig** (*dict*) – A dictionary that provides parameters to control pagination.

- **MaxItems** (*integer*) –
  
  The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

- **PageSize** (*integer*) –
  
  The size of each page.

- **StartingToken** (*string*) –
  
  A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** *dict*

**Response Syntax**

```python
{
    'domainInfos': [
        {
            'name': 'string',
            'status': 'REGISTERED'|'DEPRECATED',
            'description': 'string'
        },
    ],
    'NextToken': 'string'
}
```

**Response Structure**

- (*dict*) –
  
  Contains a paginated collection of DomainInfo structures.

  - **domainInfos** (*list*) –
    
    A list of DomainInfo structures.

    * (*dict*) –
      
      Contains general information about a domain.

      - **name** (*string*) –
        
        The name of the domain. This name is unique within the account.

      - **status** (*string*) –
        
        The status of the domain:

        - **REGISTERED** : The domain is properly registered and available. You can use this domain for registering types and creating new workflow executions.

        - **DEPRECATED** : The domain was deprecated using DeprecateDomain, but is still in use. You should not create new workflow executions in this domain.

      - **description** (*string*) –
        
        The description of the domain provided through RegisterDomain.

  - **NextToken** (*string*) –
    
    A token to resume pagination.
class SWF.Paginator.ListOpenWorkflowExecutions

paginator = client.get_paginator('list_open_workflow_executions')

paginate(**kwargs)

Creates an iterator that will paginate through responses from SWF.Client.list_open_workflow_executions().

Request Syntax

response_iterator = paginator.paginate(
    domain='string',
    startTimeFilter={
        'oldestDate': datetime(2015, 1, 1),
        'latestDate': datetime(2015, 1, 1)
    },
    typeFilter={
        'name': 'string',
        'version': 'string'
    },
    tagFilter={
        'tag': 'string'
    },
    reverseOrder=True|False,
    executionFilter={
        'workflowId': 'string'
    },
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **domain** (string) – [REQUIRED]
  The name of the domain that contains the workflow executions to list.

- **startTimeFilter** (dict) – [REQUIRED]
  Workflow executions are included in the returned results based on whether their start times are within the range specified by this filter.
  - **oldestDate** (datetime) – [REQUIRED]
    Specifies the oldest start or close date and time to return.
  - **latestDate** (datetime) –
    Specifies the latest start or close date and time to return.

- **typeFilter** (dict) – If specified, only executions of the type specified in the filter are returned.
  - **name** (string) – [REQUIRED]
    Required. Name of the workflow type.

Note: executionFilter, typeFilter and tagFilter are mutually exclusive. You can specify at most one of these in a request.
– **version** *(string)* –

Version of the workflow type.

• **tagFilter** *(dict)* – If specified, only executions that have the matching tag are listed.

**Note:** `executionFilter`, `typeFilter` and `tagFilter` are mutually exclusive. You can specify at most one of these in a request.

– **tag** *(string)* – **[REQUIRED]**

**Required.** Specifies the tag that must be associated with the execution for it to meet the filter criteria.

• **reverseOrder** *(boolean)* – When set to `true`, returns the results in reverse order. By default the results are returned in descending order of the start time of the executions.

• **executionFilter** *(dict)* – If specified, only workflow executions matching the workflow ID specified in the filter are returned.

**Note:** `executionFilter`, `typeFilter` and `tagFilter` are mutually exclusive. You can specify at most one of these in a request.

– **workflowId** *(string)* – **[REQUIRED]**

The workflowId to pass of match the criteria of this filter.

• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

  – **MaxItems** *(integer)* –

  The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.

  – **PageSize** *(integer)* –

  The size of each page.

  – **StartingToken** *(string)* –

  A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
  'executionInfos': [
    {
      'execution': {
        'workflowId': 'string',
        'runId': 'string'
      },
      'workflowType': {
        'name': 'string',
        'version': 'string'
      },
      'startTimestamp': datetime(2015, 1, 1),
      'closeTimestamp': datetime(2015, 1, 1),
      'executionStatus': 'OPEN'|'CLOSED',
    }
  ]
}
```
Response Structure

- (dict) –

Contains a paginated list of information about workflow executions.

  - executionInfos (list) –

The list of workflow information structures.

    * (dict) –

Contains information about a workflow execution.

      - execution (dict) –

The workflow execution this information is about.

      - workflowId (string) –

The user defined identifier associated with the workflow execution.

      - runId (string) –

A system-generated unique identifier for the workflow execution.

      - workflowType (dict) –

The type of the workflow execution.

      - name (string) –

Required. The name of the workflow type.

Note: The combination of workflow type name and version must be unique with in a domain.

      - version (string) –

Required. The version of the workflow type.

Note: The combination of workflow type name and version must be unique with in a domain.

      - startTimestamp (datetime) –

The time when the execution was started.

      - closeTimestamp (datetime) –

The time when the workflow execution was closed. Set only if the execution status is CLOSED.

      - executionStatus (string) –

'closeStatus': 'COMPLETED'|'FAILED'|'CANCELED'|'TERMINATED'|'CONTINUED_AS_NEW'|'TIMED_OUT',

'parent': {
  'workflowId': 'string',
  'runId': 'string'
},
'tagList': [
  'string',
],
'cancelRequested': True|False
},
'NextToken': 'string'
The current status of the execution.

- `closeStatus (string)` –
  If the execution status is closed then this specifies how the execution was closed:
  - `COMPLETED`: the execution was successfully completed.
  - `CANCELED`: the execution was canceled. Cancellation allows the implementation to gracefully clean up before the execution is closed.
  - `TERMINATED`: the execution was force terminated.
  - `FAILED`: the execution failed to complete.
  - `TIMED_OUT`: the execution did not complete in the allotted time and was automatically timed out.
  - `CONTINUED_AS_NEW`: the execution is logically continued. This means the current execution was completed and a new execution was started to carry on the workflow.

- `parent (dict)` –
  If this workflow execution is a child of another execution then contains the workflow execution that started this execution.

- `workflowId (string)` –
  The user defined identifier associated with the workflow execution.

- `runId (string)` –
  A system-generated unique identifier for the workflow execution.

- `tagList (list)` –
  The list of tags associated with the workflow execution. Tags can be used to identify and list workflow executions of interest through the visibility APIs. A workflow execution can have a maximum of 5 tags.

- `cancelRequested (boolean)` –
  Set to true if a cancellation is requested for this workflow execution.

- `NextToken (string)` –
  A token to resume pagination.

```python
class SWF.Paginator.ListWorkflowTypes

paginator = client.get_paginator('list_workflow_types')

paginate(**kwargs)

  Creates an iterator that will paginate through responses from SWF.Client.list_workflow_types().

Request Syntax

response_iterator = paginator.paginate(
    domain='string',
    name='string',
    registrationStatus='REGISTERED'|'DEPRECATED',
    reverseOrder=True|False,
)```
PaginationConfig={
    'MaxItems': 123,
    'PageSize': 123,
    'StartingToken': 'string'
}

Parameters

- **domain (string)** – [REQUIRED]
  The name of the domain in which the workflow types have been registered.

- **name (string)** – If specified, lists the workflow type with this name.

- **registrationStatus (string)** – [REQUIRED]
  Specifies the registration status of the workflow types to list.

- **reverseOrder (boolean)** – When set to `true`, returns the results in reverse order. By default the results are returned in ascending alphabetical order of the **name** of the workflow types.

- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize (integer)** –
    The size of each page.
  - **StartingToken (string)** –
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

Return type **dict**

Returns

Response Syntax

```json
{
    'typeInfos': [
        {
            'workflowType': {
                'name': 'string',
                'version': 'string'
            },
            'status': 'REGISTERED'|'DEPRECATED',
            'description': 'string',
            'creationDate': datetime(2015, 1, 1),
            'deprecationDate': datetime(2015, 1, 1)
        },
        {
            'NextToken': 'string'
        }
    ]
}
```

Response Structure

- **(dict)** –
  Contains a paginated list of information structures about workflow types.
  - **typeInfos (list)** –
    The list of workflow type information.
* (dict) –

Contains information about a workflow type.

- **workflowType** (dict) –
  The workflow type this information is about.

- **name** (string) –
  Required. The name of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- **version** (string) –
  Required. The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- **status** (string) –
  The current status of the workflow type.

- **description** (string) –
  The description of the type registered through RegisterWorkflowType.

- **creationDate** (datetime) –
  The date when this type was registered.

- **deprecationDate** (datetime) –
  If the type is in deprecated state, then it is set to the date when the type was deprecated.

- **NextToken** (string) –
  A token to resume pagination.

```python
class SWF.Paginator.PollForDecisionTask

paginator = client.get_paginator('poll_for_decision_task')

paginate(**kwargs)

Creates an iterator that will paginate through responses from SWF.Client.poll_for_decision_task().

Request Syntax
```
```
Parameters

- **domain** (*string*) – [REQUIRED]
  The name of the domain containing the task lists to poll.

- **taskList** (*dict*) – [REQUIRED]
  Specifies the task list to poll for decision tasks.

  The specified string must not start or end with whitespace. It must not contain a colon (:), slash (/), vertical bar (|), or any control characters (u0000-u001f | u007f - u009f). Also, it must not contain the literal string quotarnquot.

  - **name** (*string*) – [REQUIRED]
    The name of the task list.

- **identity** (*string*) – Identity of the decider making the request, which is recorded in the DecisionTaskStarted event in the workflow history. This enables diagnostic tracing when problems arise. The form of this identity is user defined.

- **reverseOrder** (*boolean*) – When set to true, returns the events in reverse order. By default the results are returned in ascending order of the eventTimestamp of the events.

- **PaginationConfig** (*dict*) – A dictionary that provides parameters to control pagination.

  - **MaxItems** (*integer*) – The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

  - **PageSize** (*integer*) – The size of each page.

  - **StartingToken** (*string*) – A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict

Returns

Response Syntax

```python
{
    'taskToken': 'string',

Response Structure

- (dict) –
  A structure that represents a decision task. Decision tasks are sent to deciders in order for them to make decisions.

  - taskToken (string) –
    The opaque string used as a handle on the task. This token is used by workers to communicate progress and response information back to the system about the task.

  - startedEventId (integer) –
    The ID of the DecisionTaskStarted event recorded in the history.

  - workflowExecution (dict) –
    The workflow execution for which this decision task was created.
      * workflowId (string) –
        The user defined identifier associated with the workflow execution.
      * runId (string) –
        A system-generated unique identifier for the workflow execution.

  - workflowType (dict) –
    The type of the workflow execution for which this decision task was created.
      * name (string) –
        Required. The name of the workflow type.
      * version (string) –
        Required. The version of the workflow type.

        Note: The combination of workflow type name and version must be unique with in a domain.

  - events (list) –
    A paginated list of history events of the workflow execution. The decider uses this during the processing of the decision task.
      * (dict) –
        Event within a workflow execution. A history event can be one of these types:
          · WorkflowExecutionStarted: The workflow execution was started.
          · WorkflowExecutionCompleted: The workflow execution was closed due to successful completion.
· `WorkflowExecutionFailed`: The workflow execution closed due to a failure.
· `WorkflowExecutionTimedOut`: The workflow execution was closed because a time out was exceeded.
· `WorkflowExecutionCanceled`: The workflow execution was successfully canceled and closed.
· `WorkflowExecutionTerminated`: The workflow execution was terminated.
· `WorkflowExecution ContinuedAsNew`: The workflow execution was closed and a new execution of the same type was created with the same workflowId.
· `WorkflowExecutionCancelRequested`: A request to cancel this workflow execution was made.
· `DecisionTaskScheduled`: A decision task was scheduled for the workflow execution.
· `DecisionTaskStarted`: The decision task was dispatched to a decider.
· `DecisionTaskCompleted`: The decider successfully completed a decision task by calling `RespondDecisionTaskCompleted`.
· `DecisionTaskTimedOut`: The decision task timed out.
· `ActivityTaskScheduled`: An activity task was scheduled for execution.
· `ScheduleActivityTaskFailed`: Failed to process `ScheduleActivityTask` decision. This happens when the decision is not configured properly, for example the activity type specified is not registered.
· `ActivityTaskStarted`: The scheduled activity task was dispatched to a worker.
· `ActivityTaskCompleted`: An activity worker successfully completed an activity task by calling `RespondActivityTaskCompleted`.
· `ActivityTaskFailed`: An activity worker failed an activity task by calling `RespondActivityTaskFailed`.
· `ActivityTaskTimedOut`: The activity task timed out.
· `ActivityTaskCanceled`: The activity task was successfully canceled.
· `ActivityTaskCancelRequested`: A `RequestCancelActivityTask` decision was received by the system.
· `RequestCancelActivityTaskFailed`: Failed to process `RequestCancelActivityTask` decision. This happens when the decision is not configured properly.
· `WorkflowExecutionSignaled`: An external signal was received for the workflow execution.
· `MarkerRecorded`: A marker was recorded in the workflow history as the result of a `RecordMarker` decision.
· `TimerStarted`: A timer was started for the workflow execution due to a `StartTimer` decision.
· `StartTimerFailed`: Failed to process `StartTimer` decision. This happens when the decision is not configured properly, for example a timer already exists with the specified timer ID.
· `TimerFired`: A timer, previously started for this workflow execution, fired.
· TimerCanceled: A timer, previously started for this workflow execution, was successfully canceled.
· CancelTimerFailed: Failed to process CancelTimer decision. This happens when the decision is not configured properly, for example no timer exists with the specified timer ID.
· StartChildWorkflowExecutionInitiated: A request was made to start a child workflow execution.
· StartChildWorkflowExecutionFailed: Failed to process StartChildWorkflowExecution decision. This happens when the decision is not configured properly, for example the workflow type specified is not registered.
· ChildWorkflowExecutionStarted: A child workflow execution was successfully started.
· ChildWorkflowExecutionCompleted: A child workflow execution, started by this workflow execution, completed successfully and was closed.
· ChildWorkflowExecutionFailed: A child workflow execution, started by this workflow execution, failed to complete successfully and was closed.
· ChildWorkflowExecutionTimedOut: A child workflow execution, started by this workflow execution, timed out and was closed.
· ChildWorkflowExecutionCanceled: A child workflow execution, started by this workflow execution, was canceled and closed.
· ChildWorkflowExecutionTerminated: A child workflow execution, started by this workflow execution, was terminated.
· SignalExternalWorkflowExecutionInitiated: A request to signal an external workflow was made.
· ExternalWorkflowExecutionSignaled: A signal, requested by this workflow execution, was successfully delivered to the target external workflow execution.
· SignalExternalWorkflowExecutionFailed: The request to signal an external workflow execution failed.
· RequestCancelExternalWorkflowExecutionInitiated: A request was made to request the cancellation of an external workflow execution.
· ExternalWorkflowExecutionCancelRequested: Request to cancel an external workflow execution was successfully delivered to the target execution.
· RequestCancelExternalWorkflowExecutionFailed: Request to cancel an external workflow execution failed.
· LambdaFunctionScheduled: An AWS Lambda function was scheduled for execution.
· LambdaFunctionStarted: The scheduled function was invoked in the AWS Lambda service.
· LambdaFunctionCompleted: The AWS Lambda function successfully completed.
· LambdaFunctionFailed: The AWS Lambda function execution failed.
· LambdaFunctionTimedOut: The AWS Lambda function execution timed out.
· ScheduleLambdaFunctionFailed: Failed to process Sched-
uleLambdaFunction decision. This happens when the workflow execution does not have the proper IAM role attached to invoke AWS Lambda functions.

- **StartLambdaFunctionFailed**: Failed to invoke the scheduled function in the AWS Lambda service. This happens when the AWS Lambda service is not available in the current region, or received too many requests.

- **eventTimestamp** (*datetime*) –
  The date and time when the event occurred.

- **eventType** (*string*) –
  The type of the history event.

- **eventId** (*integer*) –
  The system generated ID of the event. This ID uniquely identifies the event with in the workflow execution history.

- **workflowExecutionStartedEventAttributes** (*dict*) –
  If the event is of type `WorkflowExecutionStarted` then this member is set and provides detailed information about the event. It is not set for other event types.

- **input** (*string*) –
  The input provided to the workflow execution (if any).

- **executionStartToCloseTimeout** (*string*) –
  The maximum duration for this workflow execution.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **taskStartToCloseTimeout** (*string*) –
  The maximum duration of decision tasks for this workflow type.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **childPolicy** (*string*) –
  The policy to use for the child workflow executions if this workflow execution is terminated, by calling the Terminate-WorkflowExecution action explicitly or due to an expired timeout.

  The supported child policies are:
  - **TERMINATE**: the child executions will be terminated.
  - **REQUEST_CANCEL**: a request to cancel will be attempted for each child execution by recording a `WorkflowExecutionCancelRequested` event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
  - **ABANDON**: no action will be taken. The child executions will continue to run.

- **taskList** (*dict*) –
The name of the task list for scheduling the decision tasks for this workflow execution.

- **name (string)** –
  The name of the task list.

- **workflowType (dict)** –
  The workflow type of this execution.
  - **name (string)** –
    Required. The name of the workflow type.
  - **version (string)** –
    Required. The version of the workflow type.
    
    **Note:** The combination of workflow type name and version must be unique within a domain.

- **tagList (list)** –
  The list of tags associated with this workflow execution. An execution can have up to 5 tags.
  - (string) –
  - **taskPriority (string)** –
  - **continuedExecutionRunId (string)** –

    If this workflow execution was started due to a ContinueAsNewWorkflowExecution decision, then it contains the runId of the previous workflow execution that was closed and continued as this execution.

- **parentWorkflowExecution (dict)** –
  The source workflow execution that started this workflow execution. The member is not set if the workflow execution was not started by a workflow.
  - **workflowId (string)** –
  - **runId (string)** –
    A system-generated unique identifier for the workflow execution.
  - **parentInitiatedEventId (integer)** –
    The ID of the StartChildWorkflowExecutionInitiated event corresponding to the StartChildWorkflowExecution decision to start this workflow execution. The source event with this ID can be found in the history of the source workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
  - **lambdaRole (string)** –
    The IAM role attached to this workflow execution to use when invoking AWS Lambda functions.
- workflowExecutionCompletedEventAttributes (dict) –
  If the event is of type WorkflowExecutionCompleted then this member is set and provides detailed information about the event. It is not set for other event types.
- result (string) –
  The result produced by the workflow execution upon successful completion.
- decisionTaskCompletedEventId (integer) –
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the CompleteWorkflowExecution decision to complete this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
- completeWorkflowExecutionFailedEventAttributes (dict) –
  If the event is of type CompleteWorkflowExecutionFailed then this member is set and provides detailed information about the event. It is not set for other event types.
- cause (string) –
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.
- decisionTaskCompletedEventId (integer) –
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the CompleteWorkflowExecution decision to complete this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
- workflowExecutionFailedEventAttributes (dict) –
  If the event is of type WorkflowExecutionFailed then this member is set and provides detailed information about the event. It is not set for other event types.
- reason (string) –
  The descriptive reason provided for the failure (if any).
- details (string) –
  The details of the failure (if any).
- decisionTaskCompletedEventId (integer) –
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the FailWorkflowExecution decision to fail this execution. This information can be useful for diagnosing problems.
by tracing back the chain of events leading up to this event.

- **failWorkflowExecutionFailedEventAttributes**(dict) –

  If the event is of type FailWorkflowExecutionFailed then this member is set and provides detailed information about the event. It is not set for other event types.

- **cause**(string) –

  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If cause is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId**(integer) –

  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the FailWorkflowExecution decision to fail this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **workflowExecutionTimedOutEventAttributes**(dict) –

  If the event is of type WorkflowExecutionTimedOut then this member is set and provides detailed information about the event. It is not set for other event types.

- **timeoutType**(string) –

  The type of timeout that caused this event.

- **childPolicy**(string) –

  The policy used for the child workflow executions of this workflow execution.

  The supported child policies are:

  - **TERMINATE:** the child executions will be terminated.
  - **REQUEST_CANCEL:** a request to cancel will be attempted for each child execution by recording a WorkflowExecutionCancelRequested event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
  - **ABANDON:** no action will be taken. The child executions will continue to run.

- **workflowExecutionCanceledEventAttributes**(dict) –

  If the event is of type WorkflowExecutionCanceled then this member is set and provides detailed information about the event. It is not set for other event types.

- **details**(string) –

  Details for the cancellation (if any).

- **decisionTaskCompletedEventId**(integer) –

  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the CancelWorkflowExecution decision for this cancella-
tion request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **cancelWorkflowExecutionFailedEventAttributes** *(dict)*
  
  If the event is of type `CancelWorkflowExecutionFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

- **cause** *(string)*
  
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see [Using IAM to Manage Access to Amazon SWF Workflows](#).

- **decisionTaskCompletedEventId** *(integer)*
  
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `CancelWorkflowExecution` decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **workflowExecutionContinuedAsNewEventAttributes** *(dict)*
  
  If the event is of type `WorkflowExecutionContinuedAsNew` then this member is set and provides detailed information about the event. It is not set for other event types.

- **input** *(string)*
  
  The input provided to the new workflow execution.

- **decisionTaskCompletedEventId** *(integer)*
  
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `ContinueAsNewWorkflowExecution` decision that started this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **newExecutionRunId** *(string)*
  
  The runId of the new workflow execution.

- **executionStartToCloseTimeout** *(string)*
  
  The total duration allowed for the new workflow execution. The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **taskList** *(dict)*
  
  Represents a task list.
The name of the task list.

- **taskPriority** *(string)* –
- **taskStartToCloseTimeout** *(string)* –

The maximum duration of decision tasks for the new workflow execution.

The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **childPolicy** *(string)* –

The policy to use for the child workflow executions of the new execution if it is terminated by calling the TerminateWorkflowExecution action explicitly or due to an expired timeout.

The supported child policies are:

- **TERMINATE**: the child executions will be terminated.
- **REQUEST_CANCEL**: a request to cancel will be attempted for each child execution by recording a WorkflowExecutionCancelRequested event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
- **ABANDON**: no action will be taken. The child executions will continue to run.

- **tagList** *(list)* –

The list of tags associated with the new workflow execution.

- **workflowType** *(dict)* –

Represents a workflow type.

- **name** *(string)* –

**Required.** The name of the workflow type.

---

**Note:** The combination of workflow type name and version must be unique within a domain.

- **version** *(string)* –

**Required.** The version of the workflow type.

---

**Note:** The combination of workflow type name and version must be unique within a domain.

- **lambdaRole** *(string)* –

The IAM role attached to this workflow execution to use when invoking AWS Lambda functions.

- **continueAsNewWorkflowExecutionFailedEventAttributes** *(dict)* –

If the event is of type ContinueAsNewWorkflowExecutionFailed then this member is set and provides detailed information about the event. It is not set for other event types.

- **cause** *(string)* –
The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

**Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId** *(integer)* –

  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `ContinueAsNewWorkflowExecution` decision that started this execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **workflowExecutionTerminatedEventAttributes** *(dict)* –

  If the event is of type `WorkflowExecutionTerminated` then this member is set and provides detailed information about the event. It is not set for other event types.

  - **reason** *(string)* –

    The reason provided for the termination (if any).

  - **details** *(string)* –

    The details provided for the termination (if any).

  - **childPolicy** *(string)* –

    The policy used for the child workflow executions of this workflow execution.

    The supported child policies are:

    - **TERMINATE**: the child executions will be terminated.
    - **REQUEST_CANCEL**: a request to cancel will be attempted for each child execution by recording a `_workflowExecutionCancelRequested` event in its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.
    - **ABANDON**: no action will be taken. The child executions will continue to run.

  - **cause** *(string)* –

    If set, indicates that the workflow execution was automatically terminated, and specifies the cause. This happens if the parent workflow execution times out or is terminated and the child policy is set to terminate child executions.

  - **workflowExecutionCancelRequestedEventAttributes** *(dict)* –

    If the event is of type `WorkflowExecutionCancelRequested` then this member is set and provides detailed information about the event. It is not set for other event types.

  - **externalWorkflowExecution** *(dict)* –

    The external workflow execution for which the cancellation was requested.
- **workflowId (string)**
  The user defined identifier associated with the workflow execution.

- **runId (string)**
  A system-generated unique identifier for the workflow execution.

- **externalInitiatedEventId (integer)**
  The ID of the `RequestCancelExternalWorkflowExecutionInitiated` event corresponding to the `RequestCancelExternalWorkflowExecution` decision to cancel this workflow execution. The source event with this ID can be found in the history of the source workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **cause (string)**
  If set, indicates that the request to cancel the workflow execution was automatically generated, and specifies the cause. This happens if the parent workflow execution times out or is terminated, and the child policy is set to cancel child executions.

- **decisionTaskScheduledEventAttributes (dict)**
  If the event is of type `DecisionTaskScheduled` then this member is set and provides detailed information about the event. It is not set for other event types.

  - **taskList (dict)**
    The name of the task list in which the decision task was scheduled.

    - **name (string)**
      The name of the task list.

    - **taskPriority (string)**
      Optional. A task priority that, if set, specifies the priority for this decision task. Valid values are integers that range from Java's `Integer.MIN_VALUE` (-2147483648) to `Integer.MAX_VALUE` (2147483647). Higher numbers indicate higher priority.

      For more information about setting task priority, see Setting Task Priority in the *Amazon Simple Workflow Developer Guide*.

    - **startToCloseTimeout (string)**
      The maximum duration for this decision task. The task is considered timed out if it does not completed within this duration.

      The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **decisionTaskStartedEventAttributes (dict)**
  If the event is of type `DecisionTaskStarted` then this member is set and provides detailed information about the decision task.

- **decisionTaskCompletedEventAttributes (dict)**
  If the event is of type `DecisionTaskCompleted` then this member is set and provides detailed information about the decision task.
event. It is not set for other event types.

- **identity (string)** –

  Identity of the decider making the request. This enables diagnostic tracing when problems arise. The form of this identity is user defined.

- **scheduledEventId (integer)** –

  The ID of the DecisionTaskScheduled event that was recorded when this decision task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **decisionTaskCompletedEventAttributes (dict)** –

  If the event is of type DecisionTaskCompleted then this member is set and provides detailed information about the event. It is not set for other event types.

- **executionContext (string)** –

  User defined context for the workflow execution.

- **scheduledEventId (integer)** –

  The ID of the DecisionTaskScheduled event that was recorded when this decision task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –

  The ID of the DecisionTaskStarted event recorded when this decision task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **decisionTaskTimedOutEventAttributes (dict)** –

  If the event is of type DecisionTaskTimedOut then this member is set and provides detailed information about the event. It is not set for other event types.

- **timeoutType (string)** –

  The type of timeout that expired before the decision task could be completed.

- **scheduledEventId (integer)** –

  The ID of the DecisionTaskScheduled event that was recorded when this decision task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –

  The ID of the DecisionTaskStarted event recorded when this decision task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityTaskScheduledEventAttributes (dict)** –

  If the event is of type ActivityTaskScheduled then this member is set and provides detailed information about the event. It is not set for other event types.
The type of the activity task.

- **name (string)** –
  The name of this activity.

**Note:** The combination of activity type name and version must be unique within a domain.

- **version (string)** –
  The version of this activity.

**Note:** The combination of activity type name and version must be unique within a domain.

- **activityId (string)** –
  The unique ID of the activity task.

- **input (string)** –
  The input provided to the activity task.

- **control (string)** –
  Optional. Data attached to the event that can be used by the decider in subsequent workflow tasks. This data is not sent to the activity.

- **scheduleToStartTimeout (string)** –
  The maximum amount of time the activity task can wait to be assigned to a worker.

- **scheduleToCloseTimeout (string)** –
  The maximum amount of time for this activity task.

- **startToCloseTimeout (string)** –
  The maximum amount of time a worker may take to process the activity task.

- **taskList (dict)** –
  The task list in which the activity task has been scheduled.

  - **name (string)** –
    The name of the task list.

  - **taskPriority (string)** –
    Optional. The priority to assign to the scheduled activity task. If set, this will override any default priority value that was assigned when the activity type was registered.

    Valid values are integers that range from Java’s `Integer.MIN_VALUE` (-2147483648) to `Integer.MAX_VALUE` (2147483647). Higher numbers indicate higher priority.

    For more information about setting task priority, see Setting Task Priority in the Amazon Simple Workflow Developer Guide.

- **decisionTaskCompletedEventId (integer)** –
  The ID of the DecisionTaskCompleted event corresponding to the decision that resulted in the scheduling of this activity task. This information can be useful for diagnosing
problems by tracing back the chain of events leading up to this event.

- **heartbeatTimeout (string)** –
  
The maximum time before which the worker processing this task must report progress by calling RecordActivityTaskHeartbeat. If the timeout is exceeded, the activity task is automatically timed out. If the worker subsequently attempts to record a heartbeat or return a result, it will be ignored.

- **activityTaskStartedEventAttributes (dict)** –
  
  If the event is of type ActivityTaskStarted then this member is set and provides detailed information about the event. It is not set for other event types.

- **identity (string)** –
  
  Identity of the worker that was assigned this task. This aids diagnostics when problems arise. The form of this identity is user defined.

- **scheduledEventId (integer)** –
  
  The ID of the ActivityTaskScheduled event that was recorded when this activity task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityTaskCompletedEventAttributes (dict)** –
  
  If the event is of type ActivityTaskCompleted then this member is set and provides detailed information about the event. It is not set for other event types.

- **result (string)** –
  
  The results of the activity task (if any).

- **scheduledEventId (integer)** –
  
  The ID of the ActivityTaskScheduled event that was recorded when this activity task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –
  
  The ID of the ActivityTaskStarted event recorded when this activity task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityTaskFailedEventAttributes (dict)** –
  
  If the event is of type ActivityTaskFailed then this member is set and provides detailed information about the event. It is not set for other event types.

- **reason (string)** –
  
  The reason provided for the failure (if any).

- **details (string)** –
  
  The details of the failure (if any).

- **scheduledEventId (integer)** –
  
  The ID of the ActivityTaskScheduled event that was recorded when this activity task was scheduled. This infor-
mation can be useful for diagnosing problems by tracing back
the chain of events leading up to this event.

- **startedEventId (integer)** –
  The ID of the ActivityTaskStarted event recorded when this activity task was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityTaskTimedOutEventAttributes (dict)** –
  If the event is of type ActivityTaskTimedOut then this member is set and provides detailed information about the event. It is not set for other event types.

- **details (string)** –
  The type of the timeout that caused this event.

- **startedEventId (integer)** –
  The ID of the ActivityTaskScheduled event that was recorded when this activity task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityTaskCanceledEventAttributes (dict)** –
  If the event is of type ActivityTaskCanceled then this member is set and provides detailed information about the event. It is not set for other event types.

- **details (string)** –
  Details of the cancellation (if any).

- **scheduledEventId (integer)** –
  The ID of the ActivityTaskScheduled event that was recorded when this activity task was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **latestCancelRequestedEventId (integer)** –
  If set, contains the ID of the last ActivityTaskCancelRequested event recorded for this activity task. This information can be useful for
diagnosing problems by tracing back the chain of events leading up to this event.

- **activityTaskCancelRequestedEventAttributes (dict)**
  
  If the event is of type `ActivityTaskCancelRequested` then this member is set and provides detailed information about the event. It is not set for other event types.

- **decisionTaskCompletedEventId (integer)**
  
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `RequestCancelActivityTask` decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **activityId (string)**

- **workflowExecutionSignaledEventAttributes (dict)**
  
  If the event is of type `WorkflowExecutionSignaled` then this member is set and provides detailed information about the event. It is not set for other event types.

- **signalName (string)**
  
  The name of the signal received. The decider can use the signal name and inputs to determine how to process the signal.

- **input (string)**
  
  Inputs provided with the signal (if any). The decider can use the signal name and inputs to determine how to process the signal.

- **externalWorkflowExecution (dict)**
  
  The workflow execution that sent the signal. This is set only if the signal was sent by another workflow execution.

- **workflowId (string)**
  
  The user defined identifier associated with the workflow execution.

- **runId (string)**
  
  A system-generated unique identifier for the workflow execution.

- **externalInitiatedEventId (integer)**
  
  The ID of the `SignalExternalWorkflowExecutionInitiated` event corresponding to the `SignalExternalWorkflow` decision to signal this workflow execution. The source event with this ID can be found in the history of the source workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event. This field is set only if the signal was initiated by another workflow execution.

- **markerRecordedEventAttributes (dict)**
  
  If the event is of type `MarkerRecorded` then this member
is set and provides detailed information about the event. It is not set for other event types.

- **markerName** *(string)* –
  The name of the marker.
- **details** *(string)* –
  Details of the marker (if any).
- **decisionTaskCompletedEventId** *(integer)* –
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the RecordMarker decision that requested this marker. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **recordMarkerFailedEventAttributes** *(dict)* –
  If the event is of type DecisionTaskFailed then this member is set and provides detailed information about the event. It is not set for other event types.
  - **markerName** *(string)* –
    The marker’s name.
  - **cause** *(string)* –
    The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If **cause** is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId** *(integer)* –
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the RecordMarkerFailed decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **timerStartedEventAttributes** *(dict)* –
  If the event is of type TimerStarted then this member is set and provides detailed information about the event. It is not set for other event types.
  - **timerId** *(string)* –
    The unique ID of the timer that was started.
  - **control** *(string)* –
    *Optional.* Data attached to the event that can be used by the decider in subsequent workflow tasks.
  - **startToFireTimeout** *(string)* –
    The duration of time after which the timer will fire.
    The duration is specified in seconds; an integer greater than or equal to 0.

- **decisionTaskCompletedEventId** *(integer)* –
The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `StartTimer` decision for this activity task. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **`timerFiredEventAttributes (dict)`**
  If the event is of type `TimerFired` then this member is set and provides detailed information about the event. It is not set for other event types.
  - **`timerId (string)`**
    The unique ID of the timer that fired.
  - **`startedEventId (integer)`**
    The ID of the `TimerStarted` event that was recorded when this timer was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **`timerCanceledEventAttributes (dict)`**
  If the event is of type `TimerCanceled` then this member is set and provides detailed information about the event. It is not set for other event types.
  - **`timerId (string)`**
    The unique ID of the timer that was canceled.
  - **`startedEventId (integer)`**
    The ID of the `TimerStarted` event that was recorded when this timer was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **`decisionTaskCompletedEventId (integer)`**
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `CancelTimer` decision to cancel this timer. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **`startChildWorkflowExecutionInitiatedEventAttributes (dict)`**
  If the event is of type `StartChildWorkflowExecutionInitiated` then this member is set and provides detailed information about the event. It is not set for other event types.
  - **`workflowId (string)`**
    The `workflowId` of the child workflow execution.
  - **`workflowType (dict)`**
    The type of the child workflow execution.
  - **`name (string)`**
    Required. The name of the workflow type.

**Note:** The combination of workflow type name and version must be unique with in a domain.
- **version** *(string)* –

  **Required.** The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique with in a domain.

- **control** *(string)* –

  **Optional.** Data attached to the event that can be used by the decider in subsequent decision tasks. This data is not sent to the activity.

- **input** *(string)* –

  The inputs provided to the child workflow execution (if any).

- **executionStartToCloseTimeout** *(string)* –

  The maximum duration for the child workflow execution. If the workflow execution is not closed within this duration, it will be timed out and force terminated.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **taskList** *(dict)* –

  The name of the task list used for the decision tasks of the child workflow execution.

- **name** *(string)* –

  The name of the task list.

- **taskPriority** *(string)* –

  **Optional.** The priority assigned for the decision tasks for this workflow execution. Valid values are integers that range from Java's `Integer.MIN_VALUE` (-2147483648) to `Integer.MAX_VALUE` (2147483647). Higher numbers indicate higher priority.

  For more information about setting task priority, see Setting Task Priority in the Amazon Simple Workflow Developer Guide.

- **decisionTaskCompletedEventId** *(integer)* –

  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the StartChildWorkflowExecution decision to request this child workflow execution. This information can be useful for diagnosing problems by tracing back the cause of events.

- **childPolicy** *(string)* –

  The policy to use for the child workflow executions if this execution gets terminated by explicitly calling the TerminateWorkflowExecution action or due to an expired timeout.

  The supported child policies are:

  - **TERMINATE:** the child executions will be terminated.
  - **REQUEST_CANCEL:** a request to cancel will be attempted for each child execution by recording a WorkflowExecutionCancelRequested event in
its history. It is up to the decider to take appropriate actions when it receives an execution history with this event.

- **ABANDON**: no action will be taken. The child executions will continue to run.

- **taskStartToCloseTimeout** *(string)*

  The maximum duration allowed for the decision tasks for this workflow execution.

  The duration is specified in seconds; an integer greater than or equal to 0. The value “NONE” can be used to specify unlimited duration.

- **tagList** *(list)*

  The list of tags to associated with the child workflow execution.

- **lambdaRole** *(string)*

  The IAM role attached to this workflow execution to use when invoking AWS Lambda functions.

- **childWorkflowExecutionStartedEventAttributes** *(dict)*

  If the event is of type `ChildWorkflowExecutionStarted` then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowExecution** *(dict)*

  The child workflow execution that was started.

- **workflowId** *(string)*

  The user defined identifier associated with the workflow execution.

- **runId** *(string)*

  A system-generated unique identifier for the workflow execution.

- **workflowType** *(dict)*

  The type of the child workflow execution.

- **name** *(string)*

  Required. The name of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- **version** *(string)*

  Required. The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- **initiatedEventId** *(integer)*

  The ID of the `StartChildWorkflowExecutionInitiated` event corresponding to the `StartChildWorkflowExecution` decision to start this child workflow execution. This information can be useful...
for diagnosing problems by tracing back the chain of events leading up to this event.

- **childWorkflowExecutionCompletedEventAttributes (dict)**

  If the event is of type ChildWorkflowExecutionCompleted then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowExecution (dict)**

  The child workflow execution that was completed.

  - **workflowId (string)**

    The user defined identifier associated with the workflow execution.

  - **runId (string)**

    A system-generated unique identifier for the workflow execution.

  - **workflowType (dict)**

    The type of the child workflow execution.

    - **name (string)**

      Required. The name of the workflow type.

      Note: The combination of workflow type name and version must be unique with in a domain.

  - **version (string)**

    Required. The version of the workflow type.

      Note: The combination of workflow type name and version must be unique with in a domain.

  - **result (string)**

    The result of the child workflow execution (if any).

  - **initiatedEventId (integer)**

    The ID of the StartChildWorkflowExecutionInitiated event corresponding to the StartChildWorkflowExecution decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

  - **startedEventId (integer)**

    The ID of the ChildWorkflowExecutionStarted event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **childWorkflowExecutionFailedEventAttributes (dict)**

  If the event is of type ChildWorkflowExecutionFailed then this member
is set and provides detailed information about the event. It is not set for other event types.

- workflowExecution (dict) –
  The child workflow execution that failed.

- workflowId (string) –
  The user defined identifier associated with the workflow execution.

- runId (string) –
  A system-generated unique identifier for the workflow execution.

- workflowType (dict) –
  The type of the child workflow execution.

  - name (string) –
    Required. The name of the workflow type.

  - version (string) –
    Required. The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique with in a domain.

- reason (string) –
  The reason for the failure (if provided).

- details (string) –
  The details of the failure (if provided).

- initiatedEventId (integer) –
  The ID of the StartChildWorkflowExecutionInitiated event corresponding to the StartChildWorkflowExecution decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- startedEventId (integer) –
  The ID of the ChildWorkflowExecutionStarted event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- childWorkflowExecutionTimedOutEventAttributes (dict) –
  If the event is of type ChildWorkflowExecutionTimedOut then this member is set and provides detailed information about the event. It is not set for other event types.

- workflowExecution (dict) –
  The child workflow execution that timed out.
- **workflowId** *(string)* –
  The user defined identifier associated with the workflow execution.
- **runId** *(string)* –
  A system-generated unique identifier for the workflow execution.
- **workflowType** *(dict)* –
  The type of the child workflow execution.
  - **name** *(string)* –
    Required. The name of the workflow type.
    
    **Note:** The combination of workflow type name and version must be unique with in a domain.
  - **version** *(string)* –
    Required. The version of the workflow type.
    
    **Note:** The combination of workflow type name and version must be unique with in a domain.
- **timeoutType** *(string)* –
  The type of the timeout that caused the child workflow execution to time out.
- **initiatedEventId** *(integer)* –
  The ID of the `StartChildWorkflowExecutionInitiated` event corresponding to the `StartChildWorkflowExecution` decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
- **startedEventId** *(integer)* –
  The ID of the `ChildWorkflowExecutionStarted` event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.
- **childWorkflowExecutionCanceledEventAttributes** *(dict)* –
  If the event is of type `ChildWorkflowExecutionCanceled` then this member is set and provides detailed information about the event. It is not set for other event types.
- **workflowExecution** *(dict)* –
  The child workflow execution that was canceled.
  - **workflowId** *(string)* –
    The user defined identifier associated with the workflow execution.
  - **runId** *(string)* –
    A system-generated unique identifier for the workflow execution.
- **workflowType** *(dict)* –  
  The type of the child workflow execution.

- **name** *(string)* –  
  **Required.** The name of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- **version** *(string)* –  
  **Required.** The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.

- **details** *(string)* –  
  Details of the cancellation (if provided).

- **initiatedEventId** *(integer)* –  
  The ID of the `StartChildWorkflowExecutionInitiated` event corresponding to the `StartChildWorkflowExecution` decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId** *(integer)* –  
  The ID of the `ChildWorkflowExecutionStarted` event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **childWorkflowExecutionTerminatedEventAttributes** *(dict)* –  
  If the event is of type `ChildWorkflowExecutionTerminated` then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowExecution** *(dict)* –  
  The child workflow execution that was terminated.

- **workflowId** *(string)* –  
  The user-defined identifier associated with the workflow execution.

- **runId** *(string)* –  
  A system-generated unique identifier for the workflow execution.

- **workflowType** *(dict)* –  
  The type of the child workflow execution.

- **name** *(string)* –  
  **Required.** The name of the workflow type.

  **Note:** The combination of workflow type name and version must be unique within a domain.
must be unique with in a domain.

- **version (string)** –
  
  Required. The version of the workflow type.

Note: The combination of workflow type name and version must be unique with in a domain.

- **initiatedEventId (integer)** –
  
  The ID of the StartChildWorkflowExecutionInitiated event corresponding to the StartChildWorkflowExecution decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –
  
  The ID of the ChildWorkflowExecutionStarted event recorded when this child workflow execution was started. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **signalExternalWorkflowExecutionInitiatedEventAttributes (dict)** –
  
  If the event is of type SignalExternalWorkflowExecutionInitiated then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowId (string)** –
  
  The workflowId of the external workflow execution.

- **runId (string)** –
  
  The runId of the external workflow execution to send the signal to.

- **signalName (string)** –
  
  The name of the signal.

- **input (string)** –
  
  Input provided to the signal (if any).

- **decisionTaskCompletedEventId (integer)** –
  
  The ID of the DecisionTaskCompleted event corresponding to the decision task that resulted in the SignalExternalWorkflowExecution decision for this signal. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **control (string)** –
  
  Optional. data attached to the event that can be used by the decider in subsequent decision tasks.

- **externalWorkflowExecutionSignaledEventAttributes (dict)** –
  
  If the event is of type
ExternalWorkflowExecutionSignaled then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowExecution** *(dict)* –
  
  The external workflow execution that the signal was delivered to.

- **workflowId** *(string)* –
  
  The user defined identifier associated with the workflow execution.

- **runId** *(string)* –
  
  A system-generated unique identifier for the workflow execution.

- **initiatedEventId** *(integer)* –
  
  The ID of the SignalExternalWorkflowExecutionInitiated event corresponding to the SignalExternalWorkflowExecution decision to request this signal. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **signalExternalWorkflowExecutionFailedEventAttributes** *(dict)* –
  
  If the event is of type SignalExternalWorkflowExecutionFailed then this member is set and provides detailed information about the event. It is not set for other event types.

  - **workflowId** *(string)* –
    
    The workflowId of the external workflow execution that the signal was being delivered to.

  - **runId** *(string)* –
    
    The runId of the external workflow execution that the signal was being delivered to.

  - **cause** *(string)* –
    
    The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If cause is set to OPERATION_NOT_PERMITTED, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **initiatedEventId** *(integer)* –
  
  The ID of the SignalExternalWorkflowExecutionInitiated event corresponding to the SignalExternalWorkflowExecution decision to request this signal. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **decisionTaskCompletedEventId** *(integer)* –
  
  The ID of the DecisionTaskCompleted event cor-
responding to the decision task that resulted in the `signalExternalWorkflowExecution` decision for this signal. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **control (string)**

- **externalWorkflowExecutionCancelRequestedEventAttributes (dict)**

  - If the event is of type `ExternalWorkflowExecutionCancelRequested` then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowExecution (dict)**

  The external workflow execution to which the cancellation request was delivered.

- **workflowId (string)**

  - The user defined identifier associated with the workflow execution.

- **runId (string)**

  A system-generated unique identifier for the workflow execution.

- **initiatedEventId (integer)**

  - The ID of the `RequestCancelExternalWorkflowExecutionInitiated` event corresponding to the `RequestCancelExternalWorkflowExecution` decision to cancel this external workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **requestCancelExternalWorkflowExecutionInitiatedEventAttributes (dict)**

  - If the event is of type `RequestCancelExternalWorkflowExecutionInitiated` then this member is set and provides detailed information about the event. It is not set for other event types.

- **workflowId (string)**

  - The `workflowId` of the external workflow execution to be canceled.

- **runId (string)**

  - The `runId` of the external workflow execution to be canceled.

- **decisionTaskCompletedEventId (integer)**

  - The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `RequestCancelExternalWorkflowExecution` decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **control (string)**
Optional. Data attached to the event that can be used by the decider in subsequent workflow tasks.

- **requestCancelExternalWorkflowExecutionFailedEventAttributes (dict)**

  If the event is of type `RequestCancelExternalWorkflowExecutionFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

  - **workflowId (string)**
    
    The `workflowId` of the external workflow to which the cancel request was to be delivered.
  
  - **runId (string)**
    
    The `runId` of the external workflow execution.
  
  - **cause (string)**
    
    The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

    **Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

  - **initiatedEventId (integer)**
    
    The ID of the `RequestCancelExternalWorkflowExecutionInitiated` event corresponding to the `RequestCancelExternalWorkflowExecution` decision to cancel this external workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

  - **decisionTaskCompletedEventId (integer)**
    
    The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `RequestCancelExternalWorkflowExecution` decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

  - **control (string)**

  - **scheduleActivityTaskFailedEventAttributes (dict)**

    If the event is of type `ScheduleActivityTaskFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

    - **activityType (dict)**
      
      The activity type provided in the `ScheduleActivityTask` decision that failed.

    - **name (string)**
      
      The name of this activity.

    **Note:** The combination of activity type name and version must be unique within a domain.
· **version** *(string)* –
  The version of this activity.

**Note:** The combination of activity type name and version must be unique with in a domain.

· **activityId** *(string)* –
  The activityId provided in the `ScheduleActivityTask` decision that failed.

· **cause** *(string)* –
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

**Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

· **decisionTaskCompletedEventId** *(integer)* –
  The ID of the `DecisionTaskCompleted` event corresponding to the decision that resulted in the scheduling of this activity task. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· **requestCancelActivityTaskFailedEventAttributes** *(dict)* –
  If the event is of type `RequestCancelActivityTaskFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

· **activityId** *(string)* –
  The activityId provided in the `RequestCancelActivityTask` decision that failed.

· **cause** *(string)* –
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

**Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

· **decisionTaskCompletedEventId** *(integer)* –
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `RequestCancelActivityTask` decision for this cancellation request. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

· **startTimerFailedEventAttributes** *(dict)* –
  If the event is of type `StartTimerFailed` then this mem-
ber is set and provides detailed information about the event. It is not set for other event types.

- **timerId (string)** –
  
The timerId provided in the `StartTimer` decision that failed.

- **cause (string)** –
  
The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

Note: If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId (integer)** –
  
The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `StartTimer` decision for this activity task. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **cancelTimerFailedEventAttributes (dict)** –
  
  If the event is of type `CancelTimerFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

  - **timerId (string)** –
    
The timerId provided in the `CancelTimer` decision that failed.

  - **cause (string)** –
    
The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  Note: If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **decisionTaskCompletedEventId (integer)** –
  
The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `CancelTimer` decision to cancel this timer. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startChildWorkflowExecutionFailedEventAttributes (dict)** –
  
  If the event is of type `StartChildWorkflowExecutionFailed` then this member is set and provides detailed information about the event. It is not set for other event types.

  - **workflowType (dict)** –
    
The workflow type provided in the
StartChildWorkflowExecution decision that failed.

- **name** *(string)* –
  Required. The name of the workflow type.

  **Note:** The combination of workflow type name and version must be unique with in a domain.

- **version** *(string)* –
  Required. The version of the workflow type.

  **Note:** The combination of workflow type name and version must be unique with in a domain.

- **cause** *(string)* –
  The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- **workflowId** *(string)* –
  The `workflowId` of the child workflow execution.

- **initiatedEventId** *(integer)* –
  The ID of the `StartChildWorkflowExecutionInitiated` event corresponding to the `StartChildWorkflowExecution` decision to start this child workflow execution. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **decisionTaskCompletedEventId** *(integer)* –
  The ID of the `DecisionTaskCompleted` event corresponding to the decision task that resulted in the `StartChildWorkflowExecution` decision to request this child workflow execution. This information can be useful for diagnosing problems by tracing back the cause of events.

- **control** *(string)* –

- **lambdaFunctionScheduledEventAttributes** *(dict)* –
  Provides details for the `LambdaFunctionScheduled` event.

- **id** *(string)* –
  The unique Amazon SWF ID for the AWS Lambda task.

- **name** *(string)* –
  The name of the scheduled AWS Lambda function.

- **input** *(string)* –
  Input provided to the AWS Lambda function.

- **startToCloseTimeout** *(string)* –
The maximum time, in seconds, that the AWS Lambda function can take to execute from start to close before it is marked as failed.

- **decisionTaskCompletedEventId (integer)** –
  The ID of the DecisionTaskCompleted event for the decision that resulted in the scheduling of this AWS Lambda function. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **lambdaFunctionStartedEventAttributes (dict)** –
  Provides details for the LambdaFunctionStarted event.

- **scheduledEventId (integer)** –
  The ID of the LambdaFunctionScheduled event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **lambdaFunctionCompletedEventAttributes (dict)** –
  Provides details for the LambdaFunctionCompleted event.

- **scheduledEventId (integer)** –
  The ID of the LambdaFunctionScheduled event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –
  The ID of the LambdaFunctionStarted event recorded in the history.

- **result (string)** –
  The result of the function execution (if any).

- **lambdaFunctionFailedEventAttributes (dict)** –
  Provides details for the LambdaFunctionFailed event.

- **scheduledEventId (integer)** –
  The ID of the LambdaFunctionScheduled event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- **startedEventId (integer)** –
  The ID of the LambdaFunctionStarted event recorded in the history.

- **reason (string)** –
  The reason provided for the failure (if any).

- **details (string)** –
  The details of the failure (if any).

- **lambdaFunctionTimedOutEventAttributes (dict)** –
  Provides details for the LambdaFunctionTimedOut event.

- **scheduledEventId (integer)** –
The ID of the `LambdaFunctionScheduled` event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- `startedEventId (integer)` –

  The ID of the `LambdaFunctionStarted` event recorded in the history.

- `timeoutType (string)` –

  The type of the timeout that caused this event.

- `scheduleLambdaFunctionFailedEventAttributes (dict)` –

  Provides details for the `ScheduleLambdaFunctionFailed` event.

  - `id (string)` –

    The unique Amazon SWF ID of the AWS Lambda task.

  - `name (string)` –

    The name of the scheduled AWS Lambda function.

  - `cause (string)` –

    The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- `decisionTaskCompletedEventId (integer)` –

  The ID of the `DecisionTaskCompleted` event corresponding to the decision that resulted in the scheduling of this AWS Lambda function. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

- `startLambdaFunctionFailedEventAttributes (dict)` –

  Provides details for the `StartLambdaFunctionFailed` event.

- `scheduledEventId (integer)` –

  The ID of the `LambdaFunctionScheduled` event that was recorded when this AWS Lambda function was scheduled. This information can be useful for diagnosing problems by tracing back the chain of events leading up to this event.

  - `cause (string)` –

    The cause of the failure. This information is generated by the system and can be useful for diagnostic purposes.

  **Note:** If `cause` is set to `OPERATION_NOT_PERMITTED`, the decision failed because it lacked sufficient permissions. For details and example IAM policies, see Using IAM to Manage Access to Amazon SWF Workflows.

- `message (string)` –
The error message (if any).

- **previousStartedEventId (integer)** –
  The ID of the DecisionTaskStarted event of the previous decision task of this workflow execution that was processed by the decider. This can be used to determine the events in the history new since the last decision task received by the decider.

- **NextToken (string)** –
  A token to resume pagination.

### WorkSpaces

#### Table of Contents

- WorkSpaces
  - Client

#### Client

**class WorkSpaces.Client**
A low-level client representing Amazon WorkSpaces:

```python
import boto3

client = boto3.client('workspaces')
```

These are the available methods:

- `can_paginate()`  
- `create_workspaces()`  
- `describe_workspace_bundles()`  
- `describe_workspace_directories()`  
- `describe_workspaces()`  
- `generate_presigned_url()`  
- `get_paginator()`  
- `get_waiter()`  
- `reboot_workspaces()`  
- `rebuild_workspaces()`  
- `terminate_workspaces()`

**can_paginate (operation_name)**
Check if an operation can be paginated.

**Parameters** `operation_name (string)` – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you'd normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginators("create_foo")`.

**Returns** `True` if the operation can be paginated, `False` otherwise.

**create_workspaces (**kwargs**)**
Creates one or more WorkSpaces.

**Note:** This operation is asynchronous and returns before the WorkSpaces are created.
Request Syntax

```python
response = client.create_workspaces(
    Workspaces=[
        {
            'DirectoryId': 'string',
            'UserName': 'string',
            'BundleId': 'string'
        },
    ],
)
```

Parameters

**Workspaces** *(list) – [REQUIRED]*

An array of structures that specify the WorkSpaces to create.

- *(dict)* –
  
  Contains information about a WorkSpace creation request.

  - **DirectoryId** *(string) – [REQUIRED]*
    
    The identifier of the AWS Directory Service directory to create the WorkSpace in. You can use the DescribeWorkspaceDirectories operation to obtain a list of the directories that are available.

  - **UserName** *(string) – [REQUIRED]*
    
    The username that the WorkSpace is assigned to. This username must exist in the AWS Directory Service directory specified by the **DirectoryId** member.

  - **BundleId** *(string) – [REQUIRED]*
    
    The identifier of the bundle to create the WorkSpace from. You can use the DescribeWorkspaceBundles operation to obtain a list of the bundles that are available.

Return type
dict

Returns

Response Syntax

```json
{}

'FailedRequests': [
    
    'WorkspaceRequest': {
        'DirectoryId': 'string',
        'UserName': 'string',
        'BundleId': 'string'
    },
    'ErrorCode': 'string',
    'ErrorMessage': 'string'
},

'PendingRequests': [
    
    'WorkspaceId': 'string',
    'DirectoryId': 'string',
    'UserName': 'string',
    'IpAddress': 'string',
    'State': 'PENDING'|'AVAILABLE'|'IMPAIRED'|'UNHEALTHY'|'REBOOTING'|'REBUILDING'|'TERMINATING'|'TERMINATED'|'SUSPENDED'|'ERROR',
    'BundleId': 'string',
    'SubnetId': 'string',
]
```
Response Structure

- **(dict)** –
  Contains the result of the CreateWorkspaces operation.

  - **FailedRequests (list)** –
    An array of structures that represent the WorkSpaces that could not be created.
    * **(dict)** –
      Contains information about a WorkSpace that could not be created.
      - **WorkspaceRequest (dict)** –
        A WorkspaceRequest object that contains the information about the WorkSpace that could not be created.
      - **DirectoryId (string)** –
        The identifier of the AWS Directory Service directory to create the WorkSpace in. You can use the DescribeWorkspaceDirectories operation to obtain a list of the directories that are available.
      - **UserName (string)** –
        The username that the WorkSpace is assigned to. This username must exist in the AWS Directory Service directory specified by the DirectoryId member.
      - **BundleId (string)** –
        The identifier of the bundle to create the WorkSpace from. You can use the DescribeWorkspaceBundles operation to obtain a list of the bundles that are available.
      - **ErrorCode (string)** –
        The error code.
      - **ErrorMessage (string)** –
        The textual error message.

  - **PendingRequests (list)** –
    An array of structures that represent the WorkSpaces that were created.
    Because this operation is asynchronous, the identifier in WorkspaceId is not immediately available. If you immediately call DescribeWorkspaces with this identifier, no information will be returned.
    * **(dict)** –
      Contains information about a WorkSpace.
      - **WorkspaceId (string)** –
        The identifier of the WorkSpace.
      - **DirectoryId (string)** –
        The identifier of the AWS Directory Service directory that the WorkSpace belongs to.
· **UserName** *(string)* –
  The user that the WorkSpace is assigned to.
· **IpAddress** *(string)* –
  The IP address of the WorkSpace.
· **State** *(string)* –
  The operational state of the WorkSpace.
· **BundleId** *(string)* –
  The identifier of the bundle that the WorkSpace was created from.
· **SubnetId** *(string)* –
  The identifier of the subnet that the WorkSpace is in.
· **ErrorMessage** *(string)* –
  If the WorkSpace could not be created, this contains a textual error message that describes the failure.
· **ErrorCode** *(string)* –
  If the WorkSpace could not be created, this contains the error code.

**describe_workspace_bundles** (**kwargs**)
Obtains information about the WorkSpace bundles that are available to your account in the specified region.

You can filter the results with either the **BundleIds** parameter, or the **Owner** parameter, but not both.

This operation supports pagination with the use of the **NextToken** request and response parameters. If more results are available, the **NextToken** response member contains a token that you pass in the next call to this operation to retrieve the next set of items.

**Request Syntax**

```python
response = client.describe_workspace_bundles(
    BundleIds=[
        'string',
    ],
    Owner='string',
    NextToken='string'
)
```

**Parameters**

- **BundleIds** *(list)* – An array of strings that contains the identifiers of the bundles to retrieve. This parameter cannot be combined with any other filter parameter.
  - *(string)* –
- **Owner** *(string)* – The owner of the bundles to retrieve. This parameter cannot be combined with any other filter parameter.

This contains one of the following values:
  - null - Retrieves the bundles that belong to the account making the call.
  - AMAZON - Retrieves the bundles that are provided by AWS.
- **NextToken** *(string)* – The **NextToken** value from a previous call to this operation. Pass null if this is the first call.

**Return type** dict

**Returns**

**Response Syntax**
{  'Bundles': [  
    {  
      'BundleId': 'string',
      'Name': 'string',
      'Owner': 'string',
      'Description': 'string',
      'UserStorage': {  
        'Capacity': 'string'
      },
      'ComputeType': {  
        'Name': 'VALUE'|'STANDARD'|'PERFORMANCE'
      }
    },
    
  },
  'NextToken': 'string'
}

Response Structure

• (dict) –
  Contains the results of the DescribeWorkspaceBundles operation.
  – Bundles (list) –
    An array of structures that contain information about the bundles.
    • (dict) –
      Contains information about a WorkSpace bundle.
      • BundleId (string) –
        The bundle identifier.
      • Name (string) –
        The name of the bundle.
      • Owner (string) –
        The owner of the bundle. This contains the owner's account identifier, or AMAZON if the bundle is provided by AWS.
      • Description (string) –
        The bundle description.
      • UserStorage (dict) –
        A UserStorage object that specifies the amount of user storage that the bundle contains.
      • Capacity (string) –
        The amount of user storage for the bundle.
      • ComputeType (dict) –
        A ComputeType object that specifies the compute type for the bundle.
      • Name (string) –
        The name of the compute type for the bundle.
  – NextToken (string) –
    If not null, more results are available. Pass this value for the NextToken parameter in a subsequent call to this operation to retrieve the next set of items. This token is valid for one day and must be used within that timeframe.
describe_workspace_directories(**kwargs)

Retrieves information about the AWS Directory Service directories in the region that are registered with Amazon WorkSpaces and are available to your account.

This operation supports pagination with the use of the NextToken request and response parameters. If more results are available, the NextToken response member contains a token that you pass in the next call to this operation to retrieve the next set of items.

**Request Syntax**

```python
response = client.describe_workspace_directories(
    DirectoryIds=[
        'string',
    ],
    NextToken='string'
)
```

**Parameters**

- **DirectoryIds (list)** – An array of strings that contains the directory identifiers to retrieve information for. If this member is null, all directories are retrieved.

- **(string)**

- **NextToken (string)** – The NextToken value from a previous call to this operation. Pass null if this is the first call.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'Directories': [
        {
            'DirectoryId': 'string',
            'Alias': 'string',
            'DirectoryName': 'string',
            'RegistrationCode': 'string',
            'SubnetIds': [
                'string',
            ],
            'DnsIpAddresses': [
                'string',
            ],
            'CustomerUserName': 'string',
            'IamRoleId': 'string',
            'DirectoryType': 'SIMPLE_AD'|'AD_CONNECTOR',
            'WorkspaceSecurityGroupId': 'string',
            'State': 'REGISTERING'|'REGISTERED'|'DEREGISTERING'|'DEREGISTERED'|'ERROR',
            'WorkspaceCreationProperties': {
                'EnableWorkDocs': True|False,
                'EnableInternetAccess': True|False,
                'DefaultOu': 'string',
                'CustomSecurityGroupId': 'string',
                'UserEnabledAsLocalAdministrator': True|False
            }
        },
        {
            'DirectoryId': 'string',
            'Alias': 'string',
            'DirectoryName': 'string',
            'RegistrationCode': 'string',
            'SubnetIds': [
                'string',
            ],
            'DnsIpAddresses': [
                'string',
            ],
            'CustomerUserName': 'string',
            'IamRoleId': 'string',
            'DirectoryType': 'SIMPLE_AD'|'AD_CONNECTOR',
            'WorkspaceSecurityGroupId': 'string',
            'State': 'REGISTERING'|'REGISTERED'|'DEREGISTERING'|'DEREGISTERED'|'ERROR',
            'WorkspaceCreationProperties': {
                'EnableWorkDocs': True|False,
                'EnableInternetAccess': True|False,
                'DefaultOu': 'string',
                'CustomSecurityGroupId': 'string',
                'UserEnabledAsLocalAdministrator': True|False
            }
        }
    ],
    'NextToken': 'string'
}
```
Response Structure

- (dict) –

  Contains the results of the DescribeWorkspaceDirectories operation.

  - Directories (list) –

    An array of structures that contain information about the directories.

      - (dict) –

        Contains information about an AWS Directory Service directory for
        use with Amazon WorkSpaces.

          - DirectoryId (string) –

            The directory identifier.

          - Alias (string) –

            The directory alias.

          - DirectoryName (string) –

            The name of the directory.

          - RegistrationCode (string) –

            The registration code for the directory. This is the code that
            users enter in their Amazon WorkSpaces client application to
            connect to the directory.

          - SubnetIds (list) –

            An array of strings that contains the identifiers of the subnets
            used with the directory.

            - (string) –

          - DnsIpAddresses (list) –

            An array of strings that contains the IP addresses of the DNS
            servers for the directory.

            - (string) –

          - CustomerUserName (string) –

            The user name for the service account.

          - IamRoleId (string) –

            The identifier of the IAM role. This is the role that allows
            Amazon WorkSpaces to make calls to other services, such as
            Amazon EC2, on your behalf.

          - DirectoryType (string) –

            The directory type.

          - WorkspaceSecurityGroupId (string) –

            The identifier of the security group that is assigned to new
            WorkSpaces.

          - State (string) –

            The state of the directory’s registration with Amazon
            WorkSpaces

          - WorkspaceCreationProperties (dict) –

            A structure that specifies the default creation properties for all
            WorkSpaces in the directory.

          - EnableWorkDocs (boolean) –

            Specifies if the directory is enabled for Amazon WorkDocs.
- **EnableInternetAccess (boolean)** –
  A public IP address will be attached to all WorkSpaces that are created or rebuilt.
- **DefaultOu (string)** –
  The organizational unit (OU) in the directory that the WorkSpace machine accounts are placed in.
- **CustomSecurityGroupId (string)** –
  The identifier of any custom security groups that are applied to the WorkSpaces when they are created.
- **UserEnabledAsLocalAdministrator (boolean)** –
  The WorkSpace user is an administrator on the WorkSpace.
- **NextToken (string)** –
  If not null, more results are available. Pass this value for the `NextToken` parameter in a subsequent call to this operation to retrieve the next set of items. This token is valid for one day and must be used within that timeframe.

### describe_workspaces (**kwargs**)

Obtains information about the specified WorkSpaces.

Only one of the filter parameters, such as `BundleId`, `DirectoryId`, or `WorkspaceIds`, can be specified at a time.

This operation supports pagination with the use of the `NextToken` request and response parameters. If more results are available, the `NextToken` response member contains a token that you pass in the next call to this operation to retrieve the next set of items.

**Request Syntax**

```python
response = client.describe_workspaces(
    WorkspaceIds=[
        'string',
    ],
    DirectoryId='string',
    UserName='string',
    BundleId='string',
    Limit=123,
    NextToken='string'
)
```

**Parameters**

- **WorkspaceIds (list)** – An array of strings that contain the identifiers of the WorkSpaces for which to retrieve information. This parameter cannot be combined with any other filter parameter.

  Because the CreateWorkspaces operation is asynchronous, the identifier returned by CreateWorkspaces is not immediately available. If you immediately call DescribeWorkspaces with this identifier, no information will be returned.

  - **(string)** –
  - **DirectoryId (string)** – Specifies the directory identifier to which to limit the WorkSpaces. Optionally, you can specify a specific directory user with the `UserName` parameter. This parameter cannot be combined with any other filter parameter.

    - **UserName (string)** – Used with the `DirectoryId` parameter to specify the directory user for which to obtain the WorkSpace.
• **BundleId (string)** – The identifier of a bundle to obtain the WorkSpaces for. All WorkSpaces that are created from this bundle will be retrieved. This parameter cannot be combined with any other filter parameter.

• **Limit (integer)** – The maximum number of items to return.

• **NextToken (string)** – The NextToken value from a previous call to this operation. Pass null if this is the first call.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Workspaces': [
        {
            'WorkspaceId': 'string',
            'DirectoryId': 'string',
            'UserName': 'string',
            'IpAddress': 'string',
            'State': 'PENDING'|'AVAILABLE'|'IMPAIRED'|'UNHEALTHY'|'REBOOTING'|'REBUILDING'|'TERMINATING'|'TERMINATED'|'SUSPENDED'|'ERROR',
            'BundleId': 'string',
            'SubnetId': 'string',
            'ErrorMessage': 'string',
            'ErrorCode': 'string'
        },
    ],
    'NextToken': 'string'
}
```

**Response Structure**

• **(dict)** –

Contains the results for the DescribeWorkspaces operation.

  • **Workspaces (list)** –

An array of structures that contain the information about the WorkSpaces. Because the CreateWorkspaces operation is asynchronous, some of this information may be incomplete for a newly-created WorkSpace.

  • **(dict)** –

Contains information about a WorkSpace.

  • **WorkspaceId (string)** –

The identifier of the WorkSpace.

  • **DirectoryId (string)** –

The identifier of the AWS Directory Service directory that the WorkSpace belongs to.

  • **UserName (string)** –

The user that the WorkSpace is assigned to.

  • **IpAddress (string)** –

The IP address of the WorkSpace.

  • **State (string)** –

The operational state of the WorkSpace.

  • **BundleId (string)** –

The identifier of the bundle that the WorkSpace was created from.
· **SubnetId (string)** –
  The identifier of the subnet that the WorkSpace is in.

· **ErrorMessage (string)** –
  If the WorkSpace could not be created, this contains a textual error message that describes the failure.

· **ErrorCode (string)** –
  If the WorkSpace could not be created, this contains the error code.

· **NextToken (string)** –
  If not null, more results are available. Pass this value for the `NextToken` parameter in a subsequent call to this operation to retrieve the next set of items. This token is valid for one day and must be used within that timeframe.

### generate_presigned_url

```python
generate_presigned_url (ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)
```

Generate a presigned url given a client, its method, and arguments

**Parameters**

- **ClientMethod (string)** – The client method to presign for
- **Params (dict)** – The parameters normally passed to `ClientMethod`.
- **ExpiresIn (int)** – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod (string)** – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns**

The presigned url

### get_paginators

```python
get_paginators (operation_name)
```

Create a paginator for an operation.

**Parameters**

- **operation_name (string)** – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginators("create_foo")`.

**Raises**

- **OperationNotPageableError** Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

**Return type**

L{botocore.paginate.Paginator}

**Returns**

A paginator object.

### get_waiter

```python
get_waiter (waiter_name)
```

### reboot_workspaces (**kwargs)

Reboots the specified WorkSpaces.

To be able to reboot a WorkSpace, the WorkSpace must have a `State` of AVAILABLE, IMPAIRED, or INOPERABLE.

**Note:** This operation is asynchronous and will return before the WorkSpaces have rebooted.

**Request Syntax**

```python
response = client.reboot_workspaces(
    RebootWorkspaceRequests=[
        {
            'WorkspaceId': 'string'
        },
    ],
)
```
Parameters  RebootWorkspaceRequests (list) – [REQUIRED]

An array of structures that specify the WorkSpaces to reboot.

- (dict) –

  Contains information used with the RebootWorkspaces operation to reboot a
  WorkSpace.

  - WorkspaceId (string) – [REQUIRED]

    The identifier of the WorkSpace to reboot.

Return type  dict

Returns

Response Syntax

```python
{
  'FailedRequests': [
    {
      'WorkspaceId': 'string',
      'ErrorCode': 'string',
      'ErrorMessage': 'string'
    },
  ]
}
```

Response Structure

- (dict) –

  Contains the results of the RebootWorkspaces operation.

  - FailedRequests (list) –

    An array of structures that represent any WorkSpaces that could not be
    rebooted.

    - (dict) –

      Contains information about a WorkSpace that could not be rebooted
      ( RebootWorkspaces ), rebuilt ( RebuildWorkspaces ), or terminated
      ( TerminateWorkspaces ).

      - WorkspaceId (string) –

        The identifier of the WorkSpace.

      - ErrorCode (string) –

        The error code.

      - ErrorMessage (string) –

        The textual error message.

rebuild_workspaces (**kwargs)

Rebuilds the specified WorkSpaces.

Rebuilding a WorkSpace is a potentially destructive action that can result in the loss of data. Rebuilding
a WorkSpace causes the following to occur:

- The system is restored to the image of the bundle that the WorkSpace is created from. Any appli-
cations that have been installed, or system settings that have been made since the WorkSpace was
created will be lost.
• The data drive (D drive) is re-created from the last automatic snapshot taken of the data drive. The current contents of the data drive are overwritten. Automatic snapshots of the data drive are taken every 12 hours, so the snapshot can be as much as 12 hours old.

To be able to rebuild a WorkSpace, the WorkSpace must have a State of AVAILABLE or ERROR.

**Note:** This operation is asynchronous and will return before the WorkSpaces have been completely rebuilt.

**Request Syntax**

```python
response = client.rebuild_workspaces(
    RebuildWorkspaceRequests=[
        {
            'WorkspaceId': 'string'
        },
    ]
)
```

**Parameters**

- **RebuildWorkspaceRequests (list) – [REQUIRED]**
  
  An array of structures that specify the WorkSpaces to rebuild.
  ```
  • (dict) –
    
    Contains information used with the RebuildWorkspaces operation to rebuild a WorkSpace.
    ```
    ```
    - **WorkspaceId (string) – [REQUIRED]**
      
      The identifier of the WorkSpace to rebuild.
    ```

**Return type**

dict

**Returns**

**Response Syntax**

```python
{
    'FailedRequests': [
        {
            'WorkspaceId': 'string',
            'ErrorCode': 'string',
            'ErrorMessage': 'string'
        },
    ]
}
```

**Response Structure**

- **(dict) –**
  
  Contains the results of the RebuildWorkspaces operation.
  ```
  - **FailedRequests (list) –**
    
    An array of structures that represent any WorkSpaces that could not be rebuilt.
    ```
    ```
    • (dict) –
      
      Contains information about a WorkSpace that could not be rebooted (RebootWorkspaces), rebuilt (RebuildWorkspaces), or terminated (TerminateWorkspaces).
      ```
      ```
      - **WorkspaceId (string) –**
        
        The identifier of the WorkSpace.
- **ErrorCode** *(string)* –
  The error code.
- **ErrorMessage** *(string)* –
  The textual error message.

**terminate_workspaces(** **kwargs)**

Terminates the specified WorkSpaces.

Terminating a WorkSpace is a permanent action and cannot be undone. The user’s data is not maintained and will be destroyed. If you need to archive any user data, contact Amazon Web Services before terminating the WorkSpace.

You can terminate a WorkSpace that is in any state except **SUSPENDED**.

**Note:** This operation is asynchronous and will return before the WorkSpaces have been completely terminated.

**Request Syntax**

```python
response = client.terminate_workspaces(
    TerminateWorkspaceRequests=[
        {
            'WorkspaceId': 'string'
        },
    ]
)
```

**Parameters**

- **TerminateWorkspaceRequests** *(list)* – [REQUIRED]
  An array of structures that specify the WorkSpaces to terminate.
  ```
  • **(dict)** –
    Contains information used with the TerminateWorkspaces operation to terminate a WorkSpace.
    • **WorkspaceId** *(string)* – [REQUIRED]
      The identifier of the WorkSpace to terminate.
  ```

**Return type** *dict*

**Returns**

**Response Syntax**

```json
{
    'FailedRequests': [
        {
            'WorkspaceId': 'string',
            'ErrorCode': 'string',
            'ErrorMessage': 'string'
        },
    ]
}
```

**Response Structure**

- **(dict)** –
  Contains the results of the TerminateWorkspaces operation.
FailedRequests (list) –

An array of structures that represent any WorkSpaces that could not be terminated.

* (dict) –

Contains information about a WorkSpace that could not be rebooted (RebootWorkspaces), rebuilt (RebuildWorkspaces), or terminated (TerminateWorkspaces).

  · WorkspaceId (string) –
    The identifier of the WorkSpace.
  · ErrorCode (string) –
    The error code.
  · ErrorMessage (string) –
    The textual error message.

3.2 Core

3.2.1 Core References

Boto3 Reference

class boto3.NullHandler (level=0)

Initializes the instance - basically setting the formatter to None and the filter list to empty.

    emit (record)

boto3.client (*args, **kwargs)

Create a low-level service client by name using the default session.

    See boto3.session.Session.client()

boto3.resource (*args, **kwargs)

Create a resource service client by name using the default session.

    See boto3.session.Session.resource()

boto3.set_stream_logger (name='boto3', level=10, format_string=None)

Add a stream handler for the given name and level to the logging module. By default, this logs all boto3 messages to stdout.

    >>> import boto3
    >>> boto3.set_stream_logger('boto3.resources', logging.INFO)

Parameters

  · name (string) – Log name
  · level (int) – Logging level, e.g. logging.INFO
  · format_string (str) – Log message format

boto3.setup_default_session (**kwargs)

Set up a default session, passing through any parameters to the session constructor. There is no need to call this unless you wish to pass custom parameters, because a default session will be created for you.
class boto3.resources.collection.CollectionFactory
A factory to create new CollectionManager and ResourceCollection subclasses from a Collection model. These subclasses include methods to perform batch operations.

load_from_definition (service_name, resource_name, collection_name, model, resource_defs)
Loads a collection from a model, creating a new CollectionManager subclass with the correct properties and methods, named based on the service and resource name, e.g. ec2.InstanceCollectionManager. It also creates a new ResourceCollection subclass which is used by the new manager class.

Parameters
• service_name (string) – Name of the service to look up
• resource_name (string) – Name of the resource to look up. For services, this should match the service_name.
• model (dict) – The collection definition.
• resource_defs (dict) – The service’s resource definitions, used to load collection resources (e.g. sqs.Queue).

Return type Subclass of CollectionManager
Returns The collection class.

class boto3.resources.collection.CollectionManager (model, parent, factory, resource_defs, service_model)
A collection manager provides access to resource collection instances, which can be iterated and filtered. The manager exposes some convenience functions that are also found on resource collections, such as all() and filter().

Get all items:

```python
>>> for bucket in s3.buckets.all():
...    print(bucket.name)
```

Get only some items via filtering:

```python
>>> for queue in sqs.queues.filter(QueueNamePrefix='AWS'):
...    print(queue.url)
```

Get whole pages of items:

```python
>>> for page in s3.Bucket('boto3').objects.pages():
...    for obj in page:
...        print(obj.key)
```

A collection manager is not iterable. You must call one of the methods that return a ResourceCollection before trying to iterate, slice, or convert to a list.

See the Collections guide for a high-level overview of collections, including when remote service requests are performed.

Parameters
• model (Collection) – Collection model
• parent (ServiceResource) – The collection’s parent resource
• factory (ResourceFactory) – The resource factory to create new resources
• resource_defs (dict) – Service resource definitions.
• service_model (botocore.model.ServiceModel) – The Botocore service model

all()
Get all items from the collection, optionally with a custom page size and item count limit.

This method returns an iterable generator which yields individual resource instances. Example use:
# Iterate through items
```python
>>> for queue in sqs.queues.all():
...     print(queue.url)
'https://url1'
'https://url2'
```

# Convert to list
```python
>>> queues = list(sqs.queues.all())
>>> len(queues)
2
```

**filter(**kwargs)**

Get items from the collection, passing keyword arguments along as parameters to the underlying service operation, which are typically used to filter the results.

This method returns an iterable generator which yields individual resource instances. Example use:

```python
# Iterate through items
>>> for queue in sqs.queues.filter(Param='foo'):
...     print(queue.url)
'https://url1'
'https://url2'

# Convert to list
>>> queues = list(sqs.queues.filter(Param='foo'))
>>> len(queues)
2
```

**Return type** ResourceCollection

**iterator(**kwargs)**

Get a resource collection iterator from this manager.

**Return type** ResourceCollection

**Returns** An iterable representing the collection of resources

**limit**(count)

Return at most this many resources.

```python
>>> for bucket in s3.buckets.limit(5):
...     print(bucket.name)
'bucket1'
'bucket2'
'bucket3'
'bucket4'
'bucket5'
```

**Parameters** count (int) – Return no more than this many items

**Return type** ResourceCollection

**page_size**(count)

Fetch at most this many resources per service request.

```python
>>> for obj in s3.Bucket('boto3').objects.page_size(100):
...     print(obj.key)
```

**Parameters** count (int) – Fetch this many items per request

**Return type** ResourceCollection
A generator which yields pages of resource instances after doing the appropriate service operation calls and handling any pagination on your behalf. Non-paginated calls will return a single page of items.

Page size, item limit, and filter parameters are applied if they have previously been set.

```python
>>> bucket = s3.Bucket('boto3')
>>> for page in bucket.objects.pages():
...   for obj in page:
...     print(obj.key)
'key1'
'key2'
```

**Return type**  list(ServiceResource)

**Returns**  List of resource instances

class boto3.resources.collection.ResourceCollection(model, parent, handler, **kwargs)

Represents a collection of resources, which can be iterated through, optionally with filtering. Collections automatically handle pagination for you.

See Collections for a high-level overview of collections, including when remote service requests are performed.

**Parameters**

- `model` (Collection) – Collection model
- `parent` (ServiceResource) – The collection’s parent resource
- `handler` (ResourceHandler) – The resource response handler used to create resource instances

**all()**

Get all items from the collection, optionally with a custom page size and item count limit.

This method returns an iterable generator which yields individual resource instances. Example use:

```python
# Iterate through items
>>> for queue in sqs.queues.all():
...   print(queue.url)
'https://url1'
'https://url2'
```

```python
# Convert to list
>>> queues = list(sqs.queues.all())
>>> len(queues)
2
```

**filter(**kwargs)**

Get items from the collection, passing keyword arguments along as parameters to the underlying service operation, which are typically used to filter the results.

This method returns an iterable generator which yields individual resource instances. Example use:

```python
# Iterate through items
>>> for queue in sqs.queues.filter(Param='foo'):
...   print(queue.url)
'https://url1'
'https://url2'
```

```python
# Convert to list
>>> queues = list(sqs.queues.filter(Param='foo'))
>>> len(queues)
2
```
Return type ResourceCollection

limit(count)

Return at most this many resources.

```python
>>> for bucket in s3.buckets.limit(5):
...     print(bucket.name)
'bucket1'
'bucket2'
'bucket3'
'bucket4'
'bucket5'
```

Parameters count (int) – Return no more than this many items

Return type ResourceCollection

page_size(count)

Fetch at most this many resources per service request.

```python
>>> for obj in s3.Bucket('boto3').objects.page_size(100):
...     print(obj.key)
```

Parameters count (int) – Fetch this many items per request

Return type ResourceCollection

pages()

A generator which yields pages of resource instances after doing the appropriate service operation calls and handling any pagination on your behalf. Non-paginated calls will return a single page of items.

Page size, item limit, and filter parameters are applied if they have previously been set.

```python
>>> bucket = s3.Bucket('boto3')
>>> for page in bucket.objects.pages():
...     for obj in page:
...         print(obj.key)
'key1'
'key2'
```

Return type list(ServiceResource)

Returns List of resource instances

Resources Reference

Resource Model

The models defined in this file represent the resource JSON description format and provide a layer of abstraction from the raw JSON. The advantages of this are:

- Pythonic interface (e.g. action.request.operation)
- Consumers need not change for minor JSON changes (e.g. renamed field)

These models are used both by the resource factory to generate resource classes as well as by the documentation generator.

```python
class boto3.resources.model.Action(name, definition, resource_defs)

A service operation action.

Parameters
```
• name (string) – The name of the action
• definition (dict) – The JSON definition
• resource_defs (dict) – All resources defined in the service

name = None
   (string) The name of the action

path = None
   (string) The JMESPath search path or None

request = None
   (Request) This action’s request or None

resource = None
   (ResponseResource) This action’s resource or None

class boto3.resources.model.Collection(name, definition, resource_defs)
A group of resources. See Action.

Parameters
• name (string) – The name of the collection
• definition (dict) – The JSON definition
• resource_defs (dict) – All resources defined in the service

batch_actions
Get a list of batch actions supported by the resource type contained in this action. This is a shortcut for accessing the same information through the resource model.

   Return type list(Action)

class boto3.resources.model.DefinitionWithParams(definition)
An item which has parameters exposed via the params property. A request has an operation and parameters, while a waiter has a name, a low-level waiter name and parameters.

Parameters definition (dict) – The JSON definition

params
Get a list of auto-filled parameters for this request.

   Type list(Parameter)

class boto3.resources.model.Identifier(name)
A resource identifier, given by its name.

Parameters name (string) – The name of the identifier

name = None
   (string) The name of the identifier

class boto3.resources.model.Parameter(target, source, name=None, path=None, value=None, **kwargs)
An auto-filled parameter which has a source and target. For example, the QueueUrl may be auto-filled from a resource’s url identifier when making calls to queue.receive_messages.

Parameters
• target (string) – The destination parameter name, e.g. QueueUrl
• source_type (string) – Where the source is defined.
• source (string) – The source name, e.g. Url

name = None
   (string) The name of the source, if given

path = None
   (string) The JMESPath query of the source

source = None
   (string) Where the source is defined

target = None
   (string) The destination parameter name
value = None

(string|int|float|bool) The source constant value

class boto3.resources.model.Request (definition)
A service operation action request.

Parameters definition (dict) – The JSON definition

operation = None

(string) The name of the low-level service operation

params
Get a list of auto-filled parameters for this request.

Type list(Parameter)

class boto3.resources.model.ResourceModel (name, definition, resource_defs)
A model representing a resource, defined via a JSON description format. A resource has identifiers, attributes, actions, sub-resources, references and collections. For more information on resources, see Resources.

Parameters

• name (string) – The name of this resource, e.g. sqs or Queue
• definition (dict) – The JSON definition
• resource_defs (dict) – All resources defined in the service

actions
Get a list of actions for this resource.

Type list(Action)

batch_actions
Get a list of batch actions for this resource.

Type list(Action)

collections
Get a list of collections for this resource.

Type list(Collection)

get_attributes (shape)
Get a dictionary of attribute names to original name and shape models that represent the attributes of this resource. Looks like the following:

```python
{
    'some_name': ('SomeName', <Shape...>)
}
```

Parameters shape (botocore.model.Shape) – The underlying shape for this resource.

Return type dict

Returns Mapping of resource attributes.

identifiers
Get a list of resource identifiers.

Type list(Identifier)

load
Get the load action for this resource, if it is defined.

Type Action or None

load_rename_map (shape=None)
Load a name translation map given a shape. This will set up renamed values for any collisions, e.g. if the shape, an action, and a subresource all are all named foo then the resource will have an action foo, a subresource named Foo and a property named foo_attribute. This is the order of precedence, from most important to least important:

• Load action (resource.load)
• Identifiers
• Actions
Batch actions are only exposed on collections, so do not get modified here. Subresources use upper camel casing, so are unlikely to collide with anything but other subresources.

Creates a structure like this:

```python
renames = {
    ('action', 'id'): 'id_action',
    ('collection', 'id'): 'id_collection',
    ('attribute', 'id'): 'id_attribute'
}
```

```python
# Get the final name for an action named 'id'
name = renames.get(('action', 'id'), 'id')
```

**Parameters**

**shape** *(botocore.model.Shape)* – The underlying shape for this resource.

**name** = None

*(string)* The name of this resource

**references**

Get a list of reference resources.

*Type* list(ResponseResource)

**shape** = None

*(string)* The service shape name for this resource or None

**subresources**

Get a list of sub-resources.

*Type* list(:py:class:`ResponseResource`)

**waiters**

Get a list of waiters for this resource.

*Type* list(Waiter)

**class** boto3.resources.model.ResponseResource *(definition, resource_def)*

A resource response to create after performing an action.

**Parameters**

- **definition** *(dict)* – The JSON definition
- **resource_def** *(dict)* – All resources defined in the service

**identifiers**

A list of resource identifiers.

*Type* list(Identifier)

**model**

Get the resource model for the response resource.

*Type* ResourceModel

**path** = None

*(string)* The JMESPath search query or None

**type** = None

*(string)* The name of the response resource type

**class** boto3.resources.model.Waiter *(name, definition)*

An event waiter specification.
Parameters

- **name** *(string)* – Name of the waiter
- **definition** *(dict)* – The JSON definition

**PREFIX** = ‘WaitUntil’

**name** = None *(string)* The name of this waiter

**params**
Get a list of auto-filled parameters for this request.

**waiter_name** = None *(string)* The name of the underlying event waiter

Request Parameters

**boto3.resources.params.build_param_structure**(params, target, value)

This method provides a basic reverse JMESPath implementation that lets you go from a JMESPath-like string to a possibly deeply nested object. The params are mutated in-place, so subsequent calls can modify the same element by its index.

```python
>>> build_param_structure(params, 'test[0]', 1)
>>> print(params)
{'test': [1]}
```

```python
>>> build_param_structure(params, 'foo.bar[0].baz', 'hello world')
>>> print(params)
{'test': [1], 'foo': {'bar': [{'baz': 'hello, world'}]}}
```

**boto3.resources.params.create_request_parameters**(parent, request_model, params=None)

Handle request parameters that can be filled in from identifiers, resource data members or constants.

By passing params, you can invoke this method multiple times and build up a parameter dict over time, which is particularly useful for reverse JMESPath expressions that append to lists.

**Parameters**

- **parent** *(ServiceResource)* – The resource instance to which this action is attached.
- **request_model** *(Request)* – The action request model.
- **params** *(dict)* – If set, then add to this existing dict. It is both edited in-place and returned.

**Return type** dict

**Returns** Pre-filled parameters to be sent to the request operation.

**boto3.resources.params.get_data_member**(parent, path)

Get a data member from a parent using a JMESPath search query, loading the parent if required. If the parent cannot be loaded and no data is present then an exception is raised.

**Parameters**

- **parent** *(ServiceResource)* – The resource instance to which contains data we are interested in.
- **path** *(string)* – The JMESPath expression to query

**Raises** ResourceLoadException When no data is present and the resource cannot be loaded.

**Returns** The queried data or None.
Response Handlers

class boto3.resources.response.RawHandler(search_path)

A raw action response handler. This passed through the response dictionary, optionally after performing a JMESPath search if one has been defined for the action.

Parameters

    search_path (string) – JMESPath expression to search in the response

Returns

    Service response
class boto3.resources.response.ResourceHandler(search_path, factory, resource_defs, service_model, resource_model, operation_name=None)

Creates a new resource or list of new resources from the low-level response based on the given response resource definition.

Parameters

    • search_path (string) – JMESPath expression to search in the response
    • factory (ResourceFactory) – The factory that created the resource class to which this action is attached.
    • resource_defs (dict) – Service resource definitions.
    • service_model (botocore.model.ServiceModel) – The Botocore service model
    • resource_model (ResponseResource) – Response resource model.
    • operation_name (string) – Name of the underlying service operation, if it exists.

Returns

    New resource instance(s).

handle_response_item(resource_cls, parent, identifiers, resource_data)

Handles the creation of a single response item by setting parameters and creating the appropriate resource instance.

Parameters

    • resource_cls (ServiceResource subclass) – The resource class to instantiate.
    • parent (ServiceResource) – The resource instance to which this action is attached.
    • identifiers (dict) – Map of identifier names to value or values.
    • resource_data (dict or None) – Data for resource attributes.

Returns

    New resource instance.

boto3.resources.response.all_not_none(iterable)

Return True if all elements of the iterable are not None (or if the iterable is empty). This is like the built-in all, except checks against None, so 0 and False are allowable values.

boto3.resources.response.build_empty_response(search_path, operation_name, service_model)

Creates an appropriate empty response for the type that is expected, based on the service model’s shape type. For example, a value that is normally a list would then return an empty list. A structure would return an empty dict, and a number would return None.

Parameters

    • search_path (string) – JMESPath expression to search in the response
    • operation_name (string) – Name of the underlying service operation.
    • service_model (botocore.model.ServiceModel) – The Botocore service model

Returns

    An appropriate empty value

boto3.resources.response.build_identifiers(identifiers, parent, params=None, raw_response=None)

Builds a mapping of identifier names to values based on the identifier source location, type, and target. Identifier values may be scalars or lists depending on the source type and location.
Parameters

- **identifiers (list)** – List of Parameter definitions
- **parent (ServiceResource)** – The resource instance to which this action is attached.
- **params (dict)** – Request parameters sent to the service.
- **raw_response (dict)** – Low-level operation response.

Return type  list

Returns An ordered list of (name, value) identifier tuples.

Resource Actions

class boto3.resources.action.BatchAction (action_model, factory=None, resource_defs=None, service_model=None)

An action which operates on a batch of items in a collection, typically a single page of results from the collection’s underlying service operation call. For example, this allows you to delete up to 999 S3 objects in a single operation rather than calling .delete() on each one individually.

Parameters

- **action_model (Action)** – The action model.
- **factory (ResourceFactory)** – The factory that created the resource class to which this action is attached.
- **resource_defs (dict)** – Service resource definitions.
- **service_model (botocore.model.ServiceModel)** – The Botocore service model

class boto3.resources.action.ServiceAction (action_model, factory=None, resource_defs=None, service_model=None)

A class representing a callable action on a resource, for example sqs.get_queue_by_name(...) or s3.Bucket(‘foo’).delete(). The action may construct parameters from existing resource identifiers and may return either a raw response or a new resource instance.

Parameters

- **factory (ResourceFactory)** – The factory that created the resource class to which this action is attached.
- **resource_defs (dict)** – Service resource definitions.
- **service_model (botocore.model.ServiceModel)** – The Botocore service model

class boto3.resources.action.WaiterAction (waiter_model, waiter_resource_name)

A class representing a callable waiter action on a resource, for example s3.Bucket(‘foo’).wait_until_bucket_exists(). The waiter action may construct parameters from existing resource identifiers.

Parameters

- **waiter_resource_name (string)** – The name of the waiter action for the resource. It usually begins with a wait_until_

Resource Base

class boto3.resources.base.ResourceMeta (service_name, identifiers=None, client=None, data=None, resource_model=None)

An object containing metadata about a resource.

```python
client = None
(BaseClient) Low-level Botocore client

copy ()
Create a copy of this metadata object.
```
data = None
    (dict) Loaded resource data attributes

identifiers = None
    (list) List of identifier names

service_name = None
    (str) The service name, e.g. ‘s3’

class boto3.resources.base.ServiceResource (*args, **kwargs)
    A base class for resources.

Parameters:
client (botocore.client) – A low-level Botocore client instance
meta = None
    Stores metadata about this resource instance, such as the service_name, the low-level client and any cached data from when the instance was hydrated. For example:

    # Get a low-level client from a resource instance
    client = resource.meta.client
    response = client.operation(Param='foo')

    # Print the resource instance's service short name
    print(resource.meta.service_name)

    See ResourceMeta for more information.

Resource Factory

class boto3.resources.factory.ResourceFactory (emitter)
    A factory to create new ServiceResource classes from a ResourceModel. There are two types of lookups that can be done: one on the service itself (e.g. an SQS resource) and another on models contained within the service (e.g. an SQS Queue resource).

load_from_definition (service_name, resource_name, model, resource_defs, service_model)
    Loads a resource from a model, creating a new ServiceResource subclass with the correct properties and methods, named based on the service and resource name, e.g. EC2.Instance.

Parameters:
• service_name (str) – Name of the service to look up
• resource_name (str) – Name of the resource to look up. For services, this should match the service_name.
• model (dict) – The service or resource definition.
• resource_defs (dict) – The service’s resource definitions, used to load subresources (e.g. sqs.Queue).
• service_model (botocore.model.ServiceModel) – The Botocore service model, required only if the resource shape contains members. This is used to expose lazy-loaded attributes on the resource.

Return type: Subclass of ServiceResource
Returns: The service or resource class.

Session Reference

class boto3.session.Session (aws_access_key_id=None, aws_secret_access_key=None, aws_session_token=None, region_name=None, boto-core_session=None, profile_name=None)
    A session stores configuration state and allows you to create service clients and resources.

Parameters:
• `aws_access_key_id` (string) – AWS access key ID
• `aws_secret_access_key` (string) – AWS secret access key
• `aws_session_token` (string) – AWS temporary session token
• `region_name` (string) – Default region when creating new connections
• `botocore_session` (botocore.session.Session) – Use this Botocore session instead of creating a new default one.
• `profile_name` (string) – The name of a profile to use. If not given, then the default profile is used.

`client(service_name, region_name=None, api_version=None, use_ssl=True, verify=None, endpoint_url=None, aws_access_key_id=None, aws_secret_access_key=None, aws_session_token=None, config=None)`

Create a low-level service client by name.

**Parameters**

- `service_name` (string) – The name of a service, e.g. ‘s3’ or ‘ec2’. You can get a list of available services via `get_available_services()`.
- `region_name` (string) – The name of the region associated with the client. A client is associated with a single region.
- `api_version` (string) – The API version to use. By default, botocore will use the latest API version when creating a client. You only need to specify this parameter if you want to use a previous API version of the client.
- `use_ssl` (boolean) – Whether or not to use SSL. By default, SSL is used. Note that not all services support non-ssl connections.
- `verify` (boolean/string) – Whether or not to verify SSL certificates. By default SSL certificates are verified. You can provide the following values:
  - False - do not validate SSL certificates. SSL will still be used (unless `use_ssl` is False), but SSL certificates will not be verified.
  - path/to/cert/bundle.pem - A filename of the CA cert bundle to uses. You can specify this argument if you want to use a different CA cert bundle than the one used by botocore.
- `endpoint_url` (string) – The complete URL to use for the constructed client. Normally, botocore will automatically construct the appropriate URL to use when communicating with a service. You can specify a complete URL (including the “http/https” scheme) to override this behavior. If this value is provided, then `use_ssl` is ignored.
- `aws_access_key_id` (string) – The access key to use when creating the client. This is entirely optional, and if not provided, the credentials configured for the session will automatically be used. You only need to provide this argument if you want to override the credentials used for this specific client.
- `aws_secret_access_key` (string) – The secret key to use when creating the client. Same semantics as `aws_access_key_id` above.
- `aws_session_token` (string) – The session token to use when creating the client. Same semantics as `aws_access_key_id` above.
- `config` (botocore.client.Config) – Advanced client configuration options. If `region_name` is specified in the client config, its value will take precedence over environment variables and configuration values, but not over a `region_name` value passed explicitly to the method.

**Returns** Service client instance

**events**

The event emitter for a session

**get_available_resources()**

Get a list of available services that can be loaded as resource clients via `Session.resource()`.

**Return type** list

**Returns** List of service names
get_available_services()
Get a list of available services that can be loaded as low-level clients via `Session.client()`.
Return type list
Returns List of service names

profile_name
The read-only profile name.

resource (service_name, region_name=None, api_version=None, use_ssl=True, verify=None, endpoint_url=None, aws_access_key_id=None, aws_secret_access_key=None, aws_session_token=None)
Create a resource service client by name.
Parameters
- service_name (string) – The name of a service, e.g. ‘s3’ or ‘ec2’. You can get a list of available services via `get_available_resources()`.
- region_name (string) – The name of the region associated with the client. A client is associated with a single region.
- api_version (string) – The API version to use. By default, botocore will use the latest API version when creating a client. You only need to specify this parameter if you want to use a previous API version of the client.
- use_ssl (boolean) – Whether or not to use SSL. By default, SSL is used. Note that not all services support non-ssl connections.
- verify (boolean/string) – Whether or not to verify SSL certificates. By default SSL certificates are verified. You can provide the following values:
  - False - do not validate SSL certificates. SSL will still be used (unless use_ssl is False), but SSL certificates will not be verified.
  - path/to/cert/bundle.pem - A filename of the CA cert bundle to uses. You can specify this argument if you want to use a different CA cert bundle than the one used by botocore.
- endpoint_url (string) – The complete URL to use for the constructed client. Normally, botocore will automatically construct the appropriate URL to use when communicating with a service. You can specify a complete URL (including the ‘http/https’ scheme) to override this behavior. If this value is provided, then use_ssl is ignored.
- aws_access_key_id (string) – The access key to use when creating the client. This is entirely optional, and if not provided, the credentials configured for the session will automatically be used. You only need to provide this argument if you want to override the credentials used for this specific client.
- aws_secret_access_key (string) – The secret key to use when creating the client. Same semantics as `aws_access_key_id` above.
- aws_session_token (string) – The session token to use when creating the client. Same semantics as `aws_access_key_id` above.

Returns Subclass of ServiceResource

3.3 Customizations

3.3.1 Customization References

DynamoDB Customization Reference

Valid DynamoDB Types

These are the valid item types to use with Boto3 Table Resource (dynamodb.Table) and DynamoDB:
<table>
<thead>
<tr>
<th>Python Type</th>
<th>DynamoDB Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>String (S)</td>
</tr>
<tr>
<td>integer</td>
<td>Number (N)</td>
</tr>
<tr>
<td>decimal.Decimal</td>
<td>Number (N)</td>
</tr>
<tr>
<td>boto3.dynamodb.types.Binary</td>
<td>Binary (B)</td>
</tr>
<tr>
<td>boolean</td>
<td>Boolean (BOOL)</td>
</tr>
<tr>
<td>None</td>
<td>Null (NULL)</td>
</tr>
<tr>
<td>string set</td>
<td>String Set (SS)</td>
</tr>
<tr>
<td>integer set</td>
<td>Number Set (NS)</td>
</tr>
<tr>
<td>decimal.Decimal set</td>
<td>Number Set (NS)</td>
</tr>
<tr>
<td>boto3.dynamodb.types.Binary set</td>
<td>Binary Set (BS)</td>
</tr>
<tr>
<td>list</td>
<td>List (L)</td>
</tr>
<tr>
<td>dict</td>
<td>Map (M)</td>
</tr>
</tbody>
</table>

**Custom Boto3 Types**

class boto3.dynamodb.types.Binary(value):
    A class for representing Binary in dynamodb

    Especially for Python 2, use this class to explicitly specify binary data for item in DynamoDB. It is essentially a wrapper around binary. Unicode and Python 3 string types are not allowed.

**DynamoDB Conditions**

class boto3.dynamodb.conditions.Key(name):

    begins_with(value)
        Creates a condition where the attribute begins with the value.

        Parameters value – The value that the attribute begins with.

    between(low_value, high_value)
        Creates a condition where the attribute is between the low value and the high value.

        Parameters
            • low_value – The value that the attribute is greater than.
            • high_value – The value that the attribute is less than.

    eq(value)
        Creates a condition where the attribute is equal to the value.

        Parameters value – The value that the attribute is equal to.

    gt(value)
        Creates a condition where the attribute is greater than the value.

        Parameters value – The value that the attribute is greater than.

    gte(value)
        Creates a condition where the attribute is greater than or equal to the value.

        Parameters value – The value that the attribute is greater than or equal to.

    lt(value)
        Creates a condition where the attribute is less than the value.

        Parameters value – The value that the attribute is less than.

    lte(value)
        Creates a condition where the attribute is less than or equal to the value.
Parameters value – The value that the attribute is less than or equal to.

```python
class boto3.dynamodb.conditions.Attr(name):
    Represents an DynamoDB item's attribute.

    attribute_type(value)
        Creates a condition for the attribute type.
        Parameters value – The type of the attribute.

    begins_with(value)
        Creates a condition where the attribute begins with the value.
        Parameters value – The value that the attribute begins with.

    between(low_value, high_value)
        Creates a condition where the attribute is between the low value and
        the high value.
        Parameters
        • low_value – The value that the attribute is greater than.
        • high_value – The value that the attribute is less than.

    contains(value)
        Creates a condition where the attribute contains the value.
        Parameters value – The value the attribute contains.

    eq(value)
        Creates a condition where the attribute is equal to the value.
        Parameters value – The value that the attribute is equal to.

    exists()
        Creates a condition where the attribute exists.

    gt(value)
        Creates a condition where the attribute is greater than the value.
        Parameters value – The value that the attribute is greater than.

    gte(value)
        Creates a condition where the attribute is greater than or equal to
        the value.
        Parameters value – The value that the attribute is greater than or equal to.

    is_in(value)
        Creates a condition where the attribute is in the value.
        Parameters value (list) – The value that the attribute is in.

    lt(value)
        Creates a condition where the attribute is less than the value.
        Parameters value – The value that the attribute is less than.

    lte(value)
        Creates a condition where the attribute is less than or equal to
        the value.
        Parameters value – The value that the attribute is less than or equal to.

    ne(value)
        Creates a condition where the attribute is not equal to the value
        Parameters value – The value that the attribute is not equal to.

    not_exists()
        Creates a condition where the attribute does not exist.

    size()
        Creates a condition for the attribute size.
```
Note another AttributeBase method must be called on the returned size condition to be a valid DynamoDB condition.

S3 Customization Reference

S3 Command Injection

boto3.s3.inject.bucket_download_file(self, Key, Filename, ExtraArgs=None, Callback=None, Config=None)

Download an S3 object to a file.

Usage:

```python
import boto3
s3 = boto3.resource('s3')
s3.Bucket('mybucket').download_file('hello.txt', '/tmp/hello.txt')
```

Similar behavior as S3Transfer's download_file() method, except that parameters are capitalized. Detailed examples can be found at S3Transfer's Usage.

boto3.s3.inject.bucket_load(self, *args, **kwargs)

Calls s3.Client.list_buckets() to update the attributes of the Bucket resource.

boto3.s3.inject.bucket_upload_file(self, Key, Filename, ExtraArgs=None, Callback=None, Config=None)

Upload a file to an S3 object.

Usage:

```python
import boto3
s3 = boto3.resource('s3')
s3.Bucket('mybucket').upload_file('/tmp/hello.txt', 'hello.txt')
```

Similar behavior as S3Transfer's upload_file() method, except that parameters are capitalized. Detailed examples can be found at S3Transfer's Usage.

boto3.s3.inject.download_file(self, Bucket, Filename, ExtraArgs=None, Callback=None, Config=None)

Download an S3 object to a file.

Usage:

```python
import boto3
s3 = boto3.resource('s3')
s3.meta.client.download_file('mybucket', 'hello.txt', '/tmp/hello.txt')
```

Similar behavior as S3Transfer's download_file() method, except that parameters are capitalized. Detailed examples can be found at S3Transfer's Usage.

boto3.s3.inject.inject_bucket_methods(class_attributes, **kwargs)

boto3.s3.inject.inject_object_methods(class_attributes, **kwargs)

boto3.s3.inject.inject_s3_transfer_methods(class_attributes, **kwargs)

boto3.s3.inject.object_download_file(self, Filename, ExtraArgs=None, Callback=None, Config=None)

Download an S3 object to a file.

Usage:
import boto3
s3 = boto3.resource('s3')
s3.Object('mybucket', 'hello.txt').download_file('/tmp/hello.txt')

Similar behavior as S3Transfer’s download_file() method, except that parameters are capitalized. Detailed examples can be found at S3Transfer’s Usage.

boto3.s3.inject.object_upload_file(self, Filename, ExtraArgs=None, Callback=None, Config=None)

Upload a file to an S3 object.
Usage:

import boto3
s3 = boto3.resource('s3')
s3.Object('mybucket', 'hello.txt').upload_file('/tmp/hello.txt')

Similar behavior as S3Transfer’s upload_file() method, except that parameters are capitalized. Detailed examples can be found at S3Transfer’s Usage.

boto3.s3.inject.upload_file(self, Filename, Bucket, Key, ExtraArgs=None, Callback=None, Config=None)

Upload a file to an S3 object.
Usage:

import boto3
s3 = boto3.resource('s3')
s3.meta.client.upload_file('/tmp/hello.txt', 'mybucket', 'hello.txt')

Similar behavior as S3Transfer’s upload_file() method, except that parameters are capitalized. Detailed examples can be found at S3Transfer’s Usage.

S3 Transfers

Abstractions over S3’s upload/download operations.

This module provides high level abstractions for efficient uploads/downloads. It handles several things for the user:

- Automatically switching to multipart transfers when a file is over a specific size threshold
- Uploading/downloading a file in parallel
- Throttling based on max bandwidth
- Progress callbacks to monitor transfers
- Retries. While botocore handles retries for streaming uploads, it is not possible for it to handle retries for streaming downloads. This module handles retries for both cases so you don’t need to implement any retry logic yourself.

This module has a reasonable set of defaults. It also allows you to configure many aspects of the transfer process including:

- Multipart threshold size
- Max parallel downloads
- Max bandwidth
- Socket timeouts

3.3. Customizations
• Retry amounts

There is no support for s3->s3 multipart copies at this time.

Usage  The simplest way to use this module is:

```python
client = boto3.client('s3', 'us-west-2')
transfer = S3Transfer(client)
# Upload /tmp/myfile to s3://bucket/key
transfer.upload_file('/tmp/myfile', 'bucket', 'key')

# Download s3://bucket/key to /tmp/myfile
transfer.download_file('bucket', 'key', '/tmp/myfile')
```

The `upload_file` and `download_file` methods also accept `**kwargs`, which will be forwarded through to the corresponding client operation. Here are a few examples using `upload_file`:

```python
# Making the object public
transfer.upload_file('/tmp/myfile', 'bucket', 'key',
                     extra_args={'ACL': 'public-read'})

# Setting metadata
transfer.upload_file('/tmp/myfile', 'bucket', 'key',
                     extra_args={'Metadata': {'a': 'b', 'c': 'd'}})

# Setting content type
transfer.upload_file('/tmp/myfile.json', 'bucket', 'key',
                     extra_args={'ContentType': 'application/json'})
```

The `S3Transfer` class also supports progress callbacks so you can provide transfer progress to users. Both the `upload_file` and `download_file` methods take an optional `callback` parameter. Here’s an example of how to print a simple progress percentage to the user:

```python
class ProgressPercentage(object):
    def __init__(self, filename):
        self._filename = filename
        self._size = float(os.path.getsize(filename))
        self._seen_so_far = 0
        self._lock = threading.Lock()

    def __call__(self, bytes_amount):
        # To simplify we'll assume this is hooked up
        # to a single filename.
        with self._lock:
            self._seen_so_far += bytes_amount
            percentage = (self._seen_so_far / self._size) * 100
            sys.stdout.write('
%s %s / %s (%.2f%%)
  ' % (self._filename, self._seen_so_far, self._size, percentage))

transfer = S3Transfer(boto3.client('s3', 'us-west-2'))
# Upload /tmp/myfile to s3://bucket/key and print upload progress. transfer.upload_file('/tmp/myfile', 'bucket', 'key',
callback=ProgressPercentage('/tmp/myfile'))
```
You can also provide a TransferConfig object to the S3Transfer object that gives you more fine grained control over the transfer. For example:

```python
client = boto3.client('s3', 'us-west-2')
config = TransferConfig(
    multipart_threshold=8 * 1024 * 1024,
    max_concurrency=10,
    num_download_attempts=10,
)
transfer = S3Transfer(client, config)
transfer.upload_file('/tmp/foo', 'bucket', 'key')
```

```python
class boto3.s3.transfer.MultipartDownloader (client, config, osutil, executor_cls=<class 'concurrent.futures.thread.ThreadPoolExecutor'>)

download_file (bucket, key, filename, object_size, extra_args, callback=None)
```

class boto3.s3.transfer.MultipartUploader (client, config, osutil, executor_cls=<class 'concurrent.futures.thread.ThreadPoolExecutor'>)

```python
UPLOAD_PART_ARGS = ['SSECustomerKey', 'SSECustomerAlgorithm', 'SSECustomerKeyMD5', 'RequestPayer']
upload_file (filename, bucket, key, callback, extra_args)
```

class boto3.s3.transfer.OSUtils

```python
get_file_size (filename)
open (filename, mode)
open_file_chunk_reader (filename, start_byte, size, callback)
remove_file (filename)
    Remove a file, noop if file does not exist.
rename_file (current_filename, new_filename)
```

exception boto3.s3.transfer.QueueShutdownError

```python
class boto3.s3.transfer.ReadFileChunk (fileobj, start_byte, chunk_size, full_file_size, callback=None, enable_callback=True)

Given a file object shown below:
```
|___________________________________________________| 0 1 1 full_file_size
```
```
|—chunk_size—|
```
```
start_byte
```

Parameters
- fileobj (file) – File like object
- start_byte (int) – The first byte from which to start reading.
- chunk_size (int) – The max chunk size to read. Trying to read past the end of the chunk size will behave like you’ve reached the end of the file.
- full_file_size (int) – The entire content length associated with fileobj.
- callback (function(amount_read)) – Called whenever data is read from this object.

```python
close()

disable_callback()

enable_callback()
```
classmethod from_filename(filename, start_byte, chunk_size, callback=None, enable_callback=True)

Convenience factory function to create from a filename.

Parameters

- start_byte (int) – The first byte from which to start reading.
- chunk_size (int) – The max chunk size to read. Trying to read pass the end of
  the chunk size will behave like you’ve reached the end of the file.
- full_file_size (int) – The entire content length associated with fileobj.
- callback (function(amount_read)) – Called whenever data is read from this ob-
  ject.
- enable_callback (bool) – Indicate whether to invoke callback during read() calls.

Return type  ReadFileChunk

Returns  A new instance of ReadFileChunk

read(amount=None)

seek(where)

tell()

class boto3.s3.transfer.S3Transfer(client, config=None, osutil=None)

ALLOWED_DOWNLOAD_ARGS = ['VersionId', 'SSECustomerAlgorithm', 'SSECcustomerKey', 'SSECcustomerKeyMD5', 'REQUESTPAYER']

ALLOWED_UPLOAD_ARGS = ['ACL', 'CacheControl', 'ContentDisposition', 'ContentEncoding', 'ContentLanguage', 'ContentType', 'Expires', ...

download_file(bucket, key, filename, extra_args=None, callback=None)

Download an S3 object to a file.

Variants have also been injected into S3 client, Bucket and Object. You don’t have to use
S3Transfer.download_file() directly.

upload_file(filename, bucket, key, callback=None, extra_args=None)

Upload a file to an S3 object.

Variants have also been injected into S3 client, Bucket and Object. You don’t have to use
S3Transfer.upload_file() directly.

class boto3.s3.transfer.ShutdownQueue(maxsize=0)

A queue implementation that can be shutdown.

Shutting down a queue means that this class adds a trigger_shutdown method that will trigger all subsequent
calls to put() to fail with a QueueShutdownError.

It purposefully deviates from queue.Queue, and is not meant to be a drop in replacement for queue.Queue.

put(item)

trigger_shutdown()

class boto3.s3.transfer.StreamReaderProgress(stream, callback=None)

Wrapper for a read only stream that adds progress callbacks.

read(*args, **kwargs)

class boto3.s3.transfer.TransferConfig(multipart_threshold=8388608, max_concurrency=10,
  multipart_chunksize=8388608,
  num_download_attempts=5, max_io_queue=100)

boto3.s3.transfer.disable_upload_callbacks(request, operation_name, **kwargs)

boto3.s3.transfer.enable_upload_callbacks(request, operation_name, **kwargs)

boto3.s3.transfer.random_file_extension(num_digits=8)
