  the grant. This value can be a globally unique identifier or a fully specified ARN
  of the key.
  – Key ARN Example - arn:aws:kms:us-east-
    1:123456789012:123456789012:123456789012:123456789012
  – Globally Unique Key ID Example - 123456789012:123456789012:123456789012
• GrantId (string) – Unique identifier of the grant to be retired. The grant ID is
  returned by the CreateGrant function.
  – Grant ID Example - 0123456789012345678901234567890123456789012345678901234567890123

Returns  None
**revoke_grant**(**kwargs**)  
Revoke a grant. You can revoke a grant to actively deny operations that depend on it.

**Request Syntax**

```python
response = client.revoke_grant(
    KeyId='string',
    GrantId='string'
)
```

**Parameters**

- **KeyId** *(string)* – [REQUIRED]
  
  A unique identifier for the customer master key associated with the grant. This value can be a globally unique identifier or the fully specified ARN to a key.
  
  - Key ARN Example - `arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012`
  
  - Globally Unique Key ID Example - `12345678-1234-1234-1234-123456789012`

- **GrantId** *(string)* – [REQUIRED]
  
  Identifier of the grant to be revoked.

**Returns** None

**update_alias**(**kwargs**)  
Updates an alias to associate it with a different key.

An alias name can contain only alphanumeric characters, forward slashes (/), underscores (_), and dashes (-). An alias must start with the word “alias” followed by a forward slash (alias/). An alias that begins with “aws” after the forward slash (alias/aws...) is reserved by Amazon Web Services (AWS).

An alias is not a property of a key. Therefore, an alias can be associated with and disassociated from an existing key without changing the properties of the key.

Note that you cannot create or update an alias that represents a key in another account.

**Request Syntax**

```python
response = client.update_alias(
    AliasName='string',
    TargetKeyId='string'
)
```

**Parameters**

- **AliasName** *(string)* – [REQUIRED] String that contains the name of the alias to be modified. The name must start with the word “alias” followed by a forward slash (alias/). Aliases that begin with “alias/AWS” are reserved.

- **TargetKeyId** *(string)* – [REQUIRED]
  
  Unique identifier of the customer master key to be associated with the alias. This value can be a globally unique identifier or the fully specified ARN of a key.
  
  - Key ARN Example - `arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012`
  
  - Globally Unique Key ID Example - `12345678-1234-1234-1234-123456789012`

**Returns** None

**update_key_description**(**kwargs**)  
Updates the description of a key.
Request Syntax

```python
response = client.update_key_description(
    KeyId='string',
    Description='string'
)
```

Parameters

- **KeyId** *(string)* – [REQUIRED]
  A unique identifier for the customer master key. This value can be a globally unique identifier or the fully specified ARN to a key.
  - Key ARN Example - `arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012`
  - Globally Unique Key ID Example - `12345678-1234-1234-1234-123456789012`

- **Description** *(string)* – [REQUIRED]
  New description for the key.

Returns None

Lambda

Table of Contents

- **Lambda**
  - Client
  - Paginators

Client

```python
import boto3

client = boto3.client('lambda')
```

These are the available methods:

- `add_permission()`
- `can_paginate()`
- `create_event_source_mapping()`
- `create_function()`
- `delete_event_source_mapping()`
- `delete_function()`
- `generate_presigned_url()`
- `get_event_source_mapping()`
- `get_function()`
- `get_function_configuration()`
- `get_paginators()`
- `get_policy()`
- `get_waiter()`
**add_permission**(**kwargs**)

Adds a permission to the access policy associated with the specified AWS Lambda function. In a “push event” model, the access policy attached to the Lambda function grants Amazon S3 or a user application permission for the Lambda `lambda:Invoke` action. For information about the push model, see AWS Lambda: How it Works. Each Lambda function has one access policy associated with it. You can use the `AddPermission` API to add a permission to the policy. You have one access policy but it can have multiple permission statements.

This operation requires permission for the `lambda:AddPermission` action.

**Request Syntax**

```python
response = client.add_permission(
    FunctionName='string',
    StatementId='string',
    Action='string',
    Principal='string',
    SourceArn='string',
    SourceAccount='string'
)
```

**Parameters**

- **FunctionName (string)** – [REQUIRED]
  
  Name of the Lambda function whose access policy you are updating by adding a new permission.

  You can specify an unqualified function name (for example, “Thumbnail”) or you can specify Amazon Resource Name (ARN) of the function (for example, “arn:aws:lambda:us-west-2:account-id:function:ThumbNail”). AWS Lambda also allows you to specify only the account ID qualifier (for example, “account-id:Thumbnail”). Note that the length constraint applies only to the ARN. If you specify only the function name, it is limited to 64 character in length.

- **StatementId (string)** – [REQUIRED]
  
  A unique statement identifier.

- **Action (string)** – [REQUIRED]
  
  The AWS Lambda action you want to allow in this statement. Each Lambda action is a string starting with “lambda:” followed by the API name (see Operations). For example, “lambda:CreateFunction”. You can use wildcard (“lambda:*”) to grant permission for all AWS Lambda actions.

- **Principal (string)** – [REQUIRED]
  
  The principal who is getting this permission. It can be Amazon S3 service Principal (“s3.amazonaws.com”) if you want Amazon S3 to invoke the function, an AWS account ID if you are granting cross-account permission, or any valid AWS service principal such as “sns.amazonaws.com”. For example, you might want to allow a custom application in another AWS account to push events to AWS Lambda by invoking your function.
- **SourceArn** (*string*) – This is optional; however, when granting Amazon S3 permission to invoke your function, you should specify this field with the bucket Amazon Resource Name (ARN) as its value. This ensures that only events generated from the specified bucket can invoke the function.

  **Warning:** If you add a permission for the Amazon S3 principal without providing the source ARN, any AWS account that creates a mapping to your function ARN can send events to invoke your Lambda function from Amazon S3.

- **SourceAccount** (*string*) – The AWS account ID (without a hyphen) of the source owner. For example, if the **SourceArn** identifies a bucket, then this is the bucket owner’s account ID. You can use this additional condition to ensure the bucket you specify is owned by a specific account (it is possible the bucket owner deleted the bucket and some other AWS account created the bucket). You can also use this condition to specify all sources (that is, you don’t specify the **SourceArn**) owned by a specific account.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
  'Statement': 'string'
}
```

**Response Structure**

- (*dict*) –
  - **Statement** (*string*) –
    
    The permission statement you specified in the request. The response returns the same as a string using "" as an escape character in the JSON.

**can_paginate**(operation_name)

Check if an operation can be paginated.

**Parameters** operation_name (*string*) – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

**Returns** *True* if the operation can be paginated, *False* otherwise.

**create_event_source_mapping**(**kwargs)**

Identifies a stream as an event source for a Lambda function. It can be either an Amazon Kinesis stream or an Amazon DynamoDB stream. AWS Lambda invokes the specified function when records are posted to the stream.

This is the pull model, where AWS Lambda invokes the function. For more information, go to AWS Lambda: How it Works in the AWS Lambda Developer Guide.

This association between an Amazon Kinesis stream and a Lambda function is called the event source mapping. You provide the configuration information (for example, which stream to read from and which Lambda function to invoke) for the event source mapping in the request body.

Each event source, such as an Amazon Kinesis or a DynamoDB stream, can be associated with multiple AWS Lambda function. A given Lambda function can be associated with multiple AWS event sources.

This operation requires permission for the `lambda:CreateEventSourceMapping` action.
Request Syntax

```python
response = client.create_event_source_mapping(
    EventSourceArn='string',
    FunctionName='string',
    Enabled=True|False,
    BatchSize=123,
    StartingPosition='TRIM_HORIZON'|'LATEST'
)
```

Parameters

- **EventSourceArn** *(string)* – [REQUIRED]
  
The Amazon Resource Name (ARN) of the Amazon Kinesis or the Amazon DynamoDB stream that is the event source. Any record added to this stream could cause AWS Lambda to invoke your Lambda function, it depends on the `BatchSize`. AWS Lambda POSTs the Amazon Kinesis event, containing records, to your Lambda function as JSON.

- **FunctionName** *(string)* – [REQUIRED]
  
The Lambda function to invoke when AWS Lambda detects an event on the stream.
  
  You can specify an unqualified function name (for example, “Thumbnail”) or you can specify Amazon Resource Name (ARN) of the function (for example, “arn:aws:lambda:us-west-2:account-id:function:ThumbNail”). AWS Lambda also allows you to specify only the account ID qualifier (for example, “account-id:Thumbnail”). Note that the length constraint applies only to the ARN. If you specify only the function name, it is limited to 64 character in length.

- **Enabled** *(boolean)* – Indicates whether AWS Lambda should begin polling the event source, the default is not enabled.

- **BatchSize** *(integer)* – The largest number of records that AWS Lambda will retrieve from your event source at the time of invoking your function. Your function receives an event with all the retrieved records. The default is 100 records.

- **StartingPosition** *(string)* – [REQUIRED]
  
The position in the stream where AWS Lambda should start reading. For more information, go to ShardIteratorType in the Amazon Kinesis API Reference.

Return type *dict*

Returns

Response Syntax

```json
{
    'UUID': 'string',
    'BatchSize': 123,
    'EventSourceArn': 'string',
    'FunctionArn': 'string',
    'LastModified': datetime(2015, 1, 1),
    'LastProcessingResult': 'string',
    'State': 'string',
    'StateTransitionReason': 'string'
}
```

Response Structure

- *(dict)* –
  
  Describes mapping between an Amazon Kinesis stream and a Lambda function.
– **UUID (string)** –

The AWS Lambda assigned opaque identifier for the mapping.

– **BatchSize (integer)** –

The largest number of records that AWS Lambda will retrieve from your event source at the time of invoking your function. Your function receives an event with all the retrieved records.

– **EventSourceArn (string)** –

The Amazon Resource Name (ARN) of the Amazon Kinesis stream that is the source of events.

– **FunctionArn (string)** –

The Lambda function to invoke when AWS Lambda detects an event on the stream.

– **LastModified (datetime)** –

The UTC time string indicating the last time the event mapping was updated.

– **LastProcessingResult (string)** –

The result of the last AWS Lambda invocation of your Lambda function.

– **State (string)** –

The state of the event source mapping. It can be “Creating”, “Enabled”, “Disabled”, “Enabling”, “Disabling”, “Updating”, or “Deleting”.

– **StateTransitionReason (string)** –

The reason the event source mapping is in its current state. It is either user-requested or an AWS Lambda-initiated state transition.

```python
create_function(**kwargs)
```

Creates a new Lambda function. The function metadata is created from the request parameters, and the code for the function is provided by a .zip file in the request body. If the function name already exists, the operation will fail. Note that the function name is case-sensitive.

This operation requires permission for the `lambda:CreateFunction` action.

**Request Syntax**

```python
response = client.create_function(
    FunctionName='string',
    Runtime='nodejs'|'java8',
    Role='string',
    Handler='string',
    Description='string',
    Timeout=123,
    MemorySize=123,
    Code={
        'ZipFile': b'bytes',
        'S3Bucket': 'string',
        'S3Key': 'string',
        'S3ObjectVersion': 'string'
    }
)
```

**Parameters**

- **FunctionName (string)** – [REQUIRED]
The name you want to assign to the function you are uploading. You can specify an unqualified function name (for example, “Thumbnail”) or you can specify Amazon Resource Name (ARN) of the function (for example, “arn:aws:lambda:us-west-2:account-id:function:ThumbNail”). AWS Lambda also allows you to specify only the account ID qualifier (for example, “account-id:Thumbnail”). Note that the length constraint applies only to the ARN. If you specify only the function name, it is limited to 64 character in length. The function names appear in the console and are returned in the ListFunctions API. Function names are used to specify functions to other AWS Lambda APIs, such as Invite.

- **Runtime (string)** – [REQUIRED]
  
The runtime environment for the Lambda function you are uploading. Currently, Lambda supports “java” and “nodejs” as the runtime.

- **Role (string)** – [REQUIRED]
  
The Amazon Resource Name (ARN) of the IAM role that Lambda assumes when it executes your function to access any other Amazon Web Services (AWS) resources. For more information, see AWS Lambda: How it Works

- **Handler (string)** – [REQUIRED]
  
The function within your code that Lambda calls to begin execution. For Node.js, it is the module-name .*export* value in your function. For Java, it can be package.class-name::handler or package.class-name. For more information, see Lambda Function Handler (Java).

- **Description (string)** – A short, user-defined function description. Lambda does not use this value. Assign a meaningful description as you see fit.

- **Timeout (integer)** – The function execution time at which Lambda should terminate the function. Because the execution time has cost implications, we recommend you set this value based on your expected execution time. The default is 3 seconds.

- **MemorySize (integer)** – The amount of memory, in MB, your Lambda function is given. Lambda uses this memory size to infer the amount of CPU and memory allocated to your function. Your function use-case determines your CPU and memory requirements. For example, a database operation might need less memory compared to an image processing function. The default value is 128 MB. The value must be a multiple of 64 MB.

- **Code (dict)** – [REQUIRED]
  
The code for the Lambda function.

  - **ZipFile (bytes)** –
    
    A base64-encoded .zip file containing your deployment package. For more information about creating a .zip file, go to Execution Permissions in the AWS Lambda Developer Guide.

  - **S3Bucket (string)** –
    
    Amazon S3 bucket name where the .zip file containing your deployment package is stored. This bucket must reside in the same AWS region where you are creating the Lambda function.

  - **S3Key (string)** –
    
    The Amazon S3 object (the deployment package) key name you want to upload.

  - **S3ObjectVersion (string)** –
    
    The Amazon S3 object (the deployment package) version you want to upload.
Return type: dict

Response Syntax

```python
{
    'FunctionName': 'string',
    'FunctionArn': 'string',
    'Runtime': 'nodejs'|'java8',
    'Role': 'string',
    'Handler': 'string',
    'CodeSize': 123,
    'Description': 'string',
    'Timeout': 123,
    'MemorySize': 123,
    'LastModified': 'string'
}
```

Response Structure

- (dict) –
  A complex type that describes function metadata.
  - **FunctionName** *(string)* –
    The name of the function.
  - **FunctionArn** *(string)* –
    The Amazon Resource Name (ARN) assigned to the function.
  - **Runtime** *(string)* –
    The runtime environment for the Lambda function.
  - **Role** *(string)* –
    The Amazon Resource Name (ARN) of the IAM role that Lambda assumes when it executes your function to access any other Amazon Web Services (AWS) resources.
  - **Handler** *(string)* –
    The function Lambda calls to begin executing your function.
  - **CodeSize** *(integer)* –
    The size, in bytes, of the function .zip file you uploaded.
  - **Description** *(string)* –
    The user-provided description.
  - **Timeout** *(integer)* –
    The function execution time at which Lambda should terminate the function. Because the execution time has cost implications, we recommend you set this value based on your expected execution time. The default is 3 seconds.
  - **MemorySize** *(integer)* –
    The memory size, in MB, you configured for the function. Must be a multiple of 64 MB.
  - **LastModified** *(string)* –
    The timestamp of the last time you updated the function.
**delete_event_source_mapping(**kwargs)**

Removes an event source mapping. This means AWS Lambda will no longer invoke the function for events in the associated source.

This operation requires permission for the `lambda:DeleteEventSourceMapping` action.

**Request Syntax**

```python
response = client.delete_event_source_mapping(
    UUID='string'
)
```

**Parameters**  
**UUID (string)** – [REQUIRED]  
The event source mapping ID.

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'UUID': 'string',
    'BatchSize': 123,
    'EventSourceArn': 'string',
    'FunctionArn': 'string',
    'LastModified': datetime(2015, 1, 1),
    'LastProcessingResult': 'string',
    'State': 'string',
    'StateTransitionReason': 'string'
}
```

**Response Structure**

- (dict) –  

  Describes mapping between an Amazon Kinesis stream and a Lambda function.
  - **UUID (string)** –  
    The AWS Lambda assigned opaque identifier for the mapping.
  - **BatchSize (integer)** –  
    The largest number of records that AWS Lambda will retrieve from your event source at the time of invoking your function. Your function receives an event with all the retrieved records.
  - **EventSourceArn (string)** –  
    The Amazon Resource Name (ARN) of the Amazon Kinesis stream that is the source of events.
  - **FunctionArn (string)** –  
    The Lambda function to invoke when AWS Lambda detects an event on the stream.
  - **LastModified (datetime)** –  
    The UTC time string indicating the last time the event mapping was updated.
  - **LastProcessingResult (string)** –  
    The result of the last AWS Lambda invocation of your Lambda function.
  - **State (string)** –  

3.1. Services
The state of the event source mapping. It can be “Creating”, “Enabled”, “Disabled”, “Enabling”, “Disabling”, “Updating”, or “Deleting”.

- **StateTransitionReason (string)** –

  The reason the event source mapping is in its current state. It is either user-requested or an AWS Lambda-initiated state transition.

---

### delete_function(**kwargs)

Deletes the specified Lambda function code and configuration.

When you delete a function the associated access policy is also deleted. You will need to delete the event source mappings explicitly.

This operation requires permission for the lambda:DeleteFunction action.

**Request Syntax**

```python
response = client.delete_function(
    FunctionName='string'
)
```

**Parameters**

- **FunctionName (string)** – **[REQUIRED]**

  The Lambda function to delete.

  You can specify an unqualified function name (for example, “Thumbnail”) or you can specify Amazon Resource Name (ARN) of the function (for example, “arn:aws:lambda:us-west-2:account-id:function:Thumbnail”). AWS Lambda also allows you to specify only the account ID qualifier (for example, “account-id:Thumbnail”). Note that the length constraint applies only to the ARN. If you specify only the function name, it is limited to 64 character in length.

- **Returns**

  None

---

### generate_presigned_url(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)

Generate a presigned url given a client, its method, and arguments

**Parameters**

- **ClientMethod (string)** – The client method to presign for
- **Params (dict)** – The parameters normally passed to ClientMethod.
- **ExpiresIn (int)** – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod (string)** – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

- **Returns**

  The presigned url

---

### get_event_source_mapping(**kwargs)

Returns configuration information for the specified event source mapping (see CreateEventSourceMapping).

This operation requires permission for the lambda:GetEventSourceMapping action.

**Request Syntax**

```python
response = client.get_event_source_mapping(
    UUID='string'
)
```

**Parameters**

- **UUID (string)** – **[REQUIRED]**

  The AWS Lambda assigned ID of the event source mapping.

- **Return type**

  dict
Returns

Response Syntax

```
{
    'UUID': 'string',
    'BatchSize': 123,
    'EventSourceArn': 'string',
    'FunctionArn': 'string',
    'LastModified': datetime(2015, 1, 1),
    'LastProcessingResult': 'string',
    'State': 'string',
    'StateTransitionReason': 'string'
}
```

Response Structure

- (dict) –  
  Describes mapping between an Amazon Kinesis stream and a Lambda function.
  - **UUID** *(string)* –  
    The AWS Lambda assigned opaque identifier for the mapping.
  - **BatchSize** *(integer)* –  
    The largest number of records that AWS Lambda will retrieve from your event source at the time of invoking your function. Your function receives an event with all the retrieved records.
  - **EventSourceArn** *(string)* –  
    The Amazon Resource Name (ARN) of the Amazon Kinesis stream that is the source of events.
  - **FunctionArn** *(string)* –  
    The Lambda function to invoke when AWS Lambda detects an event on the stream.
  - **LastModified** *(datetime)* –  
    The UTC time string indicating the last time the event mapping was updated.
  - **LastProcessingResult** *(string)* –  
    The result of the last AWS Lambda invocation of your Lambda function.
  - **State** *(string)* –  
    The state of the event source mapping. It can be “Creating”, “Enabled”, “Disabled”, “Enabling”, “Disabling”, “Updating”, or “Deleting”.
  - **StateTransitionReason** *(string)* –  
    The reason the event source mapping is in its current state. It is either user-requested or an AWS Lambda-initiated state transition.

`get_function(**kwargs)`

Returns the configuration information of the Lambda function and a presigned URL link to the .zip file you uploaded with CreateFunction so you can download the .zip file. Note that the URL is valid for up to 10 minutes. The configuration information is the same information you provided as parameters when uploading the function.

This operation requires permission for the `lambda:GetFunction` action.

Request Syntax
response = client.get_function(
    FunctionName='string'
)

Parameters  **FunctionName (string)** – [REQUIRED]

The Lambda function name.

You can specify an unqualified function name (for example, “Thumbnail”) or you can specify Amazon Resource Name (ARN) of the function (for example, “arn:aws:lambda:us-west-2:account-id:function:ThumbNail”). AWS Lambda also allows you to specify only the account ID qualifier (for example, “account-id:Thumbnail”). Note that the length constraint applies only to the ARN. If you specify only the function name, it is limited to 64 character in length.

Return type dict

Returns

Response Syntax

```
{
    'Configuration': {
        'FunctionName': 'string',
        'FunctionArn': 'string',
        'Runtime': 'nodejs'|'java8',
        'Role': 'string',
        'Handler': 'string',
        'CodeSize': 123,
        'Description': 'string',
        'Timeout': 123,
        'MemorySize': 123,
        'LastModified': 'string'
    },
    'Code': {
        'RepositoryType': 'string',
        'Location': 'string'
    }
}
```

Response Structure

* (dict) –

This response contains the object for the Lambda function location (see API FunctionCodeLocation

  - **Configuration (dict)** –

    A complex type that describes function metadata.

    * **FunctionName (string)** –

      The name of the function.

    * **FunctionArn (string)** –

      The Amazon Resource Name (ARN) assigned to the function.

    * **Runtime (string)** –

      The runtime environment for the Lambda function.

    * **Role (string)** –

      The Amazon Resource Name (ARN) of the IAM role that Lambda assumes when it executes your function to access any other Amazon Web Services (AWS) resources.

* **Handler** *(string)* –
  The function Lambda calls to begin executing your function.

* **CodeSize** *(integer)* –
  The size, in bytes, of the function .zip file you uploaded.

* **Description** *(string)* –
  The user-provided description.

* **Timeout** *(integer)* –
  The function execution time at which Lambda should terminate the function. Because the execution time has cost implications, we recommend you set this value based on your expected execution time. The default is 3 seconds.

* **MemorySize** *(integer)* –
  The memory size, in MB, you configured for the function. Must be a multiple of 64 MB.

* **LastModified** *(string)* –
  The timestamp of the last time you updated the function.

  – **Code** *(dict)* –
    The object for the Lambda function location.

    * **RepositoryType** *(string)* –
      The repository from which you can download the function.

    * **Location** *(string)* –
      The presigned URL you can use to download the function’s .zip file that you previously uploaded. The URL is valid for up to 10 minutes.

**get_function_configuration(**kwargs**)**

Returns the configuration information of the Lambda function. This is the same information you provided as parameters when uploading the function by using CreateFunction.

This operation requires permission for the lambda:GetFunctionConfiguration operation.

**Request Syntax**

```python
response = client.get_function_configuration(
    FunctionName='string'
)
```

**Parameters**  
**FunctionName** *(string)* – [REQUIRED]

The name of the Lambda function for which you want to retrieve the configuration information.

You can specify an unqualified function name (for example, “Thumbnail”) or you can specify Amazon Resource Name (ARN) of the function (for example, “arn:aws:lambda:us-west-2:account-id:function:Thumbnai”). AWS Lambda also allows you to specify only the account ID qualifier (for example, “account-id:Thumbnail”). Note that the length constraint applies only to the ARN. If you specify only the function name, it is limited to 64 character in length.

**Return type**  
**dict**

**Returns**

**Response Syntax**

3.1. Services
{  
    'FunctionName': 'string',  
    'FunctionArn': 'string',  
    'Runtime': 'nodejs'|'java8',  
    'Role': 'string',  
    'Handler': 'string',  
    'CodeSize': 123,  
    'Description': 'string',  
    'Timeout': 123,  
    'MemorySize': 123,  
    'LastModified': 'string'  
}

**Response Structure**

• (dict) –

A complex type that describes function metadata.

  – **FunctionName** *(string)* –

  The name of the function.

  – **FunctionArn** *(string)* –

  The Amazon Resource Name (ARN) assigned to the function.

  – **Runtime** *(string)* –

  The runtime environment for the Lambda function.

  – **Role** *(string)* –

  The Amazon Resource Name (ARN) of the IAM role that Lambda assumes when it executes your function to access any other Amazon Web Services (AWS) resources.

  – **Handler** *(string)* –

  The function Lambda calls to begin executing your function.

  – **CodeSize** *(integer)* –

  The size, in bytes, of the function .zip file you uploaded.

  – **Description** *(string)* –

  The user-provided description.

  – **Timeout** *(integer)* –

  The function execution time at which Lambda should terminate the function. Because the execution time has cost implications, we recommend you set this value based on your expected execution time. The default is 3 seconds.

  – **MemorySize** *(integer)* –

  The memory size, in MB, you configured for the function. Must be a multiple of 64 MB.

  – **LastModified** *(string)* –

  The timestamp of the last time you updated the function.

**get_paginator**(operation_name)

Create a paginator for an operation.

**Parameters**

  operation_name *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs),
if the `create_foo` operation can be paginated, you can use the call
`client.get Paginator("create_foo")`.

- **Raises** `OperationNotPageableError` Raised if the operation is not pageable. You can use
  the `client.can_paginate` method to check if an operation is pageable.

- **Return type** `botocore.paginate.Paginator`
- **Returns** A paginator object.

```python
get_policy(**kwargs)
```

Returns the access policy, containing a list of permissions granted via the `AddPermission` API, associated with the specified bucket.

You need permission for the `lambda:GetPolicy` action.

**Request Syntax**

```python
response = client.get_policy(
    FunctionName='string'
)
```

**Parameters**

- **FunctionName** (string) – [REQUIRED]

  Function name whose access policy you want to retrieve.

  You can specify an unqualified function name (for example, “Thumbnail”) or you can specify Amazon Resource Name (ARN) of the function (for example, “arn:aws:lambda:us-west-2:account-id:function:ThumbNail”). AWS Lambda also allows you to specify only the account ID qualifier (for example, “account-id:Thumbnail”). Note that the length constraint applies only to the ARN. If you specify only the function name, it is limited to 64 character in length.

- **Return type** `dict`
- **Returns**

  **Response Syntax**

  ```
  { 'Policy': 'string'
  }
  ```

  **Response Structure**

  - (dict) –
    - **Policy** (string) –

      The access policy associated with the specified function. The response returns the same as a string using “” as an escape character in the JSON.

```python
get_waiter(waiter_name)
```

```python
invoke(**kwargs)
```

Invokes a specified Lambda function.

This operation requires permission for the `lambda:InvokeFunction` action.

**Request Syntax**

```python
response = client.invoke(
    FunctionName='string',
    InvocationType='Event'|'RequestResponse'|'DryRun',
    LogType='None'|'Tail',
    ClientContext='string',
```
Parameters

- **FunctionName (string)** – [REQUIRED]
  
  The Lambda function name.
  
  You can specify an unqualified function name (for example, “Thumbnail”) or you can specify Amazon Resource Name (ARN) of the function (for example, “arn:aws:lambda:us-west-2:account-id:function:ThumbNail”). AWS Lambda also allows you to specify only the account ID qualifier (for example, “account-id:Thumbnail”). Note that the length constraint applies only to the ARN. If you specify only the function name, it is limited to 64 character in length.

- **InvocationType (string)** – By default, the Invoke API assumes “RequestResponse” invocation type. You can optionally request asynchronous execution by specifying “Event” as the InvocationType. You can also use this parameter to request AWS Lambda to not execute the function but do some verification, such as if the caller is authorized to invoke the function and if the inputs are valid. You request this by specifying “DryRun” as the InvocationType. This is useful in a cross-account scenario when you want to verify access to a function without running it.

- **LogType (string)** – You can set this optional parameter to “Tail” in the request only if you specify the InvocationType parameter with value “RequestResponse”. In this case, AWS Lambda returns the base64-encoded last 4 KB of log data produced by your Lambda function in the x-amz-log-results header.

- **ClientContext (string)** – Using the ClientContext you can pass client-specific information to the Lambda function you are invoking. You can then process the client information in your Lambda function as you choose through the context variable. For an example of a ClientContext JSON, go to PutEvents in the Amazon Mobile Analytics API Reference and User Guide.

  The ClientContext JSON must be base64-encoded.

- **Payload (bytes)** – JSON that you want to provide to your Lambda function as input.

Return type  dict

Returns

Response Syntax

```python
{
    'StatusCode': 123,
    'FunctionError': 'string',
    'LogResult': 'string',
    'Payload': b'bytes'
}
```

Response Structure

- (dict) –
  
  Upon success, returns an empty response. Otherwise, throws an exception.

  - **StatusCode (integer)** –

    The HTTP status code will be in the 200 range for successful request. For the “RequestResponse” invocation type this status code will be 200. For the “Event” invocation type this status code will be 202. For the “DryRun” invocation type the status code will be 204.
- **FunctionError** *(string)* –

  Indicates whether an error occurred while executing the Lambda function. If an error occurred this field will have one of two values: *Handled* or *Unhandled*. **Handled** errors are errors that are reported by the function while the **Unhandled** errors are those detected and reported by AWS Lambda. Unhandled errors include out of memory errors and function timeouts. For information about how to report an **Handled** error, see [Programming Model](#).

- **LogResult** *(string)* –

  It is the base64-encoded logs for the Lambda function invocation. This is present only if the invocation type is “RequestResponse” and the logs were requested.

- **Payload** *(bytes)* –

  It is the JSON representation of the object returned by the Lambda function. In This is present only if the invocation type is “RequestResponse”.

  In the event of a function error this field contains a message describing the error. For the **Handled** errors the Lambda function will report this message. For **Unhandled** errors AWS Lambda reports the message.

```python
invoke_async(**kwargs)
```

**Warning:** This API is deprecated. We recommend you use [Invoke API](#) (see **Invoke**).

Submits an invocation request to AWS Lambda. Upon receiving the request, Lambda executes the specified function asynchronously. To see the logs generated by the Lambda function execution, see the CloudWatch logs console.

This operation requires permission for the *lambda:InvokeFunction* action.

**Request Syntax**

```python
response = client.invoke_async(
    FunctionName='string',
    InvokeArgs=b'bytes'
)
```

**Parameters**

- **FunctionName** *(string)* – [REQUIRED]
  
  The Lambda function name.

- **InvokeArgs** *(bytes)* – [REQUIRED]
  
  JSON that you want to provide to your Lambda function as input.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Status': 123
}
```

**Response Structure**

- *(dict)* –

  Upon success, it returns empty response. Otherwise, throws an exception.
list_event_source_mappings(**kwargs)

Returns a list of event source mappings you created using the CreateEventSourceMapping (see CreateEventSourceMapping), where you identify a stream as an event source. This list does not include Amazon S3 event sources.

For each mapping, the API returns configuration information. You can optionally specify filters to retrieve specific event source mappings.

This operation requires permission for the lambda:ListEventSourceMappings action.

**Request Syntax**

```python
response = client.list_event_source_mappings(
    EventSourceArn='string',
    FunctionName='string',
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **EventSourceArn (string)** – The Amazon Resource Name (ARN) of the Amazon Kinesis stream.
- **FunctionName (string)** – The name of the Lambda function.

You can specify an unqualified function name (for example, “Thumbnail”) or you can specify Amazon Resource Name (ARN) of the function (for example, “arn:aws:lambda:us-west-2:account-id:function:Thumbnail”). AWS Lambda also allows you to specify only the account ID qualifier (for example, “account-id:Thumbnail”). Note that the length constraint applies only to the ARN. If you specify only the function name, it is limited to 64 character in length.

- **Marker (string)** – Optional string. An opaque pagination token returned from a previous ListEventSourceMappings operation. If present, specifies to continue the list from where the returning call left off.
- **MaxItems (integer)** – Optional integer. Specifies the maximum number of event sources to return in response. This value must be greater than 0.

**Return type** dict

**Response Syntax**

```python
{
    'NextMarker': 'string',
    'EventSourceMappings': [
        {
            'UUID': 'string',
            'BatchSize': 123,
            'EventSourceArn': 'string',
            'FunctionArn': 'string',
            'LastModified': datetime(2015, 1, 1),
            'LastProcessingResult': 'string',
            'State': 'string',
            'StateTransitionReason': 'string'
        },
    ],
}
```
Response Structure
  • (dict) –
    Contains a list of event sources (see API_EventSourceMappingConfiguration )
    – NextMarker (string) –
      A string, present if there are more event source mappings.
    – EventSourceMappings (list) –
      An array of EventSourceMappingConfiguration objects.
        * (dict) –
          Describes mapping between an Amazon Kinesis stream and a Lambda function.
            · UUID (string) –
              The AWS Lambda assigned opaque identifier for the mapping.
            · BatchSize (integer) –
              The largest number of records that AWS Lambda will retrieve from your event source at the time of invoking your function. Your function receives an event with all the retrieved records.
            · EventSourceArn (string) –
              The Amazon Resource Name (ARN) of the Amazon Kinesis stream that is the source of events.
            · FunctionArn (string) –
              The Lambda function to invoke when AWS Lambda detects an event on the stream.
            · LastModified (datetime) –
              The UTC time string indicating the last time the event mapping was updated.
            · LastProcessingResult (string) –
              The result of the last AWS Lambda invocation of your Lambda function.
            · State (string) –
              The state of the event source mapping. It can be “Creating”, “Enabled”, “Disabled”, “Enabling”, “Disabling”, “Updating”, or “Deleting”.
            · StateTransitionReason (string) –
              The reason the event source mapping is in its current state. It is either user-requested or an AWS Lambda-initiated state transition.

list_functions(**kwargs)
Returns a list of your Lambda functions. For each function, the response includes the function configuration information. You must use GetFunction to retrieve the code for your function.

This operation requires permission for the lambda:ListFunctions action.

Request Syntax

    response = client.list_functions(
        Marker='string',
        **kwargs,
    )
MaxItems=123

Parameters

- **Marker** (*string*) – Optional string. An opaque pagination token returned from a previous `ListFunctions` operation. If present, indicates where to continue the listing.

- **MaxItems** (*integer*) – Optional integer. Specifies the maximum number of AWS Lambda functions to return in response. This parameter value must be greater than 0.

Return type: dict

Returns

Response Syntax

```
{
    'NextMarker': 'string',
    'Functions': [
        {
            'FunctionName': 'string',
            'FunctionArn': 'string',
            'Runtime': 'nodejs'|'java8',
            'Role': 'string',
            'Handler': 'string',
            'CodeSize': 123,
            'Description': 'string',
            'Timeout': 123,
            'MemorySize': 123,
            'LastModified': 'string'
        },
    ],
}
```

Response Structure

- *(dict)* –

  Contains a list of AWS Lambda function configurations (see `FunctionConfiguration`).

  - **NextMarker** (*string*) –

    A string, present if there are more functions.

  - **Functions** (*list*) –

    A list of Lambda functions.

    - *(dict)* –

      A complex type that describes function metadata.

      - **FunctionName** (*string*) –

        The name of the function.

      - **FunctionArn** (*string*) –

        The Amazon Resource Name (ARN) assigned to the function.

      - **Runtime** (*string*) –

        The runtime environment for the Lambda function.

      - **Role** (*string*) –

        The Amazon Resource Name (ARN) of the IAM role that Lambda assumes when it executes your function to access any
other Amazon Web Services (AWS) resources.

- **Handler** (string) –
  The function Lambda calls to begin executing your function.

- **CodeSize** (integer) –
  The size, in bytes, of the function .zip file you uploaded.

- **Description** (string) –
  The user-provided description.

- **Timeout** (integer) –
  The function execution time at which Lambda should terminate the function. Because the execution time has cost implications, we recommend you set this value based on your expected execution time. The default is 3 seconds.

- **MemorySize** (integer) –
  The memory size, in MB, you configured for the function. Must be a multiple of 64 MB.

- **LastModified** (string) –
  The timestamp of the last time you updated the function.

---

**remove_permission(** **kwargs **)**

You can remove individual permissions from an access policy associated with a Lambda function by providing a Statement ID.

Note that removal of a permission will cause an active event source to lose permission to the function.

You need permission for the `lambda:RemovePermission` action.

**Request Syntax**

```python
response = client.remove_permission(
    FunctionName='string',
    StatementId='string'
)
```

**Parameters**

- **FunctionName** (string) – [REQUIRED]
  Lambda function whose access policy you want to remove a permission from.
  
  You can specify an unqualified function name (for example, "Thumbnail") or you can specify an Amazon Resource Name (ARN) of the function (for example, "arn:aws:lambda:us-west-2:account-id:function:Thumbnail"). AWS Lambda also allows you to specify only the account ID qualifier (for example, "account-id:Thumbnail"). Note that the length constraint applies only to the ARN. If you specify only the function name, it is limited to 64 character in length.

- **StatementId** (string) – [REQUIRED]
  Statement ID of the permission to remove.

**Returns** None

---

**update_event_source_mapping(** **kwargs **)**

You can update an event source mapping. This is useful if you want to change the parameters of the existing mapping without losing your position in the stream. You can change which function will receive the stream records, but to change the stream itself, you must create a new mapping.

This operation requires permission for the `lambda:UpdateEventSourceMapping` action.
Request Syntax

```python
response = client.update_event_source_mapping(
    UUID='string',
    FunctionName='string',
    Enabled=True|False,
    BatchSize=123
)
```

Parameters

- **UUID (string)** – [REQUIRED]
  
  The event source mapping identifier.

- **FunctionName (string)** – The Lambda function to which you want the stream records sent.
  
  You can specify an unqualified function name (for example, “Thumbnail”) or you can specify Amazon Resource Name (ARN) of the function (for example, “arn:aws:lambda:us-west-2:account-id:function:ThumbNail”). AWS Lambda also allows you to specify only the account ID qualifier (for example, “account-id:Thumbnail”). Note that the length constraint applies only to the ARN. If you specify only the function name, it is limited to 64 characters in length.

- **Enabled (boolean)** – Specifies whether AWS Lambda should actively poll the stream or not. If disabled, AWS Lambda will not poll the stream.

- **BatchSize (integer)** – The maximum number of stream records that can be sent to your Lambda function for a single invocation.

Return type  dict

Returns

Response Syntax

```json
{
    'UUID': 'string',
    'BatchSize': 123,
    'EventSourceArn': 'string',
    'FunctionArn': 'string',
    'LastModified': datetime(2015, 1, 1),
    'LastProcessingResult': 'string',
    'State': 'string',
    'StateTransitionReason': 'string'
}
```

Response Structure

- *(dict)* –

  Describes mapping between an Amazon Kinesis stream and a Lambda function.

  - **UUID (string)** –
    
    The AWS Lambda assigned opaque identifier for the mapping.

  - **BatchSize (integer)** –
    
    The largest number of records that AWS Lambda will retrieve from your event source at the time of invoking your function. Your function receives an event with all the retrieved records.

  - **EventSourceArn (string)** –
    
    The Amazon Resource Name (ARN) of the Amazon Kinesis stream that is the source of events.
- **FunctionArn (string)** –
  The Lambda function to invoke when AWS Lambda detects an event on the stream.

- **LastModified (datetime)** –
  The UTC time string indicating the last time the event mapping was updated.

- **LastProcessingResult (string)** –
  The result of the last AWS Lambda invocation of your Lambda function.

- **State (string)** –
  The state of the event source mapping. It can be “Creating”, “Enabled”, “Disabled”, “Enabling”, “Disabling”, “Updating”, or “Deleting”.

- **StateTransitionReason (string)** –
  The reason the event source mapping is in its current state. It is either user-requested or an AWS Lambda-initiated state transition.

**update_function_code(**kwargs)**

Updates the code for the specified Lambda function. This operation must only be used on an existing Lambda function and cannot be used to update the function configuration.

This operation requires permission for the lambda:UpdateFunctionCode action.

**Request Syntax**

```python
response = client.update_function_code(
    FunctionName='string',
    ZipFile=b'bytes',
    S3Bucket='string',
    S3Key='string',
    S3ObjectVersion='string'
)
```

**Parameters**

- **FunctionName (string)** – [REQUIRED]
  The existing Lambda function name whose code you want to replace.

  You can specify an unqualified function name (for example, “Thumbnail”) or you can specify Amazon Resource Name (ARN) of the function (for example, “arn:aws:lambda:us-west-2:account-id:function:ThumbNail”). AWS Lambda also allows you to specify only the account ID qualifier (for example, “account-id:Thumbnail”). Note that the length constraint applies only to the ARN. If you specify only the function name, it is limited to 64 character in length.

- **ZipFile (bytes)** – Based64-encoded .zip file containing your packaged source code.

- **S3Bucket (string)** – Amazon S3 bucket name where the .zip file containing your deployment package is stored. This bucket must reside in the same AWS region where you are creating the Lambda function.

- **S3Key (string)** – The Amazon S3 object (the deployment package) key name you want to upload.

- **S3ObjectVersion (string)** – The Amazon S3 object (the deployment package) version you want to upload.

**Return type** dict

**Response Syntax**
```python
{
    'FunctionName': 'string',
    'FunctionArn': 'string',
    'Runtime': 'nodejs'|'java8',
    'Role': 'string',
    'Handler': 'string',
    'CodeSize': 123,
    'Description': 'string',
    'Timeout': 123,
    'MemorySize': 123,
    'LastModified': 'string'
}

Response Structure
• (dict) –

A complex type that describes function metadata.
  – **FunctionName** (string) –
    The name of the function.
  – **FunctionArn** (string) –
    The Amazon Resource Name (ARN) assigned to the function.
  – **Runtime** (string) –
    The runtime environment for the Lambda function.
  – **Role** (string) –
    The Amazon Resource Name (ARN) of the IAM role that Lambda assumes when it executes your function to access any other Amazon Web Services (AWS) resources.
  – **Handler** (string) –
    The function Lambda calls to begin executing your function.
  – **CodeSize** (integer) –
    The size, in bytes, of the function .zip file you uploaded.
  – **Description** (string) –
    The user-provided description.
  – **Timeout** (integer) –
    The function execution time at which Lambda should terminate the function. Because the execution time has cost implications, we recommend you set this value based on your expected execution time. The default is 3 seconds.
  – **MemorySize** (integer) –
    The memory size, in MB, you configured for the function. Must be a multiple of 64 MB.
  – **LastModified** (string) –
    The timestamp of the last time you updated the function.

**update_function_configuration(**kwargs**)

Updates the configuration parameters for the specified Lambda function by using the values provided in the request. You provide only the parameters you want to change. This operation must only be used on an existing Lambda function and cannot be used to update the function’s code.

This operation requires permission for the lambda:UpdateFunctionConfiguration action.

3046 Chapter 3. API Reference
Request Syntax

```python
response = client.update_function_configuration(
    FunctionName='string',
    Role='string',
    Handler='string',
    Description='string',
    Timeout=123,
    MemorySize=123
)
```

Parameters

- **FunctionName** *(string)* – [REQUIRED]
  
The name of the Lambda function.
  
  You can specify an unqualified function name (for example, “Thumbnail”) or
  you can specify Amazon Resource Name (ARN) of the function (for example,
  also allows you to specify only the account ID qualifier (for example,
  “account-id:ThumbNail”). Note that the length constraint applies only to the ARN. If you
  specify only the function name, it is limited to 64 character in length.
- **Role** *(string)* – The Amazon Resource Name (ARN) of the IAM role that
  Lambda will assume when it executes your function.
- **Handler** *(string)* – The function that Lambda calls to begin executing your func-
  tion. For Node.js, it is the module-name.export value in your function.
- **Description** *(string)* – A short user-defined function description. AWS Lambda
  does not use this value. Assign a meaningful description as you see fit.
- **Timeout** *(integer)* – The function execution time at which AWS Lambda should
  terminate the function. Because the execution time has cost implications, we rec-
  ommend you set this value based on your expected execution time. The default
  is 3 seconds.
- **MemorySize** *(integer)* – The amount of memory, in MB, your Lambda func-
  tion is given. AWS Lambda uses this memory size to infer the amount of CPU
  allocated to your function. Your function use-case determines your CPU and
  memory requirements. For example, a database operation might need less mem-
  ory compared to an image processing function. The default value is 128 MB.
  
  The value must be a multiple of 64 MB.

Return type  dict

Returns

Response Syntax

```python
{
    'FunctionName': 'string',
    'FunctionArn': 'string',
    'Runtime': 'nodejs'|'java8',
    'Role': 'string',
    'Handler': 'string',
    'CodeSize': 123,
    'Description': 'string',
    'Timeout': 123,
    'MemorySize': 123,
    'LastModified': 'string'
}
```

Response Structure
A complex type that describes function metadata.

- **FunctionName (string)** – The name of the function.
- **FunctionArn (string)** – The Amazon Resource Name (ARN) assigned to the function.
- **Runtime (string)** – The runtime environment for the Lambda function.
- **Role (string)** – The Amazon Resource Name (ARN) of the IAM role that Lambda assumes when it executes your function to access any other Amazon Web Services (AWS) resources.
- **Handler (string)** – The function Lambda calls to begin executing your function.
- **CodeSize (integer)** – The size, in bytes, of the function .zip file you uploaded.
- **Description (string)** – The user-provided description.
- **Timeout (integer)** – The function execution time at which Lambda should terminate the function. Because the execution time has cost implications, we recommend you set this value based on your expected execution time. The default is 3 seconds.
- **MemorySize (integer)** – The memory size, in MB, you configured for the function. Must be a multiple of 64 MB.
- **LastModified (string)** – The timestamp of the last time you updated the function.

### Paginators

The available paginators are:

- `LambdaPaginator.ListEventSourceMappings`
- `LambdaPaginator.ListFunctions`

```python
class LambdaPaginator.ListEventSourceMappings

paginator = client.get_pagewriter('list_event_source_mappings')

paginate(**kwargs)

Create an iterator that will paginate through responses from
`Lambda.Client.list_event_source_mappings()`.

Request Syntax
```
response_iterator = paginator.paginate(
    EventSourceArn='string',
    FunctionName='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **EventSourceArn** *(string)* – The Amazon Resource Name (ARN) of the Amazon Kinesis stream.
- **FunctionName** *(string)* – The name of the Lambda function.

You can specify an unqualified function name (for example, “Thumbnail”) or you can specify Amazon Resource Name (ARN) of the function (for example, “arn:aws:lambda:us-west-2:account-id:function:ThumbNail”). AWS Lambda also allows you to specify only the account ID qualifier (for example, “account-id:Thumbnail”). Note that the length constraint applies only to the ARN. If you specify only the function name, it is limited to 64 character in length.
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* – The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* – The size of each page.
  - **StartingToken** *(string)* – A token to specify where to start pagination. This is the NextToken from a previous response.

Return type  **dict**

Returns

Response Syntax

```python
{
    'EventSourceMappings': [
        {
            'UUID': 'string',
            'BatchSize': 123,
            'EventSourceArn': 'string',
            'FunctionArn': 'string',
            'LastModified': datetime(2015, 1, 1),
            'LastProcessingResult': 'string',
            'State': 'string',
            'StateTransitionReason': 'string'
        },
        {
            'UUID': 'string',
            'BatchSize': 123,
            'EventSourceArn': 'string',
            'FunctionArn': 'string',
            'LastModified': datetime(2015, 1, 1),
            'LastProcessingResult': 'string',
            'State': 'string',
            'StateTransitionReason': 'string'
        }
    ],
    'NextToken': 'string'
}
```

Response Structure

- *(dict)* –
Contains a list of event sources (see API_EventSourceMappingConfiguration).

- **EventSourceMappings** (list) –
  An array of EventSourceMappingConfiguration objects.

  * (dict) –
  Describes mapping between an Amazon Kinesis stream and a Lambda function.
  - **UUID** (string) –
    The AWS Lambda assigned opaque identifier for the mapping.
  - **BatchSize** (integer) –
    The largest number of records that AWS Lambda will retrieve from your event source at the time of invoking your function. Your function receives an event with all the retrieved records.
  - **EventSourceArn** (string) –
    The Amazon Resource Name (ARN) of the Amazon Kinesis stream that is the source of events.
  - **FunctionArn** (string) –
    The Lambda function to invoke when AWS Lambda detects an event on the stream.
  - **LastModified** (datetime) –
    The UTC time string indicating the last time the event mapping was updated.
  - **LastProcessingResult** (string) –
    The result of the last AWS Lambda invocation of your Lambda function.
  - **State** (string) –
    The state of the event source mapping. It can be “Creating”, “Enabled”, “Disabled”, “Enabling”, “Disabling”, “Updating”, or “Deleting”.
  - **StateTransitionReason** (string) –
    The reason the event source mapping is in its current state. It is either user-requested or an AWS Lambda-initiated state transition.

- **NextToken** (string) –
  A token to resume pagination.

```python
class Lambda.Paginator.ListFunctions

paginator = client.get_paginator('list_functions')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from Lambda.Client.list_functions().

**Request Syntax**

```python
response_iterator = paginator.paginate(
    PaginationConfig={
```
Parameters  **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

- **MaxItems** *(integer)* –
  The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

- **PageSize** *(integer)* –
  The size of each page.

- **StartingToken** *(string)* –
  A token to specify where to start paginating. This is the NextToken from a previous response.

Return type *dict*

Returns

**Response Syntax**

```
{
   'Functions': [
      {
         'FunctionName': 'string',
         'FunctionArn': 'string',
         'Runtime': 'nodejs'|'java8',
         'Role': 'string',
         'Handler': 'string',
         'CodeSize': 123,
         'Description': 'string',
         'Timeout': 123,
         'MemorySize': 123,
         'LastModified': 'string'
      },
      ],
   'NextToken': 'string'
}
```

**Response Structure**

- *(dict)* –
  Contains a list of AWS Lambda function configurations (see FunctionConfiguration).
  - **Functions** *(list)* –
    A list of Lambda functions.
      - *(dict)* –
        A complex type that describes function metadata.
          - **FunctionName** *(string)* –
            The name of the function.
          - **FunctionArn** *(string)* –
            The Amazon Resource Name (ARN) assigned to the function.
- **Runtime** (**string**) –
  The runtime environment for the Lambda function.
- **Role** (**string**) –
  The Amazon Resource Name (ARN) of the IAM role that Lambda assumes when it executes your function to access any other Amazon Web Services (AWS) resources.
- **Handler** (**string**) –
  The function Lambda calls to begin executing your function.
- **CodeSize** (**integer**) –
  The size, in bytes, of the function .zip file you uploaded.
- **Description** (**string**) –
  The user-provided description.
- **Timeout** (**integer**) –
  The function execution time at which Lambda should terminate the function. Because the execution time has cost implications, we recommend you set this value based on your expected execution time. The default is 3 seconds.
- **MemorySize** (**integer**) –
  The memory size, in MB, you configured for the function. Must be a multiple of 64 MB.
- **LastModified** (**string**) –
  The timestamp of the last time you updated the function.
- **NextToken** (**string**) –
  A token to resume pagination.

### CloudWatchLogs

#### Table of Contents
- CloudWatchLogs
  - Client
  - Paginators

#### Client

```python
class CloudWatchLogs.Client

A low-level client representing Amazon CloudWatch Logs:

```import boto3

```python
client = boto3.client('logs')
```

These are the available methods:
- **can_paginate()**
- **cancel_export_task()**
- **create_export_task()**
• `create_log_group()`
• `create_log_stream()`
• `delete_destination()`
• `delete_log_group()`
• `delete_log_stream()`
• `delete_metric_filter()`
• `delete_retention_policy()`
• `delete_subscription_filter()`
• `describe.destinations()`
• `describe_export_tasks()`
• `describe_log_groups()`
• `describe_log_streams()`
• `describe_metric_filters()`
• `describe_subscription_filters()`
• `filter_log_events()`
• `generate_presigned_url()`
• `get_log_events()`
• `get_paginator()`
• `get_waiter()`
• `put_destination()`
• `put_destination_policy()`
• `put_log_events()`
• `put_metric_filter()`
• `put_retention_policy()`
• `put_subscription_filter()`
• `test_metric_filter()`

`can_paginate(operation_name)`
Check if an operation can be paginated.

Parameters **operation_name** (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

Returns True if the operation can be paginated, False otherwise.

`cancel_export_task(**kwargs)`
Cancels an export task if it is in PENDING or RUNNING state.

Request Syntax

```python
response = client.cancel_export_task(
    taskId='string'
)
```

Parameters **taskId** (string) – [REQUIRED]

Id of the export task to cancel.

Returns None

`create_export_task(**kwargs)`
Creates an ExportTask which allows you to efficiently export data from a Log Group to your Amazon S3 bucket.

This is an asynchronous call. If all the required information is provided, this API will initiate an export task and respond with the task Id. Once started, `DescribeExportTasks` can be used to get the status of an export task.
Request Syntax

```python
response = client.create_export_task(
    taskName='string',
    logGroupName='string',
    logStreamNamePrefix='string',
    from=123,
    to=123,
    destination='string',
    destinationPrefix='string'
)
```

Parameters

- **taskName (string)** – The name of the export task.
- **logGroupName (string)** – [REQUIRED]
  The name of the log group to export.
- **logStreamNamePrefix (string)** – Will only export log streams that match the provided logStreamNamePrefix. If you don’t specify a value, no prefix filter is applied.
- **from (integer)** – [REQUIRED]
  A unix timestamp indicating the start time of the range for the request. Events with a timestamp prior to this time will not be exported.
- **to (integer)** – [REQUIRED]
  A unix timestamp indicating the end time of the range for the request. Events with a timestamp later than this time will not be exported.
- **destination (string)** – [REQUIRED]
  Name of Amazon S3 bucket to which the log data will be exported. **NOTE:** Only buckets in the same AWS region are supported
- **destinationPrefix (string)** – Prefix that will be used as the start of Amazon S3 key for every object exported. If not specified, this defaults to ‘exportedlogs’.

Return type: dict

Returns

Response Syntax

```json
{
    'taskId': 'string'
}
```

Response Structure

- **(dict)** –
  - **taskId (string)** –
    Id of the export task that got created.

`create_log_group (**kwargs)`

Creates a new log group with the specified name. The name of the log group must be unique within a region for an AWS account. You can create up to 500 log groups per account.

You must use the following guidelines when naming a log group:

- Log group names can be between 1 and 512 characters long.
- Allowed characters are a-z, A-Z, 0-9, ‘_’ (underscore), ‘-’ (hyphen), ‘/’ (forward slash), and ‘.’ (period).

Request Syntax
response = client.create_log_group(
    logGroupName='string'
)

Parameters  logGroupName (string) – [REQUIRED]

The name of the log group to create.

Returns  None

create_log_stream(**kwargs)
Creates a new log stream in the specified log group. The name of the log stream must be unique within
the log group. There is no limit on the number of log streams that can exist in a log group.

You must use the following guidelines when naming a log stream:
• Log stream names can be between 1 and 512 characters long.
• The ‘:’ colon character is not allowed.

Request Syntax

response = client.create_log_stream(
    logGroupName='string',
    logStreamName='string'
)

Parameters
•  logGroupName (string) – [REQUIRED]
  The name of the log group under which the log stream is to be created.
•  logStreamName (string) – [REQUIRED]
  The name of the log stream to create.

Returns  None

delete_destination(**kwargs)
Deletes the destination with the specified name and eventually disables all the subscription filters that
publish to it. This will not delete the physical resource encapsulated by the destination.

Request Syntax

response = client.delete_destination(
    destinationName='string'
)

Parameters  destinationName (string) – [REQUIRED]

The name of destination to delete.

Returns  None

delete_log_group(**kwargs)
Deletes the log group with the specified name and permanently deletes all the archived log events associ-
ated with it.

Request Syntax

response = client.delete_log_group(
    logGroupName='string'
)

Parameters  logGroupName (string) – [REQUIRED]

The name of the log group to delete.
Returns None

delete_log_stream(**kwargs)
    Deletes a log stream and permanently deletes all the archived log events associated with it.

Request Syntax

response = client.delete_log_stream(
    logGroupName='string',
    logStreamName='string'
)

Parameters

- logGroupName (string) – [REQUIRED]
    The name of the log group under which the log stream to delete belongs.
- logStreamName (string) – [REQUIRED]
    The name of the log stream to delete.

Returns None

delete_metric_filter(**kwargs)
    Deletes a metric filter associated with the specified log group.

Request Syntax

response = client.delete_metric_filter(
    logGroupName='string',
    filterName='string'
)

Parameters

- logGroupName (string) – [REQUIRED]
    The name of the log group that is associated with the metric filter to delete.
- filterName (string) – [REQUIRED]
    The name of the metric filter to delete.

Returns None

delete_retention_policy(**kwargs)
    Deletes the retention policy of the specified log group. Log events would not expire if they belong to log
groups without a retention policy.

Request Syntax

response = client.delete_retention_policy(
    logGroupName='string'
)

Parameters logGroupName (string) – [REQUIRED]
    The name of the log group that is associated with the retention policy to delete.

Returns None

delete_subscription_filter(**kwargs)
    Deletes a subscription filter associated with the specified log group.

Request Syntax
response = client.delete_subscription_filter(
    logGroupName='string',
    filterName='string'
)

Parameters

• **logGroupName** *(string) – [REQUIRED]*
  The name of the log group that is associated with the subscription filter to delete.

• **filterName** *(string) – [REQUIRED]*
  The name of the subscription filter to delete.

Returns

None

describe_destinations(**kwargs)**

Returns all the destinations that are associated with the AWS account making the request. The list returned in the response is ASCII-sorted by destination name.

By default, this operation returns up to 50 destinations. If there are more destinations to list, the response would contain a `nextToken` value in the response body. You can also limit the number of destinations returned in the response by specifying the `limit` parameter in the request.

Request Syntax

response = client.describe_destinations(
    DestinationNamePrefix='string',
    nextToken='string',
    limit=123
)

Parameters

• **DestinationNamePrefix** *(string)* – Will only return destinations that match the provided destinationNamePrefix. If you don’t specify a value, no prefix is applied.

• **nextToken** *(string)* – A string token used for pagination that points to the next page of results. It must be a value obtained from the response of the previous request. The token expires after 24 hours.

• **limit** *(integer)* – The maximum number of results to return.

Return type

`dict`

Returns

Response Syntax

```{json}
{
    'destinations': [
        {
            'destinationName': 'string',
            'targetArn': 'string',
            'roleArn': 'string',
            'accessPolicy': 'string',
            'arn': 'string',
            'creationTime': 123
        },
    ],
    'nextToken': 'string'
}
```

Response Structure

• *(dict)* –
– destinations (list) –
  * (dict) –
  A cross account destination that is the recipient of subscription log events.
  · destinationName (string) –
    Name of the destination.
  · targetArn (string) –
    ARN of the physical target where the log events will be delivered (eg. ARN of a Kinesis stream).
  · roleArn (string) –
    A role for impersonation for delivering log events to the target.
  · accessPolicy (string) –
    An IAM policy document that governs which AWS accounts can create subscription filters against this destination.
  · arn (string) –
    ARN of this destination.
  · creationTime (integer) –
    A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC specifying when this destination was created.

– nextToken (string) –
  A string token used for pagination that points to the next page of results. It must be a value obtained from the response of the previous request. The token expires after 24 hours.

**describe_export_tasks** (**kwargs)**

Returns all the export tasks that are associated with the AWS account making the request. The export tasks can be filtered based on TaskId or TaskStatus.

By default, this operation returns up to 50 export tasks that satisfy the specified filters. If there are more export tasks to list, the response would contain a nextToken value in the response body. You can also limit the number of export tasks returned in the response by specifying the limit parameter in the request.

**Request Syntax**

```
response = client.describe_export_tasks(
    taskId='string',
    statusCode='CANCELLED'|'COMPLETED'|'FAILED'|'PENDING'|'PENDING_CANCEL'|'RUNNING',
    nextToken='string',
    limit=123
)
```

**Parameters**

- **taskId (string)** – Export task that matches the specified task Id will be returned. This can result in zero or one export task.
- **statusCode (string)** – All export tasks that matches the specified status code will be returned. This can return zero or more export tasks.
- **nextToken (string)** – A string token used for pagination that points to the next page of results. It must be a value obtained from the response of the previous DescribeExportTasks request.
- **limit (integer)** – The maximum number of items returned in the response. If you don’t specify a value, the request would return up to 50 items.

**Return type**  
**dict**

**Returns**

**Response Syntax**

```json
{
  'exportTasks': [
    {
      'taskId': 'string',
      'taskName': 'string',
      'logGroupName': 'string',
      'from': 123,
      'to': 123,
      'destination': 'string',
      'destinationPrefix': 'string',
      'status': {
        'code': 'CANCELLED'|'COMPLETED'|'FAILED'|'PENDING'|'PENDING CANCEL',
        'message': 'string'
      },
      'executionInfo': {
        'creationTime': 123,
        'completionTime': 123
      }
    },
    
  ],
  'nextToken': 'string'
}
```

**Response Structure**

- **(dict)** –
  - **exportTasks (list)** –
    A list of export tasks.
    - **(dict)** –
      Represents an export task.
      - **taskId (string)** –
        Id of the export task.
      - **taskName (string)** –
        The name of the export task.
      - **logGroupName (string)** –
        The name of the log group from which logs data was exported.
      - **from (integer)** –
        A unix timestamp indicating the start time of the range for the request. Events with a timestamp prior to this time were not exported.
      - **to (integer)** –
        A unix timestamp indicating the end time of the range for the request. Events with a timestamp later than this time were not exported.
      - **destination (string)** –
        The name of the destination to which logs data was exported.
      - **destinationPrefix (string)** –
        The prefix for the log stream that was exported.
Name of Amazon S3 bucket to which the log data was exported.

- destinationPrefix (string) –
  
  Prefix that was used as the start of Amazon S3 key for every object exported.

- status (dict) –
  
  Status of the export task.

- code (string) –
  
  Status code of the export task.

- message (string) –
  
  Status message related to the code.

- executionInfo (dict) –
  
  Execution info about the export task.

- creationTime (integer) –
  
  A point in time when the export task got created.

- completionTime (integer) –
  
  A point in time when the export task got completed.

- nextToken (string) –
  
  A string token used for pagination that points to the next page of results. It must be a value obtained from the response of the previous request. The token expires after 24 hours.

describe_log_groups(**kwargs)

Returns all the log groups that are associated with the AWS account making the request. The list returned in the response is ASCII-sorted by log group name.

By default, this operation returns up to 50 log groups. If there are more log groups to list, the response would contain a nextToken value in the response body. You can also limit the number of log groups returned in the response by specifying the limit parameter in the request.

Request Syntax

```python
response = client.describe_log_groups(
    logGroupNamePrefix='string',
    nextToken='string',
    limit=123
)
```

Parameters

- logGroupNamePrefix (string) – Will only return log groups that match the provided logGroupNamePrefix. If you don’t specify a value, no prefix filter is applied.

- nextToken (string) – A string token used for pagination that points to the next page of results. It must be a value obtained from the response of the previous DescribeLogGroups request.

- limit (integer) – The maximum number of items returned in the response. If you don’t specify a value, the request would return up to 50 items.

Return type dict

Returns

Response Syntax
response = client.describe_log_streams(
    logGroupName='string',
    logStreamNamePrefix='string',
    orderBy='LogStreamName'|'LastEventTime',
    descending=True|False,
    nextToken='string',
)
Parameters

- **logGroupName** *(string) – [REQUIRED]*
  The log group name for which log streams are to be listed.

- **logStreamNamePrefix** *(string)* – Will only return log streams that match the provided logStreamNamePrefix. If you don’t specify a value, no prefix filter is applied.

- **orderBy** *(string)* – Specifies what to order the returned log streams by. Valid arguments are ‘LogStreamName’ or ‘LastEventTime’. If you don’t specify a value, results are ordered by LogStreamName. If ‘LastEventTime’ is chosen, the request cannot also contain a logStreamNamePrefix.

- **descending** *(boolean)* – If set to true, results are returned in descending order. If you don’t specify a value or set it to false, results are returned in ascending order.

- **nextToken** *(string)* – A string token used for pagination that points to the next page of results. It must be a value obtained from the response of the previous DescribeLogStreams request.

- **limit** *(integer)* – The maximum number of items returned in the response. If you don’t specify a value, the request would return up to 50 items.

Return type  dict

Returns

Response Syntax

```
{
    'logStreams': [
        {
            'logStreamName': 'string',
            'creationTime': 123,
            'firstEventTimestamp': 123,
            'lastEventTimestamp': 123,
            'lastIngestionTime': 123,
            'uploadSequenceToken': 'string',
            'arn': 'string',
            'storedBytes': 123
        },
    ],
    'nextToken': 'string'
}
```

Response Structure

- *(dict)* –
  - **logStreams** *(list)* –
    A list of log streams.
  - *(dict)* –
    A log stream is sequence of log events from a single emitter of logs.
    - **logStreamName** *(string)* –
    - **creationTime** *(integer)* –
      A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.
    - **firstEventTimestamp** *(integer)* –
A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

- **lastEventTimestamp (integer)** –
  A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

- **lastIngestionTime (integer)** –
  A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

- **uploadSequenceToken (string)** –
  A string token used for making PutLogEvents requests. A sequenceToken can only be used once, and PutLogEvents requests must include the sequenceToken obtained from the response of the previous request.

- **arn (string)** –

- **storedBytes (integer)** –

- **nextToken (string)** –
  A string token used for pagination that points to the next page of results. It must be a value obtained from the response of the previous request. The token expires after 24 hours.

**describe_metric_filters(**kwargs**)**

Returns all the metrics filters associated with the specified log group. The list returned in the response is ASCII-sorted by filter name.

By default, this operation returns up to 50 metric filters. If there are more metric filters to list, the response would contain a nextToken value in the response body. You can also limit the number of metric filters returned in the response by specifying the limit parameter in the request.

**Request Syntax**

```python
response = client.describe_metric_filters(
    logGroupName='string',
    filterNamePrefix='string',
    nextToken='string',
    limit=123
)
```

**Parameters**

- **logGroupName (string)** – [REQUIRED]
  The log group name for which metric filters are to be listed.

- **filterNamePrefix (string)** – Will only return metric filters that match the provided filterNamePrefix. If you don’t specify a value, no prefix filter is applied.

- **nextToken (string)** – A string token used for pagination that points to the next page of results. It must be a value obtained from the response of the previous DescribeMetricFilters request.

- **limit (integer)** – The maximum number of items returned in the response. If you don’t specify a value, the request would return up to 50 items.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'metricFilters': [
```
Metric filters can be used to express how Amazon CloudWatch Logs would extract metric observations from ingested log events and transform them to metric data in a CloudWatch metric.

- **filterName** *(string)* –
  A name for a metric or subscription filter.

- **filterPattern** *(string)* –
  A symbolic description of how Amazon CloudWatch Logs should interpret the data in each log event. For example, a log event may contain timestamps, IP addresses, strings, and so on. You use the filter pattern to specify what to look for in the log event message.

- **metricTransformations** *(list)* –
  - *(dict)* –
    - **metricName** *(string)* –
      The name of the CloudWatch metric to which the monitored log information should be published. For example, you may publish to a metric called ErrorCount.
    - **metricNamespace** *(string)* –
      The destination namespace of the new CloudWatch metric.
    - **metricValue** *(string)* –
      What to publish to the metric. For example, if you’re counting the occurrences of a particular term like “Error”, the value will be “1” for each occurrence. If you’re counting the bytes transferred the published value will be the value in the log event.
    - **creationTime** *(integer)* –
      A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

- **nextToken** *(string)* –
  A string token used for pagination that points to the next page of results. It must be a value obtained from the response of the previous request. The
token expires after 24 hours.

describe_subscription_filters(**kwargs)

Returns all the subscription filters associated with the specified log group. The list returned in the response is ASCII-sorted by filter name.

By default, this operation returns up to 50 subscription filters. If there are more subscription filters to list, the response would contain a nextToken value in the response body. You can also limit the number of subscription filters returned in the response by specifying the limit parameter in the request.

Request Syntax

```python
response = client.describe_subscription_filters(
    logGroupName='string',
    filterNamePrefix='string',
    nextToken='string',
    limit=123
)
```

Parameters

- **logGroupName (string)** – [REQUIRED]
  The log group name for which subscription filters are to be listed.
- **filterNamePrefix (string)** – Will only return subscription filters that match the provided filterNamePrefix. If you don’t specify a value, no prefix filter is applied.
- **nextToken (string)** – A string token used for pagination that points to the next page of results. It must be a value obtained from the response of the previous request. The token expires after 24 hours.
- **limit (integer)** – The maximum number of results to return.

Return type: dict

Returns

Response Syntax

```json
{
    'subscriptionFilters': [
        {
            'filterName': 'string',
            'logGroupName': 'string',
            'filterPattern': 'string',
            'destinationArn': 'string',
            'roleArn': 'string',
            'creationTime': 123
        },
        {
            'filterName': 'string',
            'logGroupName': 'string',
            'filterPattern': 'string',
            'destinationArn': 'string',
            'roleArn': 'string',
            'creationTime': 123
        }
    ],
    'nextToken': 'string'
}
```

Response Structure

- (dict) –
  - subscriptionFilters (list) –
    * (dict) –
      - filterName (string) –
        A name for a metric or subscription filter.
      - logGroupName (string) –
      - filterPattern (string) –
A symbolic description of how Amazon CloudWatch Logs should interpret the data in each log event. For example, a log event may contain timestamps, IP addresses, strings, and so on. You use the filter pattern to specify what to look for in the log event message.

- **destinationArn** *(string)* –
- **roleArn** *(string)* –
- **creationTime** *(integer)* –

A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

- **nextToken** *(string)* –

A string token used for pagination that points to the next page of results. It must be a value obtained from the response of the previous request. The token expires after 24 hours.

### filter_log_events(**kwargs)**

Retrieves log events, optionally filtered by a filter pattern from the specified log group. You can provide an optional time range to filter the results on the event timestamp. You can limit the streams searched to an explicit list of logStreamNames.

By default, this operation returns as much matching log events as can fit in a response size of 1MB, up to 10,000 log events, or all the events found within a time-bounded scan window. If the response includes a nextToken, then there is more data to search, and the search can be resumed with a new request providing the nextToken. The response will contain a list of searchedLogStreams that contains information about which streams were searched in the request and whether they have been searched completely or require further pagination. The limit parameter in the request can be used to specify the maximum number of events to return in a page.

#### Request Syntax

```python
response = client.filter_log_events(
    logGroupName='string',
    logStreamNames=[
        'string',
    ],
    startTime=123,
    endTime=123,
    filterPattern='string',
    nextToken='string',
    limit=123,
    interleaved=True|False
)
```

#### Parameters

- **logGroupName** *(string)* – [REQUIRED]
  
  The name of the log group to query.

- **logStreamNames** *(list)* – Optional list of log stream names within the specified log group to search. Defaults to all the log streams in the log group.
  
  - *(string)* –

- **startTime** *(integer)* – A unix timestamp indicating the start time of the range for the request. If provided, events with a timestamp prior to this time will not be returned.

- **endTime** *(integer)* – A unix timestamp indicating the end time of the range for the request. If provided, events with a timestamp later than this time will not be returned.
• **filterPattern** *(string)* – A valid CloudWatch Logs filter pattern to use for filtering the response. If not provided, all the events are matched.

• **nextToken** *(string)* – A pagination token obtained from a FilterLogEvents response to continue paginating the FilterLogEvents results.

• **limit** *(integer)* – The maximum number of events to return in a page of results. Default is 10,000 events.

• **interleaved** *(boolean)* – If provided, the API will make a best effort to provide responses that contain events from multiple log streams within the log group interleaved in a single response. If not provided, all the matched log events in the first log stream will be searched first, then those in the next log stream, etc.

**Return type** `dict`

**Returns**

**Response Syntax**

```plaintext
{
  'events': [  
    {  
      'logStreamName': 'string',
      'timestamp': 123,
      'message': 'string',
      'ingestionTime': 123,
      'eventId': 'string'
    },
  ],
  'searchedLogStreams': [  
    {'logStreamName': 'string',
     'searchedCompletely': True|False
    },
  ],
  'nextToken': 'string'
}
```

**Response Structure**

• *(dict)* –

  • **events** *(list)* –

    A list of `FilteredLogEvent` objects representing the matched events from the request.

    • *(dict)* –

      Represents a matched event from a FilterLogEvents request.

      • **logStreamName** *(string)* –

        The name of the log stream this event belongs to.

      • **timestamp** *(integer)* –

        A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

      • **message** *(string)* –

        The data contained in the log event.

      • **ingestionTime** *(integer)* –

        A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

      • **eventId** *(string)* –
A unique identifier for this event.

- **searchedLogStreams** *(list)*
  A list of `SearchLogStream` objects indicating which log streams have been searched in this request and whether each has been searched completely or still has more to be paginated.

  - *(dict)*
    An object indicating the search status of a log stream in a `FilterLogEvents` request.
    - **logStreamName** *(string)*
      The name of the log stream.
    - **searchedCompletely** *(boolean)*
      Indicates whether all the events in this log stream were searched or more data exists to search by paginating further.

- **nextToken** *(string)*
  A pagination token obtained from a `FilterLogEvents` response to continue paginating the `FilterLogEvents` results.

---

### generate_presigned_url *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

**Parameters**

- **ClientMethod** *(string)* – The client method to presign for
- **Params** *(dict)* – The parameters normally passed to `ClientMethod`
- **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns**

The presigned url

---

### get_log_events(**kwargs**)

Retrieves log events from the specified log stream. You can provide an optional time range to filter the results on the event timestamp.

By default, this operation returns as much log events as can fit in a response size of 1MB, up to 10,000 log events. The response will always include a `nextForwardToken` and a `nextBackwardToken` in the response body. You can use any of these tokens in subsequent `GetLogEvents` requests to paginate through events in either forward or backward direction. You can also limit the number of log events returned in the response by specifying the `limit` parameter in the request.

**Request Syntax**

```python
response = client.get_log_events(
    logGroupName='string',
    logStreamName='string',
    startTime=123,
    endTime=123,
    nextToken='string',
    limit=123,
    startFromHead=True|False
)
```

**Parameters**

- **logGroupName** *(string)* – [REQUIRED]
  The name of the log group to query.
• logStreamName (string) – [REQUIRED]
  The name of the log stream to query.

• startTime (integer) – A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

• endTime (integer) – A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

• nextToken (string) – A string token used for pagination that points to the next page of results. It must be a value obtained from the nextForwardToken or nextBackwardToken fields in the response of the previous GetLogEvents request.

• limit (integer) – The maximum number of log events returned in the response. If you don’t specify a value, the request would return as many log events as can fit in a response size of 1MB, up to 10,000 log events.

• startFromHead (boolean) – If set to true, the earliest log events would be returned first. The default is false (the latest log events are returned first).

Return type  dict

Returns

Response Syntax

```python
{
    'events': [
        {
            'timestamp': 123,
            'message': 'string',
            'ingestionTime': 123
        },
    ],
    'nextForwardToken': 'string',
    'nextBackwardToken': 'string'
}
```

Response Structure

• (dict) –
  • events (list) –
    • (dict) –
      • timestamp (integer) –
        A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.
      • message (string) –
      • ingestionTime (integer) –
        A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

    • nextForwardToken (string) –
      A string token used for pagination that points to the next page of results. It must be a value obtained from the response of the previous request. The token expires after 24 hours.

    • nextBackwardToken (string) –
      A string token used for pagination that points to the next page of results. It must be a value obtained from the response of the previous request. The token expires after 24 hours.
**get_paginator** *(operation_name)*  
Create a paginator for an operation.

Parameters **operation_name** *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

Raises **OperationNotPageableError** Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

Return type **L{botocore.paginate.Paginator}**  
Returns A paginator object.

**get_waiter** *(waiter_name)*  

**put_destination** (**kwargs**)

Creates or updates a **Destination**. A destination encapsulates a physical resource (such as a Kinesis stream) and allows you to subscribe to a real-time stream of log events of a different account, ingested through `PutLogEvents` requests. Currently, the only supported physical resource is an Amazon Kinesis stream belonging to the same account as the destination.

A destination controls what is written to its Amazon Kinesis stream through an access policy. By default, `PutDestination` does not set any access policy with the destination, which means a cross-account user will not be able to call `PutSubscriptionFilter` against this destination. To enable that, the destination owner must call `PutDestinationPolicy` after `PutDestination`.

Request Syntax

```
response = client.put_destination(
    destinationName='string',
    targetArn='string',
    roleArn='string'
)
```

Parameters

- **destinationName** *(string)* – [REQUIRED]
  
  A name for the destination.

- **targetArn** *(string)* – [REQUIRED]
  
  The ARN of an Amazon Kinesis stream to deliver matching log events to.

- **roleArn** *(string)* – [REQUIRED]
  
  The ARN of an IAM role that grants Amazon CloudWatch Logs permissions to do Amazon Kinesis PutRecord requests on the destination stream.

Return type **dict**  
Returns

Response Syntax

```
{
    'destination': {
        'destinationName': 'string',
        'targetArn': 'string',
        'roleArn': 'string',
        'accessPolicy': 'string',
        'arn': 'string',
        'creationTime': 123
    }
}
```
Response Structure

- (dict) –
  - destination (dict) –
    A cross account destination that is the recipient of subscription log events.
      - destinationName (string) –
        Name of the destination.
      - targetArn (string) –
        ARN of the physical target where the log events will be delivered (eg. ARN of a Kinesis stream).
      - roleArn (string) –
        A role for impersonation for delivering log events to the target.
      - accessPolicy (string) –
        An IAM policy document that governs which AWS accounts can create subscription filters against this destination.
      - arn (string) –
        ARN of this destination.
      - creationTime (integer) –
        A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC specifying when this destination was created.

**put_destination_policy(**kwargs**)

Creates or updates an access policy associated with an existing Destination. An access policy is an IAM policy document that is used to authorize claims to register a subscription filter against a given destination.

**Request Syntax**

```python
response = client.put_destination_policy(
    destinationName='string',
    accessPolicy='string'
)
```

**Parameters**

- destinationName (string) – [REQUIRED]
  A name for an existing destination.

- accessPolicy (string) – [REQUIRED]
  An IAM policy document that authorizes cross-account users to deliver their log events to associated destination.

**Returns** None

**put_log_events(**kwargs**)

Uploads a batch of log events to the specified log stream.

Every PutLogEvents request must include the sequenceToken obtained from the response of the previous request. An upload in a newly created log stream does not require a sequenceToken.

The batch of events must satisfy the following constraints:

- The maximum batch size is 1,048,576 bytes, and this size is calculated as the sum of all event messages in UTF-8, plus 26 bytes for each log event.
- None of the log events in the batch can be more than 2 hours in the future.
- None of the log events in the batch can be older than 14 days or the retention period of the log group.
• The log events in the batch must be in chronological order by their timestamp.
• The maximum number of log events in a batch is 10,000.

Request Syntax

```python
response = client.put_log_events(
    logGroupName='string',
    logStreamName='string',
    logEvents=[
        {
            'timestamp': 123,
            'message': 'string'
        },
    ],
    sequenceToken='string'
)
```

Parameters

- **logGroupName (string)** – [REQUIRED]
  The name of the log group to put log events to.
- **logStreamName (string)** – [REQUIRED]
  The name of the log stream to put log events to.
- **logEvents (list)** – [REQUIRED]
  A list of log events belonging to a log stream.
  - (dict) –
    A log event is a record of some activity that was recorded by the application or resource being monitored. The log event record that Amazon CloudWatch Logs understands contains two properties: the timestamp of when the event occurred, and the raw event message.
    * **timestamp (integer)** – [REQUIRED]
      A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.
    * **message (string)** – [REQUIRED]
    * **sequenceToken (string)** – A string token that must be obtained from the response of the previous PutLogEvents request.

Return type  dict

Returns

Response Syntax

```
{
    'nextSequenceToken': 'string',
    'rejectedLogEventsInfo': {
        'tooNewLogEventStartIndex': 123,
        'tooOldLogEventEndIndex': 123,
        'expiredLogEventEndIndex': 123
    }
}
```

Response Structure

- (dict) –
  - **nextSequenceToken (string)** –
    A string token used for making PutLogEvents requests. A sequenceToken can only be used once, and PutLogEvents requests
must include the `sequenceToken` obtained from the response of the previous request.

- `rejectedLogEventsInfo (dict)`
  - `tooNewLogEventStartIndex (integer)`
  - `tooOldLogEventEndIndex (integer)`
  - `expiredLogEventEndIndex (integer)`

`put_metric_filter (**kwargs)`

Creates or updates a metric filter and associates it with the specified log group. Metric filters allow you to configure rules to extract metric data from log events ingested through `PutLogEvents` requests.

The maximum number of metric filters that can be associated with a log group is 100.

**Request Syntax**

```python
response = client.put_metric_filter(
    logGroupName='string',
    filterName='string',
    filterPattern='string',
    metricTransformations=[
        {
            'metricName': 'string',
            'metricNamespace': 'string',
            'metricValue': 'string'
        },
    ],
)
```

**Parameters**

- `logGroupName (string)` – [REQUIRED]
  The name of the log group to associate the metric filter with.

- `filterName (string)` – [REQUIRED]
  A name for the metric filter.

- `filterPattern (string)` – [REQUIRED]
  A valid CloudWatch Logs filter pattern for extracting metric data out of ingested log events.

- `metricTransformations (list)` – [REQUIRED]
  A collection of information needed to define how metric data gets emitted.
    - `(dict)`
      - `metricName (string)` – [REQUIRED]
        The name of the CloudWatch metric to which the monitored log information should be published. For example, you may publish to a metric called ErrorCount.
      - `metricNamespace (string)` – [REQUIRED]
        The destination namespace of the new CloudWatch metric.
      - `metricValue (string)` – [REQUIRED]
        What to publish to the metric. For example, if you’re counting the occurrences of a particular term like “Error”, the value will be “1” for each occurrence. If you’re counting the bytes transferred the published value will be the value in the log event.

**Returns** None
**put_retention_policy(**kwargs)\n
Sets the retention of the specified log group. A retention policy allows you to configure the number of
days you want to retain log events in the specified log group.

**Request Syntax**

```python
response = client.put_retention_policy(
    logGroupName='string',
    retentionInDays=123
)
```

**Parameters**

- `logGroupName (string)` – [REQUIRED]
  The name of the log group to associate the retention policy with.
- `retentionInDays (integer)` – [REQUIRED]
  Specifies the number of days you want to retain log events in the specified log
  group. Possible values are: 1, 3, 5, 7, 14, 30, 60, 90, 120, 150, 180, 365, 400,
  545, 731, 1827, 3653.

**Returns** None

**put_subscription_filter(**kwargs)\n
Creates or updates a subscription filter and associates it with the specified log group. Subscription filters
allow you to subscribe to a real-time stream of log events ingested through PutLogEvents requests
and have them delivered to a specific destination. Currently, the supported destinations are:
- A Amazon Kinesis stream belonging to the same account as the subscription filter, for same-account
delivery.
- A logical destination (used via an ARN of Destination ) belonging to a different account, for
cross-account delivery.
Currently there can only be one subscription filter associated with a log group.

**Request Syntax**

```python
response = client.put_subscription_filter(
    logGroupName='string',
    filterName='string',
    filterPattern='string',
    destinationArn='string',
    roleArn='string'
)
```

**Parameters**

- `logGroupName (string)` – [REQUIRED]
  The name of the log group to associate the subscription filter with.
- `filterName (string)` – [REQUIRED]
  A name for the subscription filter.
- `filterPattern (string)` – [REQUIRED]
  A valid CloudWatch Logs filter pattern for subscribing to a filtered stream of log
  events.
- `destinationArn (string)` – [REQUIRED]
  The ARN of the destination to deliver matching log events to. Currently, the
  supported destinations are:
  - A Amazon Kinesis stream belonging to the same account as the subscrip-
  tion filter, for same-account delivery.
– A logical destination (used via an ARN of Destination) belonging to a different account, for cross-account delivery.

• **roleArn** *(string)* – The ARN of an IAM role that grants Amazon CloudWatch Logs permissions to deliver ingested log events to the destination stream. You don’t need to provide the ARN when you are working with a logical destination (used via an ARN of Destination) for cross-account delivery.

Returns None

test_metric_filter(**kwargs)**

Tests the filter pattern of a metric filter against a sample of log event messages. You can use this operation to validate the correctness of a metric filter pattern.

Request Syntax

```python
response = client.test_metric_filter(
    filterPattern='string',
    logEventMessages=['string',
                      'string'],
)
```

Parameters

• **filterPattern** *(string)* – [REQUIRED]
  
  A symbolic description of how Amazon CloudWatch Logs should interpret the data in each log event. For example, a log event may contain timestamps, IP addresses, strings, and so on. You use the filter pattern to specify what to look for in the log event message.

• **logEventMessages** *(list)* – [REQUIRED]
  
  A list of log event messages to test.

Return type dict

Returns

Response Syntax

```json
{
    'matches': [
        {
            'eventNumber': 123,
            'eventMessage': 'string',
            'extractedValues': {
                'string': 'string'
            }
        },
    ]
}
```

Response Structure

• *(dict)* –
  
  • **matches** *(list)* –
    
    • *(dict)* –
      
      • **eventNumber** *(integer)* –
      
      • **eventMessage** *(string)* –
      
      • **extractedValues** *(dict)* –
      
      • *(string)* –
      
      • *(string)* –
Paginators

The available paginators are:

- `CloudWatchLogs.Paginator.DescribeDestinations`
- `CloudWatchLogs.Paginator.DescribeLogGroups`
- `CloudWatchLogs.Paginator.DescribeLogStreams`
- `CloudWatchLogs.Paginator.DescribeMetricFilters`
- `CloudWatchLogs.Paginator.DescribeSubscriptionFilters`
- `CloudWatchLogs.Paginator.FilterLogEvents`

class `CloudWatchLogs.Paginator.DescribeDestinations`

```python
paginator = client.get_paginator('describe_destinations')
```

`paginate(**kwargs)`

Creates an iterator that will paginate through responses from `CloudWatchLogs.Client.describe_destinations()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    DestinationNamePrefix='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **DestinationNamePrefix** *(string)* – Will only return destinations that match the provided destinationNamePrefix. If you don’t specify a value, no prefix is applied.

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  - **MaxItems** *(integer)* – The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  
  - **PageSize** *(integer)* – The size of each page.
  
  - **StartingToken** *(string)* – A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** *dict*

**Returns**

**Response Syntax**
{  
    'destinations': [  
        {  
            'destinationName': 'string',  
            'targetArn': 'string',  
            'roleArn': 'string',  
            'accessPolicy': 'string',  
            'arn': 'string',  
            'creationTime': 123  
        },  
    ],  
    'NextToken': 'string'  
}  

Response Structure  
• (dict) –  
  • destinations (list) –  
    • (dict) –  
      A cross account destination that is the recipient of subscription log events.  
      • destinationName (string) –  
        Name of the destination.  
      • targetArn (string) –  
        ARN of the physical target where the log events will be delivered (e.g. ARN of a Kinesis stream).  
      • roleArn (string) –  
        A role for impersonation for delivering log events to the target.  
      • accessPolicy (string) –  
        An IAM policy document that governs which AWS accounts can create subscription filters against this destination.  
      • arn (string) –  
        ARN of this destination.  
      • creationTime (integer) –  
        A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC specifying when this destination was created.  
    • NextToken (string) –  
      A token to resume pagination.  

class CloudWatchLogs.Paginator.DescribeLogGroups  

paginate (**kwargs)  
Creates an iterator that will paginate through responses from  
CloudWatchLogs.Client.describe_log_groups().  

Request Syntax  

3.1. Services
response_iterator = paginator.paginate(
    logGroupNamePrefix='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **logGroupNamePrefix** *(string)* – Will only return log groups that match the provided logGroupNamePrefix. If you don’t specify a value, no prefix filter is applied.
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –
    The size of each page.
  - **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  *dict*

Returns

Response Syntax

```python
{
    'logGroups': [
        {
            'logGroupName': 'string',
            'creationTime': 123,
            'retentionInDays': 123,
            'metricFilterCount': 123,
            'arn': 'string',
            'storedBytes': 123
        },
        {
            'logGroupName': 'string',
            'creationTime': 123,
            'retentionInDays': 123,
            'metricFilterCount': 123,
            'arn': 'string',
            'storedBytes': 123
        }
    ],
    'NextToken': 'string'
}
```

Response Structure

- *(dict)* –
  - **logGroups** *(list)* –
    A list of log groups.
    * *(dict)* –
      - **logGroupName** *(string)* –
      - **creationTime** *(integer)* –

    A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.
**retentionInDays** *(integer)* –

Specifies the number of days you want to retain log events in the specified log group. Possible values are: 1, 3, 5, 7, 14, 30, 60, 90, 120, 150, 180, 365, 400, 545, 731, 1827, 3653.

**metricFilterCount** *(integer)* –

The number of metric filters associated with the log group.

**arn** *(string)* –

**storedBytes** *(integer)* –

**NextToken** *(string)* –

A token to resume pagination.

class CloudWatchLogs.Paginator.DescribeLogStreams

```python
paginator = client.get_paginator('describe_log_streams')

paginate(**kwargs)
```

 Creates an iterator that will paginate through responses from CloudWatchLogs.Client.describe_log_streams().

**Request Syntax**

```python
response_iterator = paginator.paginate(
    logGroupName='string',
    logStreamNamePrefix='string',
    orderBy='LogStreamName'|'LastEventTime',
    descending=True|False,
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **logGroupName** *(string)* – [REQUIRED]

  The log group name for which log streams are to be listed.

- **logStreamNamePrefix** *(string)* – Will only return log streams that match the provided logStreamNamePrefix. If you don’t specify a value, no prefix filter is applied.

- **orderBy** *(string)* – Specifies what to order the returned log streams by. Valid arguments are ‘LogStreamName’ or ‘LastEventTime’. If you don’t specify a value, results are ordered by LogStreamName. If ‘LastEventTime’ is chosen, the request cannot also contain a logStreamNamePrefix.

- **descending** *(boolean)* – If set to true, results are returned in descending order. If you don’t specify a value or set it to false, results are returned in ascending order.

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

  - **MaxItems** *(integer)* –

    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
– **PageSize** *(integer)* –

The size of each page.

– **StartingToken** *(string)* –

A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'logStreams': [
        {
            'logStreamName': 'string',
            'creationTime': 123,
            'firstEventTimestamp': 123,
            'lastEventTimestamp': 123,
            'lastIngestionTime': 123,
            'uploadSequenceToken': 'string',
            'arn': 'string',
            'storedBytes': 123
        },
        
        'NextToken': 'string'
    ]
}
```

**Response Structure**

- *(dict)* –
  - **logStreams** *(list)* –

A list of log streams.

- *(dict)* –

A log stream is a sequence of log events from a single emitter of logs.

  - **logStreamName** *(string)* –

  - **creationTime** *(integer)* –

A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

  - **firstEventTimestamp** *(integer)* –

A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

  - **lastEventTimestamp** *(integer)* –

A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

  - **lastIngestionTime** *(integer)* –

A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

  - **uploadSequenceToken** *(string)* –

A string token used for making PutLogEvents requests. A `sequenceToken` can only be used once, and PutLogEvents requests must include the `sequenceToken` obtained from the response of the previous request.

  - **arn** *(string)* –
Boto3 Documentation, Release 1.1.4

storedBytes (integer) –
– NextToken (string) –
A token to resume pagination.

class CloudWatchLogs.Paginator.DescribeMetricFilters

paginator = client.get_paginator('describe_metric_filters')

paginate (**kwargs)
Creates an iterator that will paginate through responses from CloudWatchLogs.Client.describe_metric_filters().

Request Syntax

response_iterator = paginator.paginate(
    logGroupName='string',
    filterNamePrefix='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

• logGroupName (string) – [REQUIRED]
The log group name for which metric filters are to be listed.

• filterNamePrefix (string) – Will only return metric filters that match the provided filterNamePrefix. If you don’t specify a value, no prefix filter is applied.

• PaginationConfig (dict) – A dictionary that provides parameters to control pagination.
    – MaxItems (integer) –
The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

    – PageSize (integer) –
The size of each page.

    – StartingToken (string) –
A token to specify where to start paginating. This is the NextToken from a previous response.

Return type dict

Returns

Response Syntax

{
    'metricFilters': [
        {
            'filterName': 'string',
            'filterPattern': 'string',
            'metricTransformations': [
                {'metricName': 'string'},
            ]
        },
    ]
}
Metric filters can be used to express how Amazon CloudWatch Logs would extract metric observations from ingested log events and transform them to metric data in a CloudWatch metric.

- **filterName** *(string)*
  A name for a metric or subscription filter.

- **filterPattern** *(string)*
  A symbolic description of how Amazon CloudWatch Logs should interpret the data in each log event. For example, a log event may contain timestamps, IP addresses, strings, and so on. You use the filter pattern to specify what to look for in the log event message.

- **metricTransformations** *(list)*
  - *(dict)*
    - **metricName** *(string)*
      The name of the CloudWatch metric to which the monitored log information should be published. For example, you may publish to a metric called ErrorCount.
    - **metricNamespace** *(string)*
      The destination namespace of the new CloudWatch metric.
    - **metricValue** *(string)*
      What to publish to the metric. For example, if you’re counting the occurrences of a particular term like “Error”, the value will be “1” for each occurrence. If you’re counting the bytes transferred the published value will be the value in the log event.
    - **creationTime** *(integer)*
      A point in time expressed as the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

- **NextToken** *(string)*
  A token to resume pagination.

```python
class CloudWatchLogs.Paginator.DescribeSubscriptionFilters

paginator = client.get_paginatrix('describe_subscription_filters')
```
**paginate**(**kwargs**)

Creates an iterator that will paginate through responses from `CloudWatchLogs.Client.describe_subscription_filters()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    logGroupName='string',
    filterNamePrefix='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **logGroupName** *(string)* – [REQUIRED]
  
  The log group name for which subscription filters are to be listed.

- **filterNamePrefix** *(string)* – Will only return subscription filters that match the provided filterNamePrefix. If you don’t specify a value, no prefix filter is applied.

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  - **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

  - **PageSize** *(integer)* –
    
    The size of each page.

  - **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'subscriptionFilters': [
        {
            'filterName': 'string',
            'logGroupName': 'string',
            'filterPattern': 'string',
            'destinationArn': 'string',
            'roleArn': 'string',
            'creationTime': 123
        },
        {
            'filterName': 'string',
            'logGroupName': 'string',
            'filterPattern': 'string',
            'destinationArn': 'string',
            'roleArn': 'string',
            'creationTime': 123
        }
    ],
    'NextToken': 'string'
}
```

**Response Structure**

- *(dict)* –
  
  - **subscriptionFilters** *(list)* –
    
    - *(dict)* –
A name for a metric or subscription filter.

- **logGroupName (string)** –
  The name of the log group to query.

- **logStreamNames (list)** – Optional list of log stream names within the specified log group to search. Defaults to all the log streams in the log group.

- **startTime (integer)** – A unix timestamp indicating the start time of the range for the request. If provided, events with a timestamp prior to this time will not be returned.

```python
class CloudWatchLogs.Paginator.FilterLogEvents

paginator = client.get_paginator('filter_log_events')

paginate(**kwargs)

Creates an iterator that will paginate through responses from CloudWatchLogs.Client.filter_log_events().

Request Syntax

```
• **endTime** (*integer*) – A unix timestamp indicating the end time of the range for the request. If provided, events with a timestamp later than this time will not be returned.

• **filterPattern** (*string*) – A valid CloudWatch Logs filter pattern to use for filtering the response. If not provided, all the events are matched.

• **interleaved** (*boolean*) – If provided, the API will make a best effort to provide responses that contain events from multiple log streams within the log group interleaved in a single response. If not provided, all the matched log events in the first log stream will be searched first, then those in the next log stream, etc.

• **PaginationConfig** (*dict*) – A dictionary that provides parameters to control pagination.

  - **MaxItems** (*integer*) –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.

  - **PageSize** (*integer*) –
    
    The size of each page.

  - **StartingToken** (*string*) –
    
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
  'events': [
    {
      'logStreamName': 'string',
      'timestamp': 123,
      'message': 'string',
      'ingestionTime': 123,
      'eventId': 'string'
    },
  ],
  'searchedLogStreams': [
    {
      'logStreamName': 'string',
      'searchedCompletely': True|False
    },
  ],
  'NextToken': 'string'
}
```

**Response Structure**

- **(dict)** –
  - **events** (*list*) –
    
    A list of `FilteredLogEvent` objects representing the matched events from the request.

  - **(dict)** –
    
    Represents a matched event from a `FilterLogEvents` request.

    - **logStreamName** (*string*) –
      
      The name of the log stream this event belongs to.
· timestamp (integer) –
  A point in time expressed as the number of milliseconds since
  Jan 1, 1970 00:00:00 UTC.
· message (string) –
  The data contained in the log event.
· ingestionTime (integer) –
  A point in time expressed as the number of milliseconds since
  Jan 1, 1970 00:00:00 UTC.
· eventId (string) –
  A unique identifier for this event.

- searchedLogStreams (list) –
  A list of SearchedLogStream objects indicating which log streams
  have been searched in this request and whether each has been searched
  completely or still has more to be paginated.
  * (dict) –
    An object indicating the search status of a log stream in a
    FilterLogEvents request.
    · logStreamName (string) –
      The name of the log stream.
    · searchedCompletely (boolean) –
      Indicates whether all the events in this log stream were
      searched or more data exists to search by paginating further.

- NextToken (string) –
  A token to resume pagination.

MachineLearning

Client

class MachineLearning.Client
  A low-level client representing Amazon Machine Learning:

  import boto3
  client = boto3.client('machinelearning')

  These are the available methods:
  * can_paginate()
  * create_batch_prediction()
  * create_data_source_from_rds()
can_paginate(operation_name)
Check if an operation can be paginated.

Parameters operation_name (string) – The operation name. This is the same name as
the method name on the client. For example, if the method name is create_foo,
and you’d normally invoke the operation as client.create_foo(**kwargs),
if the create_foo operation can be paginated, you can use the call
client.get_paginator("create_foo").

Returns True if the operation can be paginated, False otherwise.

create_batch_prediction(**kwargs)
Generates predictions for a group of observations. The observations to process exist in one or more data
files referenced by a DataSource. This operation creates a new BatchPrediction, and uses an
MLModel and the data files referenced by the DataSource as information sources.

CreateBatchPrediction is an asynchronous operation. In response to
CreateBatchPrediction, Amazon Machine Learning (Amazon ML) immediately returns
and sets the BatchPrediction status to PENDING. After the BatchPrediction completes,
Amazon ML sets the status to COMPLETED.

You can poll for status updates by using the GetBatchPrediction operation and checking the Status
parameter of the result. After the COMPLETED status appears, the results are available in the location
specified by the OutputUri parameter.

Request Syntax

response = client.create_batch_prediction(
    BatchPredictionId='string',
    BatchPredictionName='string',
    MLModelId='string',
    BatchPredictionDataSourceId='string',
)
OutputUri='string'

Parameters

- **BatchPredictionId** *(string)* – [REQUIRED]
  A user-supplied ID that uniquely identifies the BatchPrediction.
- **BatchPredictionName** *(string)* – A user-supplied name or description of the BatchPrediction. BatchPredictionName can only use the UTF-8 character set.
- **MLModelId** *(string)* – [REQUIRED]
  The ID of the MLModel that will generate predictions for the group of observations.
- **BatchPredictionDataSourceId** *(string)* – [REQUIRED]
  The ID of the DataSource that points to the group of observations to predict.
- **OutputUri** *(string)* – [REQUIRED]
  The location of an Amazon Simple Storage Service (Amazon S3) bucket or directory to store the batch prediction results. The following substrings are not allowed in the s3 key portion of the “outputURI” field: ‘:’, ‘//’, ‘/.’, ‘../’.

Amazon ML needs permissions to store and retrieve the logs on your behalf. For information about how to set permissions, see the Amazon Machine Learning Developer Guide.

Return type  dict

Returns

Response Syntax

```python
{
    'BatchPredictionId': 'string'
}
```

Response Structure

- *(dict)* –
  Represents the output of a CreateBatchPrediction operation, and is an acknowledgement that Amazon ML received the request.

  The CreateBatchPrediction operation is asynchronous. You can poll for status updates by using the GetBatchPrediction operation and checking the Status parameter of the result.

  - **BatchPredictionId** *(string)* –
    A user-supplied ID that uniquely identifies the BatchPrediction. This value is identical to the value of the BatchPredictionId in the request.

**create_data_source_from_rds(** **kwargs)**

Creates a DataSource object from an Amazon Relational Database Service (Amazon RDS). A DataSource references data that can be used to perform CreateMLModel, CreateEvaluation, or CreateBatchPrediction operations.

CreateDataSourceFromRDS is an asynchronous operation. In response to CreateDataSourceFromRDS, Amazon Machine Learning (Amazon ML) immediately returns and sets the DataSource status to PENDING. After the DataSource is created and ready for use, Amazon ML sets the Status parameter to COMPLETED. DataSource in COMPLETED or PENDING
status can only be used to perform CreateMLModel, CreateEvaluation, or CreateBatchPrediction operations.

If Amazon ML cannot accept the input source, it sets the `Status` parameter to `FAILED` and includes an error message in the `Message` attribute of the `GetDataSource` operation response.

**Request Syntax**

```python
response = client.create_data_source_from_rds(
    DataSourceId='string',
    DataSourceName='string',
    RDSData={
        'DatabaseInformation': {
            'InstanceIdentifier': 'string',
            'DatabaseName': 'string'
        },
        'SelectSqlQuery': 'string',
        'DatabaseCredentials': {
            'Username': 'string',
            'Password': 'string'
        },
        'S3StagingLocation': 'string',
        'DataRearrangement': 'string',
        'DataSchema': 'string',
        'DataSchemaUri': 'string',
        'ResourceRole': 'string',
        'ServiceRole': 'string',
        'SubnetId': 'string',
        'SecurityGroupIds': ['string'],
    },
    RoleARN='string',
    ComputeStatistics=True|False
)
```

**Parameters**

- **DataSourceId** *(string)* – [REQUIRED]

  A user-supplied ID that uniquely identifies the `DataSource`. Typically, an Amazon Resource Number (ARN) becomes the ID for a `DataSource`.

- **DataSourceName** *(string)* – A user-supplied name or description of the `DataSource`.

- **RDSData** *(dict)* – [REQUIRED]

  The data specification of an Amazon RDS `DataSource`:
  - **DatabaseInformation** - *DatabaseName* - Name of the Amazon RDS database.
  - **InstanceIdentifier** - Unique identifier for the Amazon RDS database instance.
  - **DatabaseCredentials** - AWS Identity and Access Management (IAM) credentials that are used to connect to the Amazon RDS database.
  - **ResourceRole** - Role (DataPipelineDefaultResourceRole) assumed by an Amazon Elastic Compute Cloud (EC2) instance to carry out the copy task from Amazon RDS to Amazon S3. For more information, see Role templates for data pipelines.
  - **ServiceRole** - Role (DataPipelineDefaultRole) assumed by the AWS Data Pipeline service to monitor the progress of the copy task from Amazon
RDS to Amazon Simple Storage Service (S3). For more information, see Role templates for data pipelines.

- **SecurityInfo** - Security information to use to access an Amazon RDS instance. You need to set up appropriate ingress rules for the security entity IDs provided to allow access to the Amazon RDS instance. Specify a [SubnetId, SecurityGroupIds] pair for a VPC-based Amazon RDS instance.

- **SelectSqlQuery** - Query that is used to retrieve the observation data for the DataSource.

- **S3StagingLocation** - Amazon S3 location for staging RDS data. The data retrieved from Amazon RDS using SelectSqlQuery is stored in this location.

- **DataSchemaUri** - Amazon S3 location of the DataSchema.

- **DataSchema** - A JSON string representing the schema. This is not required if DataSchemaUri is specified.

- **DataRearrangement** - A JSON string representing the splitting requirement of a DataSource. Sample - "{"splitting":{\"percentBegin\":10,\"percentEnd\":60}}"

- **DatabaseInformation (dict)** - [REQUIRED]
  
  Describes the DatabaseName and InstanceIdentifier of an Amazon RDS database.

  - **InstanceIdentifier (string)** - [REQUIRED]
    
    The ID of an RDS DB instance.

  - **DatabaseName (string)** - [REQUIRED]
    
    The name of a database hosted on an RDS DB instance.

- **SelectSqlQuery (string)** - [REQUIRED]

  The query that is used to retrieve the observation data for the DataSource.

- **DatabaseCredentials (dict)** - [REQUIRED]

  The AWS Identity and Access Management (IAM) credentials that are used to connect to the Amazon RDS database.

  - **Username (string)** - [REQUIRED]
    
    The username to be used by Amazon ML to connect to a database on an Amazon RDS instance. The username should have sufficient permissions to execute an RDSSelectSqlQuery query.

  - **Password (string)** - [REQUIRED]
    
    The password to be used by Amazon ML to connect to a database on an RDS DB instance. The password should have sufficient permissions to execute the RDSSelectSqlQuery query.

- **S3StagingLocation (string)** - [REQUIRED]

  The Amazon S3 location for staging Amazon RDS data. The data retrieved from Amazon RDS using SelectSqlQuery is stored in this location.

- **DataRearrangement (string)** -

  DataRearrangement - A JSON string that represents the splitting requirement of a DataSource.

  Sample - "{"splitting":{\"percentBegin\":10,\"percentEnd\":60}}"

- **DataSchema (string)** -
A JSON string that represents the schema for an Amazon RDS DataSource. The DataSchema defines the structure of the observation data in the data file(s) referenced in the DataSource.

A DataSchema is not required if you specify a DataSchemaUri.

Define your DataSchema as a series of key-value pairs. attributes and excludedVariableNames have an array of key-value pairs for their value. Use the following format to define your DataSchema:

```json
{
    "version": "1.0",
    "recordAnnotationFieldName": "F1",
    "recordWeightFieldName": "F2",
    "targetFieldName": "F3",
    "dataFormat": "CSV",
    "dataFileContainsHeader": true,
    "attributes": [
        {
            "fieldName": "F1",
            "fieldType": "TEXT"
        },
        {
            "fieldName": "F2",
            "fieldType": "NUMERIC"
        },
        {
            "fieldName": "F3",
            "fieldType": "CATEGORICAL"
        },
        {
            "fieldName": "F4",
            "fieldType": "NUMERIC"
        },
        {
            "fieldName": "F5",
            "fieldType": "CATEGORICAL"
        },
        {
            "fieldName": "F6",
            "fieldType": "TEXT"
        },
        {
            "fieldName": "F7",
            "fieldType": "WEIGHTED_INT_SEQUENCE"
        },
        {
            "fieldName": "F8",
            "fieldType": "WEIGHTED_STRING_SEQUENCE"
        }
    ],
    "excludedVariableNames": ["F6"]
}
```

- **DataSchemaUri (string)** –
  The Amazon S3 location of the DataSchema.

- **ResourceRole (string)** – [REQUIRED]
  The role (DataPipelineDefaultResourceRole) assumed by an Amazon Elastic Compute Cloud (Amazon EC2) instance to carry out the copy operation from Amazon RDS to an Amazon S3 task. For more information, see Role templates for data pipelines.

- **ServiceRole (string)** – [REQUIRED]
  The role (DataPipelineDefaultRole) assumed by AWS Data Pipeline service to monitor the progress of the copy task from Amazon RDS to Amazon S3. For more information, see Role templates for data pipelines.

- **SubnetId (string)** – [REQUIRED]
  The subnet ID to be used to access a VPC-based RDS DB instance. This attribute is used by Data Pipeline to carry out the copy task from Amazon RDS to Amazon S3.

- **SecurityGroupIds (list)** – [REQUIRED]
  The security group IDs to be used to access a VPC-based RDS DB instance. Ensure that there are appropriate ingress rules set up to allow access to the RDS DB instance. This attribute is used by Data Pipeline to carry out the copy operation from Amazon RDS to an Amazon S3 task.

- **RoleARN (string)** – [REQUIRED]
The role that Amazon ML assumes on behalf of the user to create and activate a data pipeline in the user’s account and copy data (using the SelectSqlQuery query from Amazon RDS to Amazon S3).

- **ComputeStatistics (boolean)** – The compute statistics for a DataSource. The statistics are generated from the observation data referenced by a DataSource. Amazon ML uses the statistics internally during an MLModel training. This parameter must be set to true if the DataSource needs to be used for MLModel training.

**Return type**  
**dict**

**Returns**

**Response Syntax**

```
{
   'DataSourceId': 'string'
}
```

**Response Structure**

- (dict) –

  Represents the output of a CreateDataSourceFromRDS operation, and is an acknowledgement that Amazon ML received the request.

  The CreateDataSourceFromRDS operation is asynchronous. You can poll for updates by using the GetBatchPrediction operation and checking the Status parameter. You can inspect the Message when Status shows up as FAILED. You can also check the progress of the copy operation by going to the DataPipeline console and looking up the pipeline using the pipelineId from the describe call.

  - **DataSourceId (string)** –

    A user-supplied ID that uniquely identifies the datasource. This value should be identical to the value of the DataSourceID in the request.

**create_data_source_from_redshift(**kwargs)**

Creates a DataSource from Amazon Redshift. A DataSource references data that can be used to perform either CreateMLModel, CreateEvaluation or CreateBatchPrediction operations.

CreateDataSourceFromRedshift is an asynchronous operation. In response to CreateDataSourceFromRedshift, Amazon Machine Learning (Amazon ML) immediately returns and sets the DataSource status to PENDING. After the DataSource is created and ready for use, Amazon ML sets the Status parameter to COMPLETED. DataSource in COMPLETED or PENDING status can only be used to perform CreateMLModel, CreateEvaluation, or CreateBatchPrediction operations.

If Amazon ML cannot accept the input source, it sets the Status parameter to FAILED and includes an error message in the Message attribute of the GetDataSource operation response.

The observations should exist in the database hosted on an Amazon Redshift cluster and should be specified by a SelectSqlQuery. Amazon ML executes Unload command in Amazon Redshift to transfer the result set of SelectSqlQuery to S3StagingLocation.

After the DataSource is created, it’s ready for use in evaluations and batch predictions. If you plan to use the DataSource to train an MLModel, the DataSource requires another item – a recipe. A recipe describes the observation variables that participate in training an MLModel. A recipe describes how each input variable will be used in training. Will the variable be included or excluded from training? Will the variable be manipulated, for example, combined with another variable or split apart into word combinations? The recipe provides answers to these questions. For more information, see the Amazon Machine Learning Developer Guide.
Request Syntax

```python
response = client.create_data_source_from_redshift(
    DataSourceId='string',
    DataSourceName='string',
    DataSpec={
        'DatabaseInformation': {
            'DatabaseName': 'string',
            'ClusterIdentifier': 'string'
        },
        'SelectSqlQuery': 'string',
        'DatabaseCredentials': {
            'Username': 'string',
            'Password': 'string'
        },
        'S3StagingLocation': 'string',
        'DataRearrangement': 'string',
        'DataSchema': 'string',
        'DataSchemaUri': 'string'
    },
    RoleARN='string',
    ComputeStatistics=True|False
)
```

Parameters

- **DataSourceId** *(string)* – [REQUIRED]
  A user-supplied ID that uniquely identifies the DataSource.

- **DataSourceName** *(string)* – A user-supplied name or description of the DataSource.

- **DataSpec** *(dict)* – [REQUIRED]
  The data specification of an Amazon Redshift DataSource:
  - **DatabaseInformation** *(dict)* – [REQUIRED]
    Describes the DatabaseName and ClusterIdentifier for an Amazon Redshift DataSource.
    - **DatabaseName** *(string)* – [REQUIRED]
      The name of a database hosted on an Amazon Redshift cluster.
* **ClusterIdentifier (string)** – [REQUIRED]

  The ID of an Amazon Redshift cluster.

* **SelectSqlQuery (string)** – [REQUIRED]

  Describes the SQL Query to execute on an Amazon Redshift database for an Amazon Redshift DataSource.

* **DatabaseCredentials (dict)** – [REQUIRED]

  Describes AWS Identity and Access Management (IAM) credentials that are used to connect to the Amazon Redshift database.

  * **Username (string)** – [REQUIRED]

    A username to be used by Amazon Machine Learning (Amazon ML) to connect to a database on an Amazon Redshift cluster. The username should have sufficient permissions to execute the RedshiftSelectSqlQuery query. The username should be valid for an Amazon Redshift USER.

  * **Password (string)** – [REQUIRED]

    A password to be used by Amazon ML to connect to a database on an Amazon Redshift cluster. The password should have sufficient permissions to execute a RedshiftSelectSqlQuery query. The password should be valid for an Amazon Redshift USER.

* **S3StagingLocation (string)** – [REQUIRED]

  Describes an Amazon S3 location to store the result set of the SelectSqlQuery query.

* **DataRearrangement (string)** –

  Describes the splitting specifications for a DataSource.

* **DataSchema (string)** –

  A JSON string that represents the schema for an Amazon Redshift DataSource. The DataSchema defines the structure of the observation data in the data file(s) referenced in the DataSource.

  A DataSchema is not required if you specify a DataSchemaUri. Define your DataSchema as a series of key-value pairs. attributes and excludedVariableNames have an array of key-value pairs for their value. Use the following format to define your DataSchema.

  ```json
  {
    "version": "1.0",
    "recordAnnotationFieldName": "F1",
    "recordWeightFieldName": "F2",
    "targetFieldName": "F3",
    "dataFormat": "CSV",
    "dataFileContainsHeader": true,
    "attributes": [
      {
        "fieldName": "F1",
        "fieldType": "TEXT"
      },
      {
        "fieldName": "F2",
        "fieldType": "NUMERIC"
      },
      {
        "fieldName": "F3",
        "fieldType": "CATEGORICAL"
      },
      {
        "fieldName": "F4",
        "fieldType": "NUMERIC"
      },
      {
        "fieldName": "F5",
        "fieldType": "CATEGORICAL"
      },
      {
        "fieldName": "F6",
        "fieldType": "TEXT"
      },
      {
        "fieldName": "F7",
        "fieldType": "NUMERIC"
      }
    ]
  }
  ```
“WEIGHTED_INT_SEQUENCE” }, { “fieldName”: “F8”, “fieldType”: “WEIGHTED_STRING_SEQUENCE” } ],
“excludedVariableNames”: [ “F6” ] }

• DataSchemaUri (string) –

Describes the schema location for an Amazon Redshift DataSource.

• RoleARN (string) – [REQUIRED]

A fully specified role Amazon Resource Name (ARN). Amazon ML assumes
the role on behalf of the user to create the following:
– A security group to allow Amazon ML to execute the SelectSqlQuery
query on an Amazon Redshift cluster
– An Amazon S3 bucket policy to grant Amazon ML read/write permissions
on the S3StagingLocation

• ComputeStatistics (boolean) – The compute statistics for a DataSource
. The statistics are generated from the observation data referenced by a
DataSource. Amazon ML uses the statistics internally during MLModel
training. This parameter must be set to true if the ’’’DataSource’’’ needs to
be used for MLModel training

Return type  dict

Returns

Response Syntax

{
    'DataSourceId': 'string'
}

Response Structure

• (dict) –

Represents the output of a CreateDataSourceFromRedshift operation, and is an
acknowledgement that Amazon ML received the request.

The CreateDataSourceFromRedshift operation is asynchronous. You can poll for
updates by using the GetBatchPrediction operation and checking the Status
parameter.

• DataSourceId (string) –

A user-supplied ID that uniquely identifies the datasource. This value
should be identical to the value of the DataSourceID in the request.

create_data_source_from_s3 (**kwargs)

Creates a DataSource object. A DataSource references data that can be used to perform CreateMLModel , CreateEvaluation , or CreateBatchPrediction operations.

CreateDataSourceFromS3 is an asynchronous operation. In response to
CreateDataSourceFromS3 , Amazon Machine Learning (Amazon ML) immediately returns
and sets the DataSource status to PENDING . After the DataSource is created and ready for use,
Amazon ML sets the Status parameter to COMPLETED .DataSource in COMPLETED or PENDING
status can only be used to perform CreateMLModel , CreateEvaluation or CreateBatchPrediction
operations.

If Amazon ML cannot accept the input source, it sets the Status parameter to FAILED and includes an
error message in the Message attribute of the GetDataSource operation response.

The observation data used in a DataSource should be ready to use; that is, it should have a consistent
structure, and missing data values should be kept to a minimum. The observation data must reside in
one or more CSV files in an Amazon Simple Storage Service (Amazon S3) bucket, along with a schema
that describes the data items by name and type. The same schema must be used for all of the data files referenced by the DataSource.

After the DataSource has been created, it’s ready to use in evaluations and batch predictions. If you plan to use the DataSource to train an MLModel, the DataSource requires another item: a recipe. A recipe describes the observation variables that participate in training an MLModel. A recipe describes how each input variable will be used in training. Will the variable be included or excluded from training? Will the variable be manipulated, for example, combined with another variable, or split apart into word combinations? The recipe provides answers to these questions. For more information, see the Amazon Machine Learning Developer Guide.

Request Syntax

```python
response = client.create_data_source_from_s3(
    DataSourceId='string',
    DataSourceName='string',
    DataSpec={
        'DataLocationS3': 'string',
        'DataRearrangement': 'string',
        'DataSchema': 'string',
        'DataSchemaLocationS3': 'string'
    },
    ComputeStatistics=True|False)
```

Parameters

- **DataSourceId** *(string)* – [REQUIRED]
  A user-supplied identifier that uniquely identifies the DataSource.

- **DataSourceName** *(string)* – A user-supplied name or description of the DataSource.

- **DataSpec** *(dict)* – [REQUIRED]
  The data specification of a DataSource:
  - `DataLocationS3` - Amazon Simple Storage Service (Amazon S3) location of the observation data.
  - `DataSchemaLocationS3` - Amazon S3 location of the DataSchema.
  - `DataSchema` - A JSON string representing the schema. This is not required if `DataSchemaUri` is specified.
  - `DataRearrangement` - A JSON string representing the splitting requirement of a DataSource. Sample - `"{"splitting":{"percentBegin":10,"percentEnd":60}}"`

- **DataLocationS3** *(string)* – [REQUIRED]
  The location of the data file(s) used by a DataSource. The URI specifies a data file or an Amazon Simple Storage Service (Amazon S3) directory or bucket containing data files.

- **DataRearrangement** *(string)* –
  Describes the splitting requirement of a DataSource.

- **DataSchema** *(string)* –
  A JSON string that represents the schema for an Amazon S3 DataSource. The DataSchema defines the structure of the observation data in the data file(s) referenced in the DataSource.

Define your DataSchema as a series of key-value pairs. attributes and excludedVariableNames have an array of key-value pairs for
their value. Use the following format to define your DataSchema.

```json
{
    "version": "1.0",
    "recordAnnotationFieldName": "F1",
    "recordWeightFieldName": "F2",
    "targetFieldName": "F3",
    "dataFormat": "CSV",
    "dataFileContainsHeader": true,
    "attributes": [
        { "fieldName": "F1", "fieldType": "TEXT" },
        { "fieldName": "F2", "fieldType": "NUMERIC" },
        { "fieldName": "F3", "fieldType": "CATEGORICAL" },
        { "fieldName": "F4", "fieldType": "NUMERIC" },
        { "fieldName": "F5", "fieldType": "CATEGORICAL" },
        { "fieldName": "F6", "fieldType": "TEXT" },
        { "fieldName": "F7", "fieldType": "WEIGHTED_INT_SEQUENCE" },
        { "fieldName": "F8", "fieldType": "WEIGHTED_STRING_SEQUENCE" }
    ],
    "excludedVariableNames": [ "F6" ]
}
```

- **DataSchemaLocationS3 (string)** – Describes the schema Location in Amazon S3.

- **ComputeStatistics (boolean)** – The compute statistics for a DataSource. The statistics are generated from the observation data referenced by a DataSource. Amazon ML uses the statistics internally during an MModel training. This parameter must be set to true if the "DataSource" needs to be used for MModel training.

Return type dict

Returns

**Response Syntax**

```json
{
    'DataSourceId': 'string'
}
```

**Response Structure**

- (dict) – Represents the output of a CreateDataSourceFromS3 operation, and is an acknowledgement that Amazon ML received the request.

The CreateDataSourceFromS3 operation is asynchronous. You can poll for updates by using the GetBatchPrediction operation and checking the Status parameter.

- **DataSourceId (string)** – A user-supplied ID that uniquely identifies the datasource. This value should be identical to the value of the DataSourceID in the request.

create_evaluation (**kwargs)**

Creates a new Evaluation of an MModel. An MModel is evaluated on a set of observations associated to a DataSource. Like a DataSource for an MModel, the DataSource for an Evaluation contains values for the Target Variable. The Evaluation compares the predicted result for each observation to the actual outcome and provides a summary so that you know how effective the MModel functions on the test data. Evaluation generates a relevant performance metric such as
BinaryAUC, RegressionRMSE or MulticlassAvgFScore based on the corresponding MLModelType: BINARY, REGRESSION or MULTICLASS.

CreateEvaluation is an asynchronous operation. In response to CreateEvaluation, Amazon Machine Learning (Amazon ML) immediately returns and sets the evaluation status to PENDING. After the Evaluation is created and ready for use, Amazon ML sets the status to COMPLETED.

You can use the GetEvaluation operation to check progress of the evaluation during the creation operation.

Request Syntax

```python
response = client.create_evaluation(
    EvaluationId='string',
    EvaluationName='string',
    MLModelId='string',
    EvaluationDataSourceId='string'
)
```

Parameters

- **EvaluationId (string)** – [REQUIRED]
  A user-supplied ID that uniquely identifies the Evaluation.
- **EvaluationName (string)** – A user-supplied name or description of the Evaluation.
- **MLModelId (string)** – [REQUIRED]
  The ID of the MLModel to evaluate.
  The schema used in creating the MLModel must match the schema of the DataSource used in the Evaluation.
- **EvaluationDataSourceId (string)** – [REQUIRED]
  The ID of the DataSource for the evaluation. The schema of the DataSource must match the schema used to create the MMLModel.

Return type: dict

Returns

Response Syntax

```python
{
    'EvaluationId': 'string'
}
```

Response Structure

- **(dict)** –
  Represents the output of a CreateEvaluation operation, and is an acknowledgement that Amazon ML received the request.
  CreateEvaluation operation is asynchronous. You can poll for status updates by using the GetEvaluation operation and checking the Status parameter.

- **EvaluationId (string)** –
  The user-supplied ID that uniquely identifies the Evaluation. This value should be identical to the value of the EvaluationId in the request.

`create_ml_model(**kwargs)`

Creates a new MLModel using the data files and the recipe as information sources.
An MLModel is nearly immutable. Users can only update the MLModelName and the ScoreThreshold in an MLModel without creating a new MLModel.

CreateMLModel is an asynchronous operation. In response to CreateMLModel, Amazon Machine Learning (Amazon ML) immediately returns and sets the MLModel status to PENDING. After the MLModel is created and ready for use, Amazon ML sets the status to COMPLETED.

You can use the GetMLModel operation to check progress of the MLModel during the creation operation. CreateMLModel requires a DataSource with computed statistics, which can be created by setting ComputeStatistics to true in CreateDataSourceFromRDS, CreateDataSourceFromS3, or CreateDataSourceFromRedshift operations.

Request Syntax

```python
def create_ml_model(client):
    response = client.create_ml_model(
        MLModelId='string',
        MLModelName='string',
        MLModelType='REGRESSION'|'BINARY'|'MULTICLASS',
        Parameters={
            'string': 'string'
        },
        TrainingDataSourceId='string',
        Recipe='string',
        RecipeUri='string'
    )
```

Parameters

- **MLModelId** *(string)* – [REQUIRED]
  A user-supplied ID that uniquely identifies the MLModel.

- **MLModelName** *(string)* – A user-supplied name or description of the MLModel.

- **MLModelType** *(string)* – [REQUIRED]
  The category of supervised learning that this MLModel will address. Choose from the following types:
  - Choose REGRESSION if the MLModel will be used to predict a numeric value.
  - Choose BINARY if the MLModel result has two possible values.
  - Choose MULTICLASS if the MLModel result has a limited number of values.

For more information, see the Amazon Machine Learning Developer Guide.

- **Parameters** *(dict)* – A list of the training parameters in the MLModel. The list is implemented as a map of key/value pairs.

The following is the current set of training parameters:

- **sgd.l1RegularizationAmount** - Coefficient regularization L1 norm. It controls overfitting the data by penalizing large coefficients. This tends to drive coefficients to zero, resulting in sparse feature set. If you use this parameter, start by specifying a small value such as 1.0E-08. The value is a double that ranges from 0 to MAX_DOUBLE. The default is not to use L1 normalization. The parameter cannot be used when L2 is specified. Use this parameter sparingly.

- **sgd.l2RegularizationAmount** - Coefficient regularization L2 norm. It controls overfitting the data by penalizing large coefficients. This tends to drive coefficients to small, nonzero values. If you use this parameter, start by specifying a small value such as 1.0E-08. The value is a double that ranges from 0 to MAX_DOUBLE. The default is not to use L2 normalization.
L2 normalization. This cannot be used when L1 is specified. Use this parameter sparingly.

- `sgd.maxPasses` - Number of times that the training process traverses the observations to build the MLModel. The value is an integer that ranges from 1 to 10000. The default value is 10.

- `sgd.maxMLModelSizeInBytes` - Maximum allowed size of the model. Depending on the input data, the size of the model might affect its performance. The value is an integer that ranges from 100000 to 2147483648. The default value is 33554432.

- *(string)*
  
  String type.
  
  * *(string)*

  String type.

- **TrainingDataSourceId (string) – [REQUIRED]**

  The DataSource that points to the training data.

- **Recipe (string) –** The data recipe for creating MLModel. You must specify either the recipe or its URI. If you don’t specify a recipe or its URI, Amazon ML creates a default.

- **RecipeUri (string) –** The Amazon Simple Storage Service (Amazon S3) location and file name that contains the MLModel recipe. You must specify either the recipe or its URI. If you don’t specify a recipe or its URI, Amazon ML creates a default.

Return type  dict

Returns

Response Syntax

```python
{
    'MLModelId': 'string'
}
```

Response Structure

- *(dict)* –

  Represents the output of a CreateMLModel operation, and is an acknowledgement that Amazon ML received the request.

  The CreateMLModel operation is asynchronous. You can poll for status updates by using the GetMLModel operation and checking the `Status` parameter.

  - **MLModelId (string) –**

    A user-supplied ID that uniquely identifies the MLModel. This value should be identical to the value of the MLModelId in the request.

create_realtime_endpoint (**kwargs)**

Creates a real-time endpoint for the MLModel. The endpoint contains the URI of the MLModel; that is, the location to send real-time prediction requests for the specified MLModel.

Request Syntax

```python
response = client.create_realtime_endpoint(
    MLModelId='string'
)
```
Parameters  **MLModelId (string)** – [REQUIRED]

The ID assigned to the MLModel during creation.

**Return type**  **dict**

**Returns**

**Response Syntax**

```python
{
    'MLModelId': 'string',
    'RealtimeEndpointInfo': {
        'PeakRequestsPerSecond': 123,
        'CreatedAt': datetime(2015, 1, 1),
        'EndpointUrl': 'string',
        'EndpointStatus': 'NONE'|'READY'|'UPDATING'|'FAILED'
    }
}
```

**Response Structure**

-  **(dict)** –

Represents the output of an CreateRealtimeEndpoint operation.

The result contains the MLModelId and the endpoint information for the MLModel.

---

**Note:** The endpoint information includes the URI of the MLModel; that is, the location to send online prediction requests for the specified MLModel.

---

-  **MLModelId (string)** –

A user-supplied ID that uniquely identifies the MLModel. This value should be identical to the value of the MLModelId in the request.

-  **RealtimeEndpointInfo (dict)** –

The endpoint information of the MLModel

  -  **PeakRequestsPerSecond (integer)** –

  The maximum processing rate for the real-time endpoint for MLModel, measured in incoming requests per second.

  -  **CreatedAt (datetime)** –

  The time that the request to create the real-time endpoint for the MLModel was received. The time is expressed in epoch time.

  -  **EndpointUrl (string)** –

  The URI that specifies where to send real-time prediction requests for the MLModel.

  **Note:** Note

  The application must wait until the real-time endpoint is ready before using this URI.

  -  **EndpointStatus (string)** –

  The current status of the real-time endpoint for the MLModel. This element can have one of the following values:

  -  **NONE** - Endpoint does not exist or was previously deleted.
delete_batch_prediction(**kwargs)
Assigns the DELETED status to a BatchPrediction, rendering it unusable.

After using the DeleteBatchPrediction operation, you can use the GetBatchPrediction operation to verify that the status of the BatchPrediction changed to DELETED.

Caution: The result of the DeleteBatchPrediction operation is irreversible.

Request Syntax

response = client.delete_batch_prediction(
    BatchPredictionId='string'
)

Parameters

BatchPredictionId (string) – [REQUIRED]
A user-supplied ID that uniquely identifies the BatchPrediction.

Return type
dict

Returns

Response Syntax

{
    'BatchPredictionId': 'string'
}

Response Structure

* (dict) –

Represents the output of a DeleteBatchPrediction operation.

You can use the GetBatchPrediction operation and check the value of the Status parameter to see whether a BatchPrediction is marked as DELETED.

– BatchPredictionId (string) –

A user-supplied ID that uniquely identifies the BatchPrediction. This value should be identical to the value of the BatchPredictionID in the request.

delete_data_source(**kwargs)
Assigns the DELETED status to a DataSource, rendering it unusable.

After using the DeleteDataSource operation, you can use the GetDataSource operation to verify that the status of the DataSource changed to DELETED.

Caution: The results of the DeleteDataSource operation are irreversible.

Request Syntax

response = client.delete_data_source(
    DataSourceId='string'
)

Parameters

DataSourceId (string) – [REQUIRED]
A user-supplied ID that uniquely identifies the DataSource.

Return type
dict
Returns

Response Syntax

```python
{
   'DataSourceId': 'string'
}
```

Response Structure

- (dict) –
  Represents the output of a DeleteDataSource operation.
  - **DataSourceId** *(string)* –
    A user-supplied ID that uniquely identifies the DataSource. This value should be identical to the value of the DataSourceId in the request.

```python
def delete_evaluation(**kwargs):
    Assigns the DELETED status to an Evaluation, rendering it unusable.

    After invoking the DeleteEvaluation operation, you can use the GetEvaluation operation to verify that the status of the Evaluation changed to DELETED.

    **Caution:** The results of the DeleteEvaluation operation are irreversible.

    Request Syntax

    response = client.delete_evaluation(
        EvaluationId='string'
    )
```

Parameters

- **EvaluationId** *(string)* – [REQUIRED]
  A user-supplied ID that uniquely identifies the Evaluation to delete.

Return type
dict

Returns

Response Syntax

```python
{
   'EvaluationId': 'string'
}
```

Response Structure

- (dict) –
  Represents the output of a DeleteEvaluation operation. The output indicates that Amazon Machine Learning (Amazon ML) received the request.

  You can use the GetEvaluation operation and check the value of the Status parameter to see whether an Evaluation is marked as DELETED.
  - **EvaluationId** *(string)* –
    A user-supplied ID that uniquely identifies the Evaluation. This value should be identical to the value of the EvaluationId in the request.

```python
def delete_ml_model(**kwargs):
    Assigns the DELETED status to an MLModel, rendering it unusable.

    After using the DeleteMLModel operation, you can use the GetMLModel operation to verify that the status of the MLModel changed to DELETED.
```
Caution: The result of the `DeleteMLModel` operation is irreversible.

Request Syntax

```python
response = client.delete_ml_model(
    MLModelId='string'
)
```

Parameters

- **MLModelId** *(string) – [REQUIRED]*
  A user-supplied ID that uniquely identifies the MLModel.

Return type: dict

Returns

Response Syntax

```python
{
    'MLModelId': 'string'
}
```

Response Structure

- *(dict) –*
  Represents the output of a `DeleteMLModel` operation.

  You can use the `GetMLModel` operation and check the value of the `Status` parameter to see whether an MLModel is marked as `DELETED`.

  - **MLModelId** *(string) –*
    A user-supplied ID that uniquely identifies the MLModel. This value should be identical to the value of the `MLModelID` in the request.

`delete_realtime_endpoint (**kwargs)`

Deletes a real-time endpoint of an MLModel.

Request Syntax

```python
response = client.delete_realtime_endpoint(
    MLModelId='string'
)
```

Parameters

- **MLModelId** *(string) – [REQUIRED]*
  The ID assigned to the MLModel during creation.

Return type: dict

Returns

Response Syntax

```python
{
    'MLModelId': 'string',
    'RealtimeEndpointInfo': {
        'PeakRequestsPerSecond': 123,
        'CreatedAt': datetime(2015, 1, 1),
        'EndpointUrl': 'string',
        'EndpointStatus': 'NONE'|'READY'|'UPDATING'|'FAILED'
    }
}
```

Response Structure
• (dict) –

Represents the output of an DeleteRealtimeEndpoint operation.

The result contains the MLModelId and the endpoint information for the MLModel.

– MLModelId (string) –

A user-supplied ID that uniquely identifies the MLModel. This value should be identical to the value of the MLModelId in the request.

– RealtimeEndpointInfo (dict) –

The endpoint information of the MLModel

* PeakRequestsPerSecond (integer) –

The maximum processing rate for the real-time endpoint for MLModel, measured in incoming requests per second.

* CreatedAt (datetime) –

The time that the request to create the real-time endpoint for the MLModel was received. The time is expressed in epoch time.

* EndpointUrl (string) –

The URI that specifies where to send real-time prediction requests for the MLModel.

Note: Note

The application must wait until the real-time endpoint is ready before using this URI.

* EndpointStatus (string) –

The current status of the real-time endpoint for the MLModel. This element can have one of the following values:

- NONE - Endpoint does not exist or was previously deleted.
- READY - Endpoint is ready to be used for real-time predictions.
- UPDATING - Updating/creating the endpoint.

describe_batch_predictions(**kwargs)

Returns a list of BatchPrediction operations that match the search criteria in the request.

Request Syntax

response = client.describe_batch_predictions(
    FilterVariable='CreatedAt'|'LastUpdatedAt'|'Status'|'Name'|'IAMUser'|'MLModelId'|'DataSourceId'|'DataURI',
    EQ='string',
    GT='string',
    LT='string',
    GE='string',
    LE='string',
    NE='string',
    Prefix='string',
    SortOrder='asc'|'dsc',
    NextToken='string',
    Limit=123
)

Parameters
• **FilterVariable** *(string)* – Use one of the following variables to filter a list of BatchPrediction:
  - **CreatedAt** - Sets the search criteria to the BatchPrediction creation date.
  - **Status** - Sets the search criteria to the BatchPrediction status.
  - **Name** - Sets the search criteria to the contents of the BatchPrediction **Name**.
  - **IAMUser** - Sets the search criteria to the user account that invoked the BatchPrediction creation.
  - **MLModelId** - Sets the search criteria to the MLModel used in the BatchPrediction.
  - **DataSourceId** - Sets the search criteria to the DataSource used in the BatchPrediction.
  - **DataURI** - Sets the search criteria to the data file(s) used in the BatchPrediction. The URL can identify either a file or an Amazon Simple Storage Solution (Amazon S3) bucket or directory.

• **EQ** *(string)* – The equal to operator. The BatchPrediction results will have FilterVariable values that exactly match the value specified with EQ.

• **GT** *(string)* – The greater than operator. The BatchPrediction results will have FilterVariable values that are greater than the value specified with GT.

• **LT** *(string)* – The less than operator. The BatchPrediction results will have FilterVariable values that are less than the value specified with LT.

• **GE** *(string)* – The greater than or equal to operator. The BatchPrediction results will have FilterVariable values that are greater than or equal to the value specified with GE.

• **LE** *(string)* – The less than or equal to operator. The BatchPrediction results will have FilterVariable values that are less than or equal to the value specified with LE.

• **NE** *(string)* – The not equal to operator. The BatchPrediction results will have FilterVariable values not equal to the value specified with NE.

• **Prefix** *(string)* – A string that is found at the beginning of a variable, such as Name or Id.

For example, a Batch Prediction operation could have the Name 2014-09-09-HolidayGiftMailer. To search for this BatchPrediction, select Name for the FilterVariable and any of the following strings for the Prefix:
  - 2014-09
  - 2014-09-09
  - 2014-09-09-Holiday

• **SortOrder** *(string)* – A two-value parameter that determines the sequence of the resulting list of MLModels.
  - **asc** - Arranges the list in ascending order (A-Z, 0-9).
  - **dsc** - Arranges the list in descending order (Z-A, 9-0).
  - Results are sorted by FilterVariable.

• **NextToken** *(string)* – An ID of the page in the paginated results.

• **Limit** *(integer)* – The number of pages of information to include in the result. The range of acceptable values is 1 through 100. The default value is 100.

**Return type** *dict*

**Returns**

**Response Syntax**

Response Structure

• (dict) –

Represents the output of a DescribeBatchPredictions operation. The content is essentially a list of BatchPredictions.

  – Results (list) –

A list of BatchPrediction objects that meet the search criteria.

  * (dict) –

Represents the output of GetBatchPrediction operation.

The content consists of the detailed metadata, the status, and the data file information of a Batch Prediction:

  • BatchPredictionId (string) –

    The ID assigned to the BatchPrediction at creation. This value should be identical to the value of the BatchPredictionID in the request.

  • MLModelId (string) –

    The ID of the MLModel that generated predictions for the BatchPrediction request.

  • BatchPredictionDataSourceId (string) –

    The ID of the DataSource that points to the group of observations to predict.

  • InputDataLocationS3 (string) –

    The location of the data file or directory in Amazon Simple Storage Service (Amazon S3).

  • CreatedByIamUser (string) –

    The AWS user account that invoked the BatchPrediction. The account type can be either an AWS root account or an AWS Identity and Access Management (IAM) user account.

  • CreatedAt (datetime) –

    The time that the BatchPrediction was created. The time is expressed in epoch time.
· **LastUpdatedAt** (*datetime*) –
  The time of the most recent edit to the **BatchPrediction**. The time is expressed in epoch time.

· **Name** (*string*) –
  A user-supplied name or description of the **BatchPrediction**.

· **Status** (*string*) –
  The status of the **BatchPrediction**. This element can have one of the following values:
  - **PENDING** - Amazon Machine Learning (Amazon ML) submitted a request to generate predictions for a batch of observations.
  - **INPROGRESS** - The process is underway.
  - **FAILED** - The request to perform a batch prediction did not run to completion. It is not usable.
  - **COMPLETED** - The batch prediction process completed successfully.
  - **DELETED** - The **BatchPrediction** is marked as deleted. It is not usable.

· **OutputUri** (*string*) –
  The location of an Amazon S3 bucket or directory to receive the operation results. The following substrings are not allowed in the s3 key portion of the “outputURI” field: ‘:’, ‘//’, ‘./’, ‘../’.

· **Message** (*string*) –
  A description of the most recent details about processing the batch prediction request.

· **NextToken** (*string*) –
  The ID of the next page in the paginated results that indicates at least one more page follows.

**describe_data_sources** (**kwargs**)  
Returns a list of **DataSource** that match the search criteria in the request.

**Request Syntax**

```python
response = client.describe_data_sources(
    FilterVariable='CreatedAt'|'LastUpdatedAt'|'Status'|'Name'|'DataLocationS3'|'IAMUser',
    EQ='string',
    GT='string',
    LT='string',
    GE='string',
    LE='string',
    NE='string',
    Prefix='string',
    SortOrder='asc'|'dsc',
    NextToken='string',
    Limit=123
)
```

**Parameters**

- **FilterVariable** (*string*) – Use one of the following variables to filter a list of **DataSource**:
CreatedAt - Sets the search criteria to DataSource creation dates.
- Status - Sets the search criteria to DataSource statuses.
- Name - Sets the search criteria to the contents of DataSource Name.
- DataUri - Sets the search criteria to the URI of data files used to create the DataSource. The URI can identify either a file or an Amazon Simple Storage Service (Amazon S3) bucket or directory.
- IAMUser - Sets the search criteria to the user account that invoked the DataSource creation.

- EQ (string) – The equal to operator. The DataSource results will have FilterVariable values that exactly match the value specified with EQ.
- GT (string) – The greater than operator. The DataSource results will have FilterVariable values that are greater than the value specified with GT.
- LT (string) – The less than operator. The DataSource results will have FilterVariable values that are less than the value specified with LT.
- GE (string) – The greater than or equal to operator. The DataSource results will have FilterVariable values that are greater than or equal to the value specified with GE.
- LE (string) – The less than or equal to operator. The DataSource results will have FilterVariable values that are less than or equal to the value specified with LE.
- NE (string) – The not equal to operator. The DataSource results will have FilterVariable values not equal to the value specified with NE.
- Prefix (string) – A string that is found at the beginning of a variable, such as Name or Id.

For example, a DataSource could have the Name 2014-09-09-HolidayGiftMailer. To search for this DataSource, select Name for the FilterVariable and any of the following strings for the Prefix:
- 2014-09
- 2014-09-09
- 2014-09-09-Holiday

- SortOrder (string) – A two-value parameter that determines the sequence of the resulting list of DataSource.
  - asc - Arranges the list in ascending order (A-Z, 0-9).
  - desc - Arranges the list in descending order (Z-A, 9-0).

Results are sorted by FilterVariable.

- NextToken (string) – The ID of the page in the paginated results.
- Limit (integer) – The maximum number of DataSource to include in the result.

Return type  dict

Response Syntax

```json

Response Structure

* (dict) –

Represents the query results from a DescribeDataSources operation. The content is essentially a list of DataSource.

  – Results (list) –

A list of DataSource that meet the search criteria.

* (dict) –

Represents the output of the GetDataSource operation.

The content consists of the detailed metadata and data file information and the current status of the DataSource.

  · DataSourceId (string) –

    The ID that is assigned to the DataSource during creation.

  · DataLocationS3 (string) –

    The location and name of the data in Amazon Simple Storage Service (Amazon S3) that is used by a DataSource.

  · DataRearrangement (string) –

    A JSON string that represents the splitting requirement of a Datapointer.

  · CreatedByIamUser (string) –

    The AWS user account from which the DataSource was created. The account type can be either an AWS root account...
or an AWS Identity and Access Management (IAM) user account.

- **CreatedAt** *(datetime)* –
  The time that the DataSource was created. The time is expressed in epoch time.

- **LastUpdatedAt** *(datetime)* –
  The time of the most recent edit to the BatchPrediction. The time is expressed in epoch time.

- **DataSizeInBytes** *(integer)* –
  The total number of observations contained in the data files that the DataSource references.

- **NumberOfFiles** *(integer)* –
  The number of data files referenced by the DataSource.

- **Name** *(string)* –
  A user-supplied name or description of the DataSource.

- **Status** *(string)* –
  The current status of the DataSource. This element can have one of the following values:
  - PENDING - Amazon Machine Learning (Amazon ML) submitted a request to create a DataSource.
  - INPROGRESS - The creation process is underway.
  - FAILED - The request to create a DataSource did not run to completion. It is not usable.
  - COMPLETED - The creation process completed successfully.
  - DELETED - The DataSource is marked as deleted. It is not usable.

- **Message** *(string)* –
  A description of the most recent details about creating the DataSource.

- **RedshiftMetadata** *(dict)* –
  Describes the DataSource details specific to Amazon Redshift.

- **RedshiftDatabase** *(dict)* –
  Describes the database details required to connect to an Amazon Redshift database.

- **DatabaseName** *(string)* –
  The name of a database hosted on an Amazon Redshift cluster.

- **ClusterIdentifier** *(string)* –
  The ID of an Amazon Redshift cluster.

- **DatabaseUserName** *(string)* –
  A username to be used by Amazon Machine Learning (Amazon ML) to connect to a database on an Amazon Redshift cluster. The username should have sufficient permissions to execute the RedshiftSelectSqlQuery query. The username should be valid for an Amazon Redshift USER.
- **SelectSqlQuery (string)** –
  The SQL query that is specified during CreateDataSourceFromRedshift. Returns only if `Verbose` is true in GetDataSourceInput.

- **RDSMetadata (dict)** –
  The datasource details that are specific to Amazon RDS.

- **Database (dict)** –
  The database details required to connect to an Amazon RDS.

  - **InstanceIdentifier (string)** –
    The ID of an RDS DB instance.

  - **DatabaseName (string)** –
    The name of a database hosted on an RDS DB instance.

  - **DatabaseUserName (string)** –
    The username to be used by Amazon ML to connect to database on an Amazon RDS instance. The username should have sufficient permissions to execute an RDSSelectSqlQuery query.

- **SelectSqlQuery (string)** –
  The SQL query that is supplied during CreateDataSourceFromRDS. Returns only if `Verbose` is true in GetDataSourceInput.

- **ResourceRole (string)** –
  The role (DataPipelineDefaultResourceRole) assumed by an Amazon EC2 instance to carry out the copy task from Amazon RDS to Amazon S3. For more information, see Role templates for data pipelines.

- **ServiceRole (string)** –
  The role (DataPipelineDefaultRole) assumed by the Data Pipeline service to monitor the progress of the copy task from Amazon RDS to Amazon S3. For more information, see Role templates for data pipelines.

- **DataPipelineId (string)** –
  The ID of the Data Pipeline instance that is used to carry to copy data from Amazon RDS to Amazon S3. You can use the ID to find details about the instance in the Data Pipeline console.

- **RoleARN (string)** –
  The Amazon Resource Name (ARN) of an AWS IAM Role such as the following: arn:aws:iam::account:role/rolename.

- **ComputeStatistics (boolean)** –
  The parameter is true if statistics need to be generated from the observation data.

- **NextToken (string)** –
  An ID of the next page in the paginated results that indicates at least one more page follows.

**describe_evaluations (**kwargs**)**

Returns a list of DescribeEvaluations that match the search criteria in the request.
Request Syntax

```python
response = client.describe_evaluations(
    FilterVariable='CreatedAt'|'LastUpdatedAt'|'Status'|'Name'|'IAMUser'|'MLModelId'|'DataSourceId'|'DataUri',
    EQ='string',
    GT='string',
    LT='string',
    GE='string',
    LE='string',
    NE='string',
    Prefix='string',
    SortOrder='asc'|'dsc',
    NextToken='string',
    Limit=123
)
```

Parameters

- **FilterVariable** *(string)* – Use one of the following variable to filter a list of Evaluation objects:
  - CreatedAt - Sets the search criteria to the Evaluation creation date.
  - Status - Sets the search criteria to the Evaluation status.
  - Name - Sets the search criteria to the contents of Evaluation Name.
  - IAMUser - Sets the search criteria to the user account that invoked an Evaluation.
  - MLModelId - Sets the search criteria to the MLModel that was evaluated.
  - DataSourceId - Sets the search criteria to the DataSource used in Evaluation.
  - DataUri - Sets the search criteria to the data file(s) used in Evaluation. The URL can identify either a file or an Amazon Simple Storage Solution (Amazon S3) bucket or directory.

- **EQ** *(string)* – The equal to operator. The Evaluation results will have FilterVariable values that exactly match the value specified with EQ.

- **GT** *(string)* – The greater than operator. The Evaluation results will have FilterVariable values that are greater than the value specified with GT.

- **LT** *(string)* – The less than operator. The Evaluation results will have FilterVariable values that are less than the value specified with LT.

- **GE** *(string)* – The greater than or equal to operator. The Evaluation results will have FilterVariable values that are greater than or equal to the value specified with GE.

- **LE** *(string)* – The less than or equal to operator. The Evaluation results will have FilterVariable values that are less than or equal to the value specified with LE.

- **NE** *(string)* – The not equal to operator. The Evaluation results will have FilterVariable values not equal to the value specified with NE.

- **Prefix** *(string)* – A string that is found at the beginning of a variable, such as Name or Id.

For example, an Evaluation could have the Name 2014-09-09-HolidayGiftMailer. To search for this Evaluation, select Name for the FilterVariable and any of the following strings for the Prefix:

- 2014-09
- 2014-09-09
- 2014-09-09-Holiday
• **SortOrder** *(string)* – A two-value parameter that determines the sequence of the resulting list of Evaluation.
  – *asc* - Arranges the list in ascending order (A-Z, 0-9).
  – *dsc* - Arranges the list in descending order (Z-A, 9-0).
  Results are sorted by FilterVariable.
• **NextToken** *(string)* – The ID of the page in the paginated results.
• **Limit** *(integer)* – The maximum number of Evaluation to include in the result.

**Return type** `dict`

**Response Syntax**

```
{
  'Results': [
    {
      'EvaluationId': 'string',
      'MLModelId': 'string',
      'EvaluationDataSourceId': 'string',
      'InputDataLocationS3': 'string',
      'CreatedByIamUser': 'string',
      'CreatedAt': datetime(2015, 1, 1),
      'LastUpdatedAt': datetime(2015, 1, 1),
      'Name': 'string',
      'Status': 'PENDING'|'INPROGRESS'|'FAILED'|'COMPLETED'|'DELETED',
      'PerformanceMetrics': {
        'Properties': {
          'string': 'string'
        }
      },
      'Message': 'string'
    },
  ],
  'NextToken': 'string'
}
```

**Response Structure**

• *(dict)* – Represents the query results from a DescribeEvaluations operation. The content is essentially a list of Evaluation.
  – **Results** *(list)* – A list of Evaluation that meet the search criteria.
    • *(dict)* – Represents the output of GetEvaluation operation.
      The content consists of the detailed metadata and data file information and the current status of the Evaluation.
      - **EvaluationId** *(string)* – The ID that is assigned to the Evaluation at creation.
      - **MLModelId** *(string)* – The ID of the MLModel that is the focus of the evaluation.
      - **EvaluationDataSourceId** *(string)* – The ID of the DataSource that is used to evaluate the MLModel.
· **InputDataLocationS3** (*string*) –
  The location and name of the data in Amazon Simple Storage Server (Amazon S3) that is used in the evaluation.

· **CreatedByIamUser** (*string*) –
  The AWS user account that invoked the evaluation. The account type can be either an AWS root account or an AWS Identity and Access Management (IAM) user account.

· **CreatedAt** (*datetime*) –
  The time that the Evaluation was created. The time is expressed in epoch time.

· **LastUpdatedAt** (*datetime*) –
  The time of the most recent edit to the Evaluation. The time is expressed in epoch time.

· **Name** (*string*) –
  A user-supplied name or description of the Evaluation.

· **Status** (*string*) –
  The status of the evaluation. This element can have one of the following values:
  · **PENDING** - Amazon Machine Learning (Amazon ML) submitted a request to evaluate an MLModel.
  · **INPROGRESS** - The evaluation is underway.
  · **FAILED** - The request to evaluate an MLModel did not run to completion. It is not usable.
  · **COMPLETED** - The evaluation process completed successfully.
  · **DELETED** - The Evaluation is marked as deleted. It is not usable.

· **PerformanceMetrics** (*dict*) –
  Measurements of how well the MLModel performed, using observations referenced by the DataSource. One of the following metrics is returned, based on the type of the MLModel:
  · **BinaryAUC** - A binary MLModel uses the Area Under the Curve (AUC) technique to measure performance.
  · **RegressionRMSE** - A regression MLModel uses the Root Mean Square Error (RMSE) technique to measure performance. RMSE measures the difference between predicted and actual values for a single variable.
  · **MulticlassAvgFScore** - A multiclass MLModel uses the F1 score technique to measure performance.
  For more information about performance metrics, please see the Amazon Machine Learning Developer Guide.

· **Properties** (*dict*) –
  · (*string*) –
  · (*string*) –

· **Message** (*string*) –
  A description of the most recent details about evaluating the MLModel.

· **NextToken** (*string*) –
The ID of the next page in the paginated results that indicates at least one more page follows.

describe_ml_models(**kwargs)
    Returns a list of MLModel that match the search criteria in the request.

Request Syntax

```python
response = client.describe_ml_models(
    FilterVariable='CreatedAt'|'LastUpdatedAt'|'Status'|'Name'|'IAMUser'|'TrainingDataSourceId'|'RealtimeEndpointStatus'|'MLModelType'|'Algorithm'|'TrainingDataURI',
    EQ='string',
    GT='string',
    LT='string',
    GE='string',
    LE='string',
    NE='string',
    Prefix='string',
    SortOrder='asc'|'dsc',
    NextToken='string',
    Limit=123
)
```

Parameters

- **FilterVariable (string)** – Use one of the following variables to filter a list of MLModel:
  - `CreatedAt` - Sets the search criteria to MLModel creation date.
  - `Status` - Sets the search criteria to MLModel status.
  - `Name` - Sets the search criteria to the contents of MLModel **Name**.
  - `IAMUser` - Sets the search criteria to the user account that invoked the MLModel creation.
  - `TrainingDataSourceId` - Sets the search criteria to the DataSource used to train one or more MLModel.
  - `RealtimeEndpointStatus` - Sets the search criteria to the MLModel real-time endpoint status.
  - `MLModelType` - Sets the search criteria to MLModel type: binary, regression, or multi-class.
  - `Algorithm` - Sets the search criteria to the algorithm that the MLModel uses.
  - `TrainingDataURI` - Sets the search criteria to the data file(s) used in training a MLModel. The URL can identify either a file or an Amazon Simple Storage Service (Amazon S3) bucket or directory.

- **EQ (string)** – The equal to operator. The MLModel results will have FilterVariable values that exactly match the value specified with EQ.

- **GT (string)** – The greater than operator. The MLModel results will have FilterVariable values that are greater than the value specified with GT.

- **LT (string)** – The less than operator. The MLModel results will have FilterVariable values that are less than the value specified with LT.

- **GE (string)** – The greater than or equal to operator. The MLModel results will have FilterVariable values that are greater than or equal to the value specified with GE.

- **LE (string)** – The less than or equal to operator. The MLModel results will have FilterVariable values that are less than or equal to the value specified with LE.

- **NE (string)** – The not equal to operator. The MLModel results will have FilterVariable values not equal to the value specified with NE.
• **Prefix** *(string)* – A string that is found at the beginning of a variable, such as Name or Id.

For example, an MLModel could have the Name 2014-09-09-HolidayGiftMailer. To search for this MLModel, select Name for the FilterVariable and any of the following strings for the Prefix:
- 2014-09
- 2014-09-09
- 2014-09-09-Holiday

• **SortOrder** *(string)* – A two-value parameter that determines the sequence of the resulting list of MLModel.
  - asc - Arranges the list in ascending order (A-Z, 0-9).
  - desc - Arranges the list in descending order (Z-A, 9-0).

Results are sorted by FilterVariable.

• **NextToken** *(string)* – The ID of the page in the paginated results.

• **Limit** *(integer)* – The number of pages of information to include in the result.

The range of acceptable values is 1 through 100. The default value is 100.

Return type **dict**

Response Syntax

```python
{
    'Results': [  
        {
            'MLModelId': 'string',
            'TrainingDataSourceId': 'string',
            'CreatedByIamUser': 'string',
            'CreatedAt': datetime(2015, 1, 1),
            'LastUpdatedAt': datetime(2015, 1, 1),
            'Name': 'string',
            'Status': 'PENDING'|'INPROGRESS'|'FAILED'|'COMPLETED'|'DELETED',
            'SizeInBytes': 123,
            'EndpointInfo': {
                'PeakRequestsPerSecond': 123,
                'CreatedAt': datetime(2015, 1, 1),
                'EndpointUrl': 'string',
                'EndpointStatus': 'NONE'|'READY'|'UPDATING'|'FAILED'
            },
            'TrainingParameters': {  
                'string': 'string'
            },
            'InputDataLocationS3': 'string',
            'Algorithm': 'sgd',
            'MLModelType': 'REGRESSION'|'BINARY'|'MULTICLASS',
            'ScoreThreshold': ...,  
            'ScoreThresholdLastUpdatedAt': datetime(2015, 1, 1),
            'Message': 'string'
        }
    ],
    'NextToken': 'string'
}
```

Response Structure

• *(dict)* – Represents the output of a DescribeMLModels operation. The content is essen-
A list of MLModel that meet the search criteria.

* (dict) –

Represents the output of a GetMLModel operation.

The content consists of the detailed metadata and the current status of the MLModel.

- MLModelId (string) –
  The ID assigned to the MLModel at creation.

- TrainingDataSourceId (string) –
  The ID of the training DataSource. The CreateMLModel operation uses the TrainingDataSourceId.

- CreatedByIamUser (string) –
  The AWS user account from which the MLModel was created. The account type can be either an AWS root account or an AWS Identity and Access Management (IAM) user account.

- CreatedAt (datetime) –
  The time that the MLModel was created. The time is expressed in epoch time.

- LastUpdatedAt (datetime) –
  The time of the most recent edit to the MLModel. The time is expressed in epoch time.

- Name (string) –
  A user-supplied name or description of the MLModel.

- Status (string) –
  The current status of an MLModel. This element can have one of the following values:
  - PENDING - Amazon Machine Learning (Amazon ML) submitted a request to create an MLModel.
  - INPROGRESS - The creation process is underway.
  - FAILED - The request to create an MLModel did not run to completion. It is not usable.
  - COMPLETED - The creation process completed successfully.
  - DELETED - The MLModel is marked as deleted. It is not usable.

- SizeInBytes (integer) –
  Long integer type that is a 64-bit signed number.

- EndpointInfo (dict) –
  The current endpoint of the MLModel.

- PeakRequestsPerSecond (integer) –
  The maximum processing rate for the real-time endpoint for MLModel, measured in incoming requests per second.

- CreatedAt (datetime) –
  The time that the request to create the real-time endpoint for the MLModel was received. The time is expressed in epoch.
time.

- **EndpointUrl** *(string)* –
  The URI that specifies where to send real-time prediction requests for the `MLModel`.

**Note:** Note
The application must wait until the real-time endpoint is ready before using this URI.

- **EndpointStatus** *(string)* –
  The current status of the real-time endpoint for the `MLModel`. This element can have one of the following values:
  - NONE - Endpoint does not exist or was previously deleted.
  - READY - Endpoint is ready to be used for real-time predictions.
  - UPDATING - Updating/creating the endpoint.

- **TrainingParameters** *(dict)* –
  A list of the training parameters in the `MLModel`. The list is implemented as a map of key/value pairs.

The following is the current set of training parameters:
- **sgd.l1RegularizationAmount** - Coefficient regularization L1 norm. It controls overfitting the data by penalizing large coefficients. This tends to drive coefficients to zero, resulting in a sparse feature set. If you use this parameter, specify a small value, such as 1.0E-04 or 1.0E-08. The value is a double that ranges from 0 to MAX_DOUBLE. The default is not to use L1 normalization. The parameter cannot be used when L2 is specified. Use this parameter sparingly.
- **sgd.l2RegularizationAmount** - Coefficient regularization L2 norm. It controls overfitting the data by penalizing large coefficients. This tends to drive coefficients to small, nonzero values. If you use this parameter, specify a small value, such as 1.0E-04 or 1.0E-08. The value is a double that ranges from 0 to MAX_DOUBLE. The default is not to use L2 normalization. This cannot be used when L1 is specified. Use this parameter sparingly.
- **sgd.maxPasses** - Number of times that the training process traverses the observations to build the `MLModel`. The value is an integer that ranges from 1 to 10000. The default value is 10.
- **sgd.maxMLModelSizeInBytes** - Maximum allowed size of the model. Depending on the input data, the model size might affect performance. The value is an integer that ranges from 100000 to 2147483648. The default value is 33554432.

- **(string)** –
  String type.
- **(string)** –
  String type.
- **InputDataLocationS3** *(string)* –
  The location of the data file or directory in Amazon Simple
Storage Service (Amazon S3).
- **Algorithm (string)** –
  The algorithm used to train the MLModel. The following algorithm is supported:
  - SGD – Stochastic gradient descent. The goal of SGD is to minimize the gradient of the loss function.
- **MLModelType (string)** –
  Identifies the MLModel category. The following are the available types:
  - REGRESSION - Produces a numeric result. For example, “What listing price should a house have?”.
  - BINARY - Produces one of two possible results. For example, “Is this a child-friendly web site?”.
  - MULTICLASS - Produces more than two possible results. For example, “Is this a HIGH, LOW or MEDIUM risk trade?”.
- **ScoreThreshold (float)** –
- **ScoreThresholdLastUpdatedAt (datetime)** –
  The time of the most recent edit to the ScoreThreshold. The time is expressed in epoch time.
- **Message (string)** –
  A description of the most recent details about accessing the MLModel.
- **NextToken (string)** –
  The ID of the next page in the paginated results that indicates at least one more page follows.

**generate_presigned_url** *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*
Generate a presigned url given a client, its method, and arguments

**Parameters**
- **ClientMethod (string)** – The client method to presign for
- **Params (dict)** – The parameters normally passed to ClientMethod.
- **ExpiresIn (int)** – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod (string)** – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns** The presigned url

**get_batch_prediction** (**kwargs)**
Returns a BatchPrediction that includes detailed metadata, status, and data file information for a Batch Prediction request.

**Request Syntax**

```python
response = client.get_batch_prediction(
    BatchPredictionId='string'
)
```

**Parameters**
- **BatchPredictionId (string)** – [REQUIRED]
  An ID assigned to the BatchPrediction at creation.

**Return type** dict

**Returns**
Response Syntax

```
{
    'BatchPredictionId': 'string',
    'MLModelId': 'string',
    'BatchPredictionDataSourceId': 'string',
    'InputDataLocationS3': 'string',
    'CreatedByIamUser': 'string',
    'CreatedAt': datetime(2015, 1, 1),
    'LastUpdatedAt': datetime(2015, 1, 1),
    'Name': 'string',
    'Status': 'PENDING'|'INPROGRESS'|'FAILED'|'COMPLETED'|'DELETED',
    'OutputUri': 'string',
    'LogUri': 'string',
    'Message': 'string'
}
```

Response Structure

- `(dict)` –

  Represents the output of a GetBatchPrediction operation and describes a BatchPrediction.

  - **BatchPredictionId (string)** –
    
    An ID assigned to the BatchPrediction at creation. This value should be identical to the value of the BatchPredictionID in the request.

  - **MLModelId (string)** –
    
    The ID of the MLModel that generated predictions for the BatchPrediction request.

  - **BatchPredictionDataSourceId (string)** –
    
    The ID of the DataSource that was used to create the BatchPrediction.

  - **InputDataLocationS3 (string)** –
    
    The location of the data file or directory in Amazon Simple Storage Service (Amazon S3).

  - **CreatedByIamUser (string)** –
    
    The AWS user account that invoked the BatchPrediction. The account type can be either an AWS root account or an AWS Identity and Access Management (IAM) user account.

  - **CreatedAt (datetime)** –
    
    The time when the BatchPrediction was created. The time is expressed in epoch time.

  - **LastUpdatedAt (datetime)** –
    
    The time of the most recent edit to BatchPrediction. The time is expressed in epoch time.

  - **Name (string)** –
    
    A user-supplied name or description of the BatchPrediction.

  - **Status (string)** –
    
    The status of the BatchPrediction, which can be one of the following values:
* PENDING - Amazon Machine Learning (Amazon ML) submitted a request to generate batch predictions.
* INPROGRESS - The batch predictions are in progress.
* FAILED - The request to perform a batch prediction did not run to completion. It is not usable.
* COMPLETED - The batch prediction process completed successfully.
* DELETED - The BatchPrediction is marked as deleted. It is not usable.

- **OutputUri** *(string)* –
  The location of an Amazon S3 bucket or directory to receive the operation results.

- **LogUri** *(string)* –
  A link to the file that contains logs of the CreateBatchPrediction operation.

- **Message** *(string)* –
  A description of the most recent details about processing the batch prediction request.

`get_data_source(**kwargs)`

Returns a `DataSource` that includes metadata and data file information, as well as the current status of the `DataSource`.

`GetDataSource` provides results in normal or verbose format. The verbose format adds the schema description and the list of files pointed to by the `DataSource` to the normal format.

**Request Syntax**

```python
response = client.get_data_source(
    DataSourceId='string',
    Verbose=True|False
)
```

**Parameters**

- **DataSourceId** *(string)* – [REQUIRED]
  The ID assigned to the `DataSource` at creation.

- **Verbose** *(boolean)* – Specifies whether the `GetDataSource` operation should return `DataSourceSchema` .
  If true, `DataSourceSchema` is returned.
  If false, `DataSourceSchema` is not returned.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'DataSourceId': 'string',
    'DataLocationS3': 'string',
    'DataRearrangement': 'string',
    'CreatedByIamUser': 'string',
    'CreatedAt': datetime(2015, 1, 1),
    'LastUpdatedAt': datetime(2015, 1, 1),
    'DataSizeInBytes': 123,
    'NumberOfFiles': 123,
    'Name': 'string',
}
```
Response Structure

- (dict) – Represents the output of a GetDataSource operation and describes a DataSource.
  - **DataSourceId** *(string)* – The ID assigned to the DataSource at creation. This value should be identical to the value of the DataSourceId in the request.
  - **DataLocationS3** *(string)* – The location of the data file or directory in Amazon Simple Storage Service (Amazon S3).
  - **DataRearrangement** *(string)* – A JSON string that captures the splitting rearrangement requirement of the DataSource.
  - **CreatedByIamUser** *(string)* – The AWS user account from which the DataSource was created. The account type can be either an AWS root account or an AWS Identity and Access Management (IAM) user account.
  - **CreatedAt** *(datetime)* – The time that the DataSource was created. The time is expressed in epoch time.
  - **LastUpdatedAt** *(datetime)* – The time of the most recent edit to the DataSource. The time is expressed in epoch time.
  - **DataSizeInBytes** *(integer)* – The total size of observations in the data files.
- **NumberOfFiles** *(integer)*
  The number of data files referenced by the `DataSource`.

- **Name** *(string)*
  A user-supplied name or description of the `DataSource`.

- **Status** *(string)*
  The current status of the `DataSource`. This element can have one of the following values:
  - **PENDING** - Amazon Machine Language (Amazon ML) submitted a request to create a `DataSource`.
  - **INPROGRESS** - The creation process is underway.
  - **FAILED** - The request to create a `DataSource` did not run to completion. It is not usable.
  - **COMPLETED** - The creation process completed successfully.
  - **DELETED** - The `DataSource` is marked as deleted. It is not usable.

- **LogUri** *(string)*
  A link to the file containing logs of either create `DataSource` operation.

- **Message** *(string)*
  The description of the most recent details about creating the `DataSource`.

- **RedshiftMetadata** *(dict)*
  Describes the `DataSource` details specific to Amazon Redshift.
  - **RedshiftDatabase** *(dict)*
    Describes the database details required to connect to an Amazon Redshift database.
    - **DatabaseName** *(string)*
      The name of a database hosted on an Amazon Redshift cluster.
    - **ClusterIdentifier** *(string)*
      The ID of an Amazon Redshift cluster.

- **DatabaseUserName** *(string)*
  A username to be used by Amazon Machine Learning (Amazon ML) to connect to a database on an Amazon Redshift cluster. The username should have sufficient permissions to execute the `RedshiftSelectSqlQuery` query. The username should be valid for an Amazon Redshift `USER`.

- **SelectSqlQuery** *(string)*
  The SQL query that is specified during `CreateDataSourceFromRedshift` if `Verbose` is true in `GetDataSourceInput`.

- **RDSMetadata** *(dict)*
  The datasource details that are specific to Amazon RDS.
  - **Database** *(dict)*
    The database details required to connect to an Amazon RDS.
    - **InstanceIdentifier** *(string)*
      The ID of an RDS DB instance.
- **DatabaseName** *(string)* –
  The name of a database hosted on an RDS DB instance.
  *
  - **DatabaseUserName** *(string)* –
    The username to be used by Amazon ML to connect to database on an Amazon RDS instance. The username should have sufficient permissions to execute an RDSSelectSqlQuery query.
  *
  - **SelectSqlQuery** *(string)* –
    The SQL query that is supplied during CreateDataSourceFromRDS. Returns only if **Verbose** is true in **GetDataSourceInput**.
  *
  - **ResourceRole** *(string)* –
    The role (DataPipelineDefaultResourceRole) assumed by an Amazon EC2 instance to carry out the copy task from Amazon RDS to Amazon S3. For more information, see Role templates for data pipelines.
  *
  - **ServiceRole** *(string)* –
    The role (DataPipelineDefaultRole) assumed by the Data Pipeline service to monitor the progress of the copy task from Amazon RDS to Amazon S3. For more information, see Role templates for data pipelines.
  *
  - **DataPipelineId** *(string)* –
    The ID of the Data Pipeline instance that is used to carry to copy data from Amazon RDS to Amazon S3. You can use the ID to find details about the instance in the Data Pipeline console.
  *
  - **RoleARN** *(string)* –
    The Amazon Resource Name (ARN) of an AWS IAM Role such as the following: arn:aws:iam::account:role/rolename.
  *
  - **ComputeStatistics** *(boolean)* –
    The parameter is *true* if statistics need to be generated from the observation data.
  *
  - **DataSourceSchema** *(string)* –
    The schema used by all of the data files of this **DataSource**.

**Note:**

This parameter is provided as part of the verbose format.

```python
get_evaluation(**kwargs)
```

Returns an Evaluation that includes metadata as well as the current status of the Evaluation.

**Request Syntax**

```python
response = client.get_evaluation(
    EvaluationId='string'
)
```

**Parameters**

- **EvaluationId** *(string)* – [REQUIRED]
  The ID of the Evaluation to retrieve. The evaluation of each MLModel is recorded and cataloged. The ID provides the means to access the information.

**Return type**

dict
Returns

Response Syntax

```
{
    'EvaluationId': 'string',
    'MLModelId': 'string',
    'EvaluationDataSourceId': 'string',
    'InputDataLocationS3': 'string',
    'CreatedByIamUser': 'string',
    'CreatedAt': datetime(2015, 1, 1),
    'LastUpdatedAt': datetime(2015, 1, 1),
    'Name': 'string',
    'Status': 'PENDING'|'INPROGRESS'|'FAILED'|'COMPLETED'|'DELETED',
    'PerformanceMetrics': {
        'Properties': {
            'string': 'string'
        }
    },
    'LogUri': 'string',
    'Message': 'string'
}
```

Response Structure

  - **EvaluationId (string)** – The evaluation ID which is same as the EvaluationId in the request.

  - **MLModelId (string)** – The ID of the MLModel that was the focus of the evaluation.

  - **EvaluationDataSourceId (string)** – The DataSource used for this evaluation.

  - **InputDataLocationS3 (string)** – The location of the data file or directory in Amazon Simple Storage Service (Amazon S3).

  - **CreatedByIamUser (string)** – The AWS user account that invoked the evaluation. The account type can be either an AWS root account or an AWS Identity and Access Management (IAM) user account.

  - **CreatedAt (datetime)** – The time that the Evaluation was created. The time is expressed in epoch time.

  - **LastUpdatedAt (datetime)** – The time of the most recent edit to the BatchPrediction. The time is expressed in epoch time.

  - **Name (string)** – A user-supplied name or description of the Evaluation.

  - **Status (string)** – The status of the evaluation. This element can have one of the following values:
* PENDING - Amazon Machine Language (Amazon ML) submitted a request to evaluate an MLModel.
* INPROGRESS - The evaluation is underway.
* FAILED - The request to evaluate an MLModel did not run to completion. It is not usable.
* COMPLETED - The evaluation process completed successfully.
* DELETED - The Evaluation is marked as deleted. It is not usable.

- **PerformanceMetrics (dict)** –
  Measurements of how well the MLModel performed using observations referenced by the DataSource. One of the following metric is returned based on the type of the MLModel:
  * BinaryAUC: A binary MLModel uses the Area Under the Curve (AUC) technique to measure performance.
  * RegressionRMSE: A regression MLModel uses the Root Mean Square Error (RMSE) technique to measure performance. RMSE measures the difference between predicted and actual values for a single variable.
  * MulticlassAvgFScore: A multiclass MLModel uses the F1 score technique to measure performance.

For more information about performance metrics, please see the Amazon Machine Learning Developer Guide.

- **Properties (dict)** –
  · (string) –
  · (string) –

- **LogUri (string)** –
  A link to the file that contains logs of the CreateEvaluation operation.

- **Message (string)** –
  A description of the most recent details about evaluating the MLModel.

```python
get_ml_model(**kwargs)
```
Returns an MLModel that includes detailed metadata, and data source information as well as the current status of the MLModel.

GetMLModel provides results in normal or verbose format.

**Request Syntax**

```python
response = client.get_ml_model(
    MLModelId='string',
    Verbose=True|False
)
```

**Parameters**

- **MLModelId (string)** – [REQUIRED]
  The ID assigned to the MLModel at creation.
- **Verbose (boolean)** – Specifies whether the GetMLModel operation should return Recipe.
  If true, Recipe is returned.
  If false, Recipe is not returned.

**Return type** dict

3.1. Services
Response Syntax

```
{  
    'MLModelId': 'string',  
    'TrainingDataSourceId': 'string',  
    'CreatedByIamUser': 'string',  
    'CreatedAt': datetime(2015, 1, 1),  
    'LastUpdatedAt': datetime(2015, 1, 1),  
    'Name': 'string',

    'Message': 'string',  
    'Recipe': 'string',  
    'Schema': 'string'  
}
```

Response Structure

- `(dict)` –

  Represents the output of a GetMLModel operation, and provides detailed information about a MLModel.

  - `MLModelId (string)` –

    The MLModel ID which is same as the `MLModelId` in the request.

  - `TrainingDataSourceId (string)` –

    The ID of the training `DataSource`.

  - `CreatedByIamUser (string)` –

    The AWS user account from which the `MLModel` was created. The account type can be either an AWS root account or an AWS Identity and Access Management (IAM) user account.

  - `CreatedAt (datetime)` –

    The time that the `MLModel` was created. The time is expressed in epoch time.

  - `LastUpdatedAt (datetime)` –

    The time of the most recent edit to the `MLModel`. The time is expressed in epoch time.

  - `Name (string)` –

    A user-supplied name or description of the `MLModel`.

  - `Status (string)` –
The current status of the MLModel. This element can have one of the following values:

- **PENDING** - Amazon Machine Learning (Amazon ML) submitted a request to describe a MLModel.
- **INPROGRESS** - The request is processing.
- **FAILED** - The request did not run to completion. It is not usable.
- **COMPLETED** - The request completed successfully.
- **DELETED** - The MLModel is marked as deleted. It is not usable.

- **SizeInBytes** *(integer)*

  Long integer type that is a 64-bit signed number.

- **CurrentMLModelInfo** *(dict)*

  The current endpoint of the MLModel.

- **PeakRequestsPerSecond** *(integer)*

  The maximum processing rate for the real-time endpoint for MLModel, measured in incoming requests per second.

- **CreatedAt** *(datetime)*

  The time that the request to create the real-time endpoint for the MLModel was received. The time is expressed in epoch time.

- **EndpointUrl** *(string)*

  The URI that specifies where to send real-time prediction requests for the MLModel.

  **Note:** Note

  The application must wait until the real-time endpoint is ready before using this URI.

- **EndpointStatus** *(string)*

  The current status of the real-time endpoint for the MLModel. This element can have one of the following values:

  - **NONE** - Endpoint does not exist or was previously deleted.
  - **READY** - Endpoint is ready to be used for real-time predictions.
  - **UPDATING** - Updating/creating the endpoint.

- **TrainingParameters** *(dict)*

  A list of the training parameters in the MLModel. The list is implemented as a map of key/value pairs.

  The following is the current set of training parameters:

  - **sgd.l1RegularizationAmount** - Coefficient regularization L1 norm. It controls overfitting the data by penalizing large coefficients. This tends to drive coefficients to zero, resulting in a sparse feature set. If you use this parameter, specify a small value, such as 1.0E-04 or 1.0E-08. The value is a double that ranges from 0 to MAX_DOUBLE. The default is not to use L1 normalization. The parameter cannot be used when L2 is specified. Use this parameter sparingly.

  - **sgd.l2RegularizationAmount** - Coefficient regularization L2 norm. It controls overfitting the data by penalizing large coefficients. This tends to drive coefficients to small, nonzero values. If you use this parameter, specify a small value, such as 1.0E-04 or 1.0E-08. The value is a double that ranges from 0 to
MAX_DOUBLE. The default is not to use L2 normalization. This parameter cannot be used when L1 is specified. Use this parameter sparingly.

* sgd.maxPasses - The number of times that the training process traverses the observations to build the MLModel. The value is an integer that ranges from 1 to 10000. The default value is 10.
* sgd.maxMLModelSizeInBytes - The maximum allowed size of the model. Depending on the input data, the model size might affect performance. The value is an integer that ranges from 100000 to 2147483648. The default value is 33554432.

* (string) –
  String type.
    - (string) –
      String type.

  – InputDataLocationS3 (string) –
    The location of the data file or directory in Amazon Simple Storage Service (Amazon S3).

  – MLModelType (string) –
    Identifies the MLModel category. The following are the available types:
    * REGRESSION – Produces a numeric result. For example, “What listing price should a house have?"
    * BINARY – Produces one of two possible results. For example, “Is this an e-commerce website?"
    * MULTICLASS – Produces more than two possible results. For example, “Is this a HIGH, LOW or MEDIUM risk trade?"

  – ScoreThreshold (float) –
    The scoring threshold is used in binary classification MLModels, and marks the boundary between a positive prediction and a negative prediction.
    Output values greater than or equal to the threshold receive a positive result from the MLModel, such as true. Output values less than the threshold receive a negative response from the MLModel, such as false.

  – ScoreThresholdLastUpdatedAt (datetime) –
    The time of the most recent edit to the ScoreThreshold. The time is expressed in epoch time.

  – LogUri (string) –
    A link to the file that contains logs of the CreateMLModel operation.

  – Message (string) –
    Description of the most recent details about accessing the MLModel.

  – Recipe (string) –
    The recipe to use when training the MLModel. The Recipe provides detailed information about the observation data to use during training, as well as manipulations to perform on the observation data during training.

**Note:** Note
This parameter is provided as part of the verbose format.

  – Schema (string) –
The schema used by all of the data files referenced by the `DataSource`.

**Note:** Note

This parameter is provided as part of the verbose format.

---

**get Paginator** *(operation_name)*

Create a paginator for an operation.

**Parameters**

- **operation_name** *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.getPaginator("create_foo")`.

**Raises** `OperationNotPageableError` Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

**Return type**

L{botocore.paginate.Paginator}

**Returns**

A paginator object.

---

**get Waiter** *(waiter_name)*

**predict** *(**kwargs)*

Generates a prediction for the observation using the specified ML Model.

**Note:** Note

Not all response parameters will be populated. Whether a response parameter is populated depends on the type of model requested.

---

**Request Syntax**

```python
response = client.predict(
    MLModelId='string',
    Record={
        'string': 'string'
    },
    PredictEndpoint='string'
)
```

**Parameters**

- **MLModelId** *(string)* – [REQUIRED]
  
  A unique identifier of the MLModel.

- **Record** *(dict)* – [REQUIRED]
  
  A map of variable name-value pairs that represent an observation.
  - *(string)* –
    
    The name of a variable. Currently it’s used to specify the name of the target value, label, weight, and tags.
  - *(string)* –
    
    The value of a variable. Currently it’s used to specify values of the target value, weights, and tag variables and for filtering variable values.

- **PredictEndpoint** *(string)* – [REQUIRED]

**Return type**

dict

**Returns**

Response Syntax
{  
    'Prediction': {  
        'predictedLabel': 'string',  
        'predictedValue': 'string',  
        'predictedScores': {  
            'string': 'string',  
        },  
        'details': {  
            'string': 'string',  
        }  
    }  
}  

Response Structure

- **(dict)** –
  
  - **Prediction (dict)** –
    
    The output from a Predict operation:
    
    * Details - Contains the following attributes: DetailsAttributes.PREDICTIVE_MODEL_TYPE - REGRESSION | BINARY | MULTICLASS DetailsAttributes.ALGORITHM - SGD
    * PredictedLabel - Present for either a BINARY or MULTICLASS MLModel request.
    * PredictedScores - Contains the raw classification score corresponding to each label.
    * PredictedValue - Present for a REGRESSION MLModel request.
    * predictedLabel (string) – The prediction label for either a BINARY or MULTICLASS MLModel.
    * predictedValue (float) – The prediction value for REGRESSION MLModel.
    * predictedScores (dict) – Provides the raw classification score corresponding to each label.
      - (string) –
      - (float) –
    * details (dict) – Provides any additional details regarding the prediction.
      - (string) – Contains the key values of DetailsMap: PredictiveModelType - Indicates the type of the MLModel. Algorithm - Indicates the algorithm was used for the MLModel
      - (string) –

**update_batch_prediction(**kwargs**)

Updates the BatchPredictionName of a BatchPrediction.

You can use the GetBatchPrediction operation to view the contents of the updated data element.

Request Syntax

```python
response = client.update_batch_prediction(
    BatchPredictionId='string',
    BatchPredictionName='string'
)
```

Parameters
• **BatchPredictionId** *(string)* – [REQUIRED]
  
The ID assigned to the `BatchPrediction` during creation.

• **BatchPredictionName** *(string)* – [REQUIRED]
  
  A new user-supplied name or description of the `BatchPrediction`.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'BatchPredictionId': 'string'
}
```

**Response Structure**

- *(dict)* –
  
  Represents the output of an `UpdateBatchPrediction` operation.

  You can see the updated content by using the `GetBatchPrediction` operation.

  • **BatchPredictionId** *(string)* –
    
    The ID assigned to the `BatchPrediction` during creation. This value should be identical to the value of the `BatchPredictionId` in the request.

**update_data_source** (**kwargs**)

Updates the `DataSourceName` of a `DataSource`.

You can use the `GetDataSource` operation to view the contents of the updated data element.

**Request Syntax**

```python
response = client.update_data_source(
    DataSourceId='string',
    DataSourceName='string'
)
```

**Parameters**

- **DataSourceId** *(string)* – [REQUIRED]
  
  The ID assigned to the `DataSource` during creation.

- **DataSourceName** *(string)* – [REQUIRED]
  
  A new user-supplied name or description of the `DataSource` that will replace the current description.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'DataSourceId': 'string'
}
```

**Response Structure**

- *(dict)* –
  
  Represents the output of an `UpdateDataSource` operation.

  You can see the updated content by using the `GetBatchPrediction` operation.
– **DataSourceId** *(string)* –

The ID assigned to the DataSource during creation. This value should be identical to the value of the DataSourceId in the request.

**update_evaluation(** **kwargs**)**

Updates the EvaluationName of an Evaluation.

You can use the GetEvaluation operation to view the contents of the updated data element.

**Request Syntax**

```python
response = client.update_evaluation(
    EvaluationId='string',
    EvaluationName='string'
)
```

**Parameters**

- **EvaluationId** *(string)* – [REQUIRED]
  The ID assigned to the Evaluation during creation.

- **EvaluationName** *(string)* – [REQUIRED]
  A new user-supplied name or description of the Evaluation that will replace the current content.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{}
```

**Response Structure**

- *(dict)* –
  Represents the output of an UpdateEvaluation operation.

  You can see the updated content by using the GetEvaluation operation.

  - **EvaluationId** *(string)* –
    The ID assigned to the Evaluation during creation. This value should be identical to the value of the Evaluation in the request.

**update_ml_model(** **kwargs**)**

Updates the MLModelName and the ScoreThreshold of an MLModel.

You can use the GetMLModel operation to view the contents of the updated data element.

**Request Syntax**

```python
response = client.update_ml_model(
    MLModelId='string',
    MLModelName='string',
    ScoreThreshold=...
)
```

**Parameters**

- **MLModelId** *(string)* – [REQUIRED]
  The ID assigned to the MLModel during creation.
• **MLModelName** *(string)* – A user-supplied name or description of the MLModel.

*ScoreThreshold* *(float)* – The ScoreThreshold used in binary classification MLModel that marks the boundary between a positive prediction and a negative prediction.

Output values greater than or equal to the ScoreThreshold receive a positive result from the MLModel, such as `true`. Output values less than the ScoreThreshold receive a negative response from the MLModel, such as `false`.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'MLModelId': 'string'
}
```

**Response Structure**

• *(dict)* –

  Represents the output of an UpdateMLModel operation.

  You can see the updated content by using the GetMLModel operation.

  • **MLModelId** *(string)* –

    The ID assigned to the MLModel during creation. This value should be identical to the value of the MLModelID in the request.

**Paginators**

The available paginators are:

• `MachineLearning.Paginator.DescribeBatchPredictions`

• `MachineLearning.Paginator.DescribeDataSources`

• `MachineLearning.Paginator.DescribeEvaluations`

• `MachineLearning.Paginator.DescribeMLModels`

class `MachineLearning.Paginator.DescribeBatchPredictions`

```python
paginator = client.get_paginator('describe_batch_predictions')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `MachineLearning.Client.describe_batch_predictions()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    FilterVariable='CreatedAt'|'LastUpdatedAt'|'Status'|'Name'|'IAMUser'|'MLModelId'|'DataSourceId'|'DataURI',
    EQ='string',
    GT='string',
    LT='string',
    GE='string',
```
Parameters

- **FilterVariable** *(string)* – Use one of the following variables to filter a list of BatchPrediction:
  - `CreatedAt` - Sets the search criteria to the BatchPrediction creation date.
  - `Status` - Sets the search criteria to the BatchPrediction status.
  - `Name` - Sets the search criteria to the contents of the BatchPrediction **Name**.
  - `IAMUser` - Sets the search criteria to the user account that invoked the BatchPrediction creation.
  - `MLModelId` - Sets the search criteria to the MLModel used in the BatchPrediction.
  - `DataSourceId` - Sets the search criteria to the DataSource used in the BatchPrediction.
  - `DataURI` - Sets the search criteria to the data file(s) used in the BatchPrediction. The URL can identify either a file or an Amazon Simple Storage Solution (Amazon S3) bucket or directory.

- **EQ (string)** – The equal to operator. The BatchPrediction results will have FilterVariable values that exactly match the value specified with EQ.

- **GT (string)** – The greater than operator. The BatchPrediction results will have FilterVariable values that are greater than the value specified with GT.

- **LT (string)** – The less than operator. The BatchPrediction results will have FilterVariable values that are less than the value specified with LT.

- **GE (string)** – The greater than or equal to operator. The BatchPrediction results will have FilterVariable values that are greater than or equal to the value specified with GE.

- **LE (string)** – The less than or equal to operator. The BatchPrediction results will have FilterVariable values that are less than or equal to the value specified with LE.

- **NE (string)** – The not equal to operator. The BatchPrediction results will have FilterVariable values not equal to the value specified with NE.

- **Prefix (string)** – A string that is found at the beginning of a variable, such as Name or Id.

For example, a Batch Prediction operation could have the Name 2014-09-09-HolidayGiftMailer. To search for this BatchPrediction, select Name for the FilterVariable and any of the following strings for the Prefix:
  - 2014-09
  - 2014-09-09
  - 2014-09-09-Holiday

- **SortOrder (string)** – A two-value parameter that determines the sequence of the resulting list of MLModels.
- `asc` - Arranges the list in ascending order (A-Z, 0-9).
- `dsc` - Arranges the list in descending order (Z-A, 9-0).

Results are sorted by `FilterVariable`.

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –
    
    The size of each page.
  - **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Results': [
        {
            'BatchPredictionId': 'string',
            'MLModelId': 'string',
            'BatchPredictionDataSourceId': 'string',
            'InputDataLocationS3': 'string',
            'CreatedByIamUser': 'string',
            'CreatedAt': datetime(2015, 1, 1),
            'LastUpdatedAt': datetime(2015, 1, 1),
            'Name': 'string',
            'Status': 'PENDING'|'INPROGRESS'|'FAILED'|'COMPLETED'|'DELETED',
            'OutputUri': 'string',
            'Message': 'string'
        },
    ],
}
```

**Response Structure**

- *(dict)* –
  
  Represents the output of a DescribeBatchPredictions operation. The content is essentially a list of `BatchPrediction`s.
  - **Results** *(list)* –
    
    A list of `BatchPrediction` objects that meet the search criteria.
    - *(dict)* –
      
      Represents the output of GetBatchPrediction operation.
      
      The content consists of the detailed metadata, the status, and the data file information of a `Batch Prediction`.
      - **BatchPredictionId** *(string)* –
        
        The ID assigned to the `BatchPrediction` at creation. This value should be identical to the value of the `BatchPredictionID` in the request.
· **MLModelId** *(string)* –
  The ID of the **MLModel** that generated predictions for the **BatchPrediction** request.

· **BatchPredictionDataSourceId** *(string)* –
  The ID of the **DataSource** that points to the group of observations to predict.

· **InputDataLocationS3** *(string)* –
  The location of the data file or directory in Amazon Simple Storage Service (Amazon S3).

· **CreatedByIamUser** *(string)* –
  The AWS user account that invoked the **BatchPrediction**. The account type can be either an AWS root account or an AWS Identity and Access Management (IAM) user account.

· **CreatedAt** *(datetime)* –
  The time that the **BatchPrediction** was created. The time is expressed in epoch time.

· **LastUpdatedAt** *(datetime)* –
  The time of the most recent edit to the **BatchPrediction**. The time is expressed in epoch time.

· **Name** *(string)* –
  A user-supplied name or description of the **BatchPrediction**.

· **Status** *(string)* –
  The status of the **BatchPrediction**. This element can have one of the following values:
  · **PENDING** - Amazon Machine Learning (Amazon ML) submitted a request to generate predictions for a batch of observations.
  · **INPROGRESS** - The process is underway.
  · **FAILED** - The request to perform a batch prediction did not run to completion. It is not usable.
  · **COMPLETED** - The batch prediction process completed successfully.
  · **DELETED** - The **BatchPrediction** is marked as deleted. It is not usable.

· **OutputUri** *(string)* –
  The location of an Amazon S3 bucket or directory to receive the operation results. The following substrings are not allowed in the s3 key portion of the “outputURI” field: ‘:’, ‘/’, ‘./’, ‘../’.

· **Message** *(string)* –
  A description of the most recent details about processing the batch prediction request.

```python
class MachineLearning.Paginator.DescribeDataSources

paginator = client.get Paginator('describe_data_sources')
```
**paginate**(**kwargs**)  
Creates an iterator that will paginate through responses from `MachineLearning.Client.describe_data_sources()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    FilterVariable='CreatedAt'|'LastUpdatedAt'|'Status'|'Name'|'DataLocationS3'|'IAMUser',
    EQ='string',
    GT='string',
    LT='string',
    GE='string',
    LE='string',
    NE='string',
    Prefix='string',
    SortOrder='asc'|'dsc',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **FilterVariable** (*string*) – Use one of the following variables to filter a list of `DataSource`:
  - `CreatedAt` - Sets the search criteria to `DataSource` creation dates.
  - `Status` - Sets the search criteria to `DataSource` statuses.
  - `Name` - Sets the search criteria to the contents of `DataSource` Name.
  - `DataUri` - Sets the search criteria to the URI of data files used to create the `DataSource`. The URI can identify either a file or an Amazon Simple Storage Service (Amazon S3) bucket or directory.
  - `IAMUser` - Sets the search criteria to the user account that invoked the `DataSource` creation.
- **EQ** (*string*) – The equal to operator. The `DataSource` results will have `FilterVariable` values that exactly match the value specified with EQ.
- **GT** (*string*) – The greater than operator. The `DataSource` results will have `FilterVariable` values that are greater than the value specified with GT.
- **LT** (*string*) – The less than operator. The `DataSource` results will have `FilterVariable` values that are less than the value specified with LT.
- **GE** (*string*) – The greater than or equal to operator. The `DataSource` results will have `FilterVariable` values that are greater than or equal to the value specified with GE.
- **LE** (*string*) – The less than or equal to operator. The `DataSource` results will have `FilterVariable` values that are less than or equal to the value specified with LE.
- **NE** (*string*) – The not equal to operator. The `DataSource` results will have `FilterVariable` values not equal to the value specified with NE.
- **Prefix** (*string*) – A string that is found at the beginning of a variable, such as Name or Id.

For example, a `DataSource` could have the Name 2014-09-09-HolidayGiftMailer. To search for this `DataSource`, select Name for the `FilterVariable` and any of the following strings for the `Prefix`:
• **SortOrder** *(string)* – A two-value parameter that determines the sequence of the resulting list of DataSource.
  
  – *asc* - Arranges the list in ascending order (A-Z, 0-9).
  – *dsc* - Arranges the list in descending order (Z-A, 9-0).

  Results are sorted by FilterVariable.

• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

  – **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

  – **PageSize** *(integer)* –

    The size of each page.

  – **StartingToken** *(string)* –

    A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** *dict*

**Returns**

**Response Syntax**

```json
{
  'Results': [
    {
      'DataSourceId': 'string',
      'DataLocationS3': 'string',
      'DataRearrangement': 'string',
      'CreatedByIamUser': 'string',
      'CreatedAt': datetime(2015, 1, 1),
      'LastUpdatedAt': datetime(2015, 1, 1),
      'DataSizeInBytes': 123,
      'NumberOfFiles': 123,
      'Name': 'string',
      'Status': 'PENDING'|'INPROGRESS'|'FAILED'|'COMPLETED'|'DELETED',
      'Message': 'string',
      'RedshiftMetadata': {
        'RedshiftDatabase': {
          'DatabaseName': 'string',
          'ClusterIdentifier': 'string'
        },
        'DatabaseUserName': 'string',
        'SelectSqlQuery': 'string'
      },
      'RDSMetadata': {
        'Database': {
          'InstanceIdentifier': 'string',
          'DatabaseName': 'string'
        },
        'DatabaseUserName': 'string',
        'SelectSqlQuery': 'string',
        'ResourceRole': 'string',
        'ServiceRole': 'string'
      }
    }
  ]
}
```
Response Structure

- *(dict)* –
  Represents the query results from a DescribeDataSources operation. The content is essentially a list of *DataSource*.  
  - **Results** *(list)* –
    A list of *DataSource* that meet the search criteria.  
    - *(dict)* –
      Represents the output of the GetDataSource operation. The content consists of the detailed metadata and data file information and the current status of the *DataSource*.
        - **DataSourceId** *(string)* –
          The ID that is assigned to the *DataSource* during creation.
        - **DataLocationS3** *(string)* –
          The location and name of the data in Amazon Simple Storage Service (Amazon S3) that is used by a *DataSource*.
        - **DataRearrangement** *(string)* –
          A JSON string that represents the splitting requirement of a *Datasource*.
        - **CreatedByIamUser** *(string)* –
          The AWS user account from which the *DataSource* was created. The account type can be either an AWS root account or an AWS Identity and Access Management (IAM) user account.
        - **CreatedAt** *(datetime)* –
          The time that the *DataSource* was created. The time is expressed in epoch time.
        - **LastUpdatedAt** *(datetime)* –
          The time of the most recent edit to the *BatchPrediction*. The time is expressed in epoch time.
        - **DataSizeInBytes** *(integer)* –
          The total number of observations contained in the data files that the *DataSource* references.
        - **NumberOfFiles** *(integer)* –
          The number of data files referenced by the *DataSource*.
        - **Name** *(string)* –
          A user-supplied name or description of the *DataSource*.
        - **Status** *(string)* –
The current status of the `DataSource`. This element can have one of the following values:
- **PENDING** - Amazon Machine Learning (Amazon ML) submitted a request to create a `DataSource`.
- **INPROGRESS** - The creation process is underway.
- **FAILED** - The request to create a `DataSource` did not run to completion. It is not usable.
- **COMPLETED** - The creation process completed successfully.
- **DELETED** - The `DataSource` is marked as deleted. It is not usable.
- **Message** *(string)* –
  A description of the most recent details about creating the `DataSource`.
- **RedshiftMetadata** *(dict)* –
  Describes the `DataSource` details specific to Amazon Redshift.
- **RedshiftDatabase** *(dict)* –
  Describes the database details required to connect to an Amazon Redshift database.
- **DatabaseName** *(string)* –
  The name of a database hosted on an Amazon Redshift cluster.
- **ClusterIdentifier** *(string)* –
  The ID of an Amazon Redshift cluster.
- **DatabaseUserName** *(string)* –
  A username to be used by Amazon Machine Learning (Amazon ML) to connect to a database on an Amazon Redshift cluster. The username should have sufficient permissions to execute the `RedshiftSelectSqlQuery` query. The username should be valid for an Amazon Redshift USER.
- **SelectSqlQuery** *(string)* –
  The SQL query that is specified during `CreateDataSourceFromRedshift`. Returns only if `Verbose` is true in `GetDataSourceInput`.
- **RDSMetadata** *(dict)* –
  The datasource details that are specific to Amazon RDS.
- **Database** *(dict)* –
  The database details required to connect to an Amazon RDS.
- **InstanceIdentifier** *(string)* –
  The ID of an RDS DB instance.
- **DatabaseName** *(string)* –
  The name of a database hosted on an RDS instance.
- **DatabaseUserName** *(string)* –
  The username to be used by Amazon ML to connect to database on an Amazon RDS instance. The username should have sufficient permissions to execute an `RDSSelectSqlQuery` query.
- **SelectSqlQuery** *(string)* –
  The SQL query that is supplied during `CreateDataSourceFromRDS`. Returns only if `Verbose` is true in `GetDataSourceInput`.
- **ResourceRole** *(string)* –
  The role (DataPipelineDefaultResourceRole) assumed by an Amazon EC2 instance to carry out the copy task from Amazon RDS to Amazon S3. For more information, see Role templates for data pipelines.
- **ServiceRole** *(string)* –
  The role (DataPipelineDefaultRole) assumed by the Data Pipeline service to monitor the progress of the copy task from Amazon RDS to Amazon S3. For more information, see Role templates for data pipelines.
- **DataPipelineId** *(string)* –
  The ID of the Data Pipeline instance that is used to carry to copy data from Amazon RDS to Amazon S3. You can use the ID to find details about the instance in the Data Pipeline console.
- **RoleARN** *(string)* –
  The Amazon Resource Name (ARN) of an AWS IAM Role such as the following: arn:aws:iam::account:role/rolename.
- **ComputeStatistics** *(boolean)* –
  The parameter is `true` if statistics need to be generated from the observation data.

```python
class MachineLearning.Paginator.DescribeEvaluations

paginator = client.get_paginator('describe_evaluations')

paginate(**kwargs)
# Creates an iterator that will paginate through responses from MachineLearning.Client.describe_evaluations().

Request Syntax

response_iterator = paginator.paginate(
    FilterVariable='CreatedAt'|'LastUpdatedAt'|'Status'|'Name'|'IAMUser'|'MLModelId'|'DataSourceId'|'DataURI',
    EQ='string',
    GT='string',
    LT='string',
    GE='string',
    LE='string',
    NE='string',
    Prefix='string',
    SortOrder='asc'|'dsc',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```
Parameters

- **FilterVariable (string)** – Use one of the following variable to filter a list of Evaluation objects:
  - `CreatedAt` - Sets the search criteria to the Evaluation creation date.
  - `Status` - Sets the search criteria to the Evaluation status.
  - `Name` - Sets the search criteria to the contents of Evaluation Name.
  - `IAMUser` - Sets the search criteria to the user account that invoked an Evaluation.
  - `MLModelId` - Sets the search criteria to the MLModel that was evaluated.
  - `DataSourceId` - Sets the search criteria to the DataSource used in Evaluation.
  - `DataUri` - Sets the search criteria to the data file(s) used in Evaluation. The URL can identify either a file or an Amazon Simple Storage Solution (Amazon S3) bucket or directory.

- **EQ (string)** – The equal to operator. The Evaluation results will have FilterVariable values that exactly match the value specified with EQ.

- **GT (string)** – The greater than operator. The Evaluation results will have FilterVariable values that are greater than the value specified with GT.

- **LT (string)** – The less than operator. The Evaluation results will have FilterVariable values that are less than the value specified with LT.

- **GE (string)** – The greater than or equal to operator. The Evaluation results will have FilterVariable values that are greater than or equal to the value specified with GE.

- **LE (string)** – The less than or equal to operator. The Evaluation results will have FilterVariable values that are less than or equal to the value specified with LE.

- **NE (string)** – The not equal to operator. The Evaluation results will have FilterVariable values not equal to the value specified with NE.

- **Prefix (string)** – A string that is found at the beginning of a variable, such as Name or Id.

  For example, an Evaluation could have the Name 2014-09-09-HolidayGiftMailer. To search for this Evaluation, select Name for the FilterVariable and any of the following strings for the Prefix:
  - 2014-09
  - 2014-09-09
  - 2014-09-09-Holiday

- **SortOrder (string)** – A two-value parameter that determines the sequence of the resulting list of Evaluation.
  - `asc` - Arranges the list in ascending order (A-Z, 0-9).
  - `dsc` - Arranges the list in descending order (Z-A, 9-0).

  Results are sorted by FilterVariable.

- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** – The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize (integer)** – The size of each page.
  - **StartingToken (string)** –
A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict

Returns

Response Syntax

```
{
    'Results': [
        {
            'EvaluationId': 'string',
            'MLModelId': 'string',
            'EvaluationDataSourceId': 'string',
            'InputDataLocationS3': 'string',
            'CreatedByIamUser': 'string',
            'CreatedAt': datetime(2015, 1, 1),
            'LastUpdatedAt': datetime(2015, 1, 1),
            'Name': 'string',
            'Status': 'PENDING'|'INPROGRESS'|'FAILED'|'COMPLETED'|'DELETED',
            'PerformanceMetrics': {
                'Properties': {
                    'string': 'string'
                }
            },
            'Message': 'string'
        },
        {
            ...
        }
    ]
}
```

Response Structure

- (dict) –

Represents the query results from a DescribeEvaluations operation. The content is essentially a list of Evaluation.

- Results (list) –

A list of Evaluation that meet the search criteria.

- (dict) –

Represents the output of GetEvaluation operation.

The content consists of the detailed metadata and data file information and the current status of the Evaluation.

- EvaluationId (string) –

The ID that is assigned to the Evaluation at creation.

- MLModelId (string) –

The ID of the MLModel that is the focus of the evaluation.

- EvaluationDataSourceId (string) –

The ID of the DataSource that is used to evaluate the MLModel.

- InputDataLocationS3 (string) –

The location and name of the data in Amazon Simple Storage Server (Amazon S3) that is used in the evaluation.

- CreatedByIamUser (string) –
The AWS user account that invoked the evaluation. The account type can be either an AWS root account or an AWS Identity and Access Management (IAM) user account.

- **CreatedAt** *(datetime)* –
  The time that the Evaluation was created. The time is expressed in epoch time.

- **LastUpdatedAt** *(datetime)* –
  The time of the most recent edit to the Evaluation. The time is expressed in epoch time.

- **Name** *(string)* –
  A user-supplied name or description of the Evaluation.

- **Status** *(string)* –
  The status of the evaluation. This element can have one of the following values:
  - **PENDING** - Amazon Machine Learning (Amazon ML) submitted a request to evaluate an MLModel.
  - **INPROGRESS** - The evaluation is underway.
  - **FAILED** - The request to evaluate an MLModel did not run to completion. It is not usable.
  - **COMPLETED** - The evaluation process completed successfully.
  - **DELETED** - The Evaluation is marked as deleted. It is not usable.

- **PerformanceMetrics** *(dict)* –
  Measurements of how well the MLModel performed, using observations referenced by the DataSource. One of the following metrics is returned, based on the type of the MLModel:
  - **BinaryAUC** - A binary MLModel uses the Area Under the Curve (AUC) technique to measure performance.
  - **RegressionRMSE** - A regression MLModel uses the Root Mean Square Error (RMSE) technique to measure performance. RMSE measures the difference between predicted and actual values for a single variable.
  - **MulticlassAvgFScore** - A multiclass MLModel uses the F1 score technique to measure performance.
  For more information about performance metrics, please see the Amazon Machine Learning Developer Guide.

- **Properties** *(dict)* –
  - **(string)** –
  - **(string)** –

- **Message** *(string)* –
  A description of the most recent details about evaluating the MLModel.

```python
class MachineLearning.Paginator.DescribeMLModels

    pager = client.get_paginator('describe_ml_models')

    paginate(**kwargs)```
Creates an iterator that will paginate through responses from `MachineLearning.Client.describe_ml_models()`.

Request Syntax

```python
response_iterator = paginator.paginate(
    FilterVariable='CreatedAt'|'LastUpdatedAt'|'Status'|'Name'|'IAMUser'|'TrainingDataSourceId'|'RealtimeEndpointStatus'|'MLModelType'|'Algorithm'|'TrainingDataURI',
    EQ='string',
    GT='string',
    LT='string',
    GE='string',
    LE='string',
    NE='string',
    Prefix='string',
    SortOrder='asc'|'dsc',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **FilterVariable** *(string)* – Use one of the following variables to filter a list of `MLModel`

  - `CreatedAt` - Sets the search criteria to `MLModel` creation date.
  - `Status` - Sets the search criteria to `MLModel` status.
  - `Name` - Sets the search criteria to the contents of `MLModel` Name.
  - `IAMUser` - Sets the search criteria to the user account that invoked the `MLModel` creation.
  - `TrainingDataSourceId` - Sets the search criteria to the `DataSource` used to train one or more `MLModel`.
  - `RealtimeEndpointStatus` - Sets the search criteria to the `MLModel` real-time endpoint status.
  - `MLModelType` - Sets the search criteria to `MLModel` type: binary, regression, or multi-class.
  - `Algorithm` - Sets the search criteria to the algorithm that the `MLModel` uses.
  - `TrainingDataURI` - Sets the search criteria to the data file(s) used in training a `MLModel`. The URL can identify either a file or an Amazon Simple Storage Service (Amazon S3) bucket or directory.

- **EQ** *(string)* – The equal to operator. The `MLModel` results will have FilterVariable values that exactly match the value specified with `EQ`.

- **GT** *(string)* – The greater than operator. The `MLModel` results will have FilterVariable values that are greater than the value specified with `GT`.

- **LT** *(string)* – The less than operator. The `MLModel` results will have FilterVariable values that are less than the value specified with `LT`.

- **GE** *(string)* – The greater than or equal to operator. The `MLModel` results will have FilterVariable values that are greater than or equal to the value specified with `GE`.

- **LE** *(string)* – The less than or equal to operator. The `MLModel` results will have FilterVariable values that are less than or equal to the value specified with `LE`.

- **NE** *(string)* – The not equal to operator. The `MLModel` results will have FilterVariable values not equal to the value specified with `NE`.
- **Prefix** *(string)* – A string that is found at the beginning of a variable, such as Name or Id.

For example, an MLModel could have the Name 2014-09-09-HolidayGiftMailer. To search for this MLModel, select Name for the FilterVariable and any of the following strings for the Prefix:
  - 2014-09
  - 2014-09-09
  - 2014-09-09-Holiday

- **SortOrder** *(string)* – A two-value parameter that determines the sequence of the resulting list of MLModel.
  - asc - Arranges the list in ascending order (A-Z, 0-9).
  - desc - Arranges the list in descending order (Z-A, 9-0).

Results are sorted by FilterVariable.

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –
    The size of each page.
  - **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** *dict*

**Returns**

**Response Syntax**

```json
{
    'Results': [
        {

```
Response Structure

- (dict) –

  Represents the output of a DescribeMLModels operation. The content is essentially a list of MLModel.

  - Results (list) –

    A list of MLModel that meet the search criteria.

    * (dict) –

      Represents the output of a GetMLModel operation.

      The content consists of the detailed metadata and the current status of the MLModel.

      - MLModelId (string) –

        The ID assigned to the MLModel at creation.

      - TrainingDataSourceId (string) –

        The ID of the training DataSource. The CreateMLModel operation uses the TrainingDataSourceId.

      - CreatedByIamUser (string) –

        The AWS user account from which the MLModel was created. The account type can be either an AWS root account or an AWS Identity and Access Management (IAM) user account.

      - CreatedAt (datetime) –

        The time that the MLModel was created. The time is expressed in epoch time.

      - LastUpdatedAt (datetime) –

        The time of the most recent edit to the MLModel. The time is expressed in epoch time.

      - Name (string) –

        A user-supplied name or description of the MLModel.

      - Status (string) –

        The current status of an MLModel. This element can have one of the following values:

        - PENDING - Amazon Machine Learning (Amazon ML) submitted a request to create an MLModel.
        - INPROGRESS - The creation process is underway.
        - FAILED - The request to create an MLModel did not run to completion. It is not usable.
        - COMPLETED - The creation process completed successfully.
        - DELETED - The MLModel is marked as deleted. It is not usable.

      - SizeInBytes (integer) –
Long integer type that is a 64-bit signed number.

- **EndpointInfo** (*dict*) –
  
  The current endpoint of the MLModel.

- **PeakRequestsPerSecond** (*integer*) –
  
  The maximum processing rate for the real-time endpoint for MLModel, measured in incoming requests per second.

- **CreatedAt** (*datetime*) –
  
  The time that the request to create the real-time endpoint for the MLModel was received. The time is expressed in epoch time.

- **EndpointUrl** (*string*) –
  
  The URI that specifies where to send real-time prediction requests for the MLModel.

**Note:** Note

The application must wait until the real-time endpoint is ready before using this URI.

- **EndpointStatus** (*string*) –
  
  The current status of the real-time endpoint for the MLModel. This element can have one of the following values:
  
  - NONE - Endpoint does not exist or was previously deleted.
  - READY - Endpoint is ready to be used for real-time predictions.
  - UPDATING - Updating/creating the endpoint.

- **TrainingParameters** (*dict*) –
  
  A list of the training parameters in the MLModel. The list is implemented as a map of key/value pairs.

  The following is the current set of training parameters:
  
  - **sgd.l1RegularizationAmount** - Coefficient regularization L1 norm. It controls overfitting the data by penalizing large coefficients. This tends to drive coefficients to zero, resulting in a sparse feature set. If you use this parameter, specify a small value, such as 1.0E-04 or 1.0E-08. The value is a double that ranges from 0 to MAX_DOUBLE. The default is not to use L1 normalization. The parameter cannot be used when L2 is specified. Use this parameter sparingly.
  
  - **sgd.l2RegularizationAmount** - Coefficient regularization L2 norm. It controls overfitting the data by penalizing large coefficients. This tends to drive coefficients to small, nonzero values. If you use this parameter, specify a small value, such as 1.0E-04 or 1.0E-08. The value is a double that ranges from 0 to MAX_DOUBLE. The default is not to use L2 normalization. This cannot be used when L1 is specified. Use this parameter sparingly.
  
  - **sgd.maxPasses** - Number of times that the training process traverses the observations to build the MLModel. The value is an integer that ranges from 1 to 10000. The default value is 10.
  
  - **sgd.maxMLModelSizeInBytes** - Maximum allowed
size of the model. Depending on the input data, the model size might affect performance. The value is an integer that ranges from 100000 to 2147483648. The default value is 33554432.

- **InputDataLocationS3** *(string)* – String type.

- **Algorithm** *(string)* – The algorithm used to train the MLModel. The following algorithm is supported:
  - SGD – Stochastic gradient descent. The goal of SGD is to minimize the gradient of the loss function.

- **MLModelType** *(string)* – Identifies the MLModel category. The following are the available types:
  - REGRESSION - Produces a numeric result. For example, “What listing price should a house have?”.
  - BINARY - Produces one of two possible results. For example, “Is this a child-friendly web site?”.
  - MULTICLASS - Produces more than two possible results. For example, “Is this a HIGH, LOW or MEDIUM risk trade?”.

- **ScoreThreshold** *(float)* –

- **ScoreThresholdLastUpdatedAt** *(datetime)* – The time of the most recent edit to the ScoreThreshold. The time is expressed in epoch time.

- **Message** *(string)* – A description of the most recent details about accessing the MLModel.

### Waiters

The available waiters are:

- `MachineLearning.Waiter.DataSourceAvailable`
- `MachineLearning.Waiter.MLModelAvailable`

```python
class MachineLearning.Waiter.BatchPredictionAvailable

    waiter = client.get_waiter('batch_prediction_available')
```
**wait(**
**kwargs**)

Polls `MachineLearning.Client.describe_batch_predictions()` every 30 seconds until a successful state is reached. An error is returned after 60 failed checks.

**Request Syntax**

```python
waiter.wait(
    FilterVariable='CreatedAt'|'LastUpdatedAt'|'Status'|'Name'|'IAMUser'|'MLModelId'|'DataSourceId'|'DataURI',
    EQ='string',
    GT='string',
    LT='string',
    GE='string',
    LE='string',
    NE='string',
    Prefix='string',
    SortOrder='asc'|'dsc',
    NextToken='string',
    Limit=123
)
```

**Parameters**

- **FilterVariable** (`string`) – Use one of the following variables to filter a list of `BatchPrediction`:
  - `CreatedAt` - Sets the search criteria to the `BatchPrediction` creation date.
  - `Status` - Sets the search criteria to the `BatchPrediction` status.
  - `Name` - Sets the search criteria to the contents of the `BatchPrediction` **Name**.
  - `IAMUser` - Sets the search criteria to the user account that invoked the `BatchPrediction` creation.
  - `MLModelId` - Sets the search criteria to the `MLModel` used in the `BatchPrediction`.
  - `DataSourceId` - Sets the search criteria to the `DataSource` used in the `BatchPrediction`.
  - `DataURI` - Sets the search criteria to the data file(s) used in the `BatchPrediction`. The URL can identify either a file or an Amazon Simple Storage Solution (Amazon S3) bucket or directory.

- **EQ** (`string`) – The equal to operator. The `BatchPrediction` results will have `FilterVariable` values that exactly match the value specified with EQ.

- **GT** (`string`) – The greater than operator. The `BatchPrediction` results will have `FilterVariable` values that are greater than the value specified with GT.

- **LT** (`string`) – The less than operator. The `BatchPrediction` results will have `FilterVariable` values that are less than the value specified with LT.

- **GE** (`string`) – The greater than or equal to operator. The `BatchPrediction` results will have `FilterVariable` values that are greater than or equal to the value specified with GE.

- **LE** (`string`) – The less than or equal to operator. The `BatchPrediction` results will have `FilterVariable` values that are less than or equal to the value specified with LE.

- **NE** (`string`) – The not equal to operator. The `BatchPrediction` results will have `FilterVariable` values not equal to the value specified with NE.

- **Prefix** (`string`) – A string that is found at the beginning of a variable, such as Name or Id.

For example, a Batch Prediction operation could have the
Name 2014-09-09-HolidayGiftMailer. To search for this BatchPrediction, select Name for the FilterVariable and any of the following strings for the Prefix:
- 2014-09
- 2014-09-09
- 2014-09-09-Holiday

- **SortOrder** (string) – A two-value parameter that determines the sequence of the resulting list of MLModels.
  - `asc` - Arranges the list in ascending order (A-Z, 0-9).
  - `dsc` - Arranges the list in descending order (Z-A, 9-0).

Results are sorted by FilterVariable.

- **NextToken** (string) – An ID of the page in the paginated results.
- **Limit** (integer) – The number of pages of information to include in the result.
  The range of acceptable values is 1 through 100. The default value is 100.

Returns None

```python
class MachineLearning.Waiter.DataSourceAvailable

waiter = client.get_waiter('data_source_available')

wait(**kwargs)
    Polls MachineLearning.Client.describe_data_sources() every 30 seconds until a successful state is reached. An error is returned after 60 failed checks.

Request Syntax

waiter.wait(
    FilterVariable='CreatedAt'|'LastUpdatedAt'|'Status'|'Name'|'DataLocationS3'|'IAMUser',
    EQ='string',
    GT='string',
    LT='string',
    GE='string',
    LE='string',
    NE='string',
    Prefix='string',
    SortOrder='asc'|'dsc',
    NextToken='string',
    Limit=123
)
```

Parameters

- **FilterVariable** (string) – Use one of the following variables to filter a list of DataSource:
  - `CreatedAt` - Sets the search criteria to DataSource creation dates.
  - `Status` - Sets the search criteria to DataSource statuses.
  - `Name` - Sets the search criteria to the contents of DataSource. The URI can identify either a file or an Amazon Simple Storage Service (Amazon S3) bucket or directory.
  - `IAMUser` - Sets the search criteria to the user account that invoked the DataSource creation.

- **EQ** (string) – The equal to operator. The DataSource results will have FilterVariable values that exactly match the value specified with EQ.
• **GT** *(string)* – The greater than operator. The *DataSource* results will have *FilterVariable* values that are greater than the value specified with **GT**.

• **LT** *(string)* – The less than operator. The *DataSource* results will have *FilterVariable* values that are less than the value specified with **LT**.

• **GE** *(string)* – The greater than or equal to operator. The *DataSource* results will have *FilterVariable* values that are greater than or equal to the value specified with **GE**.

• **LE** *(string)* – The less than or equal to operator. The *DataSource* results will have *FilterVariable* values that are less than or equal to the value specified with **LE**.

• **NE** *(string)* – The not equal to operator. The *DataSource* results will have *FilterVariable* values not equal to the value specified with **NE**.

• **Prefix** *(string)* – A string that is found at the beginning of a variable, such as *Name* or *Id*.

For example, a *DataSource* could have the Name 2014-09-09-HolidayGiftMailer. To search for this *DataSource*, select *Name* for the *FilterVariable* and any of the following strings for the Prefix:

- 2014-09
- 2014-09-09
- 2014-09-09-Holiday

• **SortOrder** *(string)* – A two-value parameter that determines the sequence of the resulting list of *DataSource*.

  - asc - Arranges the list in ascending order (A-Z, 0-9).
  - desc - Arranges the list in descending order (Z-A, 9-0).

Results are sorted by *FilterVariable*.

• **NextToken** *(string)* – The ID of the page in the paginated results.

• **Limit** *(integer)* – The maximum number of *DataSource* to include in the result.

**Returns** None

class MachineLearning.Waiter.EvaluationAvailable

waiter = client.get_waiter('evaluation_available')

wait(**kwargs)

Polls *MachineLearning.Client.describe_evaluations()* every 30 seconds until a successful state is reached. An error is returned after 60 failed checks.

**Request Syntax**

```python
waiter.wait(
    FilterVariable='CreatedAt'|'LastUpdatedAt'|'Status'|'Name'|'IAMUser'|'MLModelId'|'DataSourceId'|'DataURI',
    EQ='string',
    GT='string',
    LT='string',
    GE='string',
    LE='string',
    NE='string',
    Prefix='string',
    SortOrder='asc'|'dsc',
    NextToken='string',
    Limit=123
)```
Parameters

- **FilterVariable** *(string)* – Use one of the following variable to filter a list of Evaluation objects:
  - **CreatedAt** - Sets the search criteria to the Evaluation creation date.
  - **Status** - Sets the search criteria to the Evaluation status.
  - **Name** - Sets the search criteria to the contents of Evaluation Name.
  - **IAMUser** - Sets the search criteria to the user account that invoked an Evaluation.
  - **MLModelId** - Sets the search criteria to the MLModel that was evaluated.
  - **DataSourceId** - Sets the search criteria to the DataSource used in Evaluation.
  - **DataUri** - Sets the search criteria to the data file(s) used in Evaluation. The URL can identify either a file or an Amazon Simple Storage Solution (Amazon S3) bucket or directory.
- **EQ** *(string)* – The equal to operator. The Evaluation results will have FilterVariable values that exactly match the value specified with EQ.
- **GT** *(string)* – The greater than operator. The Evaluation results will have FilterVariable values that are greater than the value specified with GT.
- **LT** *(string)* – The less than operator. The Evaluation results will have FilterVariable values that are less than the value specified with LT.
- **GE** *(string)* – The greater than or equal to operator. The Evaluation results will have FilterVariable values that are greater than or equal to the value specified with GE.
- **LE** *(string)* – The less than or equal to operator. The Evaluation results will have FilterVariable values that are less than or equal to the value specified with LE.
- **NE** *(string)* – The not equal to operator. The Evaluation results will have FilterVariable values not equal to the value specified with NE.
- **Prefix** *(string)* – A string that is found at the beginning of a variable, such as Name or Id.

For example, an Evaluation could have the Name 2014-09-09-HolidayGiftMailer. To search for this Evaluation, select Name for the FilterVariable and any of the following strings for the Prefix:
  - 2014-09
  - 2014-09-09
  - 2014-09-09-Holiday

- **SortOrder** *(string)* – A two-value parameter that determines the sequence of the resulting list of Evaluation.
  - **asc** - Arranges the list in ascending order (A-Z, 0-9).
  - **dsc** - Arranges the list in descending order (Z-A, 9-0).

Results are sorted by FilterVariable.

- **NextToken** *(string)* – The ID of the page in the paginated results.
- **Limit** *(integer)* – The maximum number of Evaluation to include in the result.

**Returns** None

class MachineLearning.Waiter.MLModelAvailable

```python
waiter = client.get_waiter('ml_model_available')
wait(**kwargs)
```
Polls `MachineLearning.Client.describe_ml_models()` every 30 seconds until a successful state is reached. An error is returned after 60 failed checks.

**Request Syntax**

```python
waiter.wait(
    FilterVariable='CreatedAt'|'LastUpdatedAt'|'Status'|'Name'|'IAMUser'|'TrainingDataSourceId'|'RealtimeEndpointStatus'|'MLModelType'|'Algorithm'|'TrainingDataURI',
    EQ='string',
    GT='string',
    LT='string',
    GE='string',
    LE='string',
    NE='string',
    Prefix='string',
    SortOrder='asc'|'dsc',
    NextToken='string',
    Limit=123
)
```

**Parameters**

- **FilterVariable** *(string)* – Use one of the following variables to filter a list of MLModel:
  - `CreatedAt` - Sets the search criteria to MLModel creation date.
  - `Status` - Sets the search criteria to MLModel status.
  - `Name` - Sets the search criteria to the contents of MLModel **Name**.
  - `IAMUser` - Sets the search criteria to the user account that invoked the MLModel creation.
  - `TrainingDataSourceId` - Sets the search criteria to the DataSource used to train one or more MLModel.
  - `RealtimeEndpointStatus` - Sets the search criteria to the MLModel real-time endpoint status.
  - `MLModelType` - Sets the search criteria to MLModel type: binary, regression, or multi-class.
  - `Algorithm` - Sets the search criteria to the algorithm that the MLModel uses.
  - `TrainingDataURI` - Sets the search criteria to the data file(s) used in training a MLModel. The URL can identify either a file or an Amazon Simple Storage Service (Amazon S3) bucket or directory.

- **EQ** *(string)* – The equal to operator. The MLModel results will have FilterVariable values that exactly match the value specified with EQ.

- **GT** *(string)* – The greater than operator. The MLModel results will have FilterVariable values that are greater than the value specified with GT.

- **LT** *(string)* – The less than operator. The MLModel results will have FilterVariable values that are less than the value specified with LT.

- **GE** *(string)* – The greater than or equal to operator. The MLModel results will have FilterVariable values that are greater than or equal to the value specified with GE.

- **LE** *(string)* – The less than or equal to operator. The MLModel results will have FilterVariable values that are less than or equal to the value specified with LE.

- **NE** *(string)* – The not equal to operator. The MLModel results will have FilterVariable values not equal to the value specified with NE.

- **Prefix** *(string)* – A string that is found at the beginning of a variable, such as Name or Id.
For example, an MLModel could have the Name 2014-09-09-HolidayGiftMailer. To search for this MLModel, select Name for the FilterVariable and any of the following strings for the Prefix:
  – 2014-09
  – 2014-09-09
  – 2014-09-09-Holiday

• SortOrder (string) – A two-value parameter that determines the sequence of the resulting list of MLModel.
  – asc - Arranges the list in ascending order (A-Z, 0-9).
  – dsc - Arranges the list in descending order (Z-A, 9-0).

Results are sorted by FilterVariable.

• NextToken (string) – The ID of the page in the paginated results.
• Limit (integer) – The number of pages of information to include in the result. The range of acceptable values is 1 through 100. The default value is 100.

Returns None

OpsWorks

Table of Contents

  – StackSummary

Client

class OpsWorks.Client
A low-level client representing AWS OpsWorks:

    import boto3

    client = boto3.client('opsworks')

These are the available methods:
  • assign_instance()
  • assign_volume()
  • associate_elastic_ip()
  • attach_elastic_load_balancer()
  • can_paginate()
  • clone_stack()
  • create_app()
  • create_deployment()
  • create_instance()
  • create_layer()
  • create_stack()
  • create_user_profile()
  • delete_app()
• delete_instance()
• delete_layer()
• delete_stack()
• delete_user_profile()
• deregister_ecs_cluster()
• deregister_elastic_ip()
• deregister_instance()
• deregister_rds_db_instance()
• deregister_volume()
• describe_agent_versions()
• describe_apps()
• describe_commands()
• describe_deployments()
• describe_ecs_clusters()
• describe_elastic_ips()
• describe_elastic_load_balancers()
• describe_instances()
• describe_layers()
• describe_load_based_auto_scaling()
• describe_my_user_profile()
• describe_permissions()
• describe_raid_arrays()
• describe_rds_db_instances()
• describe_service_errors()
• describe_stack_provisioning_parameters()
• describe_stack_summary()
• describe_stacks()
• describe_time_based_auto_scaling()
• describe_userprofiles()
• describe_volumes()
• detach_elastic_load_balancer()
• disassociate_elastic_ip()
• generate_presigned_url()
• get_hostname_suggestion()
• get Paginator()
• get_waiter()
• grant_access()
• reboot_instance()
• register_ecs_cluster()
• register_elastic_ip()
• register_instance()
• register_rds_db_instance()
• register_volume()
• set_load_based_auto_scaling()
• set_permission()
• set_time_based_auto_scaling()
• start_instance()
• start_stack()
• stop_instance()
• stop_stack()
• unassign_instance()
• unassign_volume()
• update_app()
• update_elastic_ip()
Assign a registered instance to a layer.

- You can assign registered on-premises instances to any layer type.
- You can assign registered Amazon EC2 instances only to custom layers.
- You cannot use this action with instances that were created with AWS OpsWorks.

**Required Permissions**: To use this action, an AWS Identity and Access Management (IAM) user must have a Manage permissions level for the stack or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.assign_instance(
    InstanceId='string',
    LayerIds=['string'],
)
```

**Parameters**

- **InstanceId** *(string)* – [REQUIRED]
  The instance ID.

- **LayerIds** *(list)* – [REQUIRED]
  The layer ID, which must correspond to a custom layer. You cannot assign a registered instance to a built-in layer.

**Returns** None

Assigns one of the stack’s registered Amazon EBS volumes to a specified instance. The volume must first be registered with the stack by calling RegisterVolume. After you register the volume, you must call UpdateVolume to specify a mount point before calling AssignVolume. For more information, see Resource Management.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.assign_volume(
    VolumeId='string',
    Instanceld='string'
)
```

**Parameters**

- **VolumeId** *(string)* – [REQUIRED]
  The volume ID.

- **Instanceld** *(string)* – The instance ID.
Returns None

**associate_elastic_ip(**)\n
Associates one of the stack’s registered Elastic IP addresses with a specified instance. The address must first be registered with the stack by calling RegisterElasticIp. For more information, see Resource Management.

**Required Permissions:** To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.associate_elastic_ip(
    ElasticIp='string',
    InstanceId='string'
)
```

**Parameters**

- **ElasticIp (string)** – [REQUIRED]
  
  The Elastic IP address.

- **InstanceId (string)** – The instance ID.

**Returns** None

**attach_elastic_load_balancer(**)\n
Attaches an Elastic Load Balancing load balancer to a specified layer. For more information, see Elastic Load Balancing.

**Note:** You must create the Elastic Load Balancing instance separately, by using the Elastic Load Balancing console, API, or CLI. For more information, see Elastic Load Balancing Developer Guide.

**Required Permissions:** To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.attach_elastic_load_balancer(
    ElasticLoadBalancerName='string',
    LayerId='string'
)
```

**Parameters**

- **ElasticLoadBalancerName (string)** – [REQUIRED]
  
  The Elastic Load Balancing instance’s name.

- **LayerId (string)** – [REQUIRED]
  
  The ID of the layer that the Elastic Load Balancing instance is to be attached to.

**Returns** None

**can_paginate(operation_name)**

Check if an operation can be paginated.

**Parameters operation_name (string)** – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").
Returns True if the operation can be paginated, False otherwise.

clone_stack(**kwargs)

Creates a clone of a specified stack. For more information, see Clone a Stack. By default, all parameters are set to the values used by the parent stack.

Required Permissions: To use this action, an IAM user must have an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

Request Syntax

response = client.clone_stack(
    SourceStackId='string',
    Name='string',
    Region='string',
    VpcId='string',
    Attributes={
        'string': 'string'
    },
    ServiceRoleArn='string',
    DefaultInstanceProfileArn='string',
    DefaultOs='string',
    HostnameTheme='string',
    DefaultAvailabilityZone='string',
    DefaultSubnetId='string',
    CustomJson='string',
    ConfigurationManager={
        'Name': 'string',
        'Version': 'string'
    },
    ChefConfiguration={
        'ManageBerkshelf': True|False,
        'BerkshelfVersion': 'string'
    },
    UseCustomCookbooks=True|False,
    UseOpsworksSecurityGroups=True|False,
    CustomCookbooksSource={
        'Type': 'git' | 'svn' | 'archive' | 's3',
        'Url': 'string',
        'Username': 'string',
        'Password': 'string',
        'SshKey': 'string',
        'Revision': 'string'
    },
    DefaultSshKeyName='string',
    ClonePermissions=True|False,
    CloneAppIds=[],
    DefaultRootDeviceType='ebs' | 'instance-store',
    AgentVersion='string'
)

Parameters

- **SourceStackId** *(string)* – [REQUIRED]
  The source stack ID.
- **Name** *(string)* – The cloned stack name.
• **Region** *(string)* – The cloned stack AWS region, such as “us-east-1”. For more information about AWS regions, see Regions and Endpoints.

• **VpcId** *(string)* – The ID of the VPC that the cloned stack is to be launched into. It must be in the specified region. All instances are launched into this VPC, and you cannot change the ID later.
  - If your account supports EC2 Classic, the default value is no VPC.
  - If your account does not support EC2 Classic, the default value is the default VPC for the specified region.

If the VPC ID corresponds to a default VPC and you have specified either the `DefaultAvailabilityZone` or `DefaultSubnetId` parameter only, AWS OpsWorks infers the value of the other parameter. If you specify neither parameter, AWS OpsWorks sets these parameters to the first valid Availability Zone for the specified region and the corresponding default VPC subnet ID, respectively.

If you specify a nondefault VPC ID, note the following:
  - It must belong to a VPC in your account that is in the specified region.
  - You must specify a value for `DefaultSubnetId`.

For more information on how to use AWS OpsWorks with a VPC, see Running a Stack in a VPC. For more information on default VPC and EC2 Classic, see Supported Platforms.

• **Attributes** *(dict)* – A list of stack attributes and values as key/value pairs to be added to the cloned stack.
  - *(string)*
  - *(string)* –

• **ServiceRoleArn** *(string)* – [REQUIRED]

  The stack AWS Identity and Access Management (IAM) role, which allows AWS OpsWorks to work with AWS resources on your behalf. You must set this parameter to the Amazon Resource Name (ARN) for an existing IAM role. If you create a stack by using the AWS OpsWorks console, it creates the role for you. You can obtain an existing stack’s IAM ARN programmatically by calling DescribePermissions. For more information about IAM ARNs, see Using Identifiers.

  **Note:** You must set this parameter to a valid service role ARN or the action will fail; there is no default value. You can specify the source stack’s service role ARN, if you prefer, but you must do so explicitly.

• **DefaultInstanceProfileArn** *(string)* – The Amazon Resource Name (ARN) of an IAM profile that is the default profile for all of the stack’s EC2 instances. For more information about IAM ARNs, see Using Identifiers.

• **DefaultOs** *(string)* – The stack’s operating system, which must be set to one of the following.
  - A supported Linux operating system: An Amazon Linux version, such as Amazon Linux 2015.03, Red Hat Enterprise Linux 7, Ubuntu 12.04 LTS, or Ubuntu 14.04 LTS.
  - A custom AMI: Custom. You specify the custom AMI you want to use when you create instances. For more information on how to use custom AMIs with OpsWorks, see Using Custom AMIs.

  The default option is the parent stack’s operating system. For more information on the supported operating systems, see AWS OpsWorks Operating Systems.

  **Note:** You can specify a different Linux operating system for the cloned stack,
but you cannot change from Linux to Windows or Windows to Linux.

- **HostnameTheme** *(string)* – The stack’s host name theme, with spaces are replaced by underscores. The theme is used to generate host names for the stack’s instances. By default, `HostnameTheme` is set to `Layer_Dependent`, which creates host names by appending integers to the layer’s short name. The other themes are:
  - Baked_Goods
  - Clouds
  - Europe_Cities
  - Fruits
  - Greek_Deities
  - Legendary_creatures_from_Japan
  - Planets_and_Moons
  - Roman_Deities
  - Scottish_Islands
  - US_Cities
  - Wild_Cats

To obtain a generated host name, call `GetHostNameSuggestion`, which returns a host name based on the current theme.

- **DefaultAvailabilityZone** *(string)* – The cloned stack’s default Availability Zone, which must be in the specified region. For more information, see Regions and Endpoints. If you also specify a value for `DefaultSubnetId`, the subnet must be in the same zone. For more information, see the `VpcId` parameter description.

- **DefaultSubnetId** *(string)* – The stack’s default VPC subnet ID. This parameter is required if you specify a value for the `VpcId` parameter. All instances are launched into this subnet unless you specify otherwise when you create the instance. If you also specify a value for `DefaultAvailabilityZone`, the subnet must be in that zone. For information on default values and when this parameter is required, see the `VpcId` parameter description.

- **CustomJson** *(string)* – A string that contains user-defined, custom JSON. It is used to override the corresponding default stack configuration JSON values. The string should be in the following format and must escape characters such as "":
  
  "{"key1":"value1","key2":"value2"...,"

  For more information on custom JSON, see Use Custom JSON to Modify the Stack Configuration Attributes.

- **ConfigurationManager** *(dict)* – The configuration manager. When you clone a Linux stack we recommend that you use the configuration manager to specify the Chef version: 0.9, 11.4, or 11.10. The default value is currently 11.10.
  - **Name** *(string)* –
    
    The name. This parameter must be set to “Chef”.
  - **Version** *(string)* –
    
    The Chef version. This parameter must be set to 0.9, 11.4, or 11.10. The default value is 11.4.

- **ChefConfiguration** *(dict)* – A ChefConfiguration object that specifies whether to enable Berkshelf and the Berkshelf version on Chef 11.10 stacks. For more information, see Create a New Stack.
  - **ManageBerkshelf** *(boolean)* –
    
    Whether to enable Berkshelf.
  - **BerkshelfVersion** *(string)* –
The Berkshelf version.

- **UseCustomCookbooks**(boolean) – Whether to use custom cookbooks.
- **UseOpsworksSecurityGroups**(boolean) – Whether to associate the AWS OpsWorks built-in security groups with the stack’s layers.

AWS OpsWorks provides a standard set of built-in security groups, one for each layer, which are associated with layers by default. With **UseOpsworksSecurityGroups** you can instead provide your own custom security groups. **UseOpsworksSecurityGroups** has the following settings:

- **True** - AWS OpsWorks automatically associates the appropriate built-in security group with each layer (default setting). You can associate additional security groups with a layer after you create it but you cannot delete the built-in security group.
- **False** - AWS OpsWorks does not associate built-in security groups with layers. You must create appropriate Amazon Elastic Compute Cloud (Amazon EC2) security groups and associate a security group with each layer that you create. However, you can still manually associate a built-in security group with a layer on creation; custom security groups are required only for those layers that need custom settings.

For more information, see [Create a New Stack](#).

- **CustomCookbooksSource**(dict) – Contains the information required to retrieve an app or cookbook from a repository. For more information, see [Creating Apps](#) or [Custom Recipes and Cookbooks](#).

  - **Type**(string) –
    The repository type.
  - **Url**(string) –
    The source URL.
  - **Username**(string) –
    This parameter depends on the repository type.
    * For Amazon S3 bundles, set Username to the appropriate IAM access key ID.
    * For HTTP bundles, Git repositories, and Subversion repositories, set Username to the user name.
  - **Password**(string) –
    When included in a request, the parameter depends on the repository type.
    * For Amazon S3 bundles, set Password to the appropriate IAM secret access key.
    * For HTTP bundles and Subversion repositories, set Password to the password.

For more information on how to safely handle IAM credentials, see [http://docs.aws.amazon.com/general/latest/gr/aws-access-keys-best-practices.html](http://docs.aws.amazon.com/general/latest/gr/aws-access-keys-best-practices.html).

In responses, AWS OpsWorks returns ******FILTERED****** instead of the actual value.

- **SshKey**(string) –
  In requests, the repository’s SSH key.

In responses, AWS OpsWorks returns ******FILTERED****** instead of the actual value.

- **Revision**(string) –
Boto3 Documentation, Release 1.1.4

The application’s version. AWS OpsWorks enables you to easily deploy new versions of an application. One of the simplest approaches is to have branches or revisions in your repository that represent different versions that can potentially be deployed.

- **DefaultSshKeyName** *(string)* – A default Amazon EC2 key pair name. The default value is none. If you specify a key pair name, AWS OpsWorks installs the public key on the instance and you can use the private key with an SSH client to log in to the instance. For more information, see Using SSH to Communicate with an Instance and Managing SSH Access. You can override this setting by specifying a different key pair, or no key pair, when you create an instance.

- **ClonePermissions** *(boolean)* – Whether to clone the source stack’s permissions.

- **CloneAppIds** *(list)* – A list of source stack app IDs to be included in the cloned stack.

- **DefaultRootDeviceType** *(string)* – The default root device type. This value is used by default for all instances in the cloned stack, but you can override it when you create an instance. For more information, see Storage for the Root Device.

- **AgentVersion** *(string)* – The default AWS OpsWorks agent version. You have the following options:
  - Auto-update - Set this parameter to **LATEST**. AWS OpsWorks automatically installs new agent versions on the stack’s instances as soon as they are available.
  - Fixed version - Set this parameter to your preferred agent version. To update the agent version, you must edit the stack configuration and specify a new version. AWS OpsWorks then automatically installs that version on the stack’s instances.

The default setting is **LATEST**. To specify an agent version, you must use the complete version number, not the abbreviated number shown on the console. For a list of available agent version numbers, call DescribeAgentVersions.

*Note:* You can also specify an agent version when you create or update an instance, which overrides the stack’s default setting.

**Response Syntax**

```python
{
   'StackId': 'string'
}
```

**Response Structure**

- *(dict)* – Contains the response to a CloneStack request.
  - **StackId** *(string)* – The cloned stack ID.

**create_app**( **kwargs**)  

Creates an app for a specified stack. For more information, see Creating Apps.

**Required Permissions** : To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**
response = client.create_app(
    StackId='string',
    Shortname='string',
    Name='string',
    Description='string',
    DataSources=[
        {
            'Type': 'string',
            'Arn': 'string',
            'DatabaseName': 'string'
        },
    ],
    Type='aws-flow-ruby'|'java'|'rails'|'php'|'nodejs'|'static'|'other',
    AppSource={
        'Type': 'git'|'svn'|'archive'|'s3',
        'Url': 'string',
        'Username': 'string',
        'Password': 'string',
        'SshKey': 'string',
        'Revision': 'string'
    },
    Domains=['string',
    ],
    EnableSsl=True|False,
    SslConfiguration={
        'Certificate': 'string',
        'PrivateKey': 'string',
        'Chain': 'string'
    },
    Attributes={
        'string': 'string'
    },
    Environment=[
        {
            'Key': 'string',
            'Value': 'string',
            'Secure': True|False
        },
    ]
)

Parameters
- **StackId** *(string)* – [REQUIRED]

    The stack ID.
- **Shortname** *(string)* – The app’s short name.
- **Name** *(string)* – [REQUIRED]

    The app name.
- **Description** *(string)* – A description of the app.
- **DataSources** *(list)* – The app’s data source.
    - *(dict)* –

    Describes an app’s data source.
    - **Type** *(string)* –

        The data source’s type, AutoSelectOpsworksMysqlInstance,
        OpsworksMysqlInstance, or RdsDbInstance.
• Arn (string) –
  The data source’s ARN.
• DatabaseName (string) –
  The database name.
• Type (string) – [REQUIRED]
  The app type. Each supported type is associated with a particular layer. For
  example, PHP applications are associated with a PHP layer. AWS OpsWorks
  deploys an application to those instances that are members of the corresponding
  layer. If your app isn’t one of the standard types, or you prefer to implement
  your own Deploy recipes, specify other.
• AppSource (dict) – A Source object that specifies the app repository.
  – Type (string) –
    The repository type.
  – Url (string) –
    The source URL.
  – Username (string) –
    This parameter depends on the repository type.
    * For Amazon S3 bundles, set Username to the appropriate IAM
      access key ID.
    * For HTTP bundles, Git repositories, and Subversion repositories, set
      Username to the user name.
  – Password (string) –
    When included in a request, the parameter depends on the repository type.
    * For Amazon S3 bundles, set Password to the appropriate IAM
      secret access key.
    * For HTTP bundles and Subversion repositories, set Password to
      the password.
    For more information on how to safely handle IAM credentials, see
    http://docs.aws.amazon.com/general/latest/gr/aws-access-keys-
    best-practices.html.
    In responses, AWS OpsWorks returns *****FILTERED***** instead
    of the actual value.
  – SshKey (string) –
    In requests, the repository’s SSH key.
    In responses, AWS OpsWorks returns *****FILTERED***** instead
    of the actual value.
  – Revision (string) –
    The application’s version. AWS OpsWorks enables you to easily deploy
    new versions of an application. One of the simplest approaches is to have
    branches or revisions in your repository that represent different versions
    that can potentially be deployed.
• Domains (list) – The app virtual host settings, with multiple domains separated
  by commas. For example: ‘www.example.com, example.com’
  – (string) –
• EnableSsl (boolean) – Whether to enable SSL for the app.
• SslConfiguration (dict) – An SslConfiguration object with the SSL config-
  uration.
  – Certificate (string) – [REQUIRED]
The contents of the certificate’s domain.crt file.

- **PrivateKey (string)** – [REQUIRED]
The private key; the contents of the certificate’s domain.kex file.

- **Chain (string)** –
  Optional. Can be used to specify an intermediate certificate authority key or client authentication.

- **Attributes (dict)** – One or more user-defined key/value pairs to be added to the stack attributes.
  - (string)

- **Environment (list)** – An array of `EnvironmentVariable` objects that specify environment variables to be associated with the app. After you deploy the app, these variables are defined on the associated app server instance. For more information, see `Environment Variables`.

  There is no specific limit on the number of environment variables. However, the size of the associated data structure - which includes the variables’ names, values, and protected flag values - cannot exceed 10 KB (10240 Bytes). This limit should accommodate most if not all use cases. Exceeding it will cause an exception with the message, “Environment: is too large (maximum is 10KB).”

  **Note:** This parameter is supported only by Chef 11.10 stacks. If you have specified one or more environment variables, you cannot modify the stack’s Chef version.

  - (dict)
    Represents an app’s environment variable.
    - **Key (string)** – [REQUIRED]
      (Required) The environment variable’s name, which can consist of up to 64 characters and must be specified. The name can contain upper- and lowercase letters, numbers, and underscores (_), but it must start with a letter or underscore.
    - **Value (string)** – [REQUIRED]
      (Optional) The environment variable’s value, which can be left empty. If you specify a value, it can contain up to 256 characters, which must all be printable.
    - **Secure (boolean)** –
      (Optional) Whether the variable’s value will be returned by the DescribeApps action. To conceal an environment variable’s value, set Secure to `true`. DescribeApps then returns `*****FILTERED*****` instead of the actual value. The default value for Secure is `false`.

Return type: dict

Returns

**Response Syntax**

```json
{
    'AppId': 'string'
}
```

**Response Structure**
create_deployment(**kwargs)

Runs deployment or stack commands. For more information, see Deploying Apps and Run Stack Commands.

**Required Permissions**: To use this action, an IAM user must have a Deploy or Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.create_deployment(
    StackId='string',
    AppId='string',
    InstanceIds=[
        'string',
    ],
    Command={
        'Name': 'install_dependencies'|'update_dependencies'|'update_custom_cookbooks'|'execute_recipes'|'configure'|'setup'|'deploy'|'rollback'|'start'|'stop'|'restart'|'undeploy',
        'Args': {
            'string': [  
                'string',
            ],
        }
    },
    Comment='string',
    CustomJson='string'
)
```

**Parameters**

- **StackId (string)** – [REQUIRED]
  The stack ID.

- **AppId (string)** – The app ID. This parameter is required for app deployments, but not for other deployment commands.

- **InstanceIds (list)** – The instance IDs for the deployment targets.

- **Command (dict)** – [REQUIRED]
  A DeploymentCommand object that specifies the deployment command and any associated arguments.

  - **Name (string)** – [REQUIRED]
    Specifies the operation. You can specify only one command.

For stacks, the following commands are available:

- **execute_recipes**: Execute one or more recipes. To specify the recipes, set an Args parameter named recipes to the list of recipes to be executed. For example, to execute phpapp::appsetup, set Args to{"recipes": ["phpapp::appsetup"]}.
- **install_dependencies**: Install the stack’s dependencies.
- **update_custom_cookbooks**: Update the stack’s custom cookbooks.
**update_dependencies**: Update the stack’s dependencies.

**Note**: The `update_dependencies` and `install_dependencies` commands are supported only for Linux instances. You can run the commands successfully on Windows instances, but they do nothing.

For apps, the following commands are available:

* **deploy**: Deploy an app. Ruby on Rails apps have an optional `Args` parameter named `migrate`. Set `Args` to
```
{ "migrate": ["true"] }
```
to migrate the database. The default setting is
```
{ "migrate": ["false"] }
```
* **rollback**: Roll the app back to the previous version. When you update an app, AWS OpsWorks stores the previous version, up to a maximum of five versions. You can use this command to roll an app back as many as four versions.
* **start**: Start the app’s web or application server.
* **stop**: Stop the app’s web or application server.
* **restart**: Restart the app’s web or application server.
* **undeploy**: Undeploy the app.

**Args** *(dict)* –

The arguments of those commands that take arguments. It should be set to a JSON object with the following format:
```
{ "arg_name1": ["value1", "value2", ...], "arg_name2": ["value1", "value2", ...], ...
```

The `update_dependencies` command takes two arguments:

* **upgrade_os_to**: Specifies the desired Amazon Linux version for instances whose OS you want to upgrade, such as Amazon Linux 2014.09. You must also set the `allow_reboot` argument to `true`.
* **allow_reboot**: Specifies whether to allow AWS OpsWorks to reboot the instances if necessary, after installing the updates. This argument can be set to either `true` or `false`. The default value is `false`.

For example, to upgrade an instance to Amazon Linux 2014.09, set `Args` to the following.
```
{ "upgrade_os_to": ["Amazon Linux 2014.09"], "allow_reboot": ["true"] }
```

**Return type** `dict`

**Response Syntax**
Response Structure

- **(dict)** –
  
  Contains the response to a `CreateDeployment` request.

  - **DeploymentId** *(string)* –
    
    The deployment ID, which can be used with other requests to identify the deployment.

`create_instance(**kwargs)`

Creates an instance in a specified stack. For more information, see Adding an Instance to a Layer.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.create_instance(
    StackId='string',
    LayerIds=[
        'string',
    ],
    InstanceType='string',
    AutoScalingType='load'|'timer',
    Hostname='string',
    Os='string',
    AmiId='string',
    SshKeyName='string',
    AvailabilityZone='string',
    VirtualizationType='string',
    SubnetId='string',
    Architecture='x86_64'|'i386',
    RootDeviceType='ebs'|'instance-store',
    BlockDeviceMappings=[
        {
            'DeviceName': 'string',
            'NoDevice': 'string',
            'VirtualName': 'string',
            'Ebs': {
                'SnapshotId': 'string',
                'Iops': 123,
                'VolumeSize': 123,
                'VolumeType': 'gp2'|'io1'|'standard',
                'DeleteOnTermination': True|False
            }
        },
    ],
    InstallUpdatesOnBoot=True|False,
    EbsOptimized=True|False,
    AgentVersion='string'
)
```

**Parameters**

3.1. Services
• **StackId (string)** – [REQUIRED]
  The stack ID.

• **LayerIds (list)** – [REQUIRED]
  An array that contains the instance’s layer IDs.
    – (string)

• **InstanceType (string)** – [REQUIRED]
  The instance type, such as t2.micro. For a list of supported instance types, open the stack in the console, choose **Instances**, and choose **+ Instance**. The **Size** list contains the currently supported types. For more information, see **Instance Families and Types**. The parameter values that you use to specify the various types are in the **API Name** column of the Available Instance Types table.

• **AutoScalingType (string)** – For load-based or time-based instances, the type. Windows stacks can use only time-based instances.

• **Hostname (string)** – The instance host name.

• **Os (string)** – The instance’s operating system, which must be set to one of the following:
  – A supported Linux operating system: An Amazon Linux version, such as Amazon Linux 2015.03, Red Hat Enterprise Linux 7, Ubuntu 12.04 LTS, or Ubuntu 14.04 LTS.
  – Microsoft Windows Server 2012 R2 Base.
  – A custom AMI: Custom.

  For more information on the supported operating systems, see **AWS OpsWorks Operating Systems**.

  The default option is the current Amazon Linux version. If you set this parameter to Custom, you must use the CreateInstance action’s AmiId parameter to specify the custom AMI that you want to use. For more information on the supported operating systems, see **Operating Systems** For more information on how to use custom AMIs with AWS OpsWorks, see Using Custom AMIs.

• **AmiId (string)** – A custom AMI ID to be used to create the instance. The AMI should be based on one of the supported operating systems. For more information, see Using Custom AMIs.

  **Note:** If you specify a custom AMI, you must set Os to Custom.

• **SshKeyName (string)** – The instance’s Amazon EC2 key-pair name.

• **AvailabilityZone (string)** – The instance Availability Zone. For more information, see **Regions and Endpoints**.

• **VirtualizationType (string)** – The instance’s virtualization type, paravirtual or hvm.

• **SubnetId (string)** – The ID of the instance’s subnet. If the stack is running in a VPC, you can use this parameter to override the stack’s default subnet ID value and direct AWS OpsWorks to launch the instance in a different subnet.

• **Architecture (string)** – The instance architecture. The default option is x86_64. Instance types do not necessarily support both architectures. For a list of the architectures that are supported by the different instance types, see **Instance Families and Types**.

• **RootDeviceType (string)** – The instance root device type. For more information, see **Storage for the Root Device**.

• **BlockDeviceMappings (list)** – An array of BlockDeviceMapping objects that specify the instance’s block devices. For more information, see **Block Device Mapping**.
Describes a block device mapping. This data type maps directly to the Amazon EC2 BlockDeviceMapping data type.

* **DeviceName (string)** –
  The device name that is exposed to the instance, such as /dev/sdh.
  For the root device, you can use the explicit device name or you can set this parameter to ROOT_DEVICE and AWS OpsWorks will provide the correct device name.

* **NoDevice (string)** –
  Suppresses the specified device included in the AMI’s block device mapping.

* **VirtualName (string)** –
  The virtual device name. For more information, see BlockDeviceMapping .

* **Ebs (dict)** –
  An EBSBlockDevice that defines how to configure an Amazon EBS volume when the instance is launched.
  · **SnapshotId (string)** –
    The snapshot ID.
  · **Iops (integer)** –
    The number of I/O operations per second (IOPS) that the volume supports. For more information, see EbsBlockDevice .
  · **VolumeSize (integer)** –
    The volume size, in GiB. For more information, see EbsBlockDevice .
  · **VolumeType (string)** –
    The volume type. gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, and standard for Magnetic volumes.
  · **DeleteOnTermination (boolean)** –
    Whether the volume is deleted on instance termination.

• **InstallUpdatesOnBoot (boolean)** – Whether to install operating system and package updates when the instance boots. The default value is true . To control when updates are installed, set this value to false . You must then update your instances manually by using CreateDeployment to run the update_dependencies stack command or by manually running yum (Amazon Linux) or apt-get (Ubuntu) on the instances.

**Note:** We strongly recommend using the default value of true to ensure that your instances have the latest security updates.

• **EbsOptimized (boolean)** – Whether to create an Amazon EBS-optimized instance.

• **AgentVersion (string)** – The default AWS OpsWorks agent version. You have the following options:
  - INHERIT - Use the stack’s default agent version setting.
  - version_number - Use the specified agent version. This value overrides the stack’s default setting. To update the agent version, edit the instance configuration and specify a new version. AWS OpsWorks then automatically
installs that version on the instance.

The default setting is INHERIT. To specify an agent version, you must use the complete version number, not the abbreviated number shown on the console. For a list of available agent version numbers, call DescribeAgentVersions.

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'InstanceId': 'string'
}
```

**Response Structure**

- (dict) –
  
  Contains the response to a CreateInstance request.

- **InstanceId (string)** –
  
  The instance ID.

**create_layer(**kwargs)**

Creates a layer. For more information, see How to Create a Layer.

**Note:** You should use CreateLayer for noncustom layer types such as PHP App Server only if the stack does not have an existing layer of that type. A stack can have at most one instance of each noncustom layer; if you attempt to create a second instance, CreateLayer fails. A stack can have an arbitrary number of custom layers, so you can call CreateLayer as many times as you like for that layer type.

**Required Permissions:** To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.create_layer(
    StackId='string',
    Type='aws-flow-ruby'|'ecs-cluster'|'java-app'|'lb'|'web'|'php-app'|'rails-app'|'nodejs-app'|'memcached'|'db-master'|'monitoring-master'|'custom',
    Name='string',
    Shortname='string',
    Attributes={
        'string': 'string'
    },
    CustomInstanceProfileArn='string',
    CustomJson='string',
    CustomSecurityGroupIds=[
        'string',
    ],
    Packages=[
        'string',
    ],
    VolumeConfigurations=[
        {
            'MountPoint': 'string',
            'RaidLevel': 123,
            'NumberOfDisks': 123,
            'Size': 123,
            'VolumeType': 'string',
        }
    ]
)
```
Parameters

- **StackId** *(string)* – [REQUIRED]
  
The layer stack ID.

- **Type** *(string)* – [REQUIRED]
  
The layer type. A stack cannot have more than one built-in layer of the same type. It can have any number of custom layers.

- **Name** *(string)* – [REQUIRED]
  
The layer name, which is used by the console.

- **Shortname** *(string)* – [REQUIRED]
  
  For custom layers only, use this parameter to specify the layer’s short name, which is used internally by AWS OpsWorks and by Chef recipes. The short name is also used as the name for the directory where your app files are installed. It can have a maximum of 200 characters, which are limited to the alphanumeric characters, '-', '_', and '.'.

  The built-in layers’ short names are defined by AWS OpsWorks. For more information, see the Layer Reference.

- **Attributes** *(dict)* – One or more user-defined key-value pairs to be added to the stack attributes.

  To create a cluster layer, set the EcsClusterArn attribute to the cluster’s ARN.
- (string) –
  * (string) –
  - **CustomInstanceProfileArn** *(string)* – The ARN of an IAM profile to be used for the layer’s EC2 instances. For more information about IAM ARNs, see Using Identifiers.
  - **CustomJson** *(string)* – A JSON-formatted string containing custom stack configuration and deployment attributes to be installed on the layer’s instances. For more information, see Using Custom JSON.
  - **CustomSecurityGroupIds** *(list)* – An array containing the layer custom security group IDs.
    - (string) –
  - **Packages** *(list)* – An array of Package objects that describes the layer packages.
    - (string) –
  - **VolumeConfigurations** *(list)* – A VolumeConfigurations object that describes the layer’s Amazon EBS volumes.
    - (dict) –

Describes an Amazon EBS volume configuration.
  - **MountPoint** *(string)* – [REQUIRED]
    The volume mount point. For example “/dev/sdh”.
  - **RaidLevel** *(integer)* –
    The volume RAID level.
  - **NumberOfDisks** *(integer)* – [REQUIRED]
    The number of disks in the volume.
  - **Size** *(integer)* – [REQUIRED]
    The volume size.
  - **VolumeType** *(string)* –
    The volume type:
    - standard - Magnetic
    - io1 - Provisioned IOPS (SSD)
    - gp2 - General Purpose (SSD)
  - **Iops** *(integer)* –
    For PIOPS volumes, the IOPS per disk.
- **EnableAutoHealing** *(boolean)* – Whether to disable auto healing for the layer.
- **AutoAssignElasticIps** *(boolean)* – Whether to automatically assign an Elastic IP address to the layer’s instances. For more information, see How to Edit a Layer.
- **AutoAssignPublicIps** *(boolean)* – For stacks that are running in a VPC, whether to automatically assign a public IP address to the layer’s instances. For more information, see How to Edit a Layer.
- **CustomRecipes** *(dict)* – A LayerCustomRecipes object that specifies the layer custom recipes.
  - **Setup** *(list)* –
    An array of custom recipe names to be run following a setup event.
    * (string) –
  - **Configure** *(list)* –
    An array of custom recipe names to be run following a configure event.
    * (string) –
  - **Deploy** *(list)* –
An array of custom recipe names to be run following a deploy event.
* (string) –

- Undeploy (list) –

An array of custom recipe names to be run following a undeploy event.
* (string) –

- Shutdown (list) –

An array of custom recipe names to be run following a shutdown event.
* (string) –

- **InstallUpdatesOnBoot** (boolean) – Whether to install operating system and package updates when the instance boots. The default value is true. To control when updates are installed, set this value to false. You must then update your instances manually by using CreateDeployment to run the update_dependencies stack command or by manually running `yum` (Amazon Linux) or `apt-get` (Ubuntu) on the instances.

**Note:** To ensure that your instances have the latest security updates, we strongly recommend using the default value of `true`.

- **UseEbsOptimizedInstances** (boolean) – Whether to use Amazon EBS-optimized instances.

- **LifecycleEventConfiguration** (dict) – A LifeCycleEventConfiguration object that you can use to configure the Shutdown event to specify an execution timeout and enable or disable Elastic Load Balancer connection draining.

  - **Shutdown** (dict) –

    A ShutdownEventConfiguration object that specifies the Shutdown event configuration.
    * **ExecutionTimeout** (integer) –
      The time, in seconds, that AWS OpsWorks will wait after triggering a Shutdown event before shutting down an instance.
    * **DelayUntilElbConnectionsDrained** (boolean) –
      Whether to enable Elastic Load Balancing connection draining. For more information, see Connection Draining.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'LayerId': 'string'
}
```

**Response Structure**

- (dict) –

  Contains the response to a CreateLayer request.
  - **LayerId** (string) –

    The layer ID.

**create_stack(****kwargs**)**

Creates a new stack. For more information, see Create a New Stack.

**Required Permissions** : To use this action, an IAM user must have an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.
Request Syntax

```python
response = client.create_stack(
    Name='string',
    Region='string',
    VpcId='string',
    Attributes={
        'string': 'string'
    },
    ServiceRoleArn='string',
    DefaultInstanceProfileArn='string',
    DefaultOs='string',
    HostnameTheme='string',
    DefaultAvailabilityZone='string',
    DefaultSubnetId='string',
    CustomJson='string',
    ConfigurationManager={
        'Name': 'string',
        'Version': 'string'
    },
    ChefConfiguration={
        'ManageBerkshelf': True|False,
        'BerkshelfVersion': 'string'
    },
    UseCustomCookbooks=True|False,
    UseOpsworksSecurityGroups=True|False,
    CustomCookbooksSource={
        'Type': 'git'|'svn'|'archive'|'s3',
        'Url': 'string',
        'Username': 'string',
        'Password': 'string',
        'SshKey': 'string',
        'Revision': 'string'
    },
    DefaultSshKeyName='string',
    DefaultRootDeviceType='ebs'|'instance-store',
    AgentVersion='string'
)
```

Parameters

- **Name** *(string)* – [REQUIRED]

  The stack name.

- **Region** *(string)* – [REQUIRED]

  The stack’s AWS region, such as “us-east-1”. For more information about Amazon regions, see Regions and Endpoints.

- **VpcId** *(string)* – The ID of the VPC that the stack is to be launched into. The VPC must be in the stack’s region. All instances are launched into this VPC. You cannot change the ID later.
  
  - If your account supports EC2-Classic, the default value is no VPC.
  
  - If your account does not support EC2-Classic, the default value is the default VPC for the specified region.

If the VPC ID corresponds to a default VPC and you have specified either the DefaultAvailabilityZone or the DefaultSubnetId parameter only, AWS OpsWorks infers the value of the other parameter. If you specify neither parameter, AWS OpsWorks sets these parameters to the first valid Availability
Zone for the specified region and the corresponding default VPC subnet ID, respectively.

If you specify a nondefault VPC ID, note the following:

- It must belong to a VPC in your account that is in the specified region.
- You must specify a value for DefaultSubnetId.

For more information on how to use AWS OpsWorks with a VPC, see Running a Stack in a VPC. For more information on default VPC and EC2-Classic, see Supported Platforms.

- **Attributes (dict)** – One or more user-defined key-value pairs to be added to the stack attributes.
  
  - *(string)* –

- **ServiceRoleArn (string)** – [REQUIRED]

The stack’s AWS Identity and Access Management (IAM) role, which allows AWS OpsWorks to work with AWS resources on your behalf. You must set this parameter to the Amazon Resource Name (ARN) for an existing IAM role. For more information about IAM ARNs, see Using Identifiers.

- **DefaultInstanceProfileArn (string)** – [REQUIRED]

The Amazon Resource Name (ARN) of an IAM profile that is the default profile for all of the stack’s EC2 instances. For more information about IAM ARNs, see Using Identifiers.

- **DefaultOs (string)** – The stack’s default operating system, which is installed on every instance unless you specify a different operating system when you create the instance. You can specify one of the following.
  
  - A supported Linux operating system: An Amazon Linux version, such as Amazon Linux 2015.03, Red Hat Enterprise Linux 7, Ubuntu 12.04 LTS, or Ubuntu 14.04 LTS.
  - A custom AMI: Custom. You specify the custom AMI you want to use when you create instances. For more information, see Using Custom AMIs.

The default option is the current Amazon Linux version. For more information on the supported operating systems, see AWS OpsWorks Operating Systems.

- **HostnameTheme (string)** – The stack’s host name theme, with spaces replaced by underscores. The theme is used to generate host names for the stack’s instances. By default, HostnameTheme is set to Layer_Dependent, which creates host names by appending integers to the layer’s short name. The other themes are:
  
  - Baked_Goods
  - Clouds
  - Europe_Cities
  - Fruits
  - Greek_Deities
  - Legendary_creatures_from_Japan
  - Planets_and_Moons
  - Roman_Deities
  - Scottish_Islands
  - US_Cities
  - Wild_Cats

To obtain a generated host name, call GetHostNameSuggestion, which returns a host name based on the current theme.

- **DefaultAvailabilityZone (string)** – The stack’s default Availability Zone, which
must be in the specified region. For more information, see Regions and Endpoints. If you also specify a value for DefaultSubnetId, the subnet must be in the same zone. For more information, see the VpcId parameter description.

- **DefaultSubnetId (string)** – The stack’s default VPC subnet ID. This parameter is required if you specify a value for VpcId parameter. All instances are launched into this subnet unless you specify otherwise when you create the instance. If you also specify a value for DefaultAvailabilityZone, the subnet must be in that zone. For information on default values and when this parameter is required, see the VpcId parameter description.

- **CustomJson (string)** – A string that contains user-defined, custom JSON. It can be used to override the corresponding default stack configuration attribute values or to pass data to recipes. The string should be in the following escape characters such as ‘\’:

  ```json
  "{\"key1\": \"value1\", \"key2\": \"value2\",...}"
  ```

  For more information on custom JSON, see Use Custom JSON to Modify the Stack Configuration Attributes.

- **ConfigurationManager (dict)** – The configuration manager. When you clone a stack we recommend that you use the configuration manager to specify the Chef version: 0.9, 11.4, or 11.10. The default value is currently 11.4.
  - **Name (string)** –
    The name. This parameter must be set to “Chef”.
  - **Version (string)** –
    The Chef version. This parameter must be set to 0.9, 11.4, or 11.10. The default value is 11.4.

- **ChefConfiguration (dict)** – A ChefConfiguration object that specifies whether to enable Berkshelf and the Berkshelf version on Chef 11.10 stacks. For more information, see Create a New Stack.
  - **ManageBerkshelf (boolean)** –
    Whether to enable Berkshelf.
  - **BerkshelfVersion (string)** –
    The Berkshelf version.

- **UseCustomCookbooks (boolean)** – Whether the stack uses custom cookbooks.

- **UseOpsworksSecurityGroups (boolean)** – Whether to associate the AWS OpsWorks built-in security groups with the stack’s layers.

AWS OpsWorks provides a standard set of built-in security groups, one for each layer, which are associated with layers by default. With UseOpsworksSecurityGroups you can instead provide your own custom security groups. UseOpsworksSecurityGroups has the following settings:

  - **True** - AWS OpsWorks automatically associates the appropriate built-in security group with each layer (default setting). You can associate additional security groups with a layer after you create it, but you cannot delete the built-in security group.
  - **False** - AWS OpsWorks does not associate built-in security groups with layers. You must create appropriate EC2 security groups and associate a security group with each layer that you create. However, you can still manually associate a built-in security group with a layer on creation; custom security groups are required only for those layers that need custom settings.
For more information, see `Create a New Stack`.

- **CustomCookbooksSource (dict)** – Contains the information required to retrieve an app or cookbook from a repository. For more information, see `Creating Apps` or `Custom Recipes and Cookbooks`.
  - **Type (string)** –
    The repository type.
  - **Url (string)** –
    The source URL.
  - **Username (string)** –
    This parameter depends on the repository type.
    * For Amazon S3 bundles, set `Username` to the appropriate IAM access key ID.
    * For HTTP bundles, Git repositories, and Subversion repositories, set `Username` to the user name.
  - **Password (string)** –
    When included in a request, the parameter depends on the repository type.
    * For Amazon S3 bundles, set `Password` to the appropriate IAM secret access key.
    * For HTTP bundles and Subversion repositories, set `Password` to the password.
  - **SshKey (string)** –
    In requests, the repository’s SSH key.
    In responses, AWS OpsWorks returns `*****FILTERED*****` instead of the actual value.
  - **Revision (string)** –
    The application’s version. AWS OpsWorks enables you to easily deploy new versions of an application. One of the simplest approaches is to have branches or revisions in your repository that represent different versions that can potentially be deployed.

- **DefaultSshKeyName (string)** – A default Amazon EC2 key pair name. The default value is none. If you specify a key pair name, AWS OpsWorks installs the public key on the instance and you can use the private key with an SSH client to log in to the instance. For more information, see `Using SSH to Communicate with an Instance` and `Managing SSH Access`. You can override this setting by specifying a different key pair, or no key pair, when you create an instance.

- **DefaultRootDeviceType (string)** – The default root device type. This value is the default for all instances in the stack, but you can override it when you create an instance. The default option is `instance-store`. For more information, see `Storage for the Root Device`.

- **AgentVersion (string)** – The default AWS OpsWorks agent version. You have the following options:
  - **Auto-update** - Set this parameter to `LATEST`. AWS OpsWorks automatically installs new agent versions on the stack’s instances as soon as they are available.
– Fixed version - Set this parameter to your preferred agent version. To update the agent version, you must edit the stack configuration and specify a new version. AWS OpsWorks then automatically installs that version on the stack’s instances. The default setting is LATEST. To specify an agent version, you must use the complete version number, not the abbreviated number shown on the console. For a list of available agent version numbers, call DescribeAgentVersions.

**Note:** You can also specify an agent version when you create or update an instance, which overrides the stack’s default setting.

**Return type** dict

**Returns**

**Response Syntax**

```{
    'StackId': 'string'
}
```

**Response Structure**

- (dict) –
  
  Contains the response to a CreateStack request.

  - **StackId** *(string)* –

    The stack ID, which is an opaque string that you use to identify the stack when performing actions such as DescribeStacks.

**create_user_profile(**kwargs**)

Creates a new user profile.

**Required Permissions:** To use this action, an IAM user must have an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.create_user_profile(
    IamUserArn='string',
    SshUsername='string',
    SshPublicKey='string',
    AllowSelfManagement=True|False
)
```

**Parameters**

- **IamUserArn** *(string)* – [REQUIRED]

  The user’s IAM ARN.

- **SshUsername** *(string)* – The user’s SSH user name. The allowable characters are [a-zA-Z], [0-9], ‘-’, and ‘_’. If the specified name includes other punctuation marks, AWS OpsWorks removes them. For example, my.name will be changed to myname. If you do not specify an SSH user name, AWS OpsWorks generates one from the IAM user name.

- **SshPublicKey** *(string)* – The user’s public SSH key.

- **AllowSelfManagement** *(boolean)* – Whether users can specify their own SSH public key through the My Settings page. For more information, see Setting an IAM User’s Public SSH Key.

**Return type** dict
Returns

Response Syntax

```python
{
    'IamUserArn': 'string'
}
```

Response Structure

- (dict) –
  
  Contains the response to a CreateUserProfile request.

  - IamUserArn (string) –
    
    The user’s IAM ARN.

`delete_app(**kwargs)`

Deletes a specified app.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.delete_app(
    AppId='string'
)
```

**Parameters**

- **AppId** (string) – [REQUIRED]
  
  The app ID.

**Returns**

None

`delete_instance(**kwargs)`

Deletes a specified instance, which terminates the associated Amazon EC2 instance. You must stop an instance before you can delete it.

For more information, see Deleting Instances.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.delete_instance(
    InstanceId='string',
    DeleteElasticIp=True|False,
    DeleteVolumes=True|False
)
```

**Parameters**

- **InstanceId** (string) – [REQUIRED]
  
  The instance ID.

- **DeleteElasticIp** (boolean) – Whether to delete the instance Elastic IP address.

- **DeleteVolumes** (boolean) – Whether to delete the instance’s Amazon EBS volumes.

**Returns**

None
**delete_layer(**\*\*kwargs\*)**

Deletes a specified layer. You must first stop and then delete all associated instances or unassign registered instances. For more information, see How to Delete a Layer.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.delete_layer(
    LayerId='string'
)
```

**Parameters** 

- **LayerId** *(string)* – [REQUIRED]
  - The layer ID.

**Returns** None

**delete_stack(**\*\*kwargs\*)**

Deletes a specified stack. You must first delete all instances, layers, and apps or deregister registered instances. For more information, see Shut Down a Stack.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.delete_stack(
    StackId='string'
)
```

**Parameters** 

- **StackId** *(string)* – [REQUIRED]
  - The stack ID.

**Returns** None

**delete_user_profile(**\*\*kwargs\*)**

Deletes a user profile.

**Required Permissions**: To use this action, an IAM user must have an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.delete_user_profile(
    IamUserArn='string'
)
```

**Parameters** 

- **IamUserArn** *(string)* – [REQUIRED]
  - The user’s IAM ARN.

**Returns** None

**deregister_ecs_cluster(**\*\*kwargs\*)**

Deregisters a specified Amazon ECS cluster from a stack. For more information, see Resource Management.
**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack or an attached policy that explicitly grants permissions. For more information on user permissions, see [http://docs.aws.amazon.com/opsworks/latest/userguide/opsworks-security-users.html](http://docs.aws.amazon.com/opsworks/latest/userguide/opsworks-security-users.html).

**Request Syntax**

```python
response = client.deregister_ecs_cluster(
    EcsClusterArn='string'
)
```

**Parameters**

- **EcsClusterArn** *(string)* – [REQUIRED]
  The cluster’s ARN.

**Returns**

None

---

**deregister_elastic_ip** (**kwargs**)

Deregisters a specified Elastic IP address. The address can then be registered by another stack. For more information, see [Resource Management](http://docs.aws.amazon.com/opsworks/latest/userguide/opsworks-security-users.html).

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see [Managing User Permissions](http://docs.aws.amazon.com/opsworks/latest/userguide/opsworks-security-users.html).

**Request Syntax**

```python
response = client.deregister_elastic_ip(
    ElasticIp='string'
)
```

**Parameters**

- **ElasticIp** *(string)* – [REQUIRED]
  The Elastic IP address.

**Returns**

None

---

**deregister_instance** (**kwargs**)

Deregister a registered Amazon EC2 or on-premises instance. This action removes the instance from the stack and returns it to your control. This action can not be used with instances that were created with AWS OpsWorks.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack or an attached policy that explicitly grants permissions. For more information on user permissions, see [Managing User Permissions](http://docs.aws.amazon.com/opsworks/latest/userguide/opsworks-security-users.html).

**Request Syntax**

```python
response = client.deregister_instance(
    InstanceId='string'
)
```

**Parameters**

- **InstanceId** *(string)* – [REQUIRED]
  The instance ID.

**Returns**

None

---

**deregister_rds_db_instance** (**kwargs**)

Deregisters an Amazon RDS instance.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see [Managing User Permissions](http://docs.aws.amazon.com/opsworks/latest/userguide/opsworks-security-users.html).
**Request Syntax**

```python
response = client.deregister_rds_db_instance(
    RdsDbInstanceArn='string'
)
```

**Parameters**  
**RdsDbInstanceArn (string)** – [REQUIRED]  
The Amazon RDS instance’s ARN.

**Returns**  
None

deregister_volume(**kwargs)**  
Deregisters an Amazon EBS volume. The volume can then be registered by another stack. For more information, see [Resource Management](#).

**Required Permissions**  
To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see [Managing User Permissions](#).

**Request Syntax**

```python
response = client.deregister_volume(
    VolumeId='string'
)
```

**Parameters**  
**VolumeId (string)** – [REQUIRED]  
The AWS OpsWorks volume ID, which is the GUID that AWS OpsWorks assigned to the instance when you registered the volume with the stack, not the Amazon EC2 volume ID.

**Returns**  
None

describe_agent_versions(**kwargs)**  
Describes the available AWS OpsWorks agent versions. You must specify a stack ID or a configuration manager. `DescribeAgentVersions` returns a list of available agent versions for the specified stack or configuration manager.

**Request Syntax**

```python
response = client.describe_agent_versions(
    StackId='string',
    ConfigurationManager={
        'Name': 'string',
        'Version': 'string'
    }
)
```

**Parameters**  
- **StackId (string)** – The stack ID.
- **ConfigurationManager (dict)** – The configuration manager.
  - **Name (string)** –  
    The name. This parameter must be set to “Chef”.
  - **Version (string)** –  
    The Chef version. This parameter must be set to 0.9, 11.4, or 11.10. The default value is 11.4.

**Return type**  
dict
Returns

Response Syntax

```python
{
    'AgentVersions': [
        {
            'Version': 'string',
            'ConfigurationManager': {
                'Name': 'string',
                'Version': 'string'
            }
        },
    ]
}
```

Response Structure
- (dict) –
  Contains the response to a `describeAgentVersions` request.
  - AgentVersions (list) –
    The agent versions for the specified stack or configuration manager. Note that this value is the complete version number, not the abbreviated number used by the console.
    - (dict) –
      Describes an agent version.
      - Version (string) –
        The agent version.
      - ConfigurationManager (dict) –
        The configuration manager.
      - Name (string) –
        The name. This parameter must be set to “Chef”.
      - Version (string) –
        The Chef version. This parameter must be set to 0.9, 11.4, or 11.10. The default value is 11.4.

`describe_apps(**kwargs)`
Requests a description of a specified set of apps.

**Note:** You must specify at least one of the parameters.

**Required Permissions**: To use this action, an IAM user must have a Show, Deploy, or Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

Request Syntax

```python
response = client.describe_apps(
    StackId='string',
    AppIds=[
        'string',
    ]
)
```
Parameters

- **StackId** *(string)* – The app stack ID. If you use this parameter, DescribeApps returns a description of the apps in the specified stack.

- **AppIds** *(list)* – An array of app IDs for the apps to be described. If you use this parameter, DescribeApps returns a description of the specified apps. Otherwise, it returns a description of every app.

Return type  *dict*

Returns

Response Syntax

```python
{
    'Apps': [
        {
            'AppId': 'string',
            'StackId': 'string',
            'Shortname': 'string',
            'Name': 'string',
            'Description': 'string',
            'DataSources': [
                {
                    'Type': 'string',
                    'Arn': 'string',
                    'DatabaseName': 'string'
                },
            ],
            'Type': 'aws-flow-ruby'|'java'|'rails'|'php'|'nodejs'|'static'|'other',
            'AppSource': {
                'Type': 'git'|'svn'|'archive'|'s3',
                'Url': 'string',
                'Username': 'string',
                'Password': 'string',
                'SshKey': 'string',
                'Revision': 'string'
            },
            'Domains': ['string'],
            'EnableSsl': True|False,
            'SslConfiguration': {
                'Certificate': 'string',
                'PrivateKey': 'string',
                'Chain': 'string'
            },
            'Attributes': {
                'string': 'string'
            },
            'CreatedAt': 'string',
            'Environment': [
                {
                    'Key': 'string',
                    'Value': 'string',
                    'Secure': True|False
                },
            ],
        },
    ],
}
```
Response Structure

- (dict) –
  Contains the response to a DescribeApps request.
  - Apps (list) –
    An array of App objects that describe the specified apps.
    * (dict) –
      A description of the app.
      - AppId (string) –
        The app ID.
      - StackId (string) –
        The app stack ID.
      - Shortname (string) –
        The app’s short name.
      - Name (string) –
        The app name.
      - Description (string) –
        A description of the app.
      - DataSources (list) –
        The app’s data sources.
        * (dict) –
          Describes an app’s data source.
          - Type (string) –
            The data source’s type, AutoSelectOpsworksMysqlInstance, OpsworksMysqlInstance, or RdsDbInstance.
          - Arn (string) –
            The data source’s ARN.
          - DatabaseName (string) –
            The database name.
          - Type (string) –
            The app type.
          - AppSource (dict) –
            A Source object that describes the app repository.
          - Type (string) –
            The repository type.
          - Url (string) –
            The source URL.
          - Username (string) –
            This parameter depends on the repository type.
            - For Amazon S3 bundles, set Username to the appropriate IAM access key ID.
            - For HTTP bundles, Git repositories, and Subversion repositories, set Username to the user name.
· **Password** *(string)* – 

When included in a request, the parameter depends on the repository type.
- For Amazon S3 bundles, set `Password` to the appropriate IAM secret access key.
- For HTTP bundles and Subversion repositories, set `Password` to the password.
For more information on how to safely handle IAM credentials, see [http://docs.aws.amazon.com/general/latest/gr/aws-access-keys-best-practices.html](http://docs.aws.amazon.com/general/latest/gr/aws-access-keys-best-practices.html).

In responses, AWS OpsWorks returns "******FILTERED******" instead of the actual value.

· **SshKey** *(string)* –

In requests, the repository’s SSH key.

In responses, AWS OpsWorks returns "******FILTERED******" instead of the actual value.

· **Revision** *(string)* –

The application’s version. AWS OpsWorks enables you to easily deploy new versions of an application. One of the simplest approaches is to have branches or revisions in your repository that represent different versions that can potentially be deployed.

· **Domains** *(list)* –

The app’s vhost settings with multiple domains separated by commas. For example: ‘www.example.com, example.com’

· **EnableSsl** *(boolean)* –

Whether to enable SSL for the app.

· **SslConfiguration** *(dict)* –

An `SslConfiguration` object with the SSL configuration.

· **Certificate** *(string)* –

The contents of the certificate’s domain.crt file.

· **PrivateKey** *(string)* –

The private key; the contents of the certificate’s domain.kex file.

· **Chain** *(string)* –

Optional. Can be used to specify an intermediate certificate authority key or client authentication.

· **Attributes** *(dict)* –

The stack attributes.

· **CreatedAt** *(string)* –

When the app was created.

· **Environment** *(list)* –
An array of `EnvironmentVariable` objects that specify environment variables to be associated with the app. After you deploy the app, these variables are defined on the associated app server instances. For more information, see Environment Variables.

Note: There is no specific limit on the number of environment variables. However, the size of the associated data structure - which includes the variables’ names, values, and protected flag values - cannot exceed 10 KB (10240 Bytes). This limit should accommodate most if not all use cases, but if you do exceed it, you will cause an exception (API) with an “Environment: is too large (maximum is 10KB)” message.

- **(dict)** –
  Represents an app’s environment variable.
  - **Key (string)** –
    (Required) The environment variable’s name, which can consist of up to 64 characters and must be specified. The name can contain upper- and lowercase letters, numbers, and underscores (_), but it must start with a letter or underscore.
  - **Value (string)** –
    (Optional) The environment variable’s value, which can be left empty. If you specify a value, it can contain up to 256 characters, which must all be printable.
  - **Secure (boolean)** –
    (Optional) Whether the variable’s value will be returned by the DescribeApps action. To conceal an environment variable’s value, set Secure to true. DescribeApps then returns *****FILTERED***** instead of the actual value. The default value for Secure is false.

`describe_commands(**kwargs)`
Describes the results of specified commands.

Note: You must specify at least one of the parameters.

**Required Permissions**: To use this action, an IAM user must have a Show, Deploy, or Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.describe_commands(
    DeploymentId='string',
    InstanceId='string',
    CommandIds=[
        'string',
    ],
)
```

**Parameters**
- **DeploymentId** *(string)* – The deployment ID. If you include this parameter, DescribeCommands returns a description of the commands associated with the specified deployment.

- **InstanceId** *(string)* – The instance ID. If you include this parameter, DescribeCommands returns a description of the commands associated with the specified instance.

- **CommandIds** *(list)* – An array of command IDs. If you include this parameter, DescribeCommands returns a description of the specified commands. Otherwise, it returns a description of every command.

  - *(string)* –

Return type  dict

**Response Syntax**

```json
{
   'Commands': [
   {
      'CommandId': 'string',
      'InstanceId': 'string',
      'DeploymentId': 'string',
      'CreatedAt': 'string',
      'AcknowledgedAt': 'string',
      'CompletedAt': 'string',
      'Status': 'string',
      'ExitCode': 123,
      'LogUrl': 'string',
      'Type': 'string'
   },
   ],
}
```

**Response Structure**

- *(dict)* –

  Contains the response to a DescribeCommands request.

  - **Commands** *(list)* –

    An array of Command objects that describe each of the specified commands.

    - *(dict)* –

      Describes a command.

      - **CommandId** *(string)* –

        The command ID.

      - **InstanceId** *(string)* –

        The ID of the instance where the command was executed.

      - **DeploymentId** *(string)* –

        The command deployment ID.

      - **CreatedAt** *(string)* –

        Date and time when the command was run.

      - **AcknowledgedAt** *(string)* –

        Date and time when the command was acknowledged.

      - **CompletedAt** *(string)* –

        Date and time when the command was completed.
Date when the command completed.

- **Status (string)** – The command status:
  - failed
  - successful
  - skipped
  - pending

- **ExitCode (integer)** – The command exit code.

- **LogUrl (string)** – The URL of the command log.

- **Type (string)** – The command type:
  - deploy
  - rollback
  - start
  - stop
  - restart
  - undeploy
  - update_dependencies
  - install_dependencies
  - update_custom_cookbooks
  - execute_recipes

**describe_deployments(****kwargs**

Requests a description of a specified set of deployments.

**Note:** You must specify at least one of the parameters.

**Required Permissions**: To use this action, an IAM user must have a Show, Deploy, or Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.describe_deployments(
    StackId='string',
    AppId='string',
    DeploymentIds=[
        'string',
    ]
)
```

**Parameters**

- **StackId (string)** – The stack ID. If you include this parameter, **DescribeDeployments** returns a description of the commands associated with the specified stack.

- **AppId (string)** – The app ID. If you include this parameter, **DescribeDeployments** returns a description of the commands associated with the specified app.

- **DeploymentIds (list)** – An array of deployment IDs to be described. If you include this parameter, **DescribeDeployments** returns a description of the specified deployments. Otherwise, it returns a description of every deployment.
Response Syntax

```json
{
  'Deployments': [
    {
      'DeploymentId': 'string',
      'StackId': 'string',
      'AppId': 'string',
      'CreatedAt': 'string',
      'CompletedAt': 'string',
      'Duration': 123,
      'IamUserArn': 'string',
      'Comment': 'string',
      'Command': {
        'Name': 'install_dependencies'|'update_dependencies'|'update_custom_cookbooks'|'execute_recipes'|'configure'|'setup'|'deploy'|'rollback'|'start'|'stop'|'restart'|'undeploy',
        'Args': {
          'string': ['string',
          'string',
          'string'],
        }
      },
      'Status': 'string',
      'CustomJson': 'string',
      'InstanceIds': ['string',
      'string',
      'string']
    },
  ]
}
```

Response Structure

- (dict) –
  Contains the response to a DescribeDeployments request.

- Deployments (list) –
  An array of Deployment objects that describe the deployments.

  * (dict) –
  Describes a deployment of a stack or app.

  - DeploymentId (string) –
    The deployment ID.

  - StackId (string) –
    The stack ID.

  - AppId (string) –
    The app ID.

  - CreatedAt (string) –
    Date when the deployment was created.

  - CompletedAt (string) –
    Date when the deployment completed.

  - Duration (integer) –
The deployment duration.

- **IamUserArn** *(string)* —
  The user’s IAM ARN.

- **Comment** *(string)* —
  A user-defined comment.

- **Command** *(dict)* —
  Used to specify a stack or deployment command.

- **Name** *(string)* —
  Specifies the operation. You can specify only one command.

For stacks, the following commands are available:

- **execute_recipes** : Execute one or more recipes. To specify the recipes, set an **Args** parameter named **recipes** to the list of recipes to be executed. For example, to execute **phpapp::appsetup**, set **Args** to `{"recipes": ["phpapp::appsetup"]}`.

- **install_dependencies** : Install the stack’s dependencies.

- **update_custom_cookbooks** : Update the stack’s custom cookbooks.

- **update_dependencies** : Update the stack’s dependencies.

**Note:** The **update_dependencies** and **install_dependencies** commands are supported only for Linux instances. You can run the commands successfully on Windows instances, but they do nothing.

For apps, the following commands are available:

- **deploy** : Deploy an app. Ruby on Rails apps have an optional **Args** parameter named **migrate**. Set **Args** to `{"migrate": ["true"]}` to migrate the database. The default setting is `{"migrate": ["false"]}`.

- **rollback** Roll the app back to the previous version. When you update an app, AWS OpsWorks stores the previous version, up to a maximum of five versions. You can use this command to roll an app back as many as four versions.

- **start** : Start the app’s web or application server.

- **stop** : Stop the app’s web or application server.

- **restart** : Restart the app’s web or application server.

- **undeploy** : Undeploy the app.

- **Args** *(dict)* —

The arguments of those commands that take arguments. It should be set to a JSON object with the following format:

```
{"arg_name1" : ["value1",
"value2", ...], "arg_name2" :
["value1", "value2", ...], ...
}
```

The **update_dependencies** command takes two arguments:

- **upgrade_os_to** - Specifies the desired Amazon Linux version for instances whose OS you want to upgrade, such as **Amazon Linux 2014.09**. You must also set the
allow_reboot argument to true.

- allow_reboot - Specifies whether to allow AWS OpsWorks to reboot the instances if necessary, after installing the updates. This argument can be set to either true or false. The default value is false.

For example, to upgrade an instance to Amazon Linux 2014.09, set Args to the following:

```json
{ "upgrade_os_to": ["Amazon Linux 2014.09"],
  "allow_reboot": ["true"] }
```

- (string) –
- (list) –
- (string) –
- Status (string) –

The deployment status:
- running
- successful
- failed

- CustomJson (string) –

A string that contains user-defined custom JSON. It can be used to override the corresponding default stack configuration attribute values for stack or to pass data to recipes. The string should be in the following format and must escape characters such as "":

```
{"key1": "value1",
 "key2": "value2",...}
```

For more information on custom JSON, see Use Custom JSON to Modify the Stack Configuration Attributes.

- InstanceIds (list) –

The IDs of the target instances.
- (string) –

**describe_ecs_clusters(**kwargs)**

Describes Amazon ECS clusters that are registered with a stack. If you specify only a stack ID, you can use the MaxResults and NextToken parameters to paginate the response. However, AWS OpsWorks currently supports only one cluster per layer, so the result set has a maximum of one element.

**Required Permissions**: To use this action, an IAM user must have a Show, Deploy, or Manage permissions level for the stack or an attached policy that explicitly grants permission. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.describe_ecs_clusters(
    EcsClusterArns=[
        'string',
    ],
    StackId='string',
    NextToken='string',
    MaxResults=123
)
```

**Parameters**

- **EcsClusterArns (list)** – A list of ARNs, one for each cluster to be described.
  - (string) –
• **StackId** *(string)* – A stack ID. `DescribeEcsClusters` returns a description of the cluster that is registered with the stack.

• **NextToken** *(string)* – If the previous paginated request did not return all of the remaining results, the response object’s “NextToken” parameter value is set to a token. To retrieve the next set of results, call `DescribeEcsClusters` again and assign that token to the request object’s `NextToken` parameter. If there are no remaining results, the previous response object’s `NextToken` parameter is set to `null`.

• **MaxResults** *(integer)* – To receive a paginated response, use this parameter to specify the maximum number of results to be returned with a single call. If the number of available results exceeds this maximum, the response includes a `NextToken` value that you can assign to the `NextToken` request parameter to get the next set of results.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
  'EcsClusters': [
    {
      'EcsClusterArn': 'string',
      'EcsClusterName': 'string',
      'StackId': 'string',
      'RegisteredAt': 'string'
    },
    ...
  ],
  'NextToken': 'string'
}
```

**Response Structure**

• *(dict)* –

Contains the response to a `DescribeEcsClusters` request.

  – **EcsClusters** *(list)* –

    A list of `EcsCluster` objects containing the cluster descriptions.

      * *(dict)* –

      Describes a registered Amazon ECS cluster.

        • **EcsClusterArn** *(string)* –

          The cluster’s ARN.

        • **EcsClusterName** *(string)* –

          The cluster name.

        • **StackId** *(string)* –

          The stack ID.

        • **RegisteredAt** *(string)* –

          The time and date that the cluster was registered with the stack.

  – **NextToken** *(string)* –

    If a paginated request does not return all of the remaining results, this parameter is set to a token that you can assign to the request object’s `NextToken` parameter to retrieve the next set of results. If the previ-
ous paginated request returned all of the remaining results, this parameter is set to null.

```python
describe_elastic_ips(**kwargs)
```

Describes Elastic IP addresses.

**Note:** You must specify at least one of the parameters.

**Required Permissions:** To use this action, an IAM user must have a Show, Deploy, or Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.describe_elastic_ips(
    InstanceId='string',
    StackId='string',
    Ips=['string',
         'string',
    ]
)
```

**Parameters**

- **InstanceId** *(string)* – The instance ID. If you include this parameter, `DescribeElasticIps` returns a description of the Elastic IP addresses associated with the specified instance.
- **StackId** *(string)* – A stack ID. If you include this parameter, `DescribeElasticIps` returns a description of the Elastic IP addresses that are registered with the specified stack.
- **Ips** *(list)* – An array of Elastic IP addresses to be described. If you include this parameter, `DescribeElasticIps` returns a description of the specified Elastic IP addresses. Otherwise, it returns a description of every Elastic IP address.

- *(string)* –

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'ElasticIps': [
        {
            'Ip': 'string',
            'Name': 'string',
            'Domain': 'string',
            'Region': 'string',
            'InstanceId': 'string'
        },
        ...
    ]
}
```

**Response Structure**

- *(dict)* –

  Contains the response to a `DescribeElasticIps` request.
  - **ElasticIps** *(list)* –

    An `ElasticIps` object that describes the specified Elastic IP addresses.
* (dict) –
  Describes an Elastic IP address.
    · **Ip** (string) –
      The IP address.
    · **Name** (string) –
      The name.
    · **Domain** (string) –
      The domain.
    · **Region** (string) –
      The AWS region. For more information, see Regions and Endpoints.
    · **InstanceId** (string) –
      The ID of the instance that the address is attached to.

describe_elastic_load_balancers(**kwargs)
Describes a stack’s Elastic Load Balancing instances.

**Note:** You must specify at least one of the parameters.

**Required Permissions:** To use this action, an IAM user must have a Show, Deploy, or Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.describe_elastic_load_balancers(
    StackId='string',
    LayerIds=[
        'string',
    ]
)
```

**Parameters**

- **StackId** (string) – A stack ID. The action describes the stack’s Elastic Load Balancing instances.
- **LayerIds** (list) – A list of layer IDs. The action describes the Elastic Load Balancing instances for the specified layers.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'ElasticLoadBalancers': [
        {
            'ElasticLoadBalancerName': 'string',
            'Region': 'string',
            'DnsName': 'string',
            'StackId': 'string',
            'LayerId': 'string',
            'VpcId': 'string',
            'AvailabilityZones': [
```

3.1. Services 3199
Response Structure

* (dict) –
Contains the response to a DescribeElasticLoadBalancers request.

- ElasticLoadBalancers (list) –
A list of ElasticLoadBalancer objects that describe the specified Elastic Load Balancing instances.

* (dict) –
Describes an Elastic Load Balancing instance.

- ElasticLoadBalancerName (string) –
The Elastic Load Balancing instance’s name.

- Region (string) –
The instance’s AWS region.

- DnsName (string) –
The instance’s public DNS name.

- StackId (string) –
The ID of the stack that the instance is associated with.

- LayerId (string) –
The ID of the layer that the instance is attached to.

- VpcId (string) –
The VPC ID.

- AvailabilityZones (list) –
A list of Availability Zones.

- (string) –

- SubnetIds (list) –
A list of subnet IDs, if the stack is running in a VPC.

- (string) –

- Ec2InstanceIds (list) –
A list of the EC2 instances that the Elastic Load Balancing instance is managing traffic for.

- (string) –

describe_instances (**kwargs)
Requests a description of a set of instances.

Note: You must specify at least one of the parameters.
**Required Permissions**: To use this action, an IAM user must have a Show, Deploy, or Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.describe_instances(
    StackId='string',
    LayerId='string',
    InstanceIds=[
        'string',
    ]
)
```

**Parameters**

- **StackId** *(string)* – A stack ID. If you use this parameter, `describe_instances` returns descriptions of the instances associated with the specified stack.
- **LayerId** *(string)* – A layer ID. If you use this parameter, `describe_instances` returns descriptions of the instances associated with the specified layer.
- **InstanceIds** *(list)* – An array of instance IDs to be described. If you use this parameter, `describe_instances` returns a description of the specified instances. Otherwise, it returns a description of every instance.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'Instances': [
        {
            'AgentVersion': 'string',
            'AmiId': 'string',
            'Architecture': 'x86_64' | 'i386',
            'AutoScalingType': 'load' | 'timer',
            'AvailabilityZone': 'string',
            'BlockDeviceMappings': [
                {
                    'DeviceName': 'string',
                    'NoDevice': 'string',
                    'VirtualName': 'string',
                    'Ebs': {
                        'SnapshotId': 'string',
                        'Iops': 123,
                        'VolumeSize': 123,
                        'VolumeType': 'gp2' | 'io1' | 'standard',
                        'DeleteOnTermination': True | False
                    }
                }
            ],
            'CreatedAt': 'string',
            'EbsOptimized': True | False,
            'Ec2InstanceId': 'string',
            'EcsClusterArn': 'string',
            'EcsContainerInstanceArn': 'string',
            'ElasticIp': 'string',
```
'Hostname': 'string',
'InfrastructureClass': 'string',
'InstallUpdatesOnBoot': True|False,
'InstanceId': 'string',
'InstanceProfileArn': 'string',
'InstanceType': 'string',
'LastServiceErrorId': 'string',
'LayerIds': [ 'string', ],
'Os': 'string',
'Platform': 'string',
'PrivateDns': 'string',
'PrivateIp': 'string',
'PublicDns': 'string',
'PublicIp': 'string',
'RegisteredBy': 'string',
'ReportedAgentVersion': 'string',
'ReportedOs': { 'Family': 'string', 'Name': 'string', 'Version': 'string' },
'RootDeviceType': 'ebs'|'instance-store',
'RootDeviceVolumeId': 'string',
'SecurityGroupIds': [ 'string', ],
'SshHostDsaKeyFingerprint': 'string',
'SshHostRsaKeyFingerprint': 'string',
'SshKeyName': 'string',
'StackId': 'string',
'Status': 'string',
'SubnetId': 'string',
'VirtualizationType': 'paravirtual'|'hvm'
}

Response Structure

• (dict) –

Contains the response to a DescribeInstances request.

– Instances (list) –

An array of Instance objects that describe the instances.

* (dict) –

Describes an instance.

• AgentVersion (string) –

The agent version. This parameter is set to INHERIT if the instance inherits the default stack setting or to a a version number for a fixed agent version.

• AmiId (string) –

A custom AMI ID to be used to create the instance. For more information, see Instances

• Architecture (string) –
The instance architecture: “i386” or “x86_64”.

- AutoScalingType (string) –
  For load-based or time-based instances, the type.

- AvailabilityZone (string) –
  The instance Availability Zone. For more information, see Regions and Endpoints.

- BlockDeviceMappings (list) –
  An array of BlockDeviceMapping objects that specify the instance’s block device mappings.

  (dict) –
  Describes a block device mapping. This data type maps directly to the Amazon EC2 BlockDeviceMapping data type.

  - DeviceName (string) –
    The device name that is exposed to the instance, such as /dev/sdh. For the root device, you can use the explicit device name or you can set this parameter to ROOT DEVICE and AWS OpsWorks will provide the correct device name.

  - NoDevice (string) –
    Suppresses the specified device included in the AMI’s block device mapping.

  - VirtualName (string) –
    The virtual device name. For more information, see BlockDeviceMapping.

  - Ebs (dict) –
    An EBSBlockDevice that defines how to configure an Amazon EBS volume when the instance is launched.

  - SnapshotId (string) –
    The snapshot ID.

  - Iops (integer) –
    The number of I/O operations per second (IOPS) that the volume supports. For more information, see EbsBlockDevice.

  - VolumeSize (integer) –
    The volume size, in GiB. For more information, see EbsBlockDevice.

  - VolumeType (string) –
    The volume type. gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, and standard for Magnetic volumes.

  - DeleteOnTermination (boolean) –
    Whether the volume is deleted on instance termination.

  - CreatedAt (string) –
    The time that the instance was created.

  - EbsOptimized (boolean) –
    Whether this is an Amazon EBS-optimized instance.

  - Ec2InstanceId (string) –
    The ID of the associated Amazon EC2 instance.
- **EcsClusterArn** *(string)* –
  For container instances, the Amazon ECS cluster’s ARN.
- **EcsContainerInstanceArn** *(string)* –
  For container instances, the instance’s ARN.
- **ElasticIp** *(string)* –
  The instance Elastic IP address.
- **Hostname** *(string)* –
  The instance host name.
- **InfrastructureClass** *(string)* –
  For registered instances, the infrastructure class: `ec2` or `on-premises`.
- **InstallUpdatesOnBoot** *(boolean)* –
  Whether to install operating system and package updates when the instance boots. The default value is `true`. If this value is set to `false`, you must then update your instances manually by using CreateDeployment to run the `update_dependencies` stack command or by manually running `yum` (Amazon Linux) or `apt-get` (Ubuntu) on the instances.

  **Note:** We strongly recommend using the default value of `true`, to ensure that your instances have the latest security updates.

- **InstanceId** *(string)* –
  The instance ID.
- **InstanceProfileArn** *(string)* –
  The ARN of the instance’s IAM profile. For more information about IAM ARNs, see Using Identifiers.
- **InstanceType** *(string)* –
  The instance type, such as `t2.micro`.
- **LastServiceErrorId** *(string)* –
  The ID of the last service error. For more information, call DescribeServiceErrors.
- **LayerIds** *(list)* –
  An array containing the instance layer IDs.
- **Os** *(string)* –
  The instance’s operating system.
- **Platform** *(string)* –
  The instance’s platform.
- **PrivateDns** *(string)* –
  The instance’s private DNS name.
- **PrivateIp** *(string)* –
  The instance’s private IP address.
- **PublicDns** *(string)* –
The instance public DNS name.
- **PublicIp** *(string)* –

The instance public IP address.
- **RegisteredBy** *(string)* –

For registered instances, who performed the registration.
- **ReportedAgentVersion** *(string)* –

The instance’s reported AWS OpsWorks agent version.
- **ReportedOs** *(dict)* –

For registered instances, the reported operating system.
- **Family** *(string)* –

The operating system family.
- **Name** *(string)* –

The operating system name.
- **Version** *(string)* –

The operating system version.
- **RootDeviceType** *(string)* –

The instance’s root device type. For more information, see Storage for the Root Device.
- **RootDeviceVolumeId** *(string)* –

The root device volume ID.
- **SecurityGroupIds** *(list)* –

An array containing the instance security group IDs.
- *(string)* –
- **SshHostDsaKeyFingerprint** *(string)* –

The SSH key’s Deep Security Agent (DSA) fingerprint.
- **SshHostRsaKeyFingerprint** *(string)* –

The SSH key’s RSA fingerprint.
- **SshKeyName** *(string)* –

The instance’s Amazon EC2 key-pair name.
- **StackId** *(string)* –

The stack ID.
- **Status** *(string)* –

The instance status:
- booting
- connection_lost
- online
- pending
- rebooting
- requested
- running_setup
- setup_failed
- shutting_down
- start_failed
- stopped
- stopping
- terminated
· terminating
· **SubnetId** (**string**) –
  The instance’s subnet ID; applicable only if the stack is running in a VPC.
· **VirtualizationType** (**string**) –
  The instance’s virtualization type: `paravirtual` or `hvm`.

**describe_layers(** **kwargs **)**

Requests a description of one or more layers in a specified stack.

**Note:** You must specify at least one of the parameters.

**Required Permissions:** To use this action, an IAM user must have a Show, Deploy, or Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.describe_layers(
    StackId='string',
    LayerIds=[
        'string',
    ],
)
```

**Parameters**

- **StackId** (**string**) – The stack ID.
- **LayerIds** (**list**) – An array of layer IDs that specify the layers to be described.
  
  If you omit this parameter, DescribeLayers returns a description of every layer in the specified stack.

**Return type** **dict**

**Returns**

**Response Syntax**

```json
{
    'Layers': [
        {
            'StackId': 'string',
            'LayerId': 'string',
            'Type': 'aws-flow-ruby'|'ecs-cluster'|'java-app'|'lb'|'web'|'php-app'|'memcached'|'db-master'|'monitoring-master'|'custom',
            'Name': 'string',
            'Shortname': 'string',
            'Attributes': {
                'string': 'string'
            },
            'CustomInstanceProfileArn': 'string',
            'CustomJson': 'string',
            'CustomSecurityGroupIds': [
                'string',
            ],
            'DefaultSecurityGroupNames': [
                'string',
            ],

  'DelayUntilElbConnectionsDrained': True|False
} }
Response Structure

- *(dict)* –
  
  Contains the response to a `DescribeLayers` request.

  - **Layers** *(list)* –
    
    An array of `Layer` objects that describe the layers.

    - *(dict)* –
      
      Describes a layer.

      - **StackId** *(string)* –
        
        The layer stack ID.

      - **LayerId** *(string)* –
        
        The layer ID.

      - **Type** *(string)* –
        
        The layer type.

      - **Name** *(string)* –
        
        The layer name.

      - **Shortname** *(string)* –
        
        The layer short name.

      - **Attributes** *(dict)* –
        
        The layer attributes.

        For the `HaproxyStatsPassword`, `MysqlRootPassword`, and `GangliaPassword` attributes, AWS OpsWorks returns *****FILTERED***** instead of the actual value.

        For an ECS Cluster layer, AWS OpsWorks the `EcsClusterArn` attribute is set to the cluster’s ARN.

        - *(string)* –
          
          - *(string)* –

          - **CustomInstanceProfileArn** *(string)* –
            
            The ARN of the default IAM profile to be used for the layer’s EC2 instances. For more information about IAM ARNs, see Using Identifiers.

        - **CustomJson** *(string)* –
          
          A JSON formatted string containing the layer’s custom stack configuration and deployment attributes.

        - **CustomSecurityGroupIds** *(list)* –
          
          An array containing the layer’s custom security group IDs.

        - *(string)* –

        - **DefaultSecurityGroupNames** *(list)* –
          
          An array containing the layer’s security group names.

        - *(string)* –

        - **Packages** *(list)* –
An array of Package objects that describe the layer’s packages.
· (string) –
· VolumeConfigurations (list) –
   A VolumeConfigurations object that describes the layer’s Amazon EBS volumes.
· (dict) –
   Describes an Amazon EBS volume configuration.
· MountPoint (string) –
   The volume mount point. For example “/dev/sdh”.
· RaidLevel (integer) –
   The volume RAID level.
· NumberOfDisks (integer) –
   The number of disks in the volume.
· Size (integer) –
   The volume size.
· VolumeType (string) –
   The volume type:
   · standard - Magnetic
   · io1 - Provisioned IOPS (SSD)
   · gp2 - General Purpose (SSD)
· Iops (integer) –
   For PIOPS volumes, the IOPS per disk.
· EnableAutoHealing (boolean) –
   Whether auto healing is disabled for the layer.
· AutoAssignElasticIps (boolean) –
   Whether to automatically assign an Elastic IP address to the layer’s instances. For more information, see How to Edit a Layer.
· AutoAssignPublicIps (boolean) –
   For stacks that are running in a VPC, whether to automatically assign a public IP address to the layer’s instances. For more information, see How to Edit a Layer.
· DefaultRecipes (dict) –

AWS OpsWorks supports five lifecycle events: setup, configuration, deploy, undeploy, and shutdown. For each layer, AWS OpsWorks runs a set of standard recipes for each event. In addition, you can provide custom recipes for any or all layers and events. AWS OpsWorks runs custom event recipes after the standard recipes. LayerCustomRecipes specifies the custom recipes for a particular layer to be run in response to each of the five events.

To specify a recipe, use the cookbook’s directory name in the repository followed by two colons and the recipe name, which is the recipe’s file name without the .rb extension. For example: phpapp2::dbsetup specifies the dbsetup.rb recipe in the repository’s phpapp2 folder.
- **Setup** *(list)* –
  An array of custom recipe names to be run following a `setup` event.
- **Configure** *(list)* –
  An array of custom recipe names to be run following a `configure` event.
- **Deploy** *(list)* –
  An array of custom recipe names to be run following a `deploy` event.
- **Undeploy** *(list)* –
  An array of custom recipe names to be run following a `undeploy` event.
- **Shutdown** *(list)* –
  An array of custom recipe names to be run following a `shutdown` event.
- **CustomRecipes** *(dict)* –
  A `LayerCustomRecipes` object that specifies the layer's custom recipes.
- **Setup** *(list)* –
  An array of custom recipe names to be run following a `setup` event.
- **Configure** *(list)* –
  An array of custom recipe names to be run following a `configure` event.
- **Deploy** *(list)* –
  An array of custom recipe names to be run following a `deploy` event.
- **Undeploy** *(list)* –
  An array of custom recipe names to be run following a `undeploy` event.
- **Shutdown** *(list)* –
  An array of custom recipe names to be run following a `shutdown` event.
- **CreatedAt** *(string)* –
  Date when the layer was created.
- **InstallUpdatesOnBoot** *(boolean)* –
  Whether to install operating system and package updates
when the instance boots. The default value is `true`. If this value is set to `false`, you must then update your instances manually by using CreateDeployment to run the `update_dependencies` stack command or manually running `yum` (Amazon Linux) or `apt-get` (Ubuntu) on the instances.

**Note:** We strongly recommend using the default value of `true`, to ensure that your instances have the latest security updates.

- **UseEbsOptimizedInstances**(boolean) –
  Whether the layer uses Amazon EBS-optimized instances.
- **LifecycleEventConfiguration**(dict) –
  A `LifeCycleEventConfiguration` object that specifies the Shutdown event configuration.
- **Shutdown**(dict) –
  A `ShutdownEventConfiguration` object that specifies the Shutdown event configuration.
- **ExecutionTimeout**(integer) –
  The time, in seconds, that AWS OpsWorks will wait after triggering a Shutdown event before shutting down an instance.
- **DelayUntilElbConnectionsDrained**(boolean) –
  Whether to enable Elastic Load Balancing connection draining. For more information, see [Connection Draining](#).

### describe_load_based_auto_scaling(**kwargs)**
Describes load-based auto scaling configurations for specified layers.

**Note:** You must specify at least one of the parameters.

**Required Permissions**: To use this action, an IAM user must have a Show, Deploy, or Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see [Managing User Permissions](#).

**Request Syntax**

```python
response = client.describe_load_based_auto_scaling(
    LayerIds=[
        'string',
    ]
)
```

**Parameters**
- **LayerIds**(list) – [REQUIRED]
  An array of layer IDs.
  - (string) –

**Return type**
- **dict**

**Returns**

**Response Syntax**

```python
{
    'LoadBasedAutoScalingConfigurations': [
```
{  
  'LayerId': 'string',
  'Enable': True|False,
  'UpScaling': {  
    'InstanceCount': 123,
    'ThresholdsWaitTime': 123,
    'IgnoreMetricsTime': 123,
    'CpuThreshold': 123.0,
    'MemoryThreshold': 123.0,
    'LoadThreshold': 123.0,
    'Alarms': [  
      'string',
      ]
  },
  'DownScaling': {  
    'InstanceCount': 123,
    'ThresholdsWaitTime': 123,
    'IgnoreMetricsTime': 123,
    'CpuThreshold': 123.0,
    'MemoryThreshold': 123.0,
    'LoadThreshold': 123.0,
    'Alarms': [  
      'string',
      ]
  }
  }
}

Response Structure

- (dict) –
  Contains the response to a DescribeLoadBasedAutoScaling request.
  
  - LoadBasedAutoScalingConfigurations (list) –
    An array of LoadBasedAutoScalingConfiguration objects that describe each layer’s configuration.
    * (dict) –
      Describes a layer’s load-based auto scaling configuration.
      
      - LayerId (string) –
        The layer ID.
      - Enable (boolean) –
        Whether load-based auto scaling is enabled for the layer.
      - UpScaling (dict) –
        An AutoScalingThresholds object that describes the upscaling configuration, which defines how and when AWS OpsWorks increases the number of instances.
        
        - InstanceCount (integer) –
          The number of instances to add or remove when the load exceeds a threshold.
        - ThresholdsWaitTime (integer) –
          The amount of time, in minutes, that the load must exceed a threshold before more instances are added or removed.
        - IgnoreMetricsTime (integer) –
The amount of time (in minutes) after a scaling event occurs that AWS OpsWorks should ignore metrics and suppress additional scaling events. For example, AWS OpsWorks adds new instances following an upscaling event but the instances won’t start reducing the load until they have been booted and configured. There is no point in raising additional scaling events during that operation, which typically takes several minutes. IgnoreMetricsTime allows you to direct AWS OpsWorks to suppress scaling events long enough to get the new instances online.

- **CpuThreshold** *(float)* –
  The CPU utilization threshold, as a percent of the available CPU.

- **MemoryThreshold** *(float)* –
  The memory utilization threshold, as a percent of the available memory.

- **LoadThreshold** *(float)* –
  The load threshold. For more information about how load is computed, see Load (computing).

- **Alarms** *(list)* –
  Custom Cloudwatch auto scaling alarms, to be used as thresholds. This parameter takes a list of up to five alarm names, which are case sensitive and must be in the same region as the stack.

**Note:** To use custom alarms, you must update your service role to allow `cloudwatch:DescribeAlarms`. You can either have AWS OpsWorks update the role for you when you first use this feature or you can edit the role manually. For more information, see Allowing AWS OpsWorks to Act on Your Behalf.

- **DownScaling** *(dict)* –
  An AutoScalingThresholds object that describes the downscaling configuration, which defines how and when AWS OpsWorks reduces the number of instances.

- **InstanceCount** *(integer)* –
  The number of instances to add or remove when the load exceeds a threshold.

- **ThresholdsWaitTime** *(integer)* –
  The amount of time, in minutes, that the load must exceed a threshold before more instances are added or removed.

- **IgnoreMetricsTime** *(integer)* –
  The amount of time (in minutes) after a scaling event occurs that AWS OpsWorks should ignore metrics and suppress additional scaling events. For example, AWS OpsWorks adds new instances following an upscaling event but the instances won’t start reducing the load until they have been booted and configured. There is no point in raising additional scaling
events during that operation, which typically takes several minutes. IgnoreMetricsTime allows you to direct AWS OpsWorks to suppress scaling events long enough to get the new instances online.

- **CpuThreshold** *(float)* —
  The CPU utilization threshold, as a percent of the available CPU.

- **MemoryThreshold** *(float)* —
  The memory utilization threshold, as a percent of the available memory.

- **LoadThreshold** *(float)* —
  The load threshold. For more information about how load is computed, see Load (computing).

- **Alarms** *(list)* —
  Custom Cloudwatch auto scaling alarms, to be used as thresholds. This parameter takes a list of up to five alarm names, which are case sensitive and must be in the same region as the stack.

**Note:** To use custom alarms, you must update your service role to allow `cloudwatch:DescribeAlarms`. You can either have AWS OpsWorks update the role for you when you first use this feature or you can edit the role manually. For more information, see Allowing AWS OpsWorks to Act on Your Behalf.

**describe_my_user_profile** *(string)* —
Describes a user’s SSH information.

**Required Permissions** : To use this action, an IAM user must have self-management enabled or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.describe_my_user_profile()
```

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'UserProfile': {
        'IamUserArn': 'string',
        'Name': 'string',
        'SshUsername': 'string',
        'SshPublicKey': 'string'
    }
}
```

**Response Structure**
**describe_permissions(**kwargs)**

Describes the permissions for a specified stack.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see [Managing User Permissions](#).

**Request Syntax**

```
response = client.describe_permissions(
    IamUserArn='string',
    StackId='string'
)
```

**Parameters**

- **IamUserArn (string)** – The user’s IAM ARN. For more information about IAM ARNs, see [Using Identifiers](#).
- **StackId (string)** – The stack ID.

**Return type** `dict`

**Returns**

**Response Syntax**

```
{
    'Permissions': [
        {
            'StackId': 'string',
            'IamUserArn': 'string',
            'AllowSsh': True|False,
            'AllowSudo': True|False,
            'Level': 'string'
        },
        ...
    ]
}
```

**Response Structure**

- **(dict)** – Contains the response to a `DescribePermissions` request.
  - **Permissions (list)** – An array of `Permission` objects that describe the stack permissions.
* If the request object contains only a stack ID, the array contains a Permission object with permissions for each of the stack IAM ARNs.
* If the request object contains only an IAM ARN, the array contains a Permission object with permissions for each of the user’s stack IDs.
* If the request contains a stack ID and an IAM ARN, the array contains a single Permission object with permissions for the specified stack and IAM ARN.

* (dict) –
  Describes stack or user permissions.
    · **StackId** *(string)* –
      A stack ID.
    · **IamUserArn** *(string)* –
      The Amazon Resource Name (ARN) for an AWS Identity and Access Management (IAM) role. For more information about IAM ARNs, see Using Identifiers.
    · **AllowSsh** *(boolean)* –
      Whether the user can use SSH.
    · **AllowSudo** *(boolean)* –
      Whether the user can use sudo.
    · **Level** *(string)* –
      The user’s permission level, which must be the following:
      · deny
      · show
      · deploy
      · manage
      · iam_only
      For more information on the permissions associated with these levels, see Managing User Permissions.

**describe_raid_arrays** (**kwargs)**

Describe an instance’s RAID arrays.

**Note:** You must specify at least one of the parameters.

**Required Permissions**: To use this action, an IAM user must have a Show, Deploy, or Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.describe_raid_arrays(
    InstanceId='string',
    StackId='string',
    RaidArrayIds=[
        'string',
    ]
)
```

**Parameters**
• **InstanceId** *(string)* – The instance ID. If you use this parameter, `DescribeRaidArrays` returns descriptions of the RAID arrays associated with the specified instance.

• **StackId** *(string)* – The stack ID.

• **RaidArrayIds** *(list)* – An array of RAID array IDs. If you use this parameter, `DescribeRaidArrays` returns descriptions of the specified arrays. Otherwise, it returns a description of every array.

**Return type**  `dict`

**Returns**

**Response Syntax**

```python
{
    'RaidArrays': [
        {
            'RaidArrayId': 'string',
            'InstanceId': 'string',
            'Name': 'string',
            'RaidLevel': 123,
            'NumberOfDisks': 123,
            'Size': 123,
            'Device': 'string',
            'MountPoint': 'string',
            'AvailabilityZone': 'string',
            'CreatedAt': 'string',
            'StackId': 'string',
            'VolumeType': 'string',
            'Iops': 123
        },
    ]
}
```

**Response Structure**

• *(dict)* – Contains the response to a `DescribeRaidArrays` request.

  • **RaidArrays** *(list)* – A `RaidArrays` object that describes the specified RAID arrays.

    • *(dict)* – Describes an instance’s RAID array.

      • **RaidArrayId** *(string)* –

        The array ID.
      
      • **InstanceId** *(string)* –

        The instance ID.
      
      • **Name** *(string)* –

        The array name.
      
      • **RaidLevel** *(integer)* –

        The RAID level.
      
      • **NumberOfDisks** *(integer)* –

        The number of disks in the array.
      
      • **Size** *(integer)* –

        The array’s size.
· **Device** *(string)* –
  The array’s Linux device. For example /dev/mdadm0.
  
· **MountPoint** *(string)* –
  The array’s mount point.
  
· **AvailabilityZone** *(string)* –
  The array’s Availability Zone. For more information, see Regions and Endpoints.
  
· **CreatedAt** *(string)* –
  When the RAID array was created.
  
· **StackId** *(string)* –
  The stack ID.
  
· **VolumeType** *(string)* –
  The volume type, standard or PIOPS.
  
· **Iops** *(integer)* –
  For PIOPS volumes, the IOPS per disk.

**describe_rds_db_instances(**kwargs)**

Describes Amazon RDS instances.

**Required Permissions**: To use this action, an IAM user must have a Show, Deploy, or Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
define = client.describe_rds_db_instances(
    StackId='string',
    RdsDbInstanceArns=[
        'string',
    ]
)
```

**Parameters**

- **StackId** *(string)* – [REQUIRED]
  
  The stack ID that the instances are registered with. The operation returns descriptions of all registered Amazon RDS instances.
  
- **RdsDbInstanceArns** *(list)* – An array containing the ARNs of the instances to be described.
  - *(string)* –

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'RdsDbInstances': [
        {'RdsDbInstanceArn': 'string',
         'DbInstanceIdentifier': 'string',
         'DbUser': 'string',
         'DbPassword': 'string',
         'Region': 'string',
         'Address': 'string',
         ... ]
    }
}
```
Response Structure

• (dict) –
  Contains the response to a DescribeRdsDbInstances request.
  
  – RdsDbInstances (list) –
  An array of RdsDbInstance objects that describe the instances.
  
  * (dict) –
  Describes an Amazon RDS instance.
  
  · RdsDbInstanceArn (string) –
    The instance’s ARN.
  
  · DbInstanceIdentifier (string) –
    The DB instance identifier.
  
  · DbUser (string) –
    The master user name.
  
  · DbPassword (string) –
    AWS OpsWorks returns ******FILTERED****** instead of the actual value.
  
  · Region (string) –
    The instance’s AWS region.
  
  · Address (string) –
    The instance’s address.
  
  · Engine (string) –
    The instance’s database engine.
  
  · StackId (string) –
    The ID of the stack that the instance is registered with.
  
  · MissingOnRds (boolean) –
    Set to true if AWS OpsWorks was unable to discover the Amazon RDS instance. AWS OpsWorks attempts to discover the instance only once. If this value is set to true, you must deregister the instance and then register it again.

```
describe_service_errors(**kwargs)
```

Describes AWS OpsWorks service errors.

Required Permissions: To use this action, an IAM user must have a Show, Deploy, or Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

Request Syntax

```python
response = client.describe_service_errors(
    StackId='string',
    InstanceId='string',
    ServiceErrorIds=[
```
Parameters

- **StackId** *(string)* – The stack ID. If you use this parameter, *DescribeServiceErrors* returns descriptions of the errors associated with the specified stack.
- **InstanceId** *(string)* – The instance ID. If you use this parameter, *DescribeServiceErrors* returns descriptions of the errors associated with the specified instance.
- **ServiceErrorIds** *(list)* – An array of service error IDs. If you use this parameter, *DescribeServiceErrors* returns descriptions of the specified errors. Otherwise, it returns a description of every error.

Return type  *dict*

Returns

**Response Syntax**

```python
{
    'ServiceErrors': [
        {
            'ServiceErrorId': 'string',
            'StackId': 'string',
            'InstanceId': 'string',
            'Type': 'string',
            'Message': 'string',
            'CreatedAt': 'string'
        },
    ]
}
```

**Response Structure**

- *(dict)* –

  Contains the response to a *DescribeServiceErrors* request.

  - **ServiceErrors** *(list)* –

    An array of *ServiceError* objects that describe the specified service errors.

    - *(dict)* –

      Describes an AWS OpsWorks service error.

      - **ServiceErrorId** *(string)* –

        The error ID.

      - **StackId** *(string)* –

        The stack ID.

      - **InstanceId** *(string)* –

        The instance ID.

      - **Type** *(string)* –

        The error type.

      - **Message** *(string)* –

        A message that describes the error.
**describe_stack_provisioning_parameters(**kwargs)**

Requests a description of a stack’s provisioning parameters.

**Required Permissions**: To use this action, an IAM user must have a Show, Deploy, or Manage permissions level for the stack or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.describe_stack_provisioning_parameters(
    StackId='string'
)
```

**Parameters StackId (string) – [REQUIRED]**

The stack ID

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'AgentInstallerUrl': 'string',
    'Parameters': {
        'string': 'string'
    }
}
```

**Response Structure**

* (dict) –

Contains the response to a DescribeStackProvisioningParameters request.

* AgentInstallerUrl (string) –

The AWS OpsWorks agent installer’s URL.

* Parameters (dict) –

An embedded object that contains the provisioning parameters.

* (string) –

* (string) –

**describe_stack_summary(**kwargs)**

Describes the number of layers and apps in a specified stack, and the number of instances in each state, such as running_setup or online.

**Required Permissions**: To use this action, an IAM user must have a Show, Deploy, or Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.describe_stack_summary(
    StackId='string'
)
```
Parameters StackId (string) – [REQUIRED]

The stack ID.

Return type dict

Returns

Response Syntax

```
{
    'StackSummary': {
        'StackId': 'string',
        'Name': 'string',
        'Arn': 'string',
        'LayersCount': 123,
        'AppsCount': 123,
        'InstancesCount': {
            'Assigning': 123,
            'Booting': 123,
            'ConnectionLost': 123,
            'Deregistering': 123,
            'Online': 123,
            'Pending': 123,
            'Rebooting': 123,
            'Registered': 123,
            'Requesting': 123,
            'RunningSetup': 123,
            'SetupFailed': 123,
            'ShuttingDown': 123,
            'StartFailed': 123,
            'Stopped': 123,
            'Stopping': 123,
            'Terminated': 123,
            'Terminating': 123,
            'Unassigning': 123
        }
    }
}
```

Response Structure

- (dict) –

Contains the response to a DescribeStackSummary request.

  - StackSummary (dict) –

A StackSummary object that contains the results.

  * StackId (string) –

The stack ID.

  * Name (string) –

The stack name.

  * Arn (string) –

The stack’s ARN.

  * LayersCount (integer) –

The number of layers.

  * AppsCount (integer) –

The number of apps.
InstancesCount (dict) –

An InstancesCount object with the number of instances in each status.

- Assigning (integer) –
  The number of instances in the Assigning state.
- Booting (integer) –
  The number of instances with booting status.
- ConnectionLost (integer) –
  The number of instances with connection_lost status.
- Deregistering (integer) –
  The number of instances in the Deregistering state.
- Online (integer) –
  The number of instances with online status.
- Pending (integer) –
  The number of instances with pending status.
- Rebooting (integer) –
  The number of instances with rebooting status.
- Registered (integer) –
  The number of instances in the Registered state.
- Registering (integer) –
  The number of instances in the Registering state.
- Requested (integer) –
  The number of instances with requested status.
- RunningSetup (integer) –
  The number of instances with running_setup status.
- SetupFailed (integer) –
  The number of instances with setup_failed status.
- ShuttingDown (integer) –
  The number of instances with shutting_down status.
- StartFailed (integer) –
  The number of instances with start_failed status.
- Stopped (integer) –
  The number of instances with stopped status.
- Stopping (integer) –
  The number of instances with stopping status.
- Terminated (integer) –
  The number of instances with terminated status.
- Terminating (integer) –
  The number of instances with terminating status.
- Unassigning (integer) –
  The number of instances in the Unassigning state.

describe_stacks (**kwargs)

Requests a description of one or more stacks.
**Required Permissions**: To use this action, an IAM user must have a Show, Deploy, or Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.describe_stacks(
    StackIds=[
        'string',
    ]
)
```

**Parameters**

- **StackIds** *(list)* – An array of stack IDs that specify the stacks to be described.

  If you omit this parameter, DescribeStacks returns a description of every stack.

- *(string)* –

**Return type**

- **dict**

**Returns**

**Response Syntax**

```json
{
    'Stacks': [
        {
            'StackId': 'string',
            'Name': 'string',
            'Arn': 'string',
            'Region': 'string',
            'VpcId': 'string',
            'Attributes': {
                'string': 'string'
            },
            'ServiceRoleArn': 'string',
            'DefaultInstanceProfileArn': 'string',
            'DefaultOs': 'string',
            'HostnameTheme': 'string',
            'DefaultAvailabilityZone': 'string',
            'DefaultSubnetId': 'string',
            'CustomJson': 'string',
            'ConfigurationManager': {
                'Name': 'string',
                'Version': 'string'
            },
            'ChefConfiguration': {
                'ManageBerkshelf': True|False,
                'BerkshelfVersion': 'string'
            },
            'UseCustomCookbooks': True|False,
            'UseOpsworksSecurityGroups': True|False,
            'CustomCookbooksSource': {
                'Type': 'git'|'svn'|'archive'|'s3',
                'Url': 'string',
                'Username': 'string',
                'Password': 'string',
                'SshKey': 'string',
                'Revision': 'string'
            },
            'DefaultSshKeyName': 'string',
            'CreatedAt': 'string'
        }
    ]
}
```
Response Structure

- (dict) –
  Contains the response to a DescribeStacks request.
  - Stacks (list) –
    An array of Stack objects that describe the stacks.
    * (dict) –
      Describes a stack.
      - StackId (string) –
        The stack ID.
      - Name (string) –
        The stack name.
      - Arn (string) –
        The stack’s ARN.
      - Region (string) –
        The stack AWS region, such as “us-east-1”. For more information about AWS regions, see Regions and Endpoints.
      - VpcId (string) –
        The VPC ID; applicable only if the stack is running in a VPC.
      - Attributes (dict) –
        The stack’s attributes.
        - (string) –
        - (string) –
      - ServiceRoleArn (string) –
        The stack AWS Identity and Access Management (IAM) role.
      - DefaultInstanceProfileArn (string) –
        The ARN of an IAM profile that is the default profile for all of the stack’s EC2 instances. For more information about IAM ARNs, see Using Identifiers.
      - DefaultOs (string) –
        The stack’s default operating system.
      - HostnameTheme (string) –
        The stack host name theme, with spaces replaced by underscores.
      - DefaultAvailabilityZone (string) –
        The stack’s default Availability Zone. For more information, see Regions and Endpoints.
      - DefaultSubnetId (string) –
        The default subnet ID; applicable only if the stack is running in a VPC.
CustomJson (string)

A JSON object that contains user-defined attributes to be added to the stack configuration and deployment attributes. You can use custom JSON to override the corresponding default stack configuration attribute values or to pass data to recipes. The string should be in the following format and must escape characters such as ‘”’:

```
{"key1": "value1",
 "key2": "value2",...
```

For more information on custom JSON, see Use Custom JSON to Modify the Stack Configuration Attributes.

ConfigurationManager (dict)

The configuration manager.

Name (string)

The name. This parameter must be set to “Chef”.

Version (string)

The Chef version. This parameter must be set to 0.9, 11.4, or 11.10. The default value is 11.4.

ChefConfiguration (dict)

A ChefConfiguration object that specifies whether to enable Berkshelf and the Berkshelf version. For more information, see Create a New Stack.

ManageBerkshelf (boolean)

Whether to enable Berkshelf.

BerkshelfVersion (string)

The Berkshelf version.

UseCustomCookbooks (boolean)

Whether the stack uses custom cookbooks.

UseOpsworksSecurityGroups (boolean)

Whether the stack automatically associates the AWS OpsWorks built-in security groups with the stack’s layers.

CustomCookbooksSource (dict)

Contains the information required to retrieve an app or cookbook from a repository. For more information, see Creating Apps or Custom Recipes and Cookbooks.

Type (string)

The repository type.

Url (string)

The source URL.

Username (string)

This parameter depends on the repository type. For Amazon S3 bundles, set Username to the appropriate IAM access key ID. For HTTP bundles, Git repositories, and Subversion repositories, set Username to the user name.

Password (string)
When included in a request, the parameter depends on the repository type.

- For Amazon S3 bundles, set `Password` to the appropriate IAM secret access key.
- For HTTP bundles and Subversion repositories, set `Password` to the password.

For more information on how to safely handle IAM credentials, see [http://docs.aws.amazon.com/general/latest/gr/aws-access-keys-best-practices.html](http://docs.aws.amazon.com/general/latest/gr/aws-access-keys-best-practices.html).

In responses, AWS OpsWorks returns "*****FILTERED*****" instead of the actual value.

- `Username` *(string)* –

  In requests, the repository’s SSH key.

  In responses, AWS OpsWorks returns "*****FILTERED*****" instead of the actual value.

- `Revision` *(string)* –

  The application’s version. AWS OpsWorks enables you to easily deploy new versions of an application. One of the simplest approaches is to have branches or revisions in your repository that represent different versions that can potentially be deployed.

- `DefaultSshKeyName` *(string)* –

  A default Amazon EC2 key pair for the stack’s instances. You can override this value when you create or update an instance.

- `CreatedAt` *(string)* –

  The date when the stack was created.

- `DefaultRootDeviceType` *(string)* –

  The default root device type. This value is used by default for all instances in the stack, but you can override it when you create an instance. For more information, see [Storage for the Root Device](#).  

- `AgentVersion` *(string)* –

  The agent version. This parameter is set to `LATEST` for auto-update. or a version number for a fixed agent version.

### describe_time_based_auto_scaling(**kwargs)**

Describes time-based auto scaling configurations for specified instances.

**Note:** You must specify at least one of the parameters.

**Required Permissions:** To use this action, an IAM user must have a Show, Deploy, or Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see [Managing User Permissions](#).

**Request Syntax**

```python
response = client.describe_time_based_auto_scaling(
    InstanceIds=[
        'string',
    ]
)
```
Parameters  **InstanceIds (list)** – [REQUIRED]

An array of instance IDs.

* (string) –

Return type  dict

Returns

Response Syntax

```python
{
    'TimeBasedAutoScalingConfigurations': [
        {
            'InstanceId': 'string',
            'AutoScalingSchedule': {
                'Monday': {
                    'string': 'string'
                },
                'Tuesday': {
                    'string': 'string'
                },
                'Wednesday': {
                    'string': 'string'
                },
                'Thursday': {
                    'string': 'string'
                },
                'Friday': {
                    'string': 'string'
                },
                'Saturday': {
                    'string': 'string'
                },
                'Sunday': {
                    'string': 'string'
                }
            }
        }
    ]
}
```

Response Structure

* (dict) –

Contains the response to a DescribeTimeBasedAutoScaling request.

- **TimeBasedAutoScalingConfigurations (list)** –

An array of TimeBasedAutoScalingConfiguration objects that describe the configuration for the specified instances.

* (dict) –

Describes an instance’s time-based auto scaling configuration.

* **InstanceId (string)** –

The instance ID.

* **AutoScalingSchedule (dict)** –

A WeeklyAutoScalingSchedule object with the instance schedule.

* **Monday (dict)** –
The schedule for Monday.
  · (string) –
  · (string) –
  · **Tuesday** (dict) –
    The schedule for Tuesday.
    · (string) –
    · (string) –
  · **Wednesday** (dict) –
    The schedule for Wednesday.
    · (string) –
    · (string) –
  · **Thursday** (dict) –
    The schedule for Thursday.
    · (string) –
    · (string) –
  · **Friday** (dict) –
    The schedule for Friday.
    · (string) –
    · (string) –
  · **Saturday** (dict) –
    The schedule for Saturday.
    · (string) –
    · (string) –
  · **Sunday** (dict) –
    The schedule for Sunday.
    · (string) –
    · (string) –

**describe_user_profiles** (**kwargs)
Describe specified users.

**Required Permissions**: To use this action, an IAM user must have an attached policy that explicitly grants permissions. For more information on user permissions, see [Managing User Permissions](#).

**Request Syntax**

```python
response = client.describe_user_profiles(
    IamUserArns=[
      'string',
    ]
)
```

**Parameters**  
**IamUserArns** *(list)* – An array of IAM user ARNs that identify the users to be described.
  · (string) –

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
  'UserProfiles': [
    {
      ...
    }
  ]
}
```
Response Structure
• (dict) –
  Contains the response to a DescribeUserProfiles request.
  – UserProfiles (list) –
    A Users object that describes the specified users.
    * (dict) –
      Describes a user’s SSH information.
      · IamUserArn (string) –
        The user’s IAM ARN.
      · Name (string) –
        The user’s name.
      · SshUsername (string) –
        The user’s SSH user name.
      · SshPublicKey (string) –
        The user’s SSH public key.
      · AllowSelfManagement (boolean) –
        Whether users can specify their own SSH public key through the My Settings page. For more information, see Managing User Permissions.

describe_volumes(**kwargs)
Describes an instance’s Amazon EBS volumes.

Note: You must specify at least one of the parameters.

Required Permissions : To use this action, an IAM user must have a Show, Deploy, or Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

Request Syntax

response = client.describe_volumes(
    InstanceId='string',
    StackId='string',
    RaidArrayId='string',
    VolumeIds=[
        'string',
    ],
)

Parameters
- **InstanceId** *(string)* – The instance ID. If you use this parameter, `DescribeVolumes` returns descriptions of the volumes associated with the specified instance.

- **StackId** *(string)* – A stack ID. The action describes the stack’s registered Amazon EBS volumes.

- **RaidArrayId** *(string)* – The RAID array ID. If you use this parameter, `DescribeVolumes` returns descriptions of the volumes associated with the specified RAID array.

- **VolumeIds** *(list)* – An array of volume IDs. If you use this parameter, `DescribeVolumes` returns descriptions of the specified volumes. Otherwise, it returns a description of every volume.

  - (string)

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Volumes': [
        {
            'VolumeId': 'string',
            'Ec2VolumeId': 'string',
            'Name': 'string',
            'RaidArrayId': 'string',
            'InstanceId': 'string',
            'Status': 'string',
            'Size': 123,
            'Device': 'string',
            'MountPoint': 'string',
            'Region': 'string',
            'AvailabilityZone': 'string',
            'VolumeType': 'string',
            'Iops': 123
        }
    ]
}
```

**Response Structure**

- *(dict)*

  Contains the response to a `DescribeVolumes` request.

  - **Volumes** *(list)*

    An array of volume IDs.

    - *(dict)*

      Describes an instance’s Amazon EBS volume.

      - **VolumeId** *(string)*

        The volume ID.

      - **Ec2VolumeId** *(string)*

        The Amazon EC2 volume ID.

      - **Name** *(string)*

        The volume name.

      - **RaidArrayId** *(string)*

        The RAID array ID.
· **InstanceId** *(string)* –
  The instance ID.
· **Status** *(string)* –
  The value returned by `DescribeVolumes`.
· **Size** *(integer)* –
  The volume size.
· **Device** *(string)* –
  The device name.
· **MountPoint** *(string)* –
  The volume mount point. For example “/dev/sdh”.
· **Region** *(string)* –
  The AWS region. For more information about AWS regions, see `Regions and Endpoints`.
· **AvailabilityZone** *(string)* –
  The volume Availability Zone. For more information, see `Regions and Endpoints`.
· **VolumeType** *(string)* –
  The volume type, standard or PIOPS.
· **Iops** *(integer)* –
  For PIOPS volumes, the IOPS per disk.

```python
# Boto3 Documentation, Release 1.1.4

**detach_elastic_load_balancer(**kwargs):**
Detaches a specified Elastic Load Balancing instance from its layer.

**Required Permissions:** To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see `Managing User Permissions`.

**Request Syntax**

```python
response = client.detach_elastic_load_balancer(
    ElasticLoadBalancerName='string',
    LayerId='string'
)
```

**Parameters**

- **ElasticLoadBalancerName** *(string)* – [REQUIRED]
  The Elastic Load Balancing instance’s name.
- **LayerId** *(string)* – [REQUIRED]
  The ID of the layer that the Elastic Load Balancing instance is attached to.

**Returns** None

```python
# Boto3 Documentation, Release 1.1.4

**disassociate_elastic_ip(**kwargs):**
Disassociates an Elastic IP address from its instance. The address remains registered with the stack. For more information, see `Resource Management`.

**Required Permissions:** To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see `Managing User Permissions`.

**Request Syntax**

```python
```
response = client.disassociate_elastic_ip(
    ElasticIp='string'
)

Parameters

**ElasticIp** *(string)* – [REQUIRED]

The Elastic IP address.

Returns

None

generate_presigned_url *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

Parameters

- **ClientMethod** *(string)* – The client method to presign for
- **Params** *(dict)* – The parameters normally passed to `ClientMethod`.
- **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns

The presigned url

get_hostname_suggestion (**kwargs)**

Gets a generated host name for the specified layer, based on the current host name theme.

*Required Permissions*: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

Request Syntax

response = client.get_hostname_suggestion(
    LayerId='string'
)

Parameters

**LayerId** *(string)* – [REQUIRED]

The layer ID.

Return type

dict

Returns

Response Syntax

```
{
    'LayerId': 'string',
    'Hostname': 'string'
}
```

Response Structure

- *(dict)* – Contains the response to a GetHostnameSuggestion request.
  - **LayerId** *(string)* – The layer ID.
  - **Hostname** *(string)* – The generated host name.

get Paginator *(operation_name)*

Create a paginator for an operation.
Parameters operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

Raises OperationNotPageableError Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

Return type L{botocore.paginate.Paginator} Returns A paginator object.

get_waiter (waiter_name)

grant_access (**kwargs)

Note: This action can be used only with Windows stacks.

Grants RDP access to a Windows instance for a specified time period.

Request Syntax

response = client.grant_access(
    InstanceId='string',
    ValidForInMinutes=123
)

Parameters

• InstanceId (string) – [REQUIRED]

The instance’s AWS OpsWorks ID.

• ValidForInMinutes (integer) – The length of time (in minutes) that the grant is valid. When the grant expires at the end of this period, the user will no longer be able to use the credentials to log in. If the user is logged in at the time, he or she automatically will be logged out.

Return type dict

Returns

Response Syntax

{
    'TemporaryCredential': {
        'Username': 'string',
        'Password': 'string',
        'ValidForInMinutes': 123,
        'InstanceId': 'string'
    }
}

Response Structure

• (dict) –

    Contains the response to a GrantAccess request.

    – TemporaryCredential (dict) –

        A TemporaryCredential object that contains the data needed to log in to the instance by RDP clients, such as the Microsoft Remote Desktop Connection.
**Username** *(string)* –
The user name.

**Password** *(string)* –
The password.

**ValidForInMinutes** *(integer)* –
The length of time (in minutes) that the grant is valid. When the grant expires, at the end of this period, the user will no longer be able to use the credentials to log in. If they are logged in at the time, they will be automatically logged out.

**InstanceId** *(string)* –
The instance’s AWS OpsWorks ID.

### reboot_instance(**kwargs)**
Reboots a specified instance. For more information, see [Starting, Stopping, and Rebooting Instances](#).

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see [Managing User Permissions](#).

**Request Syntax**

```python
response = client.reboot_instance(
    InstanceId='string'
)
```

**Parameters**

**InstanceId** *(string)* – [REQUIRED]
The instance ID.

**Returns**

None

### register_ecs_cluster(**kwargs)**
Registers a specified Amazon ECS cluster with a stack. You can register only one cluster with a stack. A cluster can be registered with only one stack. For more information, see [Resource Management](#).

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack or an attached policy that explicitly grants permissions. For more information on user permissions, see [Managing User Permissions](#).

**Request Syntax**

```python
response = client.register_ecs_cluster(
    EcsClusterArn='string',
    StackId='string'
)
```

**Parameters**

- **EcsClusterArn** *(string)* – [REQUIRED]
The cluster’s ARN.
- **StackId** *(string)* – [REQUIRED]
The stack ID.

**Return type**

dict

**Returns**

None

### Response Syntax
register_elastic_ip (**kwargs)

Registers an Elastic IP address with a specified stack. An address can be registered with only one stack at a time. If the address is already registered, you must first deregister it by calling DeregisterElasticIp. For more information, see Resource Management.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.register_elastic_ip(
    ElasticIp='string',
    StackId='string'
)
```

**Parameters**

- **ElasticIp** *(string)* – [REQUIRED]
  
  The Elastic IP address.

- **StackId** *(string)* – [REQUIRED]
  
  The stack ID.

**Response Syntax**

```json
{
    'ElasticIp': 'string'
}
```

**Response Structure**

- *(dict)* –

  Contains the response to a RegisterElasticIp request.

    - **ElasticIp** *(string)*
      
      The Elastic IP address.

**register_instance (**kwargs)**

Registers instances with a specified stack that were created outside of AWS OpsWorks.

**Note**: We do not recommend using this action to register instances. The complete registration operation has two primary steps, installing the AWS OpsWorks agent on the instance and registering the instance with the stack. RegisterInstance handles only the second step. You should instead use the AWS CLI register command, which performs the entire registration operation. For more information, see Registering an Instance with an AWS OpsWorks Stack.
**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.register_instance(
    StackId='string',
    Hostname='string',
    PublicIp='string',
    PrivateIp='string',
    RsaPublicKey='string',
    RsaPublicKeyFingerprint='string',
    InstanceIdentity={
        'Document': 'string',
        'Signature': 'string'
    }
)
```

**Parameters**

- **StackId** *(string)* – [REQUIRED]
  
  The ID of the stack that the instance is to be registered with.

- **Hostname** *(string)* – The instance’s hostname.

- **PublicIp** *(string)* – The instance’s public IP address.

- **PrivateIp** *(string)* – The instance’s private IP address.

- **RsaPublicKey** *(string)* – The instance’s public RSA key. This key is used to encrypt communication between the instance and the service.

- **RsaPublicKeyFingerprint** *(string)* – The instance’s public RSA key fingerprint.

- **InstanceIdentity** *(dict)* – An InstanceIdentity object that contains the instance’s identity.
  
  - **Document** *(string)* – A JSON document that contains the metadata.
  
  - **Signature** *(string)* – A signature that can be used to verify the document’s accuracy and authenticity.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'InstanceId': 'string'
}
```

**Response Structure**

- *(dict)* – Contains the response to a RegisterInstanceResult request.
  
  - **InstanceId** *(string)* – The registered instance’s AWS OpsWorks ID.

**register_rds_db_instance(**kwargs**)**

Registers an Amazon RDS instance with a stack.
Required Permissions: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

Request Syntax

```python
response = client.register_rds_db_instance(
    StackId='string',
    RdsDbInstanceArn='string',
    DbUser='string',
    DbPassword='string'
)
```

Parameters

- **StackId (string)** – [REQUIRED]
  
The stack ID.
- **RdsDbInstanceArn (string)** – [REQUIRED]
  
The Amazon RDS instance’s ARN.
- **DbUser (string)** – [REQUIRED]
  
The database’s master user name.
- **DbPassword (string)** – [REQUIRED]
  
The database password.

Returns None

register_volume(**kwargs)

Registers an Amazon EBS volume with a specified stack. A volume can be registered with only one stack at a time. If the volume is already registered, you must first deregister it by calling DeregisterVolume. For more information, see Resource Management.

Required Permissions: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

Request Syntax

```python
response = client.register_volume(
    Ec2VolumeId='string',
    StackId='string'
)
```

Parameters

- **Ec2VolumeId (string)** – The Amazon EBS volume ID.
- **StackId (string)** – [REQUIRED]
  
The stack ID.

Returns dict

Response Syntax

```python
{
    'VolumeId': 'string'
}
```

Response Structure
• (dict) –
  Contains the response to a RegisterVolume request.
    – **Volumeld** (string) –
      The volume ID.

**set_load_based_auto_scaling(**kwargs)**

Specify the load-based auto scaling configuration for a specified layer. For more information, see Managing Load with Time-based and Load-based Instances.

**Note:** To use load-based auto scaling, you must create a set of load-based auto scaling instances. Load-based auto scaling operates only on the instances from that set, so you must ensure that you have created enough instances to handle the maximum anticipated load.

**Required Permissions:** To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.set_load_based_auto_scaling(
    LayerId='string',
    Enable=True|False,
    UpScaling={
        'InstanceCount': 123,
        'ThresholdsWaitTime': 123,
        'IgnoreMetricsTime': 123,
        'CpuThreshold': 123.0,
        'MemoryThreshold': 123.0,
        'LoadThreshold': 123.0,
        'Alarms': [
            'string',
        ]
    },
    DownScaling={
        'InstanceCount': 123,
        'ThresholdsWaitTime': 123,
        'IgnoreMetricsTime': 123,
        'CpuThreshold': 123.0,
        'MemoryThreshold': 123.0,
        'LoadThreshold': 123.0,
        'Alarms': [
            'string',
        ]
    }
)
```

**Parameters**

- **LayerId** (string) – [REQUIRED]
  The layer ID.
- **Enable** (boolean) – Enables load-based auto scaling for the layer.
- **UpScaling** (dict) – An AutoScalingThresholds object with the upscaling threshold configuration. If the load exceeds these thresholds for a specified amount of time, AWS OpsWorks starts a specified number of instances.
  - **InstanceCount** (integer) –
The number of instances to add or remove when the load exceeds a threshold.

- **ThresholdsWaitTime** (*integer*) –
  The amount of time, in minutes, that the load must exceed a threshold before more instances are added or removed.

- **IgnoreMetricsTime** (*integer*) –
  The amount of time (in minutes) after a scaling event occurs that AWS OpsWorks should ignore metrics and suppress additional scaling events. For example, AWS OpsWorks adds new instances following an upscaling event but the instances won’t start reducing the load until they have been booted and configured. There is no point in raising additional scaling events during that operation, which typically takes several minutes. **IgnoreMetricsTime** allows you to direct AWS OpsWorks to suppress scaling events long enough to get the new instances online.

- **CpuThreshold** (*float*) –
  The CPU utilization threshold, as a percent of the available CPU.

- **MemoryThreshold** (*float*) –
  The memory utilization threshold, as a percent of the available memory.

- **LoadThreshold** (*float*) –
  The load threshold. For more information about how load is computed, see Load (computing).

- **Alarms** (*list*) –
  Custom Cloudwatch auto scaling alarms, to be used as thresholds. This parameter takes a list of up to five alarm names, which are case sensitive and must be in the same region as the stack.

**Note:** To use custom alarms, you must update your service role to allow `cloudwatch:DescribeAlarms`. You can either have AWS OpsWorks update the role for you when you first use this feature or you can edit the role manually. For more information, see Allowing AWS OpsWorks to Act on Your Behalf.

### DownScaling

- **InstanceCount** (*integer*) –
  The number of instances to add or remove when the load exceeds a threshold.

- **ThresholdsWaitTime** (*integer*) –
  The amount of time, in minutes, that the load must exceed a threshold before more instances are added or removed.

- **IgnoreMetricsTime** (*integer*) –
  The amount of time (in minutes) after a scaling event occurs that AWS OpsWorks should ignore metrics and suppress additional scaling events. For example, AWS OpsWorks adds new instances following an upscaling event but the instances won’t start reducing the load until they have been booted and configured. There is no point in raising additional scaling events during that operation, which typically takes several minutes.
IgnoreMetricsTime allows you to direct AWS OpsWorks to suppress scaling events long enough to get the new instances online.

- **CpuThreshold (float)** –
  The CPU utilization threshold, as a percent of the available CPU.

- **MemoryThreshold (float)** –
  The memory utilization threshold, as a percent of the available memory.

- **LoadThreshold (float)** –
  The load threshold. For more information about how load is computed, see Load (computing).

- **Alarms (list)** –
  Custom Cloudwatch auto scaling alarms, to be used as thresholds. This parameter takes a list of up to five alarm names, which are case sensitive and must be in the same region as the stack.

**Note:** To use custom alarms, you must update your service role to allow cloudwatch:DescribeAlarms. You can either have AWS OpsWorks update the role for you when you first use this feature or you can edit the role manually. For more information, see Allowing AWS OpsWorks to Act on Your Behalf.

```
* (string) –
```

**set_permission(**kwargs)**

Specifies a user’s permissions. For more information, see Security and Permissions.

**Required Permissions:** To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.set_permission(
    StackId='string',
    IamUserArn='string',
    AllowSsh=True|False,
    AllowSudo=True|False,
    Level='string'
)
```

**Parameters**

- **StackId (string)** – [REQUIRED]
  The stack ID.

- **IamUserArn (string)** – [REQUIRED]
  The user’s IAM ARN.

- **AllowSsh (boolean)** – The user is allowed to use SSH to communicate with the instance.

- **AllowSudo (boolean)** – The user is allowed to use sudo to elevate privileges.

- **Level (string)** – The user’s permission level, which must be set to one of the following strings. You cannot set your own permissions level.
  - deny
  - show
  - deploy
For more information on the permissions associated with these levels, see Managing User Permissions.

Returns
None

set_time_based_auto_scaling(**kwargs)
Specify the time-based auto scaling configuration for a specified instance. For more information, see Managing Load with Time-based and Load-based Instances.

Required Permissions: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

Request Syntax

response = client.set_time_based_auto_scaling(
    InstanceId='string',
    AutoScalingSchedule={
        'Monday': {
            'string': 'string'
        },
        'Tuesday': {
            'string': 'string'
        },
        'Wednesday': {
            'string': 'string'
        },
        'Thursday': {
            'string': 'string'
        },
        'Friday': {
            'string': 'string'
        },
        'Saturday': {
            'string': 'string'
        },
        'Sunday': {
            'string': 'string'
        }
    }
)

Parameters
• InstanceId (string) – [REQUIRED]
  The instance ID.
• AutoScalingSchedule (dict) – An AutoScalingSchedule with the instance schedule.
  – Monday (dict) –
    The schedule for Monday.
    * (string) –
      · (string) –
  – Tuesday (dict) –
    The schedule for Tuesday.
    * (string) –
      · (string) –
– **Wednesday** (*dict*) –

The schedule for Wednesday.

* (string) –
  · (string) –

– **Thursday** (*dict*) –

The schedule for Thursday.

* (string) –
  · (string) –

– **Friday** (*dict*) –

The schedule for Friday.

* (string) –
  · (string) –

– **Saturday** (*dict*) –

The schedule for Saturday.

* (string) –
  · (string) –

– **Sunday** (*dict*) –

The schedule for Sunday.

* (string) –
  · (string) –

**Returns** None

**start_instance** (**kwargs**)

Starts a specified instance. For more information, see Starting, Stopping, and Rebooting Instances.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.start_instance(
    InstanceId='string'
)
```

**Parameters**

**InstanceId** (*string*) – [REQUIRED]

The instance ID.

**Returns** None

**start_stack** (**kwargs**)

Starts a stack’s instances.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.start_stack(
    StackId='string'
)
```

**Parameters**

**StackId** (*string*) – [REQUIRED]

The stack ID.
Returns None

**stop_instance(****kwargs**

Stops a specified instance. When you stop a standard instance, the data disappears and must be reinstalled when you restart the instance. You can stop an Amazon EBS-backed instance without losing data. For more information, see Starting, Stopping, and Rebooting Instances.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.stop_instance(
    InstanceId='string'
)
```

**Parameters** `InstanceId (string)` – [REQUIRED]

- The instance ID.

**Returns** None

**stop_stack(****kwargs**

Stops a specified stack.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.stop_stack(
    StackId='string'
)
```

**Parameters** `StackId (string)` – [REQUIRED]

- The stack ID.

**Returns** None

**unassign_instance(****kwargs**

Unassigns a registered instance from all of it’s layers. The instance remains in the stack as an unassigned instance and can be assigned to another layer, as needed. You cannot use this action with instances that were created with AWS OpsWorks.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.unassign_instance(
    InstanceId='string'
)
```

**Parameters** `InstanceId (string)` – [REQUIRED]

- The instance ID.

**Returns** None
**unassign_volume(**kwargs)**

Unassigns an assigned Amazon EBS volume. The volume remains registered with the stack. For more information, see Resource Management.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.unassign_volume(
    VolumeId='string'
)
```

**Parameters**

- **VolumeId** *(string)* – [REQUIRED]

  The volume ID.

**Returns**

- None

**update_app(**kwargs)**

Updates a specified app.

**Required Permissions**: To use this action, an IAM user must have a Deploy or Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.update_app(
    AppId='string',
    Name='string',
    Description='string',
    DataSources=[
        {  
            'Type': 'string',
            'Arn': 'string',
            'DatabaseName': 'string'
        },
    ],
    Type='aws-flow-ruby'|'java'|'rails'|'php'|'nodejs'|'static'|'other',
    AppSource={
        'Type': 'git'|'svn'|'archive'|'s3',
        'Url': 'string',
        'Username': 'string',
        'Password': 'string',
        'SshKey': 'string',
        'Revision': 'string'
    },
    Domains=[
        'string',
    ],
    EnableSsl=True|False,
    SslConfiguration={
        'Certificate': 'string',
        'PrivateKey': 'string',
        'Chain': 'string'
    },
    Attributes={
        'string': 'string'
    }
)
```
Environment=[
    {
        'Key': 'string',
        'Value': 'string',
        'Secure': True|False
    },
]

Parameters

- **AppId** *(string)* – [REQUIRED]
  The app ID.

- **Name** *(string)* – The app name.

- **Description** *(string)* – A description of the app.

- **DataSources** *(list)* – The app’s data sources.
  - *(dict)* –
    Describes an app’s data source.
    - **Type** *(string)* –
      The data source’s type, *AutoSelectOpsworksMysqlInstance*, *OpsworksMysqlInstance*, or *RdsDbInstance*.
    - **Arn** *(string)* –
      The data source’s ARN.
    - **DatabaseName** *(string)* –
      The database name.

- **Type** *(string)* – The app type.

- **AppSource** *(dict)* – A `Source` object that specifies the app repository.
  - **Type** *(string)* –
    The repository type.
  - **Url** *(string)* –
    The source URL.
  - **Username** *(string)* –
    This parameter depends on the repository type.
    - For Amazon S3 bundles, set `Username` to the appropriate IAM access key ID.
    - For HTTP bundles, Git repositories, and Subversion repositories, set `Username` to the user name.
  - **Password** *(string)* –
    When included in a request, the parameter depends on the repository type.
    - For Amazon S3 bundles, set `Password` to the appropriate IAM secret access key.
    - For HTTP bundles and Subversion repositories, set `Password` to the password.

For more information on how to safely handle IAM credentials, see [http://docs.aws.amazon.com/general/latest/gr/aws-access-keys-best-practices.html](http://docs.aws.amazon.com/general/latest/gr/aws-access-keys-best-practices.html).

In responses, AWS OpsWorks returns *****FILTERED***** instead of the actual value.

- **SshKey** *(string)* –
In requests, the repository’s SSH key.

In responses, AWS OpsWorks returns *****FILTERED***** instead of the actual value.

- **Revision (string)** –
  
  The application’s version. AWS OpsWorks enables you to easily deploy new versions of an application. One of the simplest approaches is to have branches or revisions in your repository that represent different versions that can potentially be deployed.

- **Domains (list)** – The app’s virtual host settings, with multiple domains separated by commas. For example: ‘www.example.com, example.com’
  
  - **(string)** –

- **EnableSsl (boolean)** – Whether SSL is enabled for the app.

- **SslConfiguration (dict)** – An SslConfiguration object with the SSL configuration.
  
  - **Certificate (string)** – [REQUIRED]
    
    The contents of the certificate’s domain.crt file.
  
  - **PrivateKey (string)** – [REQUIRED]
    
    The private key; the contents of the certificate’s domain.kex file.
  
  - **Chain (string)** –
    
    Optional. Can be used to specify an intermediate certificate authority key or client authentication.

- **Attributes (dict)** – One or more user-defined key/value pairs to be added to the stack attributes.
  
  - **(string)** –
    
    * **(string)** –

- **Environment (list)** – An array of EnvironmentVariable objects that specify environment variables to be associated with the app. After you deploy the app, these variables are defined on the associated app server instances. For more information, see Environment Variables.

  There is no specific limit on the number of environment variables. However, the size of the associated data structure - which includes the variables’ names, values, and protected flag values - cannot exceed 10 KB (10240 Bytes). This limit should accommodate most if not all use cases. Exceeding it will cause an exception with the message, “Environment: is too large (maximum is 10KB).”

**Note:** This parameter is supported only by Chef 11.10 stacks. If you have specified one or more environment variables, you cannot modify the stack’s Chef version.

- **(dict)** –

  Represents an app’s environment variable.

  * **Key (string)** – [REQUIRED]
    
    (Required) The environment variable’s name, which can consist of up to 64 characters and must be specified. The name can contain upper- and lowercase letters, numbers, and underscores (_), but it must start with a letter or underscore.

  * **Value (string)** – [REQUIRED]
    
    (Optional) The environment variable’s value, which can be left empty. If you specify a value, it can contain up to 256 characters,
which must all be printable.

* Secure (boolean) –

  (Optional) Whether the variable’s value will be returned by the DescribeApps action. To conceal an environment variable’s value, set Secure to true. DescribeApps then returns *****FILTERED****** instead of the actual value. The default value for Secure is false.

Returns None

update_elastic_ip(**kwargs)

Updates a registered Elastic IP address’s name. For more information, see Resource Management.

Required Permissions: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

Request Syntax

```python
response = client.update_elastic_ip(
    ElasticIp='string',
    Name='string'
)
```

Parameters

- **ElasticIp (string)** – [REQUIRED]
  
  The address.

- **Name (string)** – The new name.

Returns None

update_instance(**kwargs)

Updates a specified instance.

Required Permissions: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

Request Syntax

```python
response = client.update_instance(
    InstanceId='string',
    LayerIds=[
        'string',
    ],
    InstanceType='string',
    AutoScalingType='load'|'timer',
    Hostname='string',
    Os='string',
    AmiId='string',
    SshKeyName='string',
    Architecture='x86_64'|'i386',
    InstallUpdatesOnBoot=True|False,
    EbsOptimized=True|False,
    AgentVersion='string'
)
```

Parameters
• **InstanceId** *(string)* – [REQUIRED]
  
  The instance ID.

• **LayerIds** *(list)* – The instance’s layer IDs.
  
  – *(string)* –

• **InstanceType** *(string)* – The instance type, such as t2.micro. For a list of supported instance types, open the stack in the console, choose **Instances**, and choose **+ Instance**. The **Size** list contains the currently supported types. For more information, see **Instance Families and Types**. The parameter values that you use to specify the various types are in the **API Name** column of the **Available Instance Types** table.

• **AutoScalingType** *(string)* – For load-based or time-based instances, the type. Windows stacks can use only time-based instances.

• **Hostname** *(string)* – The instance host name.

• **Os** *(string)* – The instance’s operating system, which must be set to one of the following.
  
  – A supported Linux operating system: An Amazon Linux version, such as Amazon Linux 2015.03, Red Hat Enterprise Linux 7, Ubuntu 12.04 LTS, or Ubuntu 14.04 LTS.
  – Microsoft Windows Server 2012 R2 Base.
  – A custom AMI: Custom.

  For more information on the supported operating systems, see **AWS OpsWorks Operating Systems**.

  The default option is the current Amazon Linux version. If you set this parameter to **Custom**, you must use the **AmiId** parameter to specify the custom AMI that you want to use. For more information on the supported operating systems, see **Operating Systems**. For more information on how to use custom AMIs with OpsWorks, see **Using Custom AMIs**.

  **Note:** You can specify a different Linux operating system for the updated stack, but you cannot change from Linux to Windows or Windows to Linux.

• **AmiId** *(string)* – A custom AMI ID to be used to create the instance. The AMI must be based on one of the supported operating systems. For more information, see **Instances**

  **Note:** If you specify a custom AMI, you must set **Os** to **Custom**.

• **SshKeyName** *(string)* – The instance’s Amazon EC2 key name.

• **Architecture** *(string)* – The instance architecture. Instance types do not necessarily support both architectures. For a list of the architectures that are supported by the different instance types, see **Instance Families and Types**.

• **InstallUpdatesOnBoot** *(boolean)* – Whether to install operating system and package updates when the instance boots. The default value is **true**. To control when updates are installed, set this value to **false**. You must then update your instances manually by using CreateDeployment to run the **update_dependencies** stack command or by manually running **yum** (Amazon Linux) or **apt-get** (Ubuntu) on the instances.

  **Note:** We strongly recommend using the default value of **true**, to ensure that your instances have the latest security updates.

• **EbsOptimized** *(boolean)* – This property cannot be updated.

• **AgentVersion** *(string)* – The default AWS OpsWorks agent version. You have the following options:
– INHERIT - Use the stack’s default agent version setting.
– version_number - Use the specified agent version. This value overrides
the stack’s default setting. To update the agent version, you must edit the
instance configuration and specify a new version. AWS OpsWorks then
automatically installs that version on the instance.

The default setting is INHERIT. To specify an agent version, you must use the
complete version number, not the abbreviated number shown on the console. For
a list of available agent version numbers, call DescribeAgentVersions.

Returns None

update_layer(**kwargs)
Updates a specified layer.

Required Permissions: To use this action, an IAM user must have a Manage permissions level for the
stack, or an attached policy that explicitly grants permissions. For more information on user permissions,
see Managing User Permissions.

Request Syntax

response = client.update_layer(
    LayerId='string',
    Name='string',
    Shortname='string',
    Attributes={
        'string': 'string'
    },
    CustomInstanceProfileArn='string',
    CustomJson='string',
    CustomSecurityGroupIds=[
        'string',
    ],
    Packages=[
        'string',
    ],
    VolumeConfigurations=[
        {
            'MountPoint': 'string',
            'RaidLevel': 123,
            'NumberOfDisks': 123,
            'Size': 123,
            'VolumeType': 'string',
            'Iops': 123
        },
    ],
    EnableAutoHealing=True|False,
    AutoAssignElasticIps=True|False,
    AutoAssignPublicIps=True|False,
    CustomRecipes={
        'Setup': [
            'string',
        ],
        'Configure': [
            'string',
        ],
        'Deploy': [
            'string',
        ],
        'Undeploy': [
    }
Parameters

- **LayerId** *(string)* – [REQUIRED]
  The layer ID.
- **Name** *(string)* – The layer name, which is used by the console.
- **Shortname** *(string)* – For custom layers only, use this parameter to specify the
  layer’s short name, which is used internally by AWS OpsWorks and by Chef. The
  short name is also used as the name for the directory where your app files are
  installed. It can have a maximum of 200 characters and must be in the following
  format: /A[a-z0-9-_.]+Z/.
  The built-in layers’ short names are defined by AWS OpsWorks. For more infor-
  mation, see the Layer Reference.
- **Attributes** *(dict)* – One or more user-defined key/value pairs to be added to the
  stack attributes.
  - *(string)* –
    - **CustomInstanceProfileArn** *(string)* – The ARN of an IAM profile to be used
      for all of the layer’s EC2 instances. For more information about IAM ARNs, see
      Using Identifiers.
    - **CustomJson** *(string)* – A JSON-formatted string containing custom stack con-
      figuration and deployment attributes to be installed on the layer’s instances. For
      more information, see Using Custom JSON.
    - **CustomSecurityGroupId** *(list)* – An array containing the layer’s custom security
      group IDs.
      - *(string)* –
    - **Packages** *(list)* – An array of Package objects that describe the layer’s pack-
      ages.
      - *(string)* –
    - **VolumeConfigurations** *(list)* – A VolumeConfigurations object that de-
      scribes the layer’s Amazon EBS volumes.
      - *(dict)* –
        Describes an Amazon EBS volume configuration.
        - **MountPoint** *(string)* – [REQUIRED]
          The volume mount point. For example “/dev/sdh”.
        - **RaidLevel** *(integer)* –
          The volume RAID level.
        - **NumberOfDisks** *(integer)* – [REQUIRED]
The number of disks in the volume.

* **Size (integer)** – [REQUIRED]

The volume size.

* **VolumeType (string)** –

The volume type:
- standard - Magnetic
- io1 - Provisioned IOPS (SSD)
- gp2 - General Purpose (SSD)

* **Iops (integer)** –

For PIOPS volumes, the IOPS per disk.

- **EnableAutoHealing (boolean)** – Whether to disable auto healing for the layer.
- **AutoAssignElasticIps (boolean)** – Whether to automatically assign an Elastic IP address to the layer’s instances. For more information, see How to Edit a Layer.
- **AutoAssignPublicIps (boolean)** – For stacks that are running in a VPC, whether to automatically assign a public IP address to the layer’s instances. For more information, see How to Edit a Layer.
- **CustomRecipes (dict)** – A **LayerCustomRecipes** object that specifies the layer’s custom recipes.
  - **Setup (list)** –
    An array of custom recipe names to be run following a setup event.
    * **(string)** –
  - **Configure (list)** –
    An array of custom recipe names to be run following a configure event.
    * **(string)** –
  - **Deploy (list)** –
    An array of custom recipe names to be run following a deploy event.
    * **(string)** –
  - **Undeploy (list)** –
    An array of custom recipe names to be run following a undeploy event.
    * **(string)** –
  - **Shutdown (list)** –
    An array of custom recipe names to be run following a shutdown event.
    * **(string)** –

- **InstallUpdatesOnBoot (boolean)** – Whether to install operating system and package updates when the instance boots. The default value is true. To control when updates are installed, set this value to false. You must then update your instances manually by using CreateDeployment to run the update_dependencies stack command or manually running `yum` (Amazon Linux) or `apt-get` (Ubuntu) on the instances.

**Note:** We strongly recommend using the default value of true, to ensure that your instances have the latest security updates.

- **UseEbsOptimizedInstances (boolean)** – Whether to use Amazon EBS-optimized instances.
- **LifecycleEventConfiguration (dict)** –
  - **Shutdown (dict)** –
    A ShutdownEventConfiguration object that specifies the Shutdown event configuration.
* **ExecutionTimeout** (integer) –

The time, in seconds, that AWS OpsWorks will wait after triggering a Shutdown event before shutting down an instance.

* **DelayUntilElbConnectionsDrained** (boolean) –

Whether to enable Elastic Load Balancing connection draining. For more information, see [Connection Draining](#).

Returns None

update_my_user_profile(**kwargs**)

Updates a user’s SSH public key.

**Required Permissions**: To use this action, an IAM user must have self-management enabled or an attached policy that explicitly grants permissions. For more information on user permissions, see [Managing User Permissions](#).

**Request Syntax**

```python
response = client.update_my_user_profile(
    SshPublicKey='string'
)
```

**Parameters**

- **SshPublicKey** (string) – The user’s SSH public key.

Returns None

update_rds_db_instance(**kwargs**)

Updates an Amazon RDS instance.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see [Managing User Permissions](#).

**Request Syntax**

```python
response = client.update_rds_db_instance(
    RdsDbInstanceArn='string',
    DbUser='string',
    DbPassword='string'
)
```

**Parameters**

- **RdsDbInstanceArn** (string) – [REQUIRED]

  The Amazon RDS instance’s ARN.

- **DbUser** (string) – The master user name.

- **DbPassword** (string) – The database password.

Returns None

update_stack(**kwargs**)

 Updates a specified stack.

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see [Managing User Permissions](#).

**Request Syntax**

```python
response = client.update_stack(
    StackId='string',
    Name='string',
)
```
Attributes={
    'string': 'string'
},
ServiceRoleArn='string',
DefaultInstanceProfileArn='string',
DefaultOs='string',
HostnameTheme='string',
DefaultAvailabilityZone='string',
DefaultSubnetId='string',
CustomJson='string',
ConfigurationManager={
    'Name': 'string',
    'Version': 'string'
},
ChefConfiguration={
    'ManageBerkshelf': True|False,
    'BerkshelfVersion': 'string'
},
UseCustomCookbooks=True|False,
CustomCookbooksSource={
    'Type': 'git'|'svn'|'archive'|'s3',
    'Url': 'string',
    'Username': 'string',
    'Password': 'string',
    'SshKey': 'string',
    'Revision': 'string'
},
DefaultSshKeyName='string',
DefaultRootDeviceType='ebs'|'instance-store',
UseOpsworksSecurityGroups=True|False,
AgentVersion='string'
)

Parameters

• **StackId** *(string) – [REQUIRED]*
  The stack ID.
• **Name** *(string) –* The stack’s new name.
• **Attributes** *(dict) –* One or more user-defined key-value pairs to be added to the stack attributes.
  – *(string) –
  * *(string) –*
• **ServiceRoleArn** *(string) –* Do not use this parameter. You cannot update a stack’s service role.
• **DefaultInstanceProfileArn** *(string) –* The ARN of an IAM profile that is the default profile for all of the stack’s EC2 instances. For more information about IAM ARNs, see Using Identifiers.
• **DefaultOs** *(string) –* The stack’s operating system, which must be set to one of the following:
  – A supported Linux operating system: An Amazon Linux version, such as Amazon Linux 2015.03, Red Hat Enterprise Linux 7, Ubuntu 12.04 LTS, or Ubuntu 14.04 LTS.
  – Microsoft Windows Server 2012 R2 Base.
  – A custom AMI: Custom. You specify the custom AMI you want to use when you create instances. For more information on how to use custom AMIs with OpsWorks, see Using Custom AMIs.

The default option is the stack’s current operating system. For more information.
on the supported operating systems, see AWS OpsWorks Operating Systems.

- **HostnameTheme** *(string)* – The stack’s new host name theme, with spaces replaced by underscores. The theme is used to generate host names for the stack’s instances. By default, HostnameTheme is set to **Layer_Dependent**, which creates host names by appending integers to the layer’s short name. The other themes are:
  - Baked_Goods
  - Clouds
  - Europe_Cities
  - Fruits
  - Greek_Deities
  - Legendary_creatures_from_Japan
  - Planets_and_Moons
  - Roman_Deities
  - Scottish_Islands
  - US_Cities
  - Wild_Cats

To obtain a generated host name, call `GetHostNameSuggestion`, which returns a host name based on the current theme.

- **DefaultAvailabilityZone** *(string)* – The stack’s default Availability Zone, which must be in the stack’s region. For more information, see Regions and Endpoints. If you also specify a value for DefaultSubnetId, the subnet must be in the same zone. For more information, see CreateStack.

- **DefaultSubnetId** *(string)* – The stack’s default VPC subnet ID. This parameter is required if you specify a value for the VpcId parameter. All instances are launched into this subnet unless you specify otherwise when you create the instance. If you also specify a value for DefaultAvailabilityZone, the subnet must be in that zone. For information on default values and when this parameter is required, see the **VpcId** parameter description.

- **CustomJson** *(string)* – A string that contains user-defined, custom JSON. It can be used to override the corresponding default stack configuration JSON values or to pass data to recipes. The string should be in the following format and escape characters such as `"`:
  ```json
  "{"key1": "value1", "key2": "value2",...}"
  ```

For more information on custom JSON, see Use Custom JSON to Modify the Stack Configuration Attributes.

- **ConfigurationManager** *(dict)* – The configuration manager. When you clone a stack, we recommend that you use the configuration manager to specify the Chef version: 0.9, 11.4, or 11.10. The default value is currently 11.4.
  - **Name** *(string)* –
    The name. This parameter must be set to “Chef”.
  - **Version** *(string)* –
    The Chef version. This parameter must be set to 0.9, 11.4, or 11.10. The default value is 11.4.

- **ChefConfiguration** *(dict)* – A ChefConfiguration object that specifies whether to enable Berkshelf and the Berkshelf version on Chef 11.10 stacks. For more information, see Create a New Stack.
  - **ManageBerkshelf** *(boolean)* –
    Whether to enable Berkshelf.
  - **BerkshelfVersion** *(string)* –
    The Berkshelf version.
• **UseCustomCookbooks** *(boolean)* – Whether the stack uses custom cookbooks.

• **CustomCookbooksSource** *(dict)* – Contains the information required to retrieve an app or cookbook from a repository. For more information, see Creating Apps or Custom Recipes and Cookbooks.
  
  – **Type** *(string)* –
    
    The repository type.
  
  – **Url** *(string)* –
    
    The source URL.
  
  – **Username** *(string)* –
    
    This parameter depends on the repository type.
    
    * For Amazon S3 bundles, set `Username` to the appropriate IAM access key ID.
    * For HTTP bundles, Git repositories, and Subversion repositories, set `Username` to the user name.
  
  – **Password** *(string)* –
    
    When included in a request, the parameter depends on the repository type.
    
    * For Amazon S3 bundles, set `Password` to the appropriate IAM secret access key.
    * For HTTP bundles and Subversion repositories, set `Password` to the password.

  For more information on how to safely handle IAM credentials, see http://docs.aws.amazon.com/general/latest/gr/aws-access-keys-best-practices.html.

  In responses, AWS OpsWorks returns *****FILTERED***** instead of the actual value.

  – **SshKey** *(string)* –
    
    In requests, the repository’s SSH key.

  In responses, AWS OpsWorks returns *****FILTERED***** instead of the actual value.
  
  – **Revision** *(string)* –
    
    The application’s version. AWS OpsWorks enables you to easily deploy new versions of an application. One of the simplest approaches is to have branches or revisions in your repository that represent different versions that can potentially be deployed.

• **DefaultSshKeyName** *(string)* – A default Amazon EC2 key-pair name. The default value is `none`. If you specify a key-pair name, AWS OpsWorks installs the public key on the instance and you can use the private key with an SSH client to log in to the instance. For more information, see Using SSH to Communicate with an Instance and Managing SSH Access. You can override this setting by specifying a different key pair, or no key pair, when you create an instance.

• **DefaultRootDeviceType** *(string)* – The default root device type. This value is used by default for all instances in the stack, but you can override it when you create an instance. For more information, see Storage for the Root Device.

• **UseOpsworksSecurityGroups** *(boolean)* – Whether to associate the AWS OpsWorks built-in security groups with the stack’s layers.

  AWS OpsWorks provides a standard set of built-in security groups, one for each layer, which are associated with layers by default. `UseOpsworksSecurityGroups` allows you to provide your own custom security groups instead of using the built-in groups.
UseOpsworksSecurityGroups has the following settings:

- **True** - AWS OpsWorks automatically associates the appropriate built-in security group with each layer (default setting). You can associate additional security groups with a layer after you create it, but you cannot delete the built-in security group.
- **False** - AWS OpsWorks does not associate built-in security groups with layers. You must create appropriate EC2 security groups and associate a security group with each layer that you create. However, you can still manually associate a built-in security group with a layer on. Custom security groups are required only for those layers that need custom settings.

For more information, see Create a New Stack.

**AgentVersion** *(string)* – The default AWS OpsWorks agent version. You have the following options:

- **Auto-update** - Set this parameter to `LATEST`. AWS OpsWorks automatically installs new agent versions on the stack’s instances as soon as they are available.
- **Fixed version** - Set this parameter to your preferred agent version. To update the agent version, you must edit the stack configuration and specify a new version. AWS OpsWorks then automatically installs that version on the stack’s instances.

The default setting is `LATEST`. To specify an agent version, you must use the complete version number, not the abbreviated number shown on the console. For a list of available agent version numbers, call `DescribeAgentVersions`.

Note: You can also specify an agent version when you create or update an instance, which overrides the stack’s default setting.

---

**Returns** None

**update_user_profile(**

Updates a specified user profile.

**Required Permissions** : To use this action, an IAM user must have an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = client.update_user_profile(
    IamUserArn='string',
    SshUsername='string',
    SshPublicKey='string',
    AllowSelfManagement=True|False
)
```

**Parameters**

- **IamUserArn** *(string)* – [REQUIRED]
  
  The user IAM ARN.

- **SshUsername** *(string)* – The user’s SSH username. The allowable characters are [a-zA-Z], [0-9], ‘-’, and ‘.’. If the specified name includes other punctuation marks, AWS OpsWorks removes them. For example, my.name will be changed to myname. If you do not specify an SSH user name, AWS OpsWorks generates one from the IAM user name.

- **SshPublicKey** *(string)* – The user’s new SSH public key.

- **AllowSelfManagement** *(boolean)* – Whether users can specify their own SSH public key through the My Settings page. For more information, see Managing User Permissions.
update_volume(**kwargs)
 Updates an Amazon EBS volume’s name or mount point. For more information, see Resource Management.

Required Permissions: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

Request Syntax

```python
response = client.update_volume(
    VolumeId='string',
    Name='string',
    MountPoint='string'
)
```

Parameters

- **VolumeId (string)** – [REQUIRED]
  The volume ID.
- **Name (string)** – The new name.
- **MountPoint (string)** – The new mount point.

Returns None

Service Resource

class OpsWorks.ServiceResource
 A resource representing AWS OpsWorks:

```python
import boto3

opsworks = boto3.resource('opsworks')
```

These are the resource’s available actions:

- **create_stack()**

These are the resource’s available sub-resources:

- **Layer()**
- **Stack()**
- **StackSummary()**

These are the resource’s available collections:

- **stacks**

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

create_stack(**kwargs)
 Creates a new stack. For more information, see Create a New Stack.

Required Permissions: To use this action, an IAM user must have an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

Request Syntax
stack = opsworks.create_stack(
Name='string',
Region='string',
VpcId='string',
Attributes={
    'string': 'string'
},
ServiceRoleArn='string',
DefaultInstanceProfileArn='string',
DefaultOs='string',
HostnameTheme='string',
DefaultAvailabilityZone='string',
DefaultSubnetId='string',
CustomJson='string',
ConfigurationManager={
    'Name': 'string',
    'Version': 'string'
},
ChefConfiguration={
    'ManageBerkshelf': True|False,
    'BerkshelfVersion': 'string'
},
UseCustomCookbooks=True|False,
UseOpsworksSecurityGroups=True|False,
CustomCookbooksSource={
    'Type': 'git'|'svn'|'archive'|'s3',
    'Url': 'string',
    'Username': 'string',
    'Password': 'string',
    'SshKey': 'string',
    'Revision': 'string'
},
DefaultSshKeyName='string',
DefaultRootDeviceType='ebs'|'instance-store',
AgentVersion='string'
)

Parameters

• Name (string) – [REQUIRED]

  The stack name.

• Region (string) – [REQUIRED]

  The stack’s AWS region, such as “us-east-1”. For more information about Amazon regions, see Regions and Endpoints.

• VpcId (string) – The ID of the VPC that the stack is to be launched into. The VPC must be in the stack’s region. All instances are launched into this VPC. You cannot change the ID later.
  
  – If your account supports EC2-Classic, the default value is no VPC.
  
  – If your account does not support EC2-Classic, the default value is the default VPC for the specified region.

If the VPC ID corresponds to a default VPC and you have specified either the DefaultAvailabilityZone or the DefaultSubnetId parameter only, AWS OpsWorks infers the value of the other parameter. If you specify neither parameter, AWS OpsWorks sets these parameters to the first valid Availability Zone for the specified region and the corresponding default VPC subnet ID, respectively.
If you specify a nondefault VPC ID, note the following:

– It must belong to a VPC in your account that is in the specified region.
– You must specify a value for DefaultSubnetId.

For more information on how to use AWS OpsWorks with a VPC, see Running a Stack in a VPC. For more information on default VPC and EC2-Classic, see Supported Platforms.

• Attributes (dict) – One or more user-defined key-value pairs to be added to the stack attributes.
  
  – (string) –

• ServiceRoleArn (string) – [REQUIRED]

The stack’s AWS Identity and Access Management (IAM) role, which allows AWS OpsWorks to work with AWS resources on your behalf. You must set this parameter to the Amazon Resource Name (ARN) for an existing IAM role. For more information about IAM ARNs, see Using Identifiers.

• DefaultInstanceProfileArn (string) – [REQUIRED]

The Amazon Resource Name (ARN) of an IAM profile that is the default profile for all of the stack’s EC2 instances. For more information about IAM ARNs, see Using Identifiers.

• DefaultOs (string) – The stack’s default operating system, which is installed on every instance unless you specify a different operating system when you create the instance. You can specify one of the following.
  
  – A supported Linux operating system: An Amazon Linux version, such as Amazon Linux 2015.03, Red Hat Enterprise Linux 7, Ubuntu 12.04 LTS, or Ubuntu 14.04 LTS.
  – Microsoft Windows Server 2012 R2 Base.
  – A custom AMI: Custom. You specify the custom AMI you want to use when you create instances. For more information, see Using Custom AMIs.

The default option is the current Amazon Linux version. For more information on the supported operating systems, see AWS OpsWorks Operating Systems.

• HostnameTheme (string) – The stack’s host name theme, with spaces replaced by underscores. The theme is used to generate host names for the stack’s instances. By default, HostnameTheme is set to Layer_Dependent, which creates host names by appending integers to the layer’s short name. The other themes are:
  
  – Baked_Goods
  – Clouds
  – Europe_Cities
  – Fruits
  – Greek_Deities
  – Legendary_creatures_from_Japan
  – Planets_and_Moons
  – Roman_Deities
  – Scottish_Islands
  – US_Cities
  – Wild_Cats

To obtain a generated host name, call GetHostNameSuggestion, which returns a host name based on the current theme.

• DefaultAvailabilityZone (string) – The stack’s default Availability Zone, which must be in the specified region. For more information, see Regions and Endpoints. If you also specify a value for DefaultSubnetId, the subnet must be in the same zone. For more information, see the VpcId parameter descrip-
tion.

- **DefaultSubnetId** *(string)* – The stack’s default VPC subnet ID. This parameter is required if you specify a value for the VpcId parameter. All instances are launched into this subnet unless you specify otherwise when you create the instance. If you also specify a value for DefaultAvailabilityZone, the subnet must be in that zone. For information on default values and when this parameter is required, see the VpcId parameter description.

- **CustomJson** *(string)* – A string that contains user-defined, custom JSON. It can be used to override the corresponding default stack configuration attribute values or to pass data to recipes. The string should be in the following escape characters such as ‘”’:

```
"{"key1": "value1", "key2": 
"value2"...,}"
```

For more information on custom JSON, see Use Custom JSON to Modify the Stack Configuration Attributes.

- **ConfigurationManager** *(dict)* – The configuration manager. When you clone a stack we recommend that you use the configuration manager to specify the Chef version: 0.9, 11.4, or 11.10. The default value is currently 11.4.
  - **Name** *(string)* – The name. This parameter must be set to “Chef”.
  - **Version** *(string)* – The Chef version. This parameter must be set to 0.9, 11.4, or 11.10. The default value is 11.4.

- **ChefConfiguration** *(dict)* – A ChefConfiguration object that specifies whether to enable Berkshelf and the Berkshelf version on Chef 11.10 stacks. For more information, see Create a New Stack.
  - **ManageBerkshelf** *(boolean)* – Whether to enable Berkshelf.
  - **BerkshelfVersion** *(string)* – The Berkshelf version.

- **UseCustomCookbooks** *(boolean)* – Whether the stack uses custom cookbooks.

- **UseOpsworksSecurityGroups** *(boolean)* – Whether to associate the AWS OpsWorks built-in security groups with the stack’s layers.

AWS OpsWorks provides a standard set of built-in security groups, one for each layer, which are associated with layers by default. With UseOpsworksSecurityGroups you can instead provide your own custom security groups. UseOpsworksSecurityGroups has the following settings:

  - True - AWS OpsWorks automatically associates the appropriate built-in security group with each layer (default setting). You can associate additional security groups with a layer after you create it, but you cannot delete the built-in security group.
  - False - AWS OpsWorks does not associate built-in security groups with layers. You must create appropriate EC2 security groups and associate a security group with each layer that you create. However, you can still manually associate a built-in security group with a layer on creation; custom security groups are required only for those layers that need custom settings.

For more information, see Create a New Stack.

- **CustomCookbooksSource** *(dict)* – Contains the information required to retrieve an app or cookbook from a repository. For more information, see Creating Apps.
– **Type** *(string)* –
  The repository type.

– **Url** *(string)* –
  The source URL.

– **Username** *(string)* –
  This parameter depends on the repository type.
  * For Amazon S3 bundles, set *Username* to the appropriate IAM access key ID.
  * For HTTP bundles, Git repositories, and Subversion repositories, set *Username* to the user name.

– **Password** *(string)* –
  When included in a request, the parameter depends on the repository type.
  * For Amazon S3 bundles, set *Password* to the appropriate IAM secret access key.
  * For HTTP bundles and Subversion repositories, set *Password* to the password.

For more information on how to safely handle IAM credentials, see [http://docs.aws.amazon.com/general/latest/gr/aws-access-keys-best-practices.html](http://docs.aws.amazon.com/general/latest/gr/aws-access-keys-best-practices.html).

In responses, AWS OpsWorks returns *****FILTERED***** instead of the actual value.

– **SshKey** *(string)* –
  In requests, the repository’s SSH key.

In responses, AWS OpsWorks returns *****FILTERED***** instead of the actual value.

– **Revision** *(string)* –
  The application’s version. AWS OpsWorks enables you to easily deploy new versions of an application. One of the simplest approaches is to have branches or revisions in your repository that represent different versions that can potentially be deployed.

• **DefaultSshKeyName** *(string)* – A default Amazon EC2 key pair name. The default value is none. If you specify a key pair name, AWS OpsWorks installs the public key on the instance and you can use the private key with an SSH client to log in to the instance. For more information, see [Using SSH to Communicate with an Instance](http://docs.aws.amazon.com/opsworks/latest/userguide/using-ssh.html) and [Managing SSH Access](http://docs.aws.amazon.com/opsworks/latest/userguide/using-ssh.html). You can override this setting by specifying a different key pair, or no key pair, when you create an instance.

• **DefaultRootDeviceType** *(string)* – The default root device type. This value is the default for all instances in the stack, but you can override it when you create an instance. The default option is *instance-store*. For more information, see [Storage for the Root Device](http://docs.aws.amazon.com/opsworks/latest/userguide/instancedevices.html).

• **AgentVersion** *(string)* – The default AWS OpsWorks agent version. You have the following options:
  – Auto-update - Set this parameter to LATEST. AWS OpsWorks automatically installs new agent versions on the stack’s instances as soon as they are available.
  – Fixed version - Set this parameter to your preferred agent version. To update the agent version, you must edit the stack configuration and specify a new version. AWS OpsWorks then automatically installs that version on the stack’s instances.
The default setting is `LATEST`. To specify an agent version, you must use the complete version number, not the abbreviated number shown on the console. For a list of available agent version numbers, call `DescribeAgentVersions`.

**Note:** You can also specify an agent version when you create or update an instance, which overrides the stack’s default setting.

```python
Return type  opsworks.Stack
Returns  Stack resource
```

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the *Resources Introduction Guide*.

**Layer** *(id)*

Creates a Layer resource.:  

```python
layer = opsworks.Layer('id')
```

- **Parameters**  
  - `id` *(string)* – The Layer’s id identifier. This **must** be set.
  - **Return type**  
    - **OpsWorks.Layer**
  - **Returns**  
    - A Layer resource

**Stack** *(id)*

Creates a Stack resource.:  

```python
stack = opsworks.Stack('id')
```

- **Parameters**  
  - `id` *(string)* – The Stack’s id identifier. This **must** be set.
  - **Return type**  
    - **OpsWorks.Stack**
  - **Returns**  
    - A Stack resource

**StackSummary** *(stack_id)*

Creates a StackSummary resource.:  

```python
stack_summary = opsworks.StackSummary('stack_id')
```

- **Parameters**  
  - `stack_id` *(string)* – The StackSummary’s stack_id identifier. This **must** be set.
  - **Return type**  
    - **OpsWorks.StackSummary**
  - **Returns**  
    - A StackSummary resource

Collections

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the *Resources Introduction Guide*.

**stacks**

- **all()**  
  - Creates an iterable of all Stack resources in the collection.

  **Request Syntax**  
  
  ```python
  stack_iterator = opsworks.stacks.all()
  ```

  - **Return type**  
    - `list(opsworks.Stack)`
  - **Returns**  
    - A list of Stack resources
**filter(**kwargs
)  
Creates an iterable of all Stack resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```
stack_iterator = opsworks.stacks.filter(
    StackIds=[
        'string',
    ]
)
```

**Parameters** StackIds (list) – An array of stack IDs that specify the stacks to be described. If you omit this parameter, DescribeStacks returns a description of every stack.

**Return type** list(opsworks.Stack)

**Returns** A list of Stack resources

**limit(**kwargs
)  
Creates an iterable up to a specified amount of Stack resources in the collection.

**Request Syntax**

```
stack_iterator = opsworks.stacks.limit(
    count=123
)
```

**Parameters** count (integer) – The limit to the number of resources in the iterable.

**Return type** list(opsworks.Stack)

**Returns** A list of Stack resources

**page_size(**kwargs
)  
Creates an iterable of all Stack resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```
stack_iterator = opsworks.stacks.page_size(
    count=123
)
```

**Parameters** count (integer) – The number of items returned by each service call

**Return type** list(opsworks.Stack)

**Returns** A list of Stack resources

---

**Layer**

```python
class OpsWorks.Layer(id)
A resource representing an AWS OpsWorks Layer:

import boto3

opsworks = boto3.resource('opsworks')
layer = opsworks.Layer('id')
```

**Parameters** id (string) – The Layer’s id identifier. This must be set.
These are the resource’s available identifiers:
  • id

These are the resource’s available attributes:
  • attributes
    • auto_assign_elastic_ips
    • auto_assign_public_ips
    • created_at
    • custom_instance_profile_arn
    • custom_json
    • custom_recipes
    • custom_security_group_ids
    • default_recipes
    • default_security_group_names
    • enable_auto_healing
    • install_updates_on_boot
    • layer_id
    • lifecycle_event_configuration
    • name
    • packages
    • shortname
    • stack_id
    • type
    • use_ebs_optimized_instances
    • volume_configurations

These are the resource’s available references:
  • stack

These are the resource’s available actions:
  • delete()
  • load()
  • reload()

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

id
  (string) The Layer’s id identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

attributes
  (dict)

  The layer attributes.

  For the HaproxyStatsPassword, MysqlRootPassword, and GangliaPassword attributes, AWS OpsWorks returns *****FILTERED******/ instead of the actual value

  For an ECS Cluster layer, AWS OpsWorks the EcsClusterArn attribute is set to the cluster’s ARN.

auto_assign_elastic_ips
  (boolean)

  Whether to automatically assign an Elastic IP address to the layer’s instances. For more information, see How to Edit a Layer.
**auto_assign_public_ips**

*(boolean)*

For stacks that are running in a VPC, whether to automatically assign a public IP address to the layer’s instances. For more information, see [How to Edit a Layer](#).

**created_at**

*(string)*

Date when the layer was created.

**custom_instance_profile_arn**

*(string)*

The ARN of the default IAM profile to be used for the layer’s EC2 instances. For more information about IAM ARNs, see [Using Identifiers](#).

**custom_json**

*(string)*

A JSON formatted string containing the layer’s custom stack configuration and deployment attributes.

**custom_recipes**

*(dict)*

A `LayerCustomRecipes` object that specifies the layer’s custom recipes.

**custom_security_group_ids**

*(list)*

An array containing the layer’s custom security group IDs.

**default_recipes**

*(dict)*

AWS OpsWorks supports five lifecycle events: `setup`, `configuration`, `deploy`, `undeploy`, and `shutdown`. For each layer, AWS OpsWorks runs a set of standard recipes for each event. In addition, you can provide custom recipes for any or all layers and events. AWS OpsWorks runs custom event recipes after the standard recipes. `LayerCustomRecipes` specifies the custom recipes for a particular layer to be run in response to each of the five events.

To specify a recipe, use the cookbook’s directory name in the repository followed by two colons and the recipe name, which is the recipe’s file name without the `.rb` extension. For example: `phpapp2::dbsetup` specifies the `dbsetup.rb` recipe in the repository’s `phpapp2` folder.

**default_security_group_names**

*(list)*

An array containing the layer’s security group names.

**enable_auto_healing**

*(boolean)*

Whether auto healing is disabled for the layer.

**install_updates_on_boot**

*(boolean)*

Whether to install operating system and package updates when the instance boots. The default value is `true`. If this value is set to `false`, you must then update your instances manually by using `CreateDeployment` to run the `update_dependencies` stack command or manually running `yum` (Amazon Linux) or `apt-get` (Ubuntu) on the instances.

**Note:** We strongly recommend using the default value of `true`, to ensure that your instances have the
latest security updates.

**layer_id**

*(string)*

The layer ID.

**lifecycle_event_configuration**

*(dict)*

A LifeCycleEventConfiguration object that specifies the Shutdown event configuration.

**name**

*(string)*

The layer name.

**packages**

*(list)*

An array of Package objects that describe the layer’s packages.

**shortname**

*(string)*

The layer short name.

**stack_id**

*(string)*

The layer stack ID.

**type**

*(string)*

The layer type.

**use_ebs_optimized_instances**

*(boolean)*

Whether the layer uses Amazon EBS-optimized instances.

**volume_configurations**

*(list)*

A VolumeConfigurations object that describes the layer’s Amazon EBS volumes.

References

References are related resource instances that have a belongs-to relationship. For more information about references refer to the *Resources Introduction Guide*.

**stack**

*(Stack)* The related stack if set, otherwise None.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide*.

**delete()**

Deletes a specified layer. You must first stop and then delete all associated instances or unassign registered instances. For more information, see *How to Delete a Layer*.
**Required Permissions** : To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
response = layer.delete()
```

**Returns** None

`load()`

Calls `opsworks.Client.describe_layers()` to update the attributes of the Layer resource

**Request Syntax**

```python
layer.load()
```

**Returns** None

`reload()`

Calls `opsworks.Client.describe_layers()` to update the attributes of the Layer resource

**Request Syntax**

```python
layer.reload()
```

**Returns** None

---

**Stack**

class `OpsWorks.Stack(id)`

A resource representing an AWS OpsWorks Stack:

```python
import boto3

opsworks = boto3.resource('opsworks')
stack = opsworks.Stack(id)
```

**Parameters id (string)** – The Stack’s id identifier. This **must** be set.

These are the resource’s available identifiers:

- `id`

These are the resource’s available attributes:

- `agent_version`
- `arn`
- `attributes`
- `chef_configuration`
- `configuration_manager`
- `created_at`
- `custom_cookbooks_source`
- `custom_json`
- `default_availability_zone`
- `default_instance_profile_arn`
- `default_os`
- `default_root_device_type`
- `default_ssh_key_name`
- `default_subnet_id`
• hostname_theme
• name
• region
• service_role_arn
• stack_id
• use_custom_cookbooks
• use_opsworks_security_groups
• vpc_id

These are the resource’s available actions:
• create_layer()
• delete()
• load()
• reload()

These are the resource’s available sub-resources:
• Summary()

These are the resource’s available collections:
• layers

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

id

(string) The Stack’s id identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

agent_version

(string) The agent version. This parameter is set to LATEST for auto-update, or a version number for a fixed agent version.

arn

(string) The stack’s ARN.

attributes

(dict) The stack’s attributes.

chef_configuration

(dict) A ChefConfiguration object that specifies whether to enable Berkshelf and the Berkshelf version. For more information, see Create a New Stack.

configuration_manager

(dict) The configuration manager.

created_at

(string) The date when the stack was created.
custom_cookbooks_source

dict

Contains the information required to retrieve an app or cookbook from a repository. For more information, see Creating Apps or Custom Recipes and Cookbooks.

custom_json

string

A JSON object that contains user-defined attributes to be added to the stack configuration and deployment attributes. You can use custom JSON to override the corresponding default stack configuration attribute values or to pass data to recipes. The string should be in the following format and must escape characters such as "":

"{"key1": "value1", "key2": "value2",...}"

For more information on custom JSON, see Use Custom JSON to Modify the Stack Configuration Attributes.

default_availability_zone

string

The stack’s default Availability Zone. For more information, see Regions and Endpoints.

default_instance_profile_arn

string

The ARN of an IAM profile that is the default profile for all of the stack’s EC2 instances. For more information about IAM ARNs, see Using Identifiers.

default_os

string

The stack’s default operating system.

default_root_device_type

string

The default root device type. This value is used by default for all instances in the stack, but you can override it when you create an instance. For more information, see Storage for the Root Device.

default_ssh_key_name

string

A default Amazon EC2 key pair for the stack’s instances. You can override this value when you create or update an instance.

default_subnet_id

string

The default subnet ID; applicable only if the stack is running in a VPC.

hostname_theme

string

The stack host name theme, with spaces replaced by underscores.

name

string

The stack name.

region

string
The stack AWS region, such as “us-east-1”. For more information about AWS regions, see Regions and Endpoints.

*service_role_arn*

*(string)*

The stack AWS Identity and Access Management (IAM) role.

*stack_id*

*(string)*

The stack ID.

*use_custom_cookbooks*

*(boolean)*

Whether the stack uses custom cookbooks.

*use_opsworks_security_groups*

*(boolean)*

Whether the stack automatically associates the AWS OpsWorks built-in security groups with the stack’s layers.

*vpc_id*

*(string)*

The VPC ID; applicable only if the stack is running in a VPC.

**Actions**

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

*create_layer**(**kwargs**)*

Creates a layer. For more information, see How to Create a Layer.

---

**Note:** You should use CreateLayer for noncustom layer types such as PHP App Server only if the stack does not have an existing layer of that type. A stack can have at most one instance of each noncustom layer; if you attempt to create a second instance, CreateLayer fails. A stack can have an arbitrary number of custom layers, so you can call CreateLayer as many times as you like for that layer type.

**Required Permissions:** To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see Managing User Permissions.

**Request Syntax**

```python
layer = stack.create_layer(
    Type='aws-flow-ruby'|'ecs-cluster'|'java-app'|'lb'|'web'|'php-app'|'rails-app'|'nodejs-app'|'memcached'|'db-master'|'monitoring-master'|'custom',
    Name='string',
    Shortname='string',
    Attributes={
        'string': 'string'
    },
    CustomInstanceProfileArn='string',
    CustomJson='string',
    CustomSecurityGroupIds=[
        'string',
    ],
    Packages=[
        'string',
    ],
)```

---

3.1. Services
Parameters

- **Type (string) – [REQUIRED]**
  
  The layer type. A stack cannot have more than one built-in layer of the same type. It can have any number of custom layers.

- **Name (string) – [REQUIRED]**
  
  The layer name, which is used by the console.

- **Shortname (string) – [REQUIRED]**
  
  For custom layers only, use this parameter to specify the layer's short name, which is used internally by AWS OpsWorks and by Chef recipes. The short name is also used as the name for the directory where your app files are installed. It can have a maximum of 200 characters, which are limited to the alphanumeric characters, '-', '_', and '.'.

  The built-in layers' short names are defined by AWS OpsWorks. For more information, see the Layer Reference.
• **Attributes** *(dict)* – One or more user-defined key-value pairs to be added to the stack attributes.

To create a cluster layer, set the `EcsClusterArn` attribute to the cluster’s ARN.

  – *(string)* –
    * *(string)* –

• **CustomInstanceProfileArn** *(string)* – The ARN of an IAM profile to be used for the layer’s EC2 instances. For more information about IAM ARNs, see *Using Identifiers*.

• **CustomJson** *(string)* – A JSON-formatted string containing custom stack configuration and deployment attributes to be installed on the layer’s instances. For more information, see *Using Custom JSON*.

• **CustomSecurityGroupIds** *(list)* – An array containing the layer custom security group IDs.

  – *(string)* –

• **Packages** *(list)* – An array of `Package` objects that describes the layer packages.

  – *(string)* –

• **VolumeConfigurations** *(list)* – A `VolumeConfigurations` object that describes the layer’s Amazon EBS volumes.

  – *(dict)* –

  Describes an Amazon EBS volume configuration.

    * **MountPoint** *(string)* – [REQUIRED]

      The volume mount point. For example “/dev/sdh”.

    * **RaidLevel** *(integer)* –

      The volume RAID level.

    * **NumberOfDisks** *(integer)* – [REQUIRED]

      The number of disks in the volume.

    * **Size** *(integer)* – [REQUIRED]

      The volume size.

    * **VolumeType** *(string)* –

      The volume type:

        · **standard** - Magnetic
        · **io1** - Provisioned IOPS (SSD)
        · **gp2** - General Purpose (SSD)

    * **Iops** *(integer)* –

      For PIOPS volumes, the IOPS per disk.

• **EnableAutoHealing** *(boolean)* – Whether to disable auto healing for the layer.

• **AutoAssignElasticIps** *(boolean)* – Whether to automatically assign an Elastic IP address to the layer’s instances. For more information, see *How to Edit a Layer*.

• **AutoAssignPublicIps** *(boolean)* – For stacks that are running in a VPC, whether to automatically assign a public IP address to the layer’s instances. For more information, see *How to Edit a Layer*.

• **CustomRecipes** *(dict)* – A `LayerCustomRecipes` object that specifies the layer custom recipes.

  – **Setup** *(list)* –

    An array of custom recipe names to be run following a `setup` event.

  – *(string)* –

---

3.1. Services
- **Configure** *(list)* –
  An array of custom recipe names to be run following a configure event.
  *
  - **Deploy** *(list)* –
    An array of custom recipe names to be run following a deploy event.
  *
  - **Undeploy** *(list)* –
    An array of custom recipe names to be run following a undeploy event.
  *
  - **Shutdown** *(list)* –
    An array of custom recipe names to be run following a shutdown event.
  *
  - **InstallUpdatesOnBoot** *(boolean)* – Whether to install operating system and package updates when the instance boots. The default value is true. To control when updates are installed, set this value to false. You must then update your instances manually by using CreateDeployment to run the update_dependencies stack command or by manually running `yum` (Amazon Linux) or `apt-get` (Ubuntu) on the instances.
  *
  - **UseEbsOptimizedInstances** *(boolean)* – Whether to use Amazon EBS-optimized instances.
  *
  - **LifecycleEventConfiguration** *(dict)* – A LifecycleEventConfiguration object that you can use to configure the Shutdown event to specify an execution timeout and enable or disable Elastic Load Balancer connection draining.
    *
    - **Shutdown** *(dict)* –
      A ShutdownEventConfiguration object that specifies the Shutdown event configuration.
      *
      - **ExecutionTimeout** *(integer)* –
        The time, in seconds, that AWS OpsWorks will wait after triggering a Shutdown event before shutting down an instance.
      *
      - **DelayUntilElbConnectionsDrained** *(boolean)* –
        Whether to enable Elastic Load Balancing connection draining. For more information, see [Connection Draining](#).

**Note:** To ensure that your instances have the latest security updates, we strongly recommend using the default value of true.

- **Delete** *(string)* –
  The time, in seconds, that AWS OpsWorks will wait after triggering a Shutdown event before shutting down an instance.

---

**Return type** `opsworks.Layer`

**Returns** Layer resource

**delete()**

Deletes a specified stack. You must first delete all instances, layers, and apps or deregister registered instances. For more information, see [Shut Down a Stack](#).

**Required Permissions**: To use this action, an IAM user must have a Manage permissions level for the stack, or an attached policy that explicitly grants permissions. For more information on user permissions, see [Managing User Permissions](#).

**Request Syntax**

```python
response = stack.delete()
```

**Returns** None
load()
Calls opsworks.Client.describe_stacks() to update the attributes of the Stack resource

Request Syntax

stack.load()

Returns  None

reload()
Calls opsworks.Client.describe_stacks() to update the attributes of the Stack resource

Request Syntax

stack.reload()

Returns  None

Sub-resources
Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

Summary()
Creates a StackSummary resource:

stack_summary = stack.Summary()

Returns  A StackSummary resource

Collections
Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the Resources Introduction Guide.

layers

all()
Creates an iterable of all Layer resources in the collection.

Request Syntax

layer_iterator = stack.layers.all()

Return type  list(opsworks.Layer)
Returns  A list of Layer resources

filter(**kwargs)
Creates an iterable of all Layer resources in the collection filtered by kwargs passed to method.

Request Syntax

layer_iterator = stack.layers.filter(
    LayerIds=[
        'string',
    ]
)
Parameters **LayerIds** *(list)* – An array of layer IDs that specify the layers to be described. If you omit this parameter, DescribeLayers returns a description of every layer in the specified stack.

- *(string)* – 

**Return type** list(opsworks.Layer)

**Returns** A list of Layer resources

**limit** (**kwargs**)

Creates an iterable up to a specified amount of Layer resources in the collection.

**Request Syntax**

```python
layer_iterator = stack.layers.limit(
    count=123
)
```

- **Parameters** count *(integer)* – The limit to the number of resources in the iterable.

- **Return type** list(opsworks.Layer)

- **Returns** A list of Layer resources

**page_size** (**kwargs**)

Creates an iterable of all Layer resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
layer_iterator = stack.layers.page_size(
    count=123
)
```

- **Parameters** count *(integer)* – The number of items returned by each service call

- **Return type** list(opsworks.Layer)

- **Returns** A list of Layer resources

### StackSummary

class **OpsWorks.StackSummary** *(stack_id)*

A resource representing an AWS OpsWorks StackSummary:

```python
import boto3

opsworks = boto3.resource('opsworks')
stack_summary = opsworks.StackSummary('stack_id')
```

- **Parameters** stack_id *(string)* – The StackSummary’s stack_id identifier. This must be set.

These are the resource’s available identifiers:

- **stack_id**

These are the resource’s available attributes:

- **apps_count**
- **arn**
- **instances_count**
- **layers_count**
- **name**

These are the resource’s available sub-resources:

- **Stack()**
Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

stack_id
   (string) The StackSummary’s stack_id identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

apps_count
   (integer)
   The number of apps.

arn
   (string)
   The stack’s ARN.

instances_count
   (dict)
   An InstancesCount object with the number of instances in each status.

layers_count
   (integer)
   The number of layers.

name
   (string)
   The stack name.

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

Stack()

Creates a Stack resource:

```
stack = stack_summary.Stack()
```

Return type OpsWorks.Stack
Returns A Stack resource

RDS

Table of Contents

- RDS
  - Client
  - Paginators
  - Waiters
Client

class RDS.Client
    A low-level client representing Amazon Relational Database Service (RDS):

        import boto3

        client = boto3.client('rds')

    These are the available methods:
        • add_source_identifier_to_subscription()
        • add_tags_to_resource()
        • apply_pending_maintenance_action()
        • authorize_db_security_group_ingress()
        • can_paginate()
        • copy_db_cluster_snapshot()
        • copy_db_parameter_group()
        • copy_db_snapshot()
        • copy_option_group()
        • create_db_cluster()
        • create_db_cluster_parameter_group()
        • create_db_cluster_snapshot()
        • create_db_instance()
        • create_db_instance_read_replica()
        • create_db_parameter_group()
        • create_db_security_group()
        • create_db_snapshot()
        • create_db_subnet_group()
        • create_event_subscription()
        • create_option_group()
        • delete_db_cluster()
        • delete_db_cluster_parameter_group()
        • delete_db_cluster_snapshot()
        • delete_db_instance()
        • delete_db_security_group()
        • delete_db_snapshot()
        • delete_db_subnet_group()
        • delete_event_subscription()
        • delete_option_group()
        • describe_account_attributes()
        • describe_certificates()
        • describe_db_cluster_parameter_groups()
        • describe_db_cluster_parameters()
        • describe_db_cluster_snapshots()
        • describe_db_clusters()
        • describe_db_engine_versions()
        • describe_db_instances()
        • describe_db_log_files()
        • describe_db_parameter_groups()
        • describe_db_parameters()
        • describe_db_security_groups()
        • describe_db_snapshots()
        • describe_db_subnet_groups()
add_source_identifier_to_subscription(**kwargs)

Adds a source identifier to an existing RDS event notification subscription.

Request Syntax

response = client.add_source_identifier_to_subscription(
    SubscriptionName='string',
    SourceIdentifier='string'
)

Parameters

- **SubscriptionName (string)** – [REQUIRED]
  The name of the RDS event notification subscription you want to add a source identifier to.

- **SourceIdentifier (string)** – [REQUIRED]
  The identifier of the event source to be added. An identifier must begin with a letter and must contain only ASCII letters, digits, and hyphens; it cannot end with a hyphen or contain two consecutive hyphens.
Constraints:
- If the source type is a DB instance, then a DBInstanceIdentifier must be supplied.
- If the source type is a DB security group, a DBSecurityGroupName must be supplied.
- If the source type is a DB parameter group, a DBParameterGroupName must be supplied.
- If the source type is a DB snapshot, a DBSnapshotIdentifier must be supplied.

Return type dict

Returns

Response Syntax

```python
{
    'EventSubscription': {
        'CustomerAwsId': 'string',
        'CustSubscriptionId': 'string',
        'SnsTopicArn': 'string',
        'Status': 'string',
        'SubscriptionCreationTime': 'string',
        'SourceType': 'string',
        'SourceIdsList': [
            'string',
        ],
        'EventCategoriesList': [
            'string',
        ],
        'Enabled': True|False
    }
}
```

Response Structure

- (dict) –
  Contains the results of a successful invocation of the DescribeEventSubscriptions action.

- EventSubscription (dict) –
  Contains the results of a successful invocation of the DescribeEventSubscriptions action.

  * CustomerAwsId (string) –
    The AWS customer account associated with the RDS event notification subscription.

  * CustSubscriptionId (string) –
    The RDS event notification subscription Id.

  * SnsTopicArn (string) –
    The topic ARN of the RDS event notification subscription.

  * Status (string) –
    The status of the RDS event notification subscription.

  Constraints:
  Can be one of the following: creating | modifying | deleting | active | no-permission | topic-not-exist
The status “no-permission” indicates that RDS no longer has permission to post to the SNS topic. The status “topic-not-exist” indicates that the topic was deleted after the subscription was created.

- **SubscriptionCreationTime (string)** – The time the RDS event notification subscription was created.
- **SourceType (string)** – The source type for the RDS event notification subscription.
- **SourceIdsList (list)** – A list of source IDs for the RDS event notification subscription.
  - (string) –
- **EventCategoriesList (list)** – A list of event categories for the RDS event notification subscription.
  - (string) –
- **Enabled (boolean)** – A Boolean value indicating if the subscription is enabled. True indicates the subscription is enabled.

**add_tags_to_resource (**kwargs**)**

Adds metadata tags to an Amazon RDS resource. These tags can also be used with cost allocation reporting to track cost associated with Amazon RDS resources, or used in a Condition statement in an IAM policy for Amazon RDS.

For an overview on tagging Amazon RDS resources, see Tagging Amazon RDS Resources.

**Request Syntax**

```python
response = client.add_tags_to_resource(
    ResourceName='string',
    Tags=[
    {
        'Key': 'string',
        'Value': 'string'
    },
    ]
)
```

**Parameters**

- **ResourceName (string)** – [REQUIRED]
  The Amazon RDS resource the tags will be added to. This value is an Amazon Resource Name (ARN). For information about creating an ARN, see Constructing an RDS Amazon Resource Name (ARN).

- **Tags (list)** – [REQUIRED]
  The tags to be assigned to the Amazon RDS resource.
  - (dict) –
    Metadata assigned to an Amazon RDS resource consisting of a key-value pair.
    - **Key (string)** –
      A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with
apply_pending_maintenance_action (**kwargs)
Applies a pending maintenance action to a resource (for example, to a DB instance).

Response Syntax
{
    'ResourcePendingMaintenanceActions': {
        'ResourceIdentifier': 'string',
        'PendingMaintenanceActionDetails': [
            {
                'Action': 'string',
                'AutoAppliedAfterDate': datetime(2015, 1, 1),
                'ForcedApplyDate': datetime(2015, 1, 1),
                'OptInStatus': 'string',
                'CurrentApplyDate': datetime(2015, 1, 1),
                'Description': 'string'
            }
        ]
    }
}
Response Structure

- *(dict)* –
  
  Describes the pending maintenance actions for a resource.
  
  - **ResourcePendingMaintenanceActions**(dict) –
    
    Describes the pending maintenance actions for a resource.
    
    - **ResourceIdentifier**(string) –
      
      The ARN of the resource that has pending maintenance actions.
    
    - **PendingMaintenanceActionDetails**(list) –
      
      A list that provides details about the pending maintenance actions for the resource.
      
      - *(dict)* –
        
        Provides information about a pending maintenance action for a resource.
        
        - **Action**(string) –
          
          The type of pending maintenance action that is available for the resource.
        
        - **AutoAppliedAfterDate**(datetime) –
          
          The date of the maintenance window when the action will be applied. The maintenance action will be applied to the resource during its first maintenance window after this date. If this date is specified, any next-maintenance opt-in requests are ignored.
        
        - **ForcedApplyDate**(datetime) –
          
          The date when the maintenance action will be automatically applied. The maintenance action will be applied to the resource on this date regardless of the maintenance window for the resource. If this date is specified, any immediate opt-in requests are ignored.
        
        - **OptInStatus**(string) –
          
          Indicates the type of opt-in request that has been received for the resource.
        
        - **CurrentApplyDate**(datetime) –
          
          The effective date when the pending maintenance action will be applied to the resource. This date takes into account opt-in requests received from the ApplyPendingMaintenanceAction API, the AutoAppliedAfterDate, and the ForcedApplyDate. This value is blank if an opt-in request has not been received and nothing has been specified as AutoAppliedAfterDate or ForcedApplyDate.
        
        - **Description**(string) –
          
          A description providing more detail about the maintenance action.
authorize_db_security_group_ingress(**kwargs)

Enables ingress to a DBSecurityGroup using one of two forms of authorization. First, EC2 or VPC security groups can be added to the DBSecurityGroup if the application using the database is running on EC2 or VPC instances. Second, IP ranges are available if the application accessing your database is running on the Internet. Required parameters for this API are one of CIDR range, EC2SecurityGroupId for VPC, or (EC2SecurityGroupName or EC2SecurityGroupId for non-VPC).

Note: You cannot authorize ingress from an EC2 security group in one region to an Amazon RDS DB instance in another. You cannot authorize ingress from a VPC security group in one VPC to an Amazon RDS DB instance in another.

For an overview of CIDR ranges, go to the Wikipedia Tutorial.

Request Syntax

response = client.authorize_db_security_group_ingress(
    DBSecurityGroupName='string',
    CIDRIP='string',
    EC2SecurityGroupName='string',
    EC2SecurityGroupId='string',
    EC2SecurityGroupOwnerId='string'
)

Parameters

- **DBSecurityGroupName** (string) – [REQUIRED]

  The name of the DB security group to add authorization to.

- **CIDRIP** (string) – The IP range to authorize.

- **EC2SecurityGroupName** (string) – Name of the EC2 security group to authorize. For VPC DB security groups, EC2SecurityGroupId must be provided. Otherwise, EC2SecurityGroupName or EC2SecurityGroupId must be provided.

- **EC2SecurityGroupId** (string) – Id of the EC2 security group to authorize. For VPC DB security groups, EC2SecurityGroupId must be provided. Otherwise, EC2SecurityGroupName or EC2SecurityGroupId must be provided.

- **EC2SecurityGroupOwnerId** (string) – AWS account number of the owner of the EC2 security group specified in the EC2SecurityGroupName parameter. The AWS Access Key ID is not an acceptable value. For VPC DB security groups, EC2SecurityGroupId must be provided. Otherwise, EC2SecurityGroupName must be provided.

Return type  dict

Returns

Response Syntax

```python
{
    'DBSecurityGroup': {
        'OwnerId': 'string',
        'DBSecurityGroupName': 'string',
        'DBSecurityGroupDescription': 'string',
        'VpcId': 'string',
        'EC2SecurityGroups': [
```
Response Structure

- (dict) –
  Contains the result of a successful invocation of the following actions:
  - DescribeDBSecurityGroups
  - AuthorizeDBSecurityGroupIngress
  - CreateDBSecurityGroup
  - RevokeDBSecurityGroupIngress
  This data type is used as a response element in the DescribeDBSecurityGroups
  action.

- DBSecurityGroup (dict) –
  Contains the result of a successful invocation of the following actions:
  * DescribeDBSecurityGroups
  * AuthorizeDBSecurityGroupIngress
  * CreateDBSecurityGroup
  * RevokeDBSecurityGroupIngress
  This data type is used as a response element in the DescribeDBSecurityGroups
  action.

  * OwnerId (string) –
    Provides the AWS ID of the owner of a specific DB security group.

  * DBSecurityGroupName (string) –
    Specifies the name of the DB security group.

  * DBSecurityGroupDescription (string) –
    Provides the description of the DB security group.

  * VpcId (string) –
    Provides the VpcId of the DB security group.

  * EC2SecurityGroups (list) –
    Contains a list of EC2SecurityGroup elements.

    * (dict) –
      This data type is used as a response element in the following actions:
      * AuthorizeDBSecurityGroupIngress
      * DescribeDBSecurityGroups
      * RevokeDBSecurityGroupIngress
      * Status (string) –
        Provides the status of the EC2 security group. Status can be
“authorizing”, “authorized”, “revoking”, and “revoked”.

- **EC2SecurityGroupName** *(string)* –
  Specifies the name of the EC2 security group.

- **EC2SecurityGroupId** *(string)* –
  Specifies the id of the EC2 security group.

- **EC2SecurityGroupOwnerId** *(string)* –
  Specifies the AWS ID of the owner of the EC2 security group specified in the `EC2SecurityGroupName` field.

* **IPRanges** *(list)* –
  Contains a list of IPRange elements.
  - *(dict)* –
    This data type is used as a response element in the DescribeDBSecurityGroups action.
  - **Status** *(string)* –
    Specifies the status of the IP range. Status can be “authorizing”, “authorized”, “revoking”, and “revoked”.
  - **CIDRIP** *(string)* –
    Specifies the IP range.

**can_paginate** *(operation_name)*

Check if an operation can be paginated.

**Parameters**

- **operation_name** *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

**Returns**

True if the operation can be paginated, False otherwise.

**copy_db_cluster_snapshot** (**kwargs)**

Creates a snapshot of a DB cluster. For more information on Amazon Aurora, see Aurora on Amazon RDS in the Amazon RDS User Guide.

**Request Syntax**

```python
response = client.copy_db_cluster_snapshot(
    SourceDBClusterSnapshotIdentifier='string',
    TargetDBClusterSnapshotIdentifier='string',
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ],
)
```

**Parameters**

- **SourceDBClusterSnapshotIdentifier** *(string)* – [REQUIRED]
  The identifier of the DB cluster snapshot to copy. This parameter is not case-sensitive.

  **Constraints:**
  - Must contain from 1 to 63 alphanumeric characters or hyphens.
  - First character must be a letter.
• Cannot end with a hyphen or contain two consecutive hyphens.
  Example: my-cluster-snapshot1
• TargetDBClusterSnapshotIdentifier (string) – [REQUIRED]
  The identifier of the new DB cluster snapshot to create from the source DB cluster snapshot. This parameter is not case-sensitive.
  Constraints:
  – Must contain from 1 to 63 alphanumeric characters or hyphens.
  – First character must be a letter.
  – Cannot end with a hyphen or contain two consecutive hyphens.
  Example: my-cluster-snapshot2
• Tags (list) – A list of tags.
  – (dict) –
    Metadata assigned to an Amazon RDS resource consisting of a key-value pair.
    * Key (string) –
      A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘=’, ‘+’, ‘-’ (Java regex: “^[\p{L}\p{Z}\p{N}_.:/=+\-]*$”).
    * Value (string) –
      A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘=’, ‘+’, ‘-’ (Java regex: “^[\p{L}\p{Z}\p{N}_.:/=+\-]*$”).

Return type  dict
Returns

Response Syntax

```python
{
    'DBClusterSnapshot': {
        'AvailabilityZones': [ 'string' ],
        'DBClusterSnapshotIdentifier': 'string',
        'DBClusterIdentifier': 'string',
        'SnapshotCreateTime': datetime(2015, 1, 1),
        'Engine': 'string',
        'AllocatedStorage': 123,
        'Status': 'string',
        'Port': 123,
        'VpcId': 'string',
        'ClusterCreateTime': datetime(2015, 1, 1),
        'MasterUsername': 'string',
        'EngineVersion': 'string',
        'LicenseModel': 'string',
        'SnapshotType': 'string',
        'PercentProgress': 123
    }
}
```

Response Structure
Contains the result of a successful invocation of the following actions:
- CreateDBClusterSnapshot
- DeleteDBClusterSnapshot
This data type is used as a response element in the DescribeDBClusterSnapshots action.

**DBClusterSnapshot (dict)** –
Contains the result of a successful invocation of the following actions:
* CreateDBClusterSnapshot
* DeleteDBClusterSnapshot
This data type is used as a response element in the DescribeDBClusterSnapshots action.

* AvailabilityZones (list) –
  Provides the list of EC2 Availability Zones that instances in the DB cluster snapshot can be restored in.
  
* DBClusterSnapshotIdentifier (string) –
  Specifies the identifier for the DB cluster snapshot.
* DBClusterIdentifier (string) –
  Specifies the DB cluster identifier of the DB cluster that this DB cluster snapshot was created from.
* SnapshotCreateTime (datetime) –
  Provides the time when the snapshot was taken, in Universal Coordinated Time (UTC).
* Engine (string) –
  Specifies the name of the database engine.
* AllocatedStorage (integer) –
  Specifies the allocated storage size in gigabytes (GB).
* Status (string) –
  Specifies the status of this DB cluster snapshot.
* Port (integer) –
  Specifies the port that the DB cluster was listening on at the time of the snapshot.
* VpcId (string) –
  Provides the VPC ID associated with the DB cluster snapshot.
* ClusterCreateTime (datetime) –
  Specifies the time when the DB cluster was created, in Universal Coordinated Time (UTC).
* MasterUsername (string) –
  Provides the master username for the DB cluster snapshot.
* EngineVersion (string) –
  Provides the version of the database engine for this DB cluster snapshot.
* LicenseModel (string) –
  Provides the license model information for this DB cluster snapshot.
* **SnapshotType** *(string)* –
  Provides the type of the DB cluster snapshot.
* **PercentProgress** *(integer)* –
  Specifies the percentage of the estimated data that has been transferred.

```python
copy_db_parameter_group(**kwargs)
```
Copies the specified DB parameter group.

**Request Syntax**

```python
response = client.copy_db_parameter_group(
    SourceDBParameterGroupIdentifier='string',
    TargetDBParameterGroupIdentifier='string',
    TargetDBParameterGroupDescription='string',
    Tags=[
        {'Key': 'string',
         'Value': 'string'}
    ]
)
```

**Parameters**

- **SourceDBParameterGroupIdentifier** *(string)* – [REQUIRED]
  The identifier or ARN for the source DB parameter group. For information about creating an ARN, see [Constructing an RDS Amazon Resource Name (ARN)](https://docs.aws.amazon.com/AmazonRDS/latest/userguide/RDS-ARN.html).

  Constraints:
  - Must specify a valid DB parameter group.
  - If the source DB parameter group is in the same region as the copy, specify a valid DB parameter group identifier, for example `my-db-param-group`, or a valid ARN.
  - If the source DB parameter group is in a different region than the copy, specify a valid DB parameter group ARN, for example `arn:aws:rds:us-west-2:123456789012:pg:special-parameters`.

- **TargetDBParameterGroupIdentifier** *(string)* – [REQUIRED]
  The identifier for the copied DB parameter group.

  Constraints:
  - Cannot be null, empty, or blank
  - Must contain from 1 to 255 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

  Example: `my-db-parameter-group`

- **TargetDBParameterGroupDescription** *(string)* – [REQUIRED]
  A description for the copied DB parameter group.

- **Tags** *(list)* – A list of tags.
  - *(dict)* –
    Metadata assigned to an Amazon RDS resource consisting of a key-value pair.
    - **Key** *(string)* –
A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘.’, ‘:', '!', '=', '+', '-' (Java regex: “^[^p{L}p{Z}p{N}_:\+/=+\-]*$”).

* **Value (string)** –

A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘.’, ‘:', '!', '=', '+', '-' (Java regex: “^[^p{L}p{Z}p{N}_:\+/=+\-]*$”).

**Return type**  dict

**Returns**

**Response Syntax**

```python
{
  'DBParameterGroup': {
    'DBParameterGroupName': 'string',
    'DBParameterGroupFamily': 'string',
    'Description': 'string'
  }
}
```

**Response Structure**

- **(dict)** –

  Contains the result of a successful invocation of the CreateDBParameterGroup action.

  This data type is used as a request parameter in the DeleteDBParameterGroup action, and as a response element in the DescribeDBParameterGroups action.

  - **DBParameterGroup (dict)** –

    Contains the result of a successful invocation of the CreateDBParameterGroup action.

    This data type is used as a request parameter in the DeleteDBParameterGroup action, and as a response element in the DescribeDBParameterGroups action.

    - **DBParameterGroupName (string)** –

      Provides the name of the DB parameter group.

    - **DBParameterGroupFamily (string)** –

      Provides the name of the DB parameter group family that this DB parameter group is compatible with.

    - **Description (string)** –

      Provides the customer-specified description for this DB parameter group.

**copy_db_snapshot (**kwargs)

Copies the specified DBSnapshot. The source DBSnapshot must be in the “available” state.

**Request Syntax**

```python
response = client.copy_db_snapshot(
    SourceDBSnapshotIdentifier='string',
```

3290 Chapter 3. API Reference
TargetDBSnapshotIdentifier='string',
Tags=[
  {
    'Key': 'string',
    'Value': 'string'
  },
],
CopyTags=True|False

Parameters

• **SourceDBSnapshotIdentifier (string)** – [REQUIRED]
  
The identifier for the source DB snapshot.
  
  Constraints:
  – Must specify a valid system snapshot in the “available” state.
  – If the source snapshot is in the same region as the copy, specify a valid DB
    snapshot identifier.
  – If the source snapshot is in a different region than the copy, specify a valid
    DB snapshot ARN. For more information, go to Copying a DB Snapshot.
  
  Example: rds:mydb-2012-04-02-00-01
  

• **TargetDBSnapshotIdentifier (string)** – [REQUIRED]
  
The identifier for the copied snapshot.
  
  Constraints:
  – Cannot be null, empty, or blank
  – Must contain from 1 to 255 alphanumeric characters or hyphens
  – First character must be a letter
  – Cannot end with a hyphen or contain two consecutive hyphens
  
  Example: my-db-snapshot

• **Tags (list)** – A list of tags.

  – (dict) –

    Metadata assigned to an Amazon RDS resource consisting of a key-value pair.
    
    * **Key (string)** –
      
      A key is the required name of the tag. The string value can be from
      1 to 128 Unicode characters in length and cannot be prefixed with
      “aws:” or “rds:”. The string can only contain only the set of Uni-
      code letters, digits, white-space, ‘_’, ‘‘’, ‘‘’, ‘=’, ‘+’, ‘*’ (Java regex:
      “^[\p{L}|p{Z}|p{N}_.:/=+\-]*$”).

    * **Value (string)** –
      
      A value is the optional value of the tag. The string value can be
      from 1 to 256 Unicode characters in length and cannot be prefixed with
      “aws:” or “rds:”. The string can only contain only the set of Uni-
      code letters, digits, white-space, ‘_’, ‘‘’, ‘‘’, ‘=’, ‘+’, ‘*’ (Java regex:
      “^[\p{L}|p{Z}|p{N}_.:/=+\-]*$”).

• **CopyTags (boolean)** – This property is not currently implemented.

Return type  dict
Returns

  Response Syntax
Response Structure

- (dict) –

Contains the result of a successful invocation of the following actions:

- CreateDBSnapshot
- DeleteDBSnapshot

This data type is used as a response element in the DescribeDBSnapshots action.

- DBSnapshot (dict) –

Contains the result of a successful invocation of the following actions:

- CreateDBSnapshot
- DeleteDBSnapshot

This data type is used as a response element in the DescribeDBSnapshots action.

- DBSnapshotIdentifier (string) –

  Specifies the identifier for the DB snapshot.

- DBInstanceIdentifier (string) –

  Specifies the DB instance identifier of the DB instance this DB snapshot was created from.

- SnapshotCreateTime (datetime) –

  Provides the time when the snapshot was taken, in Universal Coordinated Time (UTC).

- Engine (string) –

  Specifies the name of the database engine.

- AllocatedStorage (integer) –

  Specifies the allocated storage size in gigabytes (GB).
- **Status** *(string)* –
  Specifies the status of this DB snapshot.

- **Port** *(integer)* –
  Specifies the port that the database engine was listening on at the time of the snapshot.

- **AvailabilityZone** *(string)* –
  Specifies the name of the Availability Zone the DB instance was located in at the time of the DB snapshot.

- **VpcId** *(string)* –
  Provides the VPC ID associated with the DB snapshot.

- **InstanceCreateTime** *(datetime)* –
  Specifies the time when the snapshot was taken, in Universal Coordinated Time (UTC).

- **MasterUsername** *(string)* –
  Provides the master username for the DB snapshot.

- **EngineVersion** *(string)* –
  Specifies the version of the database engine.

- **LicenseModel** *(string)* –
  License model information for the restored DB instance.

- **SnapshotType** *(string)* –
  Provides the type of the DB snapshot.

- **Iops** *(integer)* –
  Specifies the Provisioned IOPS (I/O operations per second) value of the DB instance at the time of the snapshot.

- **OptionGroupName** *(string)* –
  Provides the option group name for the DB snapshot.

- **PercentProgress** *(integer)* –
  The percentage of the estimated data that has been transferred.

- **SourceRegion** *(string)* –
  The region that the DB snapshot was created in or copied from.

- **SourceDBSnapshotIdentifier** *(string)* –
  The DB snapshot Arn that the DB snapshot was copied from. It only has value in case of cross customer or cross region copy.

- **StorageType** *(string)* –
  Specifies the storage type associated with DB Snapshot.

- **TdeCredentialArn** *(string)* –
  The ARN from the Key Store with which to associate the instance for TDE encryption.

- **Encrypted** *(boolean)* –
  Specifies whether the DB snapshot is encrypted.

- **KmsKeyId** *(string)* –
  If Encrypted is true, the KMS key identifier for the encrypted DB snapshot.
**copy_option_group** (**kwargs)**

Copies the specified option group.

**Request Syntax**

```python
response = client.copy_option_group(
    SourceOptionGroupIdentifier='string',
    TargetOptionGroupIdentifier='string',
    TargetOptionGroupDescription='string',
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

**Parameters**

- **SourceOptionGroupIdentifier** *(string)* – [REQUIRED]
  The identifier or ARN for the source option group. For information about creating an ARN, see [Constructing an RDS Amazon Resource Name (ARN)](https://aws.amazon.com/rds/arn/).

  Constraints:
  - Must specify a valid option group.
  - If the source option group is in the same region as the copy, specify a valid option group identifier, for example `my-option-group`, or a valid ARN.
  - If the source option group is in a different region than the copy, specify a valid option group ARN, for example `arn:aws:rds:us-west-2:123456789012:og:special-options`.

- **TargetOptionGroupIdentifier** *(string)* – [REQUIRED]
  The identifier for the copied option group.

  Constraints:
  - Cannot be null, empty, or blank
  - Must contain from 1 to 255 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

  Example: `my-option-group`

- **TargetOptionGroupDescription** *(string)* – [REQUIRED]
  The description for the copied option group.

- **Tags** *(list)* – A list of tags.
  - *(dict)* –
    - **Key** *(string)* –
      A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, `_`, `,’`, `‘/’`, `‘:’`, `‘=’`, `‘+’`, `‘*’` (Java regex: “^[\p{L}|\p{Z}|\p{N}_:;=+/\-]*$”).
    - **Value** *(string)* –
A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, '-', '.', '/', '=', '+', '-' (Java regex: "^[p{L}p{Z}\p{N}\p{.-}+/=+\-]*$").

**Return type**  dict

**Returns**

**Response Syntax**

```json
{
    'OptionGroup': {
        'OptionGroupName': 'string',
        'OptionGroupDescription': 'string',
        'EngineName': 'string',
        'MajorEngineVersion': 'string',
        'Options': [
            {
                'OptionName': 'string',
                'OptionDescription': 'string',
                'Persistent': True|False,
                'Permanent': True|False,
                'Port': 123,
                'OptionSettings': [
                    {
                        'Name': 'string',
                        'Value': 'string',
                        'DefaultValue': 'string',
                        'Description': 'string',
                        'ApplyType': 'string',
                        'DataType': 'string',
                        'AllowedValues': 'string',
                        'IsModifiable': True|False,
                        'IsCollection': True|False
                    },
                ],
                'DBSecurityGroupMemberships': [ ]
            },
            ],
            'DBSecurityGroupName': 'string',
            'Status': 'string'
        },
        'VpcSecurityGroupMemberships': [ ],
        'VpcSecurityGroupId': 'string',
        'Status': 'string'
    },
    'AllowsVpcAndNonVpcInstanceMemberships': True|False,
    'VpcId': 'string'
}
```

**Response Structure**

- *(dict)*
  - **OptionGroup** *(dict)*
* OptionGroupName (string) –
  Specifies the name of the option group.
* OptionGroupDescription (string) –
  Provides a description of the option group.
* EngineName (string) –
  Indicates the name of the engine that this option group can be applied to.
* MajorEngineVersion (string) –
  Indicates the major engine version associated with this option group.
* Options (list) –
  Indicates what options are available in the option group.
  · (dict) –
    · OptionName (string) –
      The name of the option.
    · OptionDescription (string) –
      The description of the option.
    · Persistent (boolean) –
      Indicate if this option is persistent.
    · Permanent (boolean) –
      Indicate if this option is permanent.
    · Port (integer) –
      If required, the port configured for this option to use.
    · OptionSettings (list) –
      The option settings for this option.
      · (dict) –
        Option settings are the actual settings being applied or configured for that option. It is used when you modify an option group or describe option groups. For example, the NATIVE_NETWORK_ENCRYPTION option has a setting called SQLNET.ENCRYPTION_SERVER that can have several different values.
      · Name (string) –
        The name of the option that has settings that you can set.
      · Value (string) –
        The current value of the option setting.
      · DefaultValue (string) –
        The default value of the option setting.
      · Description (string) –
        The description of the option setting.
      · ApplyType (string) –
        The DB engine specific parameter type.
      · DataType (string) –
        The data type of the option setting.
**create_db_cluster(**kwargs)**

Creates a new Amazon Aurora DB cluster. For more information on Amazon Aurora, see Aurora on Amazon RDS in the Amazon RDS User Guide.

**Request Syntax**
response = client.create_db_cluster(
    AvailabilityZones=[
        'string',
    ],
    BackupRetentionPeriod=123,
    CharacterSetName='string',
    DatabaseName='string',
    DBClusterIdentifier='string',
    DBClusterParameterGroupName='string',
    VpcSecurityGroupIds=[
        'string',
    ],
    DBSubnetGroupName='string',
    Engine='string',
    EngineVersion='string',
    Port=123,
    MasterUsername='string',
    MasterUserPassword='string',
    OptionGroupName='string',
    PreferredBackupWindow='string',
    PreferredMaintenanceWindow='string',
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ],
)

Parameters

- **AvailabilityZones** *(list)* – A list of EC2 Availability Zones that instances in the DB cluster can be created in. For information on regions and Availability Zones, see Regions and Availability Zones.
  - *(string)*

- **BackupRetentionPeriod** *(integer)* – The number of days for which automated backups are retained. Setting this parameter to a positive number enables backups. Setting this parameter to 0 disables automated backups.
  Default: 1

  Constraints:
  - Must be a value from 0 to 35

- **CharacterSetName** *(string)* – A value that indicates that the DB cluster should be associated with the specified CharSet.

- **DatabaseName** *(string)* – The name for your database of up to 8 alpha-numeric characters. If you do not provide a name, Amazon RDS will not create a database in the DB cluster you are creating.

- **DBClusterIdentifier** *(string)* – The DB cluster identifier. This parameter is stored as a lowercase string.

  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens.
  - First character must be a letter.
  - Cannot end with a hyphen or contain two consecutive hyphens.

  Example: my-cluster1

- **DBClusterParameterGroupName** *(string)* – The name of the DB cluster parameter group to associate with this DB cluster. If this argument is omitted,
default.aurora5.6 for the specified engine will be used.

Constraints:
- Must be 1 to 255 alphanumeric characters
- First character must be a letter
- Cannot end with a hyphen or contain two consecutive hyphens

- **VpcSecurityGroupIds** *(list)* – A list of EC2 VPC security groups to associate with this DB cluster.
  - *(string)* –

- **DBSubnetGroupName** *(string)* – A DB subnet group to associate with this DB cluster.

- **Engine** *(string)* – The name of the database engine to be used for this DB cluster.
  Valid Values: MySQL
  Example: Aurora
  5.6.0

- **Port** *(integer)* – The port number on which the instances in the DB cluster accept connections.
  Default: 3306

- **MasterUsername** *(string)* – The name of the master user for the client DB cluster.
  Constraints:
  - Must be 1 to 16 alphanumeric characters.
  - First character must be a letter.
  - Cannot be a reserved word for the chosen database engine.

- **MasterUserPassword** *(string)* – The password for the master database user. This password can contain any printable ASCII character except “/”, “\”, or “@”.
  Constraints: Must contain from 8 to 41 characters.

- **OptionGroupName** *(string)* – A value that indicates that the DB cluster should be associated with the specified option group.
  Permanent options cannot be removed from an option group. The option group cannot be removed from a DB cluster once it is associated with a DB cluster.

- **PreferredBackupWindow** *(string)* – The daily time range during which automated backups are created if automated backups are enabled using the `BackupRetentionPeriod` parameter.
  Default: A 30-minute window selected at random from an 8-hour block of time per region. To see the time blocks available, see Adjusting the Preferred Maintenance Window in the Amazon RDS User Guide.
  Constraints:
  - Must be in the format `hh24:mi-hh24:mi`.
  - Times should be in Universal Coordinated Time (UTC).
  - Must not conflict with the preferred maintenance window.
  - Must be at least 30 minutes.

- **PreferredMaintenanceWindow** *(string)* – The weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).
  Default: A 30-minute window selected at random from an 8-hour block of time per region, occurring on a random day of the week. To see the time blocks
available, see Adjusting the Preferred Maintenance Window in the Amazon RDS User Guide.

Valid Days: Mon, Tue, Wed, Thu, Fri, Sat, Sun

Constraints: Minimum 30-minute window.

- **Tags** (*list*) – A list of tags.
  - (*dict*) –

    Metadata assigned to an Amazon RDS resource consisting of a key-value pair.
    
    - **Key** (*string*) –
      
      A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with "aws:" or "rds:"
      . The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘’, ‘,’ , ‘’ , ‘’ (Java regex: "^(\[\p{L}\p{Z}\p{N}_.:/=+-\]*)_$.")
    
    - **Value** (*string*) –
      
      A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with "aws:" or "rds:"
      . The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘’, ‘,’ , ‘’ , ‘’ (Java regex: "^(\[\p{L}\p{Z}\p{N}_.:/=+-\]*)_$.")

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'DBCluster': {
        'AllocatedStorage': 123,
        'AvailabilityZones': [string],
        'BackupRetentionPeriod': 123,
        'CharacterSetName': 'string',
        'DatabaseName': 'string',
        'DBClusterIdentifier': 'string',
        'DBClusterParameterGroup': 'string',
        'DBSubnetGroup': 'string',
        'Status': 'string',
        'PercentProgress': 'string',
        'EarliestRestorableTime': datetime(2015, 1, 1),
        'Endpoint': 'string',
        'Engine': 'string',
        'EngineVersion': 'string',
        'LatestRestorableTime': datetime(2015, 1, 1),
        'Port': 123,
        'MasterUsername': 'string',
        'DBClusterOptionGroupMemberships': [dict]
            {DBClusterOptionGroupName: 'string',
             'Status': 'string'},
        ],
    'PreferredBackupWindow': 'string',
    'PreferredMaintenanceWindow': 'string'
}
```
Response Structure

- (dict) –

Contains the result of a successful invocation of the following actions:
- CreateDBCluster
- DeleteDBCluster
- FailoverDBCluster
- ModifyDBCluster
- RestoreDBClusterFromSnapshot

This data type is used as a response element in the DescribeDBClusters action.

- DBCluster (dict) –

Contains the result of a successful invocation of the following actions:
- CreateDBCluster
- DeleteDBCluster
- FailoverDBCluster
- ModifyDBCluster
- RestoreDBClusterFromSnapshot

This data type is used as a response element in the DescribeDBClusters action.

- AllocatedStorage (integer) –

Specifies the allocated storage size in gigabytes (GB).

- AvailabilityZones (list) –

Provides the list of EC2 Availability Zones that instances in the DB cluster can be created in.

- BackupRetentionPeriod (integer) –

Specifies the number of days for which automatic DB snapshots are retained.

- CharacterSetName (string) –

If present, specifies the name of the character set that this cluster is associated with.

- DatabaseName (string) –

Contains the name of the initial database of this DB cluster that was provided at create time, if one was specified when the DB cluster was created. This same name is returned for the life of the DB cluster.
* **DBClusterIdentifier (string)** –
  Contains a user-supplied DB cluster identifier. This identifier is the unique key that identifies a DB cluster.

* **DBClusterParameterGroup (string)** –
  Specifies the name of the DB cluster parameter group for the DB cluster.

* **DBSubnetGroup (string)** –
  Specifies information on the subnet group associated with the DB cluster, including the name, description, and subnets in the subnet group.

* **Status (string)** –
  Specifies the current state of this DB cluster.

* **PercentProgress (string)** –
  Specifies the progress of the operation as a percentage.

* **EarliestRestorableTime (datetime)** –
  Specifies the earliest time to which a database can be restored with point-in-time restore.

* **Endpoint (string)** –
  Specifies the connection endpoint for the primary instance of the DB cluster.

* **Engine (string)** –
  Provides the name of the database engine to be used for this DB cluster.

* **EngineVersion (string)** –
  Indicates the database engine version.

* **LatestRestorableTime (datetime)** –
  Specifies the latest time to which a database can be restored with point-in-time restore.

* **Port (integer)** –
  Specifies the port that the database engine is listening on.

* **MasterUsername (string)** –
  Contains the master username for the DB cluster.

* **DBClusterOptionGroupMemberships (list)** –
  Provides the list of option group memberships for this DB cluster.
  · **(dict)** –
    - Contains status information for a DB cluster option group.
      · **DBClusterOptionGroupName (string)** –
        Specifies the name of the DB cluster option group.
      · **Status (string)** –
        Specifies the status of the DB cluster option group.

* **PreferredBackupWindow (string)** –
  Specifies the daily time range during which automated backups are created if automated backups are enabled, as determined by the BackupRetentionPeriod.
* **PreferredMaintenanceWindow** (*string*)

  Specifies the weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).

* **DBClusterMembers** (*list*)

  Provides the list of instances that make up the DB cluster.

  · **(dict)**

    Contains information about an instance that is part of a DB cluster.

    · **DBInstanceIdentifier** (*string*)

      Specifies the instance identifier for this member of the DB cluster.

    · **IsClusterWriter** (*boolean*)

      Value that is true if the cluster member is the primary instance for the DB cluster and false otherwise.

    · **DBClusterParameterGroupStatus** (*string*)

      Specifies the status of the DB cluster parameter group for this member of the DB cluster.

* **VpcSecurityGroups** (*list*)

  Provides a list of VPC security groups that the DB cluster belongs to.

  · **(dict)**

    This data type is used as a response element for queries on VPC security group membership.

    · **VpcSecurityGroupId** (*string*)

      The name of the VPC security group.

    · **Status** (*string*)

      The status of the VPC security group.

`create_db_cluster_parameter_group (**kwargs)`

Creates a new DB cluster parameter group.

Parameters in a DB cluster parameter group apply to all of the instances in a DB cluster.

A DB cluster parameter group is initially created with the default parameters for the database engine used by instances in the DB cluster. To provide custom values for any of the parameters, you must modify the group after creating it using `ModifyDBClusterParameterGroup` . Once you’ve created a DB cluster parameter group, you need to associate it with your DB cluster using `ModifyDBCluster` . When you associate a new DB cluster parameter group with a running DB cluster, you need to reboot the DB instances in the DB cluster without failover for the new DB cluster parameter group and associated settings to take effect.

**Warning:** After you create a DB cluster parameter group, you should wait at least 5 minutes before creating your first DB cluster that uses that DB cluster parameter group as the default parameter group. This allows Amazon RDS to fully complete the create action before the DB cluster parameter group is used as the default for a new DB cluster. This is especially important for parameters that are critical when creating the default database for a DB cluster, such as the character set for the default database defined by the `character_set_database` parameter. You can use the `Parameter Groups` option of the Amazon RDS console or the `DescribeDBClusterParameters` command to verify that your DB cluster parameter group has been created or modified.
For more information on Amazon Aurora, see Aurora on Amazon RDS in the Amazon RDS User Guide.

**Request Syntax**

```python
def create_db_cluster_parameter_group(DBClusterParameterGroupName='string',
                                     DBParameterGroupFamily='string',
                                     Description='string',
                                     Tags=[
                                          {
                                             'Key': 'string',
                                             'Value': 'string'
                                          },
                                      ]
                                 )
```

**Parameters**

- **DBClusterParameterGroupName (string)** – [REQUIRED]
  
  The name of the DB cluster parameter group.

  Constraints:
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

  **Note:** This value is stored as a lowercase string.

- **DBParameterGroupFamily (string)** – [REQUIRED]
  
  The DB cluster parameter group family name. A DB cluster parameter group can be associated with one and only one DB cluster parameter group family, and can be applied only to a DB cluster running a database engine and engine version compatible with that DB cluster parameter group family.

- **Description (string)** – [REQUIRED]
  
  The description for the DB cluster parameter group.

- **Tags (list)** – A list of tags.
  - (dict) –

    Metadata assigned to an Amazon RDS resource consisting of a key-value pair.

    - **Key (string)** –
      
      A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘:’, ‘+’, ‘-’ (Java regex: “^[\p{L}\p{Z}\p{N}.:/=+-]+$”).

    - **Value (string)** –
      
      A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘:’, ‘+’, ‘-’ (Java regex: “^[\p{L}\p{Z}\p{N}.:/=+-]+$”).

**Return type**  dict

**Returns**

**Response Syntax**
Response Structure

- (dict) –
Contains the result of a successful invocation of the CreateDBClusterParameterGroup action.

This data type is used as a request parameter in the DeleteDBClusterParameterGroup action, and as a response element in the DescribeDBClusterParameterGroups action.

- DBClusterParameterGroup (dict) –
Contains the result of a successful invocation of the CreateDBClusterParameterGroup action.

This data type is used as a request parameter in the DeleteDBClusterParameterGroup action, and as a response element in the DescribeDBClusterParameterGroups action.

- DBClusterParameterGroupName (string) –
Provides the name of the DB cluster parameter group.

- DBParameterGroupFamily (string) –
Provides the name of the DB parameter group family that this DB cluster parameter group is compatible with.

- Description (string) –
Provides the customer-specified description for this DB cluster parameter group.

create_db_cluster_snapshot (**kwargs)

Creates a snapshot of a DB cluster. For more information on Amazon Aurora, see Aurora on Amazon RDS in the Amazon RDS User Guide.

Request Syntax

response = client.create_db_cluster_snapshot(
    DBClusterSnapshotIdentifier='string',
    DBClusterIdentifier='string',
    Tags=[
    
    
    ]
)

Parameters

- DBClusterSnapshotIdentifier (string) – [REQUIRED]
  The identifier of the DB cluster snapshot. This parameter is stored as a lowercase string.
Constraints:
- Must contain from 1 to 63 alphanumeric characters or hyphens.
- First character must be a letter.
- Cannot end with a hyphen or contain two consecutive hyphens.

Example: my-cluster1-snapshot1

**DBClusterIdentifier (string)** – [REQUIRED]

The identifier of the DB cluster to create a snapshot for. This parameter is not case-sensitive.

Constraints:
- Must contain from 1 to 63 alphanumeric characters or hyphens.
- First character must be a letter.
- Cannot end with a hyphen or contain two consecutive hyphens.

Example: my-cluster1

**Tags (list)** – The tags to be assigned to the DB cluster snapshot.

- (dict) – Metadata assigned to an Amazon RDS resource consisting of a key-value pair.
  
  **Key (string)** –

  A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘=’, ‘+’, ‘-’ (Java regex: “^(\[\p{L}\p{Z}\p{N}_.:/=+\-]*$)”).

  **Value (string)** –

  A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘=’, ‘+’, ‘-’ (Java regex: “^(\[\p{L}\p{Z}\p{N}_.:/=+\-]*$)”).

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'DBClusterSnapshot': {
        'AvailabilityZones': [string],
        'DBClusterSnapshotIdentifier': 'string',
        'DBClusterIdentifier': 'string',
        'SnapshotCreateTime': datetime(2015, 1, 1),
        'Engine': 'string',
        'AllocatedStorage': 123,
        'Status': 'string',
        'Port': 123,
        'VpcId': 'string',
        'ClusterCreateTime': datetime(2015, 1, 1),
        'MasterUsername': 'string',
        'EngineVersion': 'string',
        'LicenseModel': 'string',
        'SnapshotType': 'string',
        'PercentProgress': 123
    }
}
```
Response Structure

- **(dict)** –
  Contains the result of a successful invocation of the following actions:
  - CreateDBClusterSnapshot
  - DeleteDBClusterSnapshot
  This data type is used as a response element in the DescribeDBClusterSnapshots action.

  - **DBClusterSnapshot**(dict)** –
    Contains the result of a successful invocation of the following actions:
    - CreateDBClusterSnapshot
    - DeleteDBClusterSnapshot
    This data type is used as a response element in the DescribeDBClusterSnapshots action.

    * **AvailabilityZones**(list)** –
      Provides the list of EC2 Availability Zones that instances in the DB cluster snapshot can be restored in.
      - **(string)** –
    * **DBClusterSnapshotIdentifier**(string)** –
      Specifies the identifier for the DB cluster snapshot.
    * **DBClusterIdentifier**(string)** –
      Specifies the DB cluster identifier of the DB cluster that this DB cluster snapshot was created from.
    * **SnapshotCreateTime**(datetime)** –
      Provides the time when the snapshot was taken, in Universal Coordinated Time (UTC).
    * **Engine**(string)** –
      Specifies the name of the database engine.
    * **AllocatedStorage**(integer)** –
      Specifies the allocated storage size in gigabytes (GB).
    * **Status**(string)** –
      Specifies the status of this DB cluster snapshot.
    * **Port**(integer)** –
      Specifies the port that the DB cluster was listening on at the time of the snapshot.
    * **VpcId**(string)** –
      Provides the VPC ID associated with the DB cluster snapshot.
    * **ClusterCreateTime**(datetime)** –
      Specifies the time when the DB cluster was created, in Universal Coordinated Time (UTC).
    * **MasterUsername**(string)** –
      Provides the master username for the DB cluster snapshot.
    * **EngineVersion**(string)** –
      Provides the version of the database engine for this DB cluster snapshot.
* LicenseModel *(string)* –
  Provides the license model information for this DB cluster snapshot.
* SnapshotType *(string)* –
  Provides the type of the DB cluster snapshot.
* PercentProgress *(integer)* –
  Specifies the percentage of the estimated data that has been transferred.

`create_db_instance(**kwargs)`

Creates a new DB instance.

**Request Syntax**

```python
response = client.create_db_instance(
    DBName='string',
    DBInstanceIdentifier='string',
    AllocatedStorage=123,
    DBInstanceClass='string',
    Engine='string',
    MasterUsername='string',
    MasterUserPassword='string',
    DBSecurityGroups=[
        'string',
    ],
    VpcSecurityGroupIds=[
        'string',
    ],
    AvailabilityZone='string',
    DBSubnetGroup='string',
    PreferredMaintenanceWindow='string',
    DBParameterGroupName='string',
    BackupRetentionPeriod=123,
    PreferredBackupWindow='string',
    Port=123,
    MultiAZ=True|False,
    EngineVersion='string',
    AutoMinorVersionUpgrade=True|False,
    LicenseModel='string',
    Iops=123,
    OptionGroupMember='string',
    PubliclyAccessible=True|False,
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ],
    DBClusterIdentifier='string',
    StorageType='string',
    TdeCredentialArn='string',
    TdeCredentialPassword='string',
    StorageEncrypted=True|False,
    KmsKeyId='string',
    Domain='string',
    CopyTagsToSnapshot=True|False
)
```
Parameters

- **DBName** *(string)* – The meaning of this parameter differs according to the database engine you use.

  Type: String

  **MySQL**
  The name of the database to create when the DB instance is created. If this parameter is not specified, no database is created in the DB instance.

  Constraints:
  - Must contain 1 to 64 alphanumeric characters
  - Cannot be a word reserved by the specified database engine

  **PostgreSQL**
  The name of the database to create when the DB instance is created. If this parameter is not specified, the default “postgres” database is created in the DB instance.

  Constraints:
  - Must contain 1 to 63 alphanumeric characters
  - Must begin with a letter or an underscore. Subsequent characters can be letters, underscores, or digits (0-9).
  - Cannot be a word reserved by the specified database engine

  **Oracle**
  The Oracle System ID (SID) of the created DB instance.

  Default: ORCL

  Constraints:
  - Cannot be longer than 8 characters

  **SQL Server**
  Not applicable. Must be null.

- **DBInstanceIdentifier** *(string)* – [REQUIRED]

  The DB instance identifier. This parameter is stored as a lowercase string.

  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens (1 to 15 for SQL Server).
  - First character must be a letter.
  - Cannot end with a hyphen or contain two consecutive hyphens.

  Example: mydbinstance

- **AllocatedStorage** *(integer)* – The amount of storage (in gigabytes) to be initially allocated for the database instance.

  Type: Integer

  **MySQL**
  Constraints: Must be an integer from 5 to 6144.

  **PostgreSQL**
  Constraints: Must be an integer from 5 to 6144.

  **Oracle**
  Constraints: Must be an integer from 10 to 6144.

  **SQL Server**
  Constraints: Must be an integer from 200 to 4096 (Standard Edition and Enterprise Edition) or from 20 to 4096 (Express Edition and Web Edition)
• **DBInstanceClass** *(string)* – [REQUIRED]
  
  The compute and memory capacity of the DB instance.
  
  Valid Values:  
  - `db.t1.micro` | `db.m1.small` | `db.m1.medium`  
  - `db.m1.large` | `db.m1.xlarge` | `db.m2.xlarge`  
  - `db.m2.2xlarge` | `db.m2.4xlarge` | `db.m3.medium`  
  - `db.m3.large` | `db.m3.xlarge` | `db.m3.2xlarge`  
  - `db.r3.large` | `db.r3.xlarge` | `db.r3.2xlarge`  
  - `db.r3.4xlarge` | `db.r3.8xlarge` | `db.t2.micro`  
  - `db.t2.small` | `db.t2.medium`

• **Engine** *(string)* – [REQUIRED]
  
  The name of the database engine to be used for this instance.
  
  Valid Values:  
  - `MySQL` | `oracle-se1` | `oracle-se` | `oracle-ee`  
  - `sqlserver-ee` | `sqlserver-se` | `sqlserver-ex` | `sqlserver-web`  
  - `postgres`

  Not every database engine is available for every AWS region.

• **MasterUsername** *(string)* – The name of master user for the client DB instance.

  **MySQL**
  
  Constraints:
  - Must be 1 to 16 alphanumeric characters.
  - First character must be a letter.
  - Cannot be a reserved word for the chosen database engine.
  
  Type: String

  **Oracle**
  
  Constraints:
  - Must be 1 to 30 alphanumeric characters.
  - First character must be a letter.
  - Cannot be a reserved word for the chosen database engine.

  **SQL Server**
  
  Constraints:
  - Must be 1 to 128 alphanumeric characters.
  - First character must be a letter.
  - Cannot be a reserved word for the chosen database engine.

  **PostgreSQL**
  
  Constraints:
  - Must be 1 to 63 alphanumeric characters.
  - First character must be a letter.
  - Cannot be a reserved word for the chosen database engine.

• **MasterUserPassword** *(string)* – The password for the master database user. Can be any printable ASCII character except “/”, “”", or “@”.

  Type: String

  **MySQL**
  
  Constraints: Must contain from 8 to 41 characters.

  **Oracle**
  
  Constraints: Must contain from 8 to 30 characters.

  **SQL Server**
  
  Constraints: Must contain from 8 to 128 characters.

  **PostgreSQL**
  
  Constraints: Must contain from 8 to 128 characters.
• **DBSecurityGroups** *(list)* – A list of DB security groups to associate with this DB instance.
  Default: The default DB security group for the database engine.
  – *(string)* –

• **VpcSecurityGroupIds** *(list)* – A list of EC2 VPC security groups to associate with this DB instance.
  Default: The default EC2 VPC security group for the DB subnet group’s VPC.
  – *(string)* –

• **AvailabilityZone** *(string)* – The EC2 Availability Zone that the database instance will be created in. For information on regions and Availability Zones, see Regions and Availability Zones.
  Default: A random, system-chosen Availability Zone in the endpoint’s region.

  Example: us-east-1d

  Constraint: The AvailabilityZone parameter cannot be specified if the MultiAZ parameter is set to true. The specified Availability Zone must be in the same region as the current endpoint.

• **DBSubnetGroupName** *(string)* – A DB subnet group to associate with this DB instance.

  If there is no DB subnet group, then it is a non-VPC DB instance.

• **PreferredMaintenanceWindow** *(string)* – The weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC). For more information, see DB Instance Maintenance.
  Format: *ddd:hh24:mi-ddd:hh24:mi*

  Default: A 30-minute window selected at random from an 8-hour block of time per region, occurring on a random day of the week. To see the time blocks available, see Adjusting the Preferred Maintenance Window in the Amazon RDS User Guide.

  Valid Days: Mon, Tue, Wed, Thu, Fri, Sat, Sun

  Constraints: Minimum 30-minute window.

• **DBParameterGroupName** *(string)* – The name of the DB parameter group to associate with this DB instance. If this argument is omitted, the default DBParameterGroup for the specified engine will be used.

  Constraints:
  – Must be 1 to 255 alphanumeric characters
  – First character must be a letter
  – Cannot end with a hyphen or contain two consecutive hyphens

• **BackupRetentionPeriod** *(integer)* – The number of days for which automated backups are retained. Setting this parameter to a positive number enables backups. Setting this parameter to 0 disables automated backups.
  Default: 1

  Constraints:
  – Must be a value from 0 to 35
  – Cannot be set to 0 if the DB instance is a source to Read Replicas

• **PreferredBackupWindow** *(string)* – The daily time range during which automated backups are created if automated backups are enabled, using the BackupRetentionPeriod parameter. For more information, see DB Instance Backups.
Default: A 30-minute window selected at random from an 8-hour block of time per region. To see the time blocks available, see Adjusting the Preferred Maintenance Window in the Amazon RDS User Guide.

Constraints:
- Must be in the format hh24:mi-hh24:mi.
- Times should be in Universal Coordinated Time (UTC).
- Must not conflict with the preferred maintenance window.
- Must be at least 30 minutes.

• **Port (integer)** – The port number on which the database accepts connections.
  - MySQL
    - Default: 3306
    - Valid Values: 1150–65535
    - Type: Integer
  - PostgreSQL
    - Default: 5432
    - Valid Values: 1150–65535
    - Type: Integer
  - Oracle
    - Default: 1521
    - Valid Values: 1150–65535
  - SQL Server
    - Default: 1433
    - Valid Values: 1150–65535 except for 1434, 3389, 47001, 49152, and 49152 through 49156.

• **MultiAZ (boolean)** – Specifies if the DB instance is a Multi-AZ deployment. You cannot set the AvailabilityZone parameter if the MultiAZ parameter is set to true. Do not set this value if you want a Multi-AZ deployment for a SQL Server DB instance. Multi-AZ for SQL Server is set using the Mirroring option in an option group.

• **EngineVersion (string)** – The version number of the database engine to use.

The following are the database engines and major and minor versions that are available with Amazon RDS. Not every database engine is available for every AWS region.

**MySQL**
- Version 5.1 (Only available in the following regions: ap-northeast-1, ap-southeast-1, ap-southeast-2, eu-west-1, sa-east-1, us-west-1, us-west-2): 5.1.73a | 5.1.73b
- Version 5.5 (Only available in the following regions: ap-northeast-1, ap-southeast-1, ap-southeast-2, eu-west-1, sa-east-1, us-west-1, us-west-2): 5.5.40 | 5.5.40a
- Version 5.5 (Available in all regions): 5.5.40a | 5.5.41 | 5.5.42
- Version 5.6 (Available in all regions): 5.6.19a | 5.6.19b | 5.6.21 | 5.6.21b | 5.6.22 | 5.6.23

**MySQL**
- Version 5.1 (Only available in the following regions: ap-northeast-1, ap-southeast-1, ap-southeast-2, eu-west-1, sa-east-1, us-west-1, us-west-2): 5.1.73a | 5.1.73b
– Version 5.5 (Only available in the following regions: ap-northeast-1, ap-southeast-1, ap-southeast-2, eu-west-1, sa-east-1, us-west-1, us-west-2): 5.5.40 | 5.5.40a
– Version 5.5 (Available in all regions): 5.5.40b | 5.5.41 | 5.5.42
– Version 5.6 (Available in all regions): 5.6.19a | 5.6.19b | 5.6.21 | 5.6.21b | 5.6.22 | 5.6.23
MySQL
– Version 5.1 (Only available in the following regions: ap-northeast-1, ap-southeast-1, ap-southeast-2, eu-west-1, sa-east-1, us-west-1, us-west-2): 5.1.73a | 5.1.73b
– Version 5.5 (Only available in the following regions: ap-northeast-1, ap-southeast-1, ap-southeast-2, eu-west-1, sa-east-1, us-west-1, us-west-2): 5.5.40 | 5.5.40a
– Version 5.5 (Available in all regions): 5.5.40b | 5.5.41 | 5.5.42
– Version 5.6 (Available in all regions): 5.6.19a | 5.6.19b | 5.6.21 | 5.6.21b | 5.6.22 | 5.6.23
MySQL
– Version 5.1 (Only available in the following regions: ap-northeast-1, ap-southeast-1, ap-southeast-2, eu-west-1, sa-east-1, us-west-1, us-west-2): 5.1.73a | 5.1.73b
– Version 5.5 (Only available in the following regions: ap-northeast-1, ap-southeast-1, ap-southeast-2, eu-west-1, sa-east-1, us-west-1, us-west-2): 5.5.40 | 5.5.40a
– Version 5.5 (Available in all regions): 5.5.40b | 5.5.41 | 5.5.42
– Version 5.6 (Available in all regions): 5.6.19a | 5.6.19b | 5.6.21 | 5.6.21b | 5.6.22 | 5.6.23
Oracle Database Enterprise Edition (oracle-ee)
– Version 11.2 (Only available in the following regions: ap-northeast-1, ap-southeast-1, ap-southeast-2, eu-west-1, sa-east-1, us-west-1, us-west-2): 11.2.0.2.v3 | 11.2.0.2.v4 | 11.2.0.2.v5 | 11.2.0.2.v6 | 11.2.0.2.v7
– Version 11.2 (Available in all regions): 11.2.0.3.v1 | 11.2.0.4.v1 | 11.2.0.4.v3
– Version 12.1 (Available in all regions): 12.1.0.1.v1
Oracle Database Enterprise Edition (oracle-ee)
– Version 11.2 (Only available in the following regions: ap-northeast-1, ap-southeast-1, ap-southeast-2, eu-west-1, sa-east-1, us-west-1, us-west-2): 11.2.0.2.v3 | 11.2.0.2.v4 | 11.2.0.2.v5 | 11.2.0.2.v6 | 11.2.0.2.v7
– Version 11.2 (Available in all regions): 11.2.0.3.v1 | 11.2.0.4.v1 | 11.2.0.4.v3
– Version 12.1 (Available in all regions): 12.1.0.1.v1
Oracle Database Enterprise Edition (oracle-ee)
– Version 11.2 (Only available in the following regions: ap-northeast-1, ap-southeast-1, ap-southeast-2, eu-west-1, sa-east-1, us-west-1, us-west-2): 11.2.0.2.v3 | 11.2.0.2.v4 | 11.2.0.2.v5 | 11.2.0.2.v6 | 11.2.0.2.v7
– Version 11.2 (Available in all regions): 11.2.0.3.v1 | 11.2.0.4.v1 | 11.2.0.4.v3
– Version 12.1 (Available in all regions): 12.1.0.1.v1
Oracle Database Standard Edition (oracle-se)
– Version 11.2 (Only available in the following regions: us-west-1): 11.2.0.2.v3 | 11.2.0.2.v4 | 11.2.0.2.v5 | 11.2.0.2.v6 | 11.2.0.2.v7

– Version 11.2 (Only available in the following regions: eu-central-1, us-west-1): 11.2.0.3.v1 | 11.2.0.3.v2 | 11.2.0.4.v1 | 11.2.0.4.v3

– Version 12.1 (Only available in the following regions: eu-central-1, us-west-1): 12.1.0.1.v1

Oracle Database Standard Edition (oracle-se)
– Version 11.2 (Only available in the following regions: us-west-1): 11.2.0.2.v3 | 11.2.0.2.v4 | 11.2.0.2.v5 | 11.2.0.2.v6 | 11.2.0.2.v7

– Version 11.2 (Only available in the following regions: eu-central-1, us-west-1): 11.2.0.3.v1 | 11.2.0.3.v2 | 11.2.0.4.v1 | 11.2.0.4.v3

– Version 12.1 (Only available in the following regions: eu-central-1, us-west-1): 12.1.0.1.v1

Oracle Database Standard Edition One (oracle-se1)
– Version 11.2 (Only available in the following regions: us-west-1): 11.2.0.2.v3 | 11.2.0.2.v4 | 11.2.0.2.v5 | 11.2.0.2.v6 | 11.2.0.2.v7

– Version 11.2 (Only available in the following regions: eu-central-1, us-west-1): 11.2.0.3.v1 | 11.2.0.3.v2 | 11.2.0.4.v1 | 11.2.0.4.v3

– Version 12.1 (Only available in the following regions: eu-central-1, us-west-1): 12.1.0.1.v1

Oracle Database Standard Edition One (oracle-se1)
– Version 11.2 (Only available in the following regions: us-west-1): 11.2.0.2.v3 | 11.2.0.2.v4 | 11.2.0.2.v5 | 11.2.0.2.v6 | 11.2.0.2.v7

– Version 11.2 (Only available in the following regions: eu-central-1, us-west-1): 11.2.0.3.v1 | 11.2.0.3.v2 | 11.2.0.4.v1 | 11.2.0.4.v3

– Version 12.1 (Only available in the following regions: eu-central-1, us-west-1): 12.1.0.1.v1

Oracle Database Standard Edition One (oracle-se1)
– Version 11.2 (Only available in the following regions: us-west-1): 11.2.0.2.v3 | 11.2.0.2.v4 | 11.2.0.2.v5 | 11.2.0.2.v6 | 11.2.0.2.v7

– Version 11.2 (Only available in the following regions: eu-central-1, us-west-1): 11.2.0.3.v1 | 11.2.0.3.v2 | 11.2.0.4.v1 | 11.2.0.4.v3

– Version 12.1 (Only available in the following regions: eu-central-1, us-west-1): 12.1.0.1.v1

PostgreSQL
• AutoMinorVersionUpgrade (boolean) – Indicates that minor engine upgrades will be applied automatically to the DB instance during the maintenance window.
  
  Default: true
• LicenseModel (string) – License model information for this DB instance.
  
  Valid values: license-included | bring-your-own-license | general-public-license

• Iops (integer) – The amount of Provisioned IOPS (input/output operations per second) to be initially allocated for the DB instance.
Constraints: To use PIOPS, this value must be an integer greater than 1000.

- **OptionGroupName (string)** – Indicates that the DB instance should be associated with the specified option group.

Permanent options, such as the TDE option for Oracle Advanced Security TDE, cannot be removed from an option group, and that option group cannot be removed from a DB instance once it is associated with a DB instance

- **CharacterSetName (string)** – For supported engines, indicates that the DB instance should be associated with the specified CharacterSet.

- **PubliclyAccessible (boolean)** – Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.

Default: The default behavior varies depending on whether a VPC has been requested or not. The following list shows the default behavior in each case.

  - **Default VPC**: true
  - **VPC**: false

If no DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be publicly accessible. If a specific DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be private.

- **Tags (list)** – A list of tags.
  - **(dict)** – Metadata assigned to an Amazon RDS resource consisting of a key-value pair.
    - **Key (string)** – A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘‘_’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘', (Java regex: "^([\p{L}\p{Z}\p{N}_[:=\-\+\*]+)$")
    - **Value (string)** – A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘‘_’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘’, ‘', (Java regex: "^([\p{L}\p{Z}\p{N}_[:=\-\+\*]+)$")

- **DBClusterIdentifier (string)** – The identifier of the DB cluster that the instance will belong to.

For information on creating a DB cluster, see CreateDBCluster.

Type: String

- **StorageType (string)** – Specifies the storage type to be associated with the DB instance.

Valid values: standard | gp2 | io1

If you specify io1, you must also include a value for the Iops parameter.

Default: io1 if the Iops parameter is specified; otherwise standard

- **TdeCredentialArn (string)** – The ARN from the Key Store with which to associate the instance for TDE encryption.
• **TdeCredentialPassword** *(string)* – The password for the given ARN from the Key Store in order to access the device.

• **StorageEncrypted** *(boolean)* – Specifies whether the DB instance is encrypted.

  Default: false

• **KmsKeyId** *(string)* – The KMS key identifier for an encrypted DB instance.

  The KMS key identifier is the Amazon Resource Name (ARN) for the KMS encryption key. If you are creating a DB instance with the same AWS account that owns the KMS encryption key used to encrypt the new DB instance, then you can use the KMS key alias instead of the ARN for the KM encryption key.

  If the `StorageEncrypted` parameter is true, and you do not specify a value for the `KmsKeyId` parameter, then Amazon RDS will use your default encryption key. AWS KMS creates the default encryption key for your AWS account. Your AWS account has a different default encryption key for each AWS region.

• **Domain** *(string)* – Specify the Active Directory Domain to create the instance in.

• **CopyTagsToSnapshot** *(boolean)* – This property is not currently implemented.

**Response Syntax**

```

**Response Structure**

- *(dict)* –

  Contains the result of a successful invocation of the following actions:
  - CreateDBInstance
  - DeleteDBInstance
  - ModifyDBInstance

  This data type is used as a response element in the DescribeDBInstances action.

- **DBInstance** *(dict)* –

  Contains the result of a successful invocation of the following actions:
  - CreateDBInstance
  - DeleteDBInstance
  - ModifyDBInstance

  This data type is used as a response element in the DescribeDBInstances action.

  - **DBInstanceIdentifier** *(string)* –

    Contains a user-supplied database identifier. This identifier is the unique key that identifies a DB instance.

  - **DBInstanceClass** *(string)* –

    Contains the name of the compute and memory capacity class of the DB instance.

  - **Engine** *(string)* –

    Provides the name of the database engine to be used for this DB instance.

  - **DBInstanceStatus** *(string)* –

    Specifies the current state of this database.

  - **MasterUsername** *(string)* –

    Contains the master username for the DB instance.

  - **DBName** *(string)* –

    The meaning of this parameter differs according to the database engine you use. For example, this value returns either MySQL or PostgreSQL information when returning values from CreateDBInstanceRead Replica since Read Replicas are only supported for MySQL and PostgreSQL.
MySQL, SQL Server, PostgreSQL
Contains the name of the initial database of this instance that was provided at create time, if one was specified when the DB instance was created. This same name is returned for the life of the DB instance.

Type: String

Oracle
Contains the Oracle System ID (SID) of the created DB instance. Not shown when the returned parameters do not apply to an Oracle DB instance.

* Endpoint (dict) –
Specifies the connection endpoint.
  · Address (string) –
    Specifies the DNS address of the DB instance.
  · Port (integer) –
    Specifies the port that the database engine is listening on.

* AllocatedStorage (integer) –
Specifies the allocated storage size specified in gigabytes.

* InstanceCreateTime (datetime) –
Provides the date and time the DB instance was created.

* PreferredBackupWindow (string) –
Specifies the daily time range during which automated backups are created if automated backups are enabled, as determined by the BackupRetentionPeriod.

* BackupRetentionPeriod (integer) –
Specifies the number of days for which automatic DB snapshots are retained.

* DBSecurityGroups (list) –
Provides List of DB security group elements containing only DBSecurityGroup.Name and DBSecurityGroup.Status subelements.
  · (dict) –
    This data type is used as a response element in the following actions:
    · ModifyDBInstance
    · RebootDBInstance
    · RestoreDBInstanceFromDBSnapshot
    · RestoreDBInstanceToPointInTime
    · DBSecurityGroupName (string) –
      The name of the DB security group.
    · Status (string) –
      The status of the DB security group.

* VpcSecurityGroups (list) –
Provides List of VPC security group elements that the DB instance belongs to.
  · (dict) –
This data type is used as a response element for queries on VPC security group membership.

- **VpcSecurityGroupId** *(string)* –
  The name of the VPC security group.

- **Status** *(string)* –
  The status of the VPC security group.

- **DBParameterGroups** *(list)* –
  Provides the list of DB parameter groups applied to this DB instance.
  - *(dict)* –
    The status of the DB parameter group.
    
    This data type is used as a response element in the following actions:
    - CreateDBInstance
    - CreateDBInstanceReadReplica
    - DeleteDBInstance
    - ModifyDBInstance
    - RebootDBInstance
    - RestoreDBInstanceFromDBSnapshot
      - **DBParameterGroupName** *(string)* –
        The name of the DP parameter group.
      - **ParameterApplyStatus** *(string)* –
        The status of parameter updates.

- **AvailabilityZone** *(string)* –
  Specifies the name of the Availability Zone the DB instance is located in.

- **DBSubnetGroup** *(dict)* –
  Specifies information on the subnet group associated with the DB instance, including the name, description, and subnets in the subnet group.
  - **DBSubnetGroupName** *(string)* –
    Specifies the name of the DB subnet group.
  - **DBSubnetGroupDescription** *(string)* –
    Provides the description of the DB subnet group.
  - **VpcId** *(string)* –
    Provides the VpcId of the DB subnet group.
  - **SubnetGroupStatus** *(string)* –
    Provides the status of the DB subnet group.
  - **Subnets** *(list)* –
    Contains a list of Subnet elements.
  - *(dict)* –
    This data type is used as a response element in the DescribeDBSubnetGroups action.
  - **SubnetIdentifier** *(string)* –
    Specifies the identifier of the subnet.
* **SubnetAvailabilityZone (dict)** –  
  Contains Availability Zone information.  
  This data type is used as an element in the following data type:  
  * **OrderableDBInstanceOption**  
  * **Name (string)** –  
    The name of the availability zone.  
  * **SubnetStatus (string)** –  
    Specifies the status of the subnet.  

* **PreferredMaintenanceWindow (string)** –  
  Specifies the weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).  

* **PendingModifiedValues (dict)** –  
  Specifies that changes to the DB instance are pending. This element is only included when changes are pending. Specific changes are identified by subelements.  
  * **DBInstanceClass (string)** –  
    Contains the new DBInstanceClass for the DB instance that will be applied or is in progress.  
  * **AllocatedStorage (integer)** –  
    Contains the new AllocatedStorage size for the DB instance that will be applied or is in progress.  
  * **MasterUserPassword (string)** –  
    Contains the pending or in-progress change of the master credentials for the DB instance.  
  * **Port (integer)** –  
    Specifies the pending port for the DB instance.  
  * **BackupRetentionPeriod (integer)** –  
    Specifies the pending number of days for which automated backups are retained.  
  * **MultiAZ (boolean)** –  
    Indicates that the Single-AZ DB instance is to change to a Multi-AZ deployment.  
  * **EngineVersion (string)** –  
    Indicates the database engine version.  
  * **Iops (integer)** –  
    Specifies the new Provisioned IOPS value for the DB instance that will be applied or is being applied.  
  * **DBInstanceIdentifier (string)** –  
    Contains the new DBInstanceIdentifier for the DB instance that will be applied or is in progress.  
  * **StorageType (string)** –  
    Specifies the storage type to be associated with the DB instance.  
  * **CACertificateIdentifier (string)** –
Specifies the identifier of the CA certificate for the DB instance.

* **LatestRestorableTime** *(datetime)* –

Specifies the latest time to which a database can be restored with point-in-time restore.

* **MultiAZ** *(boolean)* –

Specifies if the DB instance is a Multi-AZ deployment.

* **EngineVersion** *(string)* –

Indicates the database engine version.

* **AutoMinorVersionUpgrade** *(boolean)* –

Indicates that minor version patches are applied automatically.

* **ReadReplicaSourceDBInstanceIdentifier** *(string)* –

Contains the identifier of the source DB instance if this DB instance is a Read Replica.

* **ReadReplicaDBInstanceIdentifiers** *(list)* –

Contains one or more identifiers of the Read Replicas associated with this DB instance.

  · *(string)* –

* **LicenseModel** *(string)* –

License model information for this DB instance.

* **Iops** *(integer)* –

Specifies the Provisioned IOPS (I/O operations per second) value.

* **OptionGroupMemberships** *(list)* –

Provides the list of option group memberships for this DB instance.

  · *(dict)* –

    Provides information on the option groups the DB instance is a member of.

    · **OptionGroupName** *(string)* –

      The name of the option group that the instance belongs to.

    · **Status** *(string)* –

      The status of the DB instance’s option group membership (e.g. in-sync, pending, pending-maintenance, applying).

* **CharacterSetName** *(string)* –

If present, specifies the name of the character set that this instance is associated with.

* **SecondaryAvailabilityZone** *(string)* –

If present, specifies the name of the secondary Availability Zone for a DB instance with multi-AZ support.

* **PubliclyAccessible** *(boolean)* –

Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.
Default: The default behavior varies depending on whether a VPC has been requested or not. The following list shows the default behavior in each case.

- **Default VPC**: true
- **VPC**: false

If no DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be publicly accessible. If a specific DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be private.

* **StatusInfos** (list) –

The status of a Read Replica. If the instance is not a Read Replica, this will be blank.

- *(dict)* –
  
  Provides a list of status information for a DB instance.
  
  - **StatusType** *(string)* –
    
    This value is currently “read replication.”
  
  - **Normal** *(boolean)* –
    
    Boolean value that is true if the instance is operating normally, or false if the instance is in an error state.
  
  - **Status** *(string)* –
    
    Status of the DB instance. For a StatusType of read replica, the values can be replicating, error, stopped, or terminated.
  
  - **Message** *(string)* –
    
    Details of the error if there is an error for the instance. If the instance is not in an error state, this value is blank.

* **StorageType** *(string)* –

  Specifies the storage type associated with DB instance.

* **TdeCredentialArn** *(string)* –

  The ARN from the Key Store with which the instance is associated for TDE encryption.

* **DbInstancePort** *(integer)* –

  Specifies the port that the DB instance listens on. If the DB instance is part of a DB cluster, this can be a different port than the DB cluster port.

* **DBClusterIdentifier** *(string)* –

  If the DB instance is a member of a DB cluster, contains the name of the DB cluster that the DB instance is a member of.

* **StorageEncrypted** *(boolean)* –

  Specifies whether the DB instance is encrypted.

* **KmsKeyId** *(string)* –

  If StorageEncrypted is true, the KMS key identifier for the encrypted DB instance.

* **DbiResourceId** *(string)* –

  If StorageEncrypted is true, the region-unique, immutable identifier for the encrypted DB instance. This identifier is found...
in AWS CloudTrail log entries whenever the KMS key for the DB instance is accessed.

* **CACertificateIdentifier** *(string)* –
  The identifier of the CA certificate for this DB instance.

* **DomainMemberships** *(list)* –
  The Active Directory Domain membership records associated with the DB instance.
  - *(dict)* –
    An Active Directory Domain membership record associated with the DB instance.
    - **Domain** *(string)* –
      The identifier of the Active Directory Domain.
    - **Status** *(string)* –
      The status of the DB instance’s Active Directory Domain membership (e.g. joined, pending-join, failed etc).
    - **Connectivity** *(string)* –
      The observed connectivity of the Active Directory Domain.

* **CopyTagsToSnapshot** *(boolean)* –
  This property is not currently implemented.

`create_db_instance_read_replica(**kwargs)`

Creates a DB instance for a DB instance running MySQL or PostgreSQL that acts as a Read Replica of a source DB instance.

All Read Replica DB instances are created as Single-AZ deployments with backups disabled. All other DB instance attributes (including DB security groups and DB parameter groups) are inherited from the source DB instance, except as specified below.

**Warning:** The source DB instance must have backup retention enabled.

### Request Syntax

```python
response = client.create_db_instance_read_replica(
    DBInstanceIdentifier='string',
    SourceDBInstanceIdentifier='string',
    DBInstanceClass='string',
    AvailabilityZone='string',
    Port=123,
    AutoMinorVersionUpgrade=True|False,
    Iops=123,
    OptionGroupName='string',
    PubliclyAccessible=True|False,
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ],
    DBSubnetGroupName='string',
    StorageType='string',
    CopyTagsToSnapshot=True|False
)
```
Parameters

- **DBInstanceIdentifier** *(string)* – [REQUIRED]
  
  The DB instance identifier of the Read Replica. This identifier is the unique key that identifies a DB instance. This parameter is stored as a lowercase string.

- **SourceDBInstanceIdentifier** *(string)* – [REQUIRED]
  
  The identifier of the DB instance that will act as the source for the Read Replica. Each DB instance can have up to five Read Replicas.

  Constraints:
  - Must be the identifier of an existing DB instance.
  - Can specify a DB instance that is a MySQL Read Replica only if the source is running MySQL 5.6.
  - Can specify a DB instance that is a PostgreSQL Read Replica only if the source is running PostgreSQL 9.3.5.
  - The specified DB instance must have automatic backups enabled, its backup retention period must be greater than 0.
  - If the source DB instance is in the same region as the Read Replica, specify a valid DB instance identifier.
  - If the source DB instance is in a different region than the Read Replica, specify a valid DB instance ARN. For more information, go to Constructing a Amazon RDS Amazon Resource Name (ARN).

- **DBInstanceClass** *(string)* – The compute and memory capacity of the Read Replica.

  Valid Values:  
  - db.m1.small | db.m1.medium | db.m1.large
  - db.m1.xlarge | db.m2.xlarge | db.m2.2xlarge
  - db.m2.4xlarge | db.m3.medium | db.m3.large
  - db.m3.xlarge | db.m3.2xlarge | db.r3.large
  - db.r3.xlarge | db.r3.2xlarge | db.r3.4xlarge
  - db.r3.8xlarge | db.t2.micro | db.t2.small
  - db.t2.medium

  Default: Inherits from the source DB instance.

- **AvailabilityZone** *(string)* – The Amazon EC2 Availability Zone that the Read Replica will be created in.

  Default: A random, system-chosen Availability Zone in the endpoint’s region.

  Example: us-east-1d

- **Port** *(integer)* – The port number that the DB instance uses for connections.

  Default: Inherits from the source DB instance

  Valid Values: 1150-65535

- **AutoMinorVersionUpgrade** *(boolean)* – Indicates that minor engine upgrades will be applied automatically to the Read Replica during the maintenance window.

  Default: Inherits from the source DB instance

- **Iops** *(integer)* – The amount of Provisioned IOPS (input/output operations per second) to be initially allocated for the DB instance.

- **OptionGroupName** *(string)* – The option group the DB instance will be associated with. If omitted, the default option group for the engine specified will be used.

- **PubliclyAccessible** *(boolean)* – Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false
specifies an internal instance with a DNS name that resolves to a private IP address.

Default: The default behavior varies depending on whether a VPC has been requested or not. The following list shows the default behavior in each case.

– **Default VPC**: true
– **VPC**: false

If no DB subnet group has been specified as part of the request and the Publicly-Accessible value has not been set, the DB instance will be publicly accessible. If a specific DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be private.

**Tags** *(list)* – A list of tags.

– *(dict)* –

Metadata assigned to an Amazon RDS resource consisting of a key-value pair.

* **Key** *(string)* –

  A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘=’, ‘+’, ‘*’ (Java regex: “^[p\{L\}|p\{Z\}|p\{N\}_:=/\=\#\+\*\$].

* **Value** *(string)* –

  A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘=’, ‘+’, ‘*’ (Java regex: “^[p\{L\}|p\{Z\}|p\{N\}_:=/\=\#\+\*\$].

**DBSubnetGroupName** *(string)* – Specifies a DB subnet group for the DB instance. The new DB instance will be created in the VPC associated with the DB subnet group. If no DB subnet group is specified, then the new DB instance is not created in a VPC.

Constraints:

– Can only be specified if the source DB instance identifier specifies a DB instance in another region.

– The specified DB subnet group must be in the same region in which the operation is running.

– All Read Replicas in one region that are created from the same source DB instance must either: * Specify DB subnet groups from the same VPC. All these Read Replicas will be created in the same VPC.

– Not specify a DB subnet group. All these Read Replicas will be created outside of any VPC.

**StorageType** *(string)* – Specifies the storage type to be associated with the Read Replica.

Valid values: **standard | gp2 | iol**

If you specify iol, you must also include a value for the Iops parameter.

Default: iol if the Iops parameter is specified; otherwise **standard**

**CopyTagsToSnapshot** *(boolean)* – This property is not currently implemented.

Return type *dict*

Response Structure

• (dict) –

Contains the result of a successful invocation of the following actions:

- CreateDBInstance
- DeleteDBInstance
– ModifyDBInstance
This data type is used as a response element in the DescribeDBInstances action.

– DBInstance (dict) –
Contains the result of a successful invocation of the following actions:
* CreateDBInstance
* DeleteDBInstance
* ModifyDBInstance
This data type is used as a response element in the DescribeDBInstances action.

* DBInstanceIdentifier (string) –
Contains a user-supplied database identifier. This identifier is the unique key that identifies a DB instance.

* DBInstanceClass (string) –
Contains the name of the compute and memory capacity class of the DB instance.

* Engine (string) –
Provides the name of the database engine to be used for this DB instance.

* DBInstanceStatus (string) –
Specifies the current state of this database.

* MasterUsername (string) –
Contains the master username for the DB instance.

* DBName (string) –
The meaning of this parameter differs according to the database engine you use. For example, this value returns either MySQL or PostgreSQL information when returning values from CreateDBInstanceReadReplica since Read Replicas are only supported for MySQL and PostgreSQL.

MySQL, SQL Server, PostgreSQL
Contains the name of the initial database of this instance that was provided at create time, if one was specified when the DB instance was created. This same name is returned for the life of the DB instance.

Type: String

Oracle
Contains the Oracle System ID (SID) of the created DB instance. Not shown when the returned parameters do not apply to an Oracle DB instance.

* Endpoint (dict) –
Specifies the connection endpoint.
  · Address (string) –
    Specifies the DNS address of the DB instance.
  · Port (integer) –
    Specifies the port that the database engine is listening on.

* AllocatedStorage (integer) –
Specifies the allocated storage size specified in gigabytes.

* InstanceCreateTime (datetime) –
Provides the date and time the DB instance was created.

* **PreferredBackupWindow** *(string)* –

  Specifies the daily time range during which automated backups are created if automated backups are enabled, as determined by the BackupRetentionPeriod.

* **BackupRetentionPeriod** *(integer)* –

  Specifies the number of days for which automatic DB snapshots are retained.

* **DBSecurityGroups** *(list)* –

  Provides List of DB security group elements containing only DBSecurityGroup.Name and DBSecurityGroup.Status subelements.

  · *(dict)* –

    This data type is used as a response element in the following actions:
    · ModifyDBInstance
    · RebootDBInstance
    · RestoreDBInstanceFromDBSnapshot
    · RestoreDBInstanceToPointInTime
    · **DBSecurityGroupName** *(string)* –

      The name of the DB security group.

    · **Status** *(string)* –

      The status of the DB security group.

* **VpcSecurityGroups** *(list)* –

  Provides List of VPC security group elements that the DB instance belongs to.

  · *(dict)* –

    This data type is used as a response element for queries on VPC security group membership.

    · **VpcSecurityGroupId** *(string)* –

      The name of the VPC security group.

    · **Status** *(string)* –

      The status of the VPC security group.

* **DBParameterGroups** *(list)* –

  Provides the list of DB parameter groups applied to this DB instance.

    · *(dict)* –

      The status of the DB parameter group.

      This data type is used as a response element in the following actions:
      · CreateDBInstance
      · CreateDBInstanceReadReplica
      · DeleteDBInstance
      · ModifyDBInstance
      · RebootDBInstance
      · RestoreDBInstanceFromDBSnapshot
- **DBParameterGroupName** *(string)* – The name of the DP parameter group.
  - **ParameterApplyStatus** *(string)* – The status of parameter updates.

* **AvailabilityZone** *(string)* – Specifies the name of the Availability Zone the DB instance is located in.

* **DBSubnetGroup** *(dict)* – Specifies information on the subnet group associated with the DB instance, including the name, description, and subnets in the subnet group.
  - **DBSubnetGroupName** *(string)* – Specifies the name of the DB subnet group.
  - **DBSubnetGroupDescription** *(string)* – Provides the description of the DB subnet group.
  - **VpcId** *(string)* – Provides the VpcId of the DB subnet group.
  - **SubnetGroupStatus** *(string)* – Provides the status of the DB subnet group.
  - **Subnets** *(list)* – Contains a list of Subnet elements.
    - *(dict)* – This data type is used as a response element in the DescribeDBSubnetGroups action.
  - **SubnetIdentifier** *(string)* – Specifies the identifier of the subnet.
  - **SubnetAvailabilityZone** *(dict)* – Contains Availability Zone information.
    - *(dict)* – This data type is used as an element in the following data type:
      - **OrderableDBInstanceOption**
        - **Name** *(string)* – The name of the availability zone.
        - **SubnetStatus** *(string)* – Specifies the status of the subnet.

* **PreferredMaintenanceWindow** *(string)* – Specifies the weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).

* **PendingModifiedValues** *(dict)* – Specifies that changes to the DB instance are pending. This element is only included when changes are pending. Specific changes are identified by subelements.
  - **DBInstanceClass** *(string)* – Contains the new DBInstanceClass for the DB instance that will be applied or is in progress.
- **AllocatedStorage** *(integer)* –
  Contains the new `AllocatedStorage` size for the DB instance that will be applied or is in progress.

- **MasterUserPassword** *(string)* –
  Contains the pending or in-progress change of the master credentials for the DB instance.

- **Port** *(integer)* –
  Specifies the pending port for the DB instance.

- **BackupRetentionPeriod** *(integer)* –
  Specifies the pending number of days for which automated backups are retained.

- **MultiAZ** *(boolean)* –
  Indicates that the Single-AZ DB instance is to change to a Multi-AZ deployment.

- **EngineVersion** *(string)* –
  Indicates the database engine version.

- **Iops** *(integer)* –
  Specifies the new Provisioned IOPS value for the DB instance that will be applied or is being applied.

- **DBInstanceIdentifier** *(string)* –
  Contains the new `DBInstanceIdentifier` for the DB instance that will be applied or is in progress.

- **StorageType** *(string)* –
  Specifies the storage type to be associated with the DB instance.

- **CACertificateIdentifier** *(string)* –
  Specifies the identifier of the CA certificate for the DB instance.

- **LatestRestorableTime** *(datetime)* –
  Specifies the latest time to which a database can be restored with point-in-time restore.

- **MultiAZ** *(boolean)* –
  Specifies if the DB instance is a Multi-AZ deployment.

- **EngineVersion** *(string)* –
  Indicates the database engine version.

- **AutoMinorVersionUpgrade** *(boolean)* –
  Indicates that minor version patches are applied automatically.

- **ReadReplicaSourceDBInstanceIdentifier** *(string)* –
  Contains the identifier of the source DB instance if this DB instance is a Read Replica.

- **ReadReplicaDBInstanceIdentifiers** *(list)* –
  Contains one or more identifiers of the Read Replicas associated with this DB instance.
    - *(string)* –
* **LicenseModel** *(string)* –
  License model information for this DB instance.

* **Iops** *(integer)* –
  Specifies the Provisioned IOPS (I/O operations per second) value.

* **OptionGroupMemberships** *(list)* –
  Provides the list of option group memberships for this DB instance.
  · *(dict)* –
    Provides information on the option groups the DB instance is a member of.
  · **OptionGroupName** *(string)* –
    The name of the option group that the instance belongs to.
  · **Status** *(string)* –
    The status of the DB instance’s option group membership (e.g. in-sync, pending, pending-maintenance, applying).

* **CharacterSetName** *(string)* –
  If present, specifies the name of the character set that this instance is associated with.

* **SecondaryAvailabilityZone** *(string)* –
  If present, specifies the name of the secondary Availability Zone for a DB instance with multi-AZ support.

* **PubliclyAccessible** *(boolean)* –
  Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.

  Default: The default behavior varies depending on whether a VPC has been requested or not. The following list shows the default behavior in each case.
  · **Default VPC**: true
  · **VPC**: false

  If no DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be publicly accessible. If a specific DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be private.

* **StatusInfos** *(list)* –
  The status of a Read Replica. If the instance is not a Read Replica, this will be blank.
  · *(dict)* –
    Provides a list of status information for a DB instance.
  · **StatusType** *(string)* –
    This value is currently “read replication.”
  · **Normal** *(boolean)* –
    Boolean value that is true if the instance is operating normally, or false if the instance is in an error state.
· **Status** *(string)* –
  Status of the DB instance. For a StatusType of read replica, the values can be replicating, error, stopped, or terminated.

· **Message** *(string)* –
  Details of the error if there is an error for the instance. If the instance is not in an error state, this value is blank.

* **StorageType** *(string)* –
  Specifies the storage type associated with DB instance.

* **TdeCredentialArn** *(string)* –
  The ARN from the Key Store with which the instance is associated for TDE encryption.

* **DbInstancePort** *(integer)* –
  Specifies the port that the DB instance listens on. If the DB instance is part of a DB cluster, this can be a different port than the DB cluster port.

* **DBClusterIdentifier** *(string)* –
  If the DB instance is a member of a DB cluster, contains the name of the DB cluster that the DB instance is a member of.

* **StorageEncrypted** *(boolean)* –
  Specifies whether the DB instance is encrypted.

* **KmsKeyId** *(string)* –
  If StorageEncrypted is true, the KMS key identifier for the encrypted DB instance.

* **DbiResourceId** *(string)* –
  If StorageEncrypted is true, the region-unique, immutable identifier for the encrypted DB instance. This identifier is found in AWS CloudTrail log entries whenever the KMS key for the DB instance is accessed.

* **CACertificateIdentifier** *(string)* –
  The identifier of the CA certificate for this DB instance.

* **DomainMemberships** *(list)* –
  The Active Directory Domain membership records associated with the DB instance.
  · *(dict)* –
    An Active Directory Domain membership record associated with the DB instance.
  · **Domain** *(string)* –
    The identifier of the Active Directory Domain.
  · **Status** *(string)* –
    The status of the DB instance’s Active Directory Domain membership (e.g. joined, pending-join, failed etc).
  · **Connectivity** *(string)* –
    The observed connectivity of the Active Directory Domain.

* **CopyTagsToSnapshot** *(boolean)* –
  This property is not currently implemented.
create_db_parameter_group(**kwargs)

  Creates a new DB parameter group.

  A DB parameter group is initially created with the default parameters for the database engine used by
  the DB instance. To provide custom values for any of the parameters, you must modify the group after
  creating it using ModifyDBParameterGroup. Once you’ve created a DB parameter group, you need to
  associate it with your DB instance using ModifyDBInstance. When you associate a new DB parameter
  group with a running DB instance, you need to reboot the DB instance without failover for the new DB
  parameter group and associated settings to take effect.

  **Warning:** After you create a DB parameter group, you should wait at least 5 minutes before creating
  your first DB instance that uses that DB parameter group as the default parameter group. This allows
  Amazon RDS to fully complete the create action before the parameter group is used as the default
  for a new DB instance. This is especially important for parameters that are critical when creating the
default database for a DB instance, such as the character set for the default database defined by the
character_set_database parameter. You can use the Parameter Groups option of the Amazon
RDS console or the DescribeDBParameters command to verify that your DB parameter group has
been created or modified.

### Request Syntax

```python
response = client.create_db_parameter_group(
    DBParameterGroupName='string',
    DBParameterGroupFamily='string',
    Description='string',
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

### Parameters

- **DBParameterGroupName (string)** – [REQUIRED]
  
  The name of the DB parameter group.

  Constraints:
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

  **Note:** This value is stored as a lowercase string.

- **DBParameterGroupFamily (string)** – [REQUIRED]
  
  The DB parameter group family name. A DB parameter group can be associated
  with one and only one DB parameter group family, and can be applied only to a
  DB instance running a database engine and engine version compatible with that
  DB parameter group family.

- **Description (string)** – [REQUIRED]
  
  The description for the DB parameter group.

- **Tags (list)** – A list of tags.
  - (dict) –

  Metadata assigned to an Amazon RDS resource consisting of a key-value
  pair.
**Key (string)** –
A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘=’, ‘+’, ‘-’ (Java regex: “^([\p{L}\p{Z}\p{N}_.:/=+\-]*)$”).

**Value (string)** –
A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘=’, ‘+’, ‘-’ (Java regex: “^([\p{L}\p{Z}\p{N}_.:/=+\-]*)$”).

**Return type** dict

**Returns**

**Response Syntax**

```
{
    'DBParameterGroup': {
        'DBParameterGroupName': 'string',
        'DBParameterGroupFamily': 'string',
        'Description': 'string'
    }
}
```

**Response Structure**
- *(dict)* –
  Contains the result of a successful invocation of the CreateDBParameterGroup action.

This data type is used as a request parameter in the DeleteDBParameterGroup action, and as a response element in the DescribeDBParameterGroups action.

  - **DBParameterGroup (dict)** –
    Contains the result of a successful invocation of the CreateDBParameterGroup action.

This data type is used as a request parameter in the DeleteDBParameterGroup action, and as a response element in the DescribeDBParameterGroups action.

  - **DBParameterGroupName (string)** –
    Provides the name of the DB parameter group.

  - **DBParameterGroupFamily (string)** –
    Provides the name of the DB parameter group family that this DB parameter group is compatible with.

  - **Description (string)** –
    Provides the customer-specified description for this DB parameter group.

**create_db_security_group (**kwargs**)**
Creates a new DB security group. DB security groups control access to a DB instance.

**Request Syntax**
response = client.create_db_security_group(
    DBSecurityGroupName='string',
    DBSecurityGroupDescription='string',
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ],
)

Parameters

- **DBSecurityGroupName** *(string) – [REQUIRED]*

  The name for the DB security group. This value is stored as a lowercase string.

  Constraints:
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens
  - Must not be “Default”
  - Cannot contain spaces

  Example: mysecuritygroup

- **DBSecurityGroupDescription** *(string) – [REQUIRED]*

  The description for the DB security group.

- **Tags** *(list) – A list of tags.*

  - *(dict)* – Metadata assigned to an Amazon RDS resource consisting of a key-value pair.
    - **Key** *(string)* – A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘=’, ‘+’, ‘-’ (Java regex: “^(\[\p{L}\p{Z}\p{N}_.:/=+-]*$)”).
    - **Value** *(string)* – A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘=’, ‘+’, ‘-’ (Java regex: “^(\[\p{L}\p{Z}\p{N}_.:/=+-]*$)”).

Returns

**Response Syntax**

```json
{
    'DBSecurityGroup': {
        'OwnerId': 'string',
        'DBSecurityGroupName': 'string',
        'DBSecurityGroupDescription': 'string',
        'VpcId': 'string',
        'EC2SecurityGroups': [
            {
                'OwnerId': 'string',
                'VpcId': 'string',
                'SecurityGroups': [
                    {'GroupId': 'string', 'GroupName': 'string'}
                ]
            }]
    }
}
```
Response Structure

- **(dict)** –

  Contains the result of a successful invocation of the following actions:
  - `DescribeDBSecurityGroups`
  - `AuthorizeDBSecurityGroupIngress`
  - `CreateDBSecurityGroup`
  - `RevokeDBSecurityGroupIngress`

  This data type is used as a response element in the `DescribeDBSecurityGroups` action.

- **DBSecurityGroup** *(dict)* –

  Contains the result of a successful invocation of the following actions:
  - `DescribeDBSecurityGroups`
  - `AuthorizeDBSecurityGroupIngress`
  - `CreateDBSecurityGroup`
  - `RevokeDBSecurityGroupIngress`

  This data type is used as a response element in the `DescribeDBSecurityGroups` action.

  - **OwnerId** *(string)* –
    
    Provides the AWS ID of the owner of a specific DB security group.

  - **DBSecurityGroupName** *(string)* –
    
    Specifies the name of the DB security group.

  - **DBSecurityGroupDescription** *(string)* –
    
    Provides the description of the DB security group.

  - **VpcId** *(string)* –
    
    Provides the VpcId of the DB security group.

  - **EC2SecurityGroups** *(list)* –
    
    Contains a list of EC2SecurityGroup elements.

      - *(dict)* –

        This data type is used as a response element in the following actions:
        - `AuthorizeDBSecurityGroupIngress`
        - `DescribeDBSecurityGroups`
        - `RevokeDBSecurityGroupIngress`

        - **Status** *(string)* –

          Provides the status of the EC2 security group. Status can be
“authorizing”, “authorized”, “revoking”, and “revoked”.

- **EC2SecurityGroupName (string)** –
  Specifies the name of the EC2 security group.

- **EC2SecurityGroupId (string)** –
  Specifies the id of the EC2 security group.

- **EC2SecurityGroupOwnerId (string)** –
  Specifies the AWS ID of the owner of the EC2 security group specified in the EC2SecurityGroupName field.

* **IPRanges (list)** –
Contains a list of IPRange elements.

  - (dict) –
    This data type is used as a response element in the DescribeDBSecurityGroups action.

  - **Status (string)** –
    Specifies the status of the IP range. Status can be “authorizing”, “authorized”, “revoking”, and “revoked”.

  - **CIDRIP (string)** –
    Specifies the IP range.

### create_db_snapshot (**kwargs)**

 Creates a DBSnapshot. The source DBInstance must be in “available” state.

**Request Syntax**

```python
response = client.create_db_snapshot(
    DBSnapshotIdentifier='string',
    DBInstanceIdentifier='string',
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

**Parameters**

- **DBSnapshotIdentifier (string)** – [REQUIRED]
  The identifier for the DB snapshot.

  Constraints:
  - Cannot be null, empty, or blank
  - Must contain from 1 to 255 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

  Example: my-snapshot-id

- **DBInstanceIdentifier (string)** – [REQUIRED]
  The DB instance identifier. This is the unique key that identifies a DB instance.

  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens
- **Tags** *(list)* – A list of tags.
  - *(dict)* –

    Metadata assigned to an Amazon RDS resource consisting of a key-value pair.
    * **Key** *(string)* –
      A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘=’, ‘+’, ‘-’ (Java regex: “^([\p{L}\p{Z}\p{N}_.:/=\-\+]*)$”).
    * **Value** *(string)* –
      A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘=’, ‘+’, ‘-’ (Java regex: “^([\p{L}\p{Z}\p{N}_.:/=\-\+]*)$”).

Return type  dict
Returns

Response Syntax

```python

{
    'DBSnapshot': {
        'DBSnapshotIdentifier': 'string',
        'DBInstanceIdentifier': 'string',
        'SnapshotCreateTime': datetime(2015, 1, 1),
        'Engine': 'string',
        'AllocatedStorage': 123,
        'Status': 'string',
        'Port': 123,
        'AvailabilityZone': 'string',
        'VpcId': 'string',
        'InstanceCreateTime': datetime(2015, 1, 1),
        'MasterUsername': 'string',
        'EngineVersion': 'string',
        'LicenseModel': 'string',
        'SnapshotType': 'string',
        'Iops': 123,
        'OptionGroupName': 'string',
        'PercentProgress': 123,
        'SourceRegion': 'string',
        'SourceDBSnapshotIdentifier': 'string',
        'StorageType': 'string',
        'TdeCredentialArn': 'string',
        'Encrypted': True|False,
        'KmsKeyId': 'string'
    }
}
```

Response Structure
- *(dict)* –

Contains the result of a successful invocation of the following actions:
  - CreateDBSnapshot
  - DeleteDBSnapshot

This data type is used as a response element in the DescribeDBSnapshots action.
– **DBSnapshot** *(dict)* –

Contains the result of a successful invocation of the following actions:
- CreateDBSnapshot
- DeleteDBSnapshot

This data type is used as a response element in the DescribeDBSnapshots action.

- **DBSnapshotIdentifier** *(string)* –
  Specifies the identifier for the DB snapshot.

- **DBInstanceIdentifier** *(string)* –
  Specifies the DB instance identifier of the DB instance this DB snapshot was created from.

- **SnapshotCreateTime** *(datetime)* –
  Provides the time when the snapshot was taken, in Universal Coordinated Time (UTC).

- **Engine** *(string)* –
  Specifies the name of the database engine.

- **AllocatedStorage** *(integer)* –
  Specifies the allocated storage size in gigabytes (GB).

- **Status** *(string)* –
  Specifies the status of this DB snapshot.

- **Port** *(integer)* –
  Specifies the port that the database engine was listening on at the time of the snapshot.

- **AvailabilityZone** *(string)* –
  Specifies the name of the Availability Zone the DB instance was located in at the time of the DB snapshot.

- **VpcId** *(string)* –
  Provides the VPC ID associated with the DB snapshot.

- **InstanceCreateTime** *(datetime)* –
  Specifies the time when the snapshot was taken, in Universal Coordinated Time (UTC).

- **MasterUsername** *(string)* –
  Provides the master username for the DB snapshot.

- **EngineVersion** *(string)* –
  Specifies the version of the database engine.

- **LicenseModel** *(string)* –
  License model information for the restored DB instance.

- **SnapshotType** *(string)* –
  Provides the type of the DB snapshot.

- **Iops** *(integer)* –
  Specifies the Provisioned IOPS (I/O operations per second) value of the DB instance at the time of the snapshot.

- **OptionGroupName** *(string)* –
  Provides the option group name for the DB snapshot.
* PercentProgress (integer) –
  The percentage of the estimated data that has been transferred.
* SourceRegion (string) –
  The region that the DB snapshot was created in or copied from.
* SourceDBSnapshotIdentifier (string) –
  The DB snapshot Arn that the DB snapshot was copied from. It only has value in case of cross customer or cross region copy.
* StorageType (string) –
  Specifies the storage type associated with DB Snapshot.
* TdeCredentialArn (string) –
  The ARN from the Key Store with which to associate the instance for TDE encryption.
* Encrypted (boolean) –
  Specifies whether the DB snapshot is encrypted.
* KmsKeyId (string) –
  If Encrypted is true, the KMS key identifier for the encrypted DB snapshot.

create_db_subnet_group (**kwargs)

Creates a new DB subnet group. DB subnet groups must contain at least one subnet in at least two AZs in the region.

Request Syntax

    response = client.create_db_subnet_group(
        DBSubnetGroupName='string',
        DBSubnetGroupDescription='string',
        SubnetIds=[
            'string',
        ],
        Tags=[
            {
                'Key': 'string',
                'Value': 'string'
            },
        ]
    )

Parameters

- **DBSubnetGroupName (string) – [REQUIRED]**
  The name for the DB subnet group. This value is stored as a lowercase string.
  Constraints: Must contain no more than 255 alphanumeric characters or hyphens. Must not be “Default”.
  Example: mySubnetgroup
- **DBSubnetGroupDescription (string) – [REQUIRED]**
  The description for the DB subnet group.
- **SubnetIds (list) – [REQUIRED]**
  The EC2 Subnet IDs for the DB subnet group.
  – (string) –
- **Tags (list) – A list of tags.**
Metadata assigned to an Amazon RDS resource consisting of a key-value pair.

* **Key (string)** —
  A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘.’, ‘-’, ‘=’, ‘+’, ‘*’ (Java regex: “^(\[[p{L}\p{Z}\p{N}_.:/=+\-\]*)$”).

* **Value (string)** —
  A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘.’, ‘-’, ‘=’, ‘+’, ‘*’ (Java regex: “^(\[[p{L}\p{Z}\p{N}_.:/=+\-\]*)$”).

**Return type**  dict

**Response Syntax**

```
{
  'DBSubnetGroup': {
    'DBSubnetGroupName': 'string',
    'DBSubnetGroupDescription': 'string',
    'VpcId': 'string',
    'SubnetGroupStatus': 'string',
    'Subnets': [
      {
        'SubnetIdentifier': 'string',
        'SubnetAvailabilityZone': {
          'Name': 'string'
        },
        'SubnetStatus': 'string'
      },
    ],
  }
}
```

**Response Structure**

- **(dict)** —
  Contains the result of a successful invocation of the following actions:
  - CreateDBSubnetGroup
  - ModifyDBSubnetGroup
  - DescribeDBSubnetGroups
  - DeleteDBSubnetGroup

This data type is used as a response element in the DescribeDBSubnetGroups action.

- **DBSubnetGroup (dict)** —
  Contains the result of a successful invocation of the following actions:
  - CreateDBSubnetGroup
  - ModifyDBSubnetGroup
  - DescribeDBSubnetGroups
  - DeleteDBSubnetGroup
This data type is used as a response element in the DescribeDBSubnetGroups action.

- **DBSubnetGroupName (string)** –
  Specifies the name of the DB subnet group.

- **DBSubnetGroupDescription (string)** –
  Provides the description of the DB subnet group.

- **VpcId (string)** –
  Provides the VpcId of the DB subnet group.

- **SubnetGroupStatus (string)** –
  Provides the status of the DB subnet group.

- **Subnets (list)** –
  Contains a list of Subnet elements.
  
  - (dict) –
    This data type is used as a response element in the DescribeDBSubnetGroups action.
    - **SubnetIdentifier (string)** –
      Specifies the identifier of the subnet.
    - **SubnetAvailabilityZone (dict)** –
      Contains Availability Zone information.

    This data type is used as an element in the following data type:
    - **OrderableDBInstanceOption**
      - **Name (string)** –
        The name of the availability zone.
    - **SubnetStatus (string)** –
      Specifies the status of the subnet.

`create_event_subscription(**kwargs)`

Creates an RDS event notification subscription. This action requires a topic ARN (Amazon Resource Name) created by either the RDS console, the SNS console, or the SNS API. To obtain an ARN with SNS, you must create a topic in Amazon SNS and subscribe to the topic. The ARN is displayed in the SNS console.

You can specify the type of source (SourceType) you want to be notified of, provide a list of RDS sources (SourceIds) that triggers the events, and provide a list of event categories (EventCategories) for events you want to be notified of. For example, you can specify SourceType = db-instance, SourceIds = mydbinstance1, mydbinstance2 and EventCategories =Availability, Backup.

If you specify both the SourceType and SourceIds, such as SourceType = db-instance and SourceIdentifier = myDBInstance1, you will be notified of all the db-instance events for the specified source. If you specify a SourceType but do not specify a SourceIdentifier, you will receive notice of the events for that source type for all your RDS sources. If you do not specify either the SourceType nor the SourceIdentifier, you will be notified of events generated from all RDS sources belonging to your customer account.

**Request Syntax**

```python
response = client.create_event_subscription(
    SubscriptionName='string',
    SnsTopicArn='string',
    SourceType='string',
    EventCategories=[
        'string',
    ],
```

3.1. Services
Parameters

- **SubscriptionName** *(string)* – [REQUIRED]
  
The name of the subscription.
  
  Constraints: The name must be less than 255 characters.

- **SnsTopicArn** *(string)* – [REQUIRED]
  
The Amazon Resource Name (ARN) of the SNS topic created for event notification. The ARN is created by Amazon SNS when you create a topic and subscribe to it.

- **SourceType** *(string)* – The type of source that will be generating the events. For example, if you want to be notified of events generated by a DB instance, you would set this parameter to db-instance. If this value is not specified, all events are returned.
  
  Valid values: db-instance | db-parameter-group | db-security-group | db-snapshot

- **EventCategories** *(list)* – A list of event categories for a SourceType that you want to subscribe to. You can see a list of the categories for a given SourceType in the Events topic in the Amazon RDS User Guide or by using the DescribeEventCategories action.
  
  - *(string)* –

- **SourceIds** *(list)* – The list of identifiers of the event sources for which events will be returned. If not specified, then all sources are included in the response. An identifier must begin with a letter and must contain only ASCII letters, digits, and hyphens; it cannot end with a hyphen or contain two consecutive hyphens.
  
  Constraints:
  
  - If SourceIds are supplied, SourceType must also be provided.
  - If the source type is a DB instance, then a DBInstanceIdentifier must be supplied.
  - If the source type is a DB security group, a DBSecurityGroupName must be supplied.
  - If the source type is a DB parameter group, a DBParameterGroupName must be supplied.
  - If the source type is a DB snapshot, a DBSnapshotIdentifier must be supplied.
  
  - *(string)* –

- **Enabled** *(boolean)* – A Boolean value; set to true to activate the subscription, set to false to create the subscription but not active it.

- **Tags** *(list)* – A list of tags.
  
  - *(dict)* –

    Metadata assigned to an Amazon RDS resource consisting of a key-value pair.
pair.

* **Key** *(string)* –

A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, `'_`, `'.'`, `'/'`, `'='`, `'+', `'-' (Java regex: “^([\p{L}\p{Z}\p{N}_.:/=+-]*)$”).

* **Value** *(string)* –

A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, `'_`, `'.'`, `'/'`, `'='`, `'+', `'-' (Java regex: “^([\p{L}\p{Z}\p{N}_.:/=+-]*)$”).

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'EventSubscription': {
        'CustomerAwsId': 'string',
        'CustSubscriptionId': 'string',
        'SnsTopicArn': 'string',
        'Status': 'string',
        'SubscriptionCreationTime': 'string',
        'SourceType': 'string',
        'SourceIdsList': [
            'string',
        ],
        'EventCategoriesList': [
            'string',
        ],
        'Enabled': True|False
    }
}
```

**Response Structure**

* *(dict)* –

Contains the results of a successful invocation of the DescribeEventSubscriptions action.

  * **EventSubscription** *(dict)* –

Contains the results of a successful invocation of the DescribeEventSubscriptions action.

    * **CustomerAwsId** *(string)* –

        The AWS customer account associated with the RDS event notification subscription.

    * **CustSubscriptionId** *(string)* –

        The RDS event notification subscription Id.

    * **SnsTopicArn** *(string)* –

        The topic ARN of the RDS event notification subscription.

    * **Status** *(string)* –

        The status of the RDS event notification subscription.
Can be one of the following: creating | modifying | deleting | active | no-permission | topic-not-exist

The status “no-permission” indicates that RDS no longer has permission to post to the SNS topic. The status “topic-not-exist” indicates that the topic was deleted after the subscription was created.

* `SubscriptionCreationTime (string)` –
  The time the RDS event notification subscription was created.

* `SourceType (string)` –
  The source type for the RDS event notification subscription.

* `SourceIdsList (list)` –
  A list of source IDs for the RDS event notification subscription.
  · (string) –

* `EventCategoriesList (list)` –
  A list of event categories for the RDS event notification subscription.
  · (string) –

* `Enabled (boolean)` –
  A Boolean value indicating if the subscription is enabled. True indicates the subscription is enabled.

`create_option_group(**kwargs)`

Creates a new option group. You can create up to 20 option groups.

**Request Syntax**

```python
response = client.create_option_group(
    OptionGroupName='string',
    EngineName='string',
    MajorEngineVersion='string',
    OptionGroupDescription='string',
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        }
    ]
)
```

**Parameters**

- **OptionGroupName (string) – [REQUIRED]**
  Specifies the name of the option group to be created.
  
  Constraints:
  - Must be 1 to 255 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens
  
  Example: myoptiongroup

- **EngineName (string) – [REQUIRED]**
  Specifies the name of the engine that this option group should be associated with.

- **MajorEngineVersion (string) – [REQUIRED]**
Specifies the major version of the engine that this option group should be associated with.

- **OptionGroupDescription** *(string)* – [REQUIRED]

  The description of the option group.

- **Tags** *(list)* – A list of tags.
  - *(dict)* –

    Metadata assigned to an Amazon RDS resource consisting of a key-value pair.
    - **Key** *(string)* –
      A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘=’, ‘+’, ‘-’ (Java regex: “^([\p{L}\p{Z}\p{N}_.:/=+\-]*$)").
    - **Value** *(string)* –
      A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘=’, ‘+’, ‘-’ (Java regex: “^([\p{L}\p{Z}\p{N}_.:/=+\-]*$)").

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'OptionGroup': {
        'OptionGroupName': 'string',
        'OptionGroupDescription': 'string',
        'EngineName': 'string',
        'MajorEngineVersion': 'string',
        'Options': [
            {
                'OptionName': 'string',
                'OptionDescription': 'string',
                'Persistent': True|False,
                'Permanent': True|False,
                'Port': 123,
                'OptionSettings': [
                    {
                        'Name': 'string',
                        'Value': 'string',
                        'DefaultValue': 'string',
                        'Description': 'string',
                        'ApplyType': 'string',
                        'DataType': 'string',
                        'AllowedValues': 'string',
                        'IsModifiable': True|False,
                        'IsCollection': True|False
                    },
                ],
            }
        ],
        'DBSecurityGroupMemberships': [
            {
                'DBSecurityGroupName': 'string',
                'Status': 'string'
            }
        ]
    }
}
```
Response Structure

- (dict) –
  - OptionGroup (dict) –
    * OptionGroupName (string) –
      Specifies the name of the option group.
    * OptionGroupDescription (string) –
      Provides a description of the option group.
    * EngineName (string) –
      Indicates the name of the engine that this option group can be applied to.
    * MajorEngineVersion (string) –
      Indicates the major engine version associated with this option group.
    * Options (list) –
      Indicates what options are available in the option group.
      · (dict) –
        Option details.
        · OptionName (string) –
          The name of the option.
        · OptionDescription (string) –
          The description of the option.
        · Persistent (boolean) –
          Indicate if this option is persistent.
        · Permanent (boolean) –
          Indicate if this option is permanent.
        · Port (integer) –
          If required, the port configured for this option to use.
        · OptionSettings (list) –
          The option settings for this option.
          · (dict) –
            Option settings are the actual settings being applied or configured for that option. It is used when you modify an option group or describe option groups. For example, the NATIVE_NETWORK_ENCRYPTION option has a setting
called SQLNET.ENCRYPTION_SERVER that can have several different values.

- **Name (string)** –
  The name of the option that has settings that you can set.
- **Value (string)** –
  The current value of the option setting.
- **DefaultValue (string)** –
  The default value of the option setting.
- **Description (string)** –
  The description of the option setting.
- **ApplyType (string)** –
  The DB engine specific parameter type.
- **DataType (string)** –
  The data type of the option setting.
- **AllowedValues (string)** –
  The allowed values of the option setting.
- **IsModifiable (boolean)** –
  A Boolean value that, when true, indicates the option setting can be modified from the default.
- **IsCollection (boolean)** –
  Indicates if the option setting is part of a collection.
- **DBSecurityGroupMemberships (list)** –
  If the option requires access to a port, then this DB security group allows access to the port.
  · **DBSecurityGroupName (string)** –
    The name of the DB security group.
  · **Status (string)** –
    The status of the DB security group.
- **VpcSecurityGroupMemberships (list)** –
  If the option requires access to a port, then this VPC security group allows access to the port.
  · **VpcSecurityGroupId (string)** –
    The name of the VPC security group.
  · **Status (string)** –
    The status of the VPC security group.
* **AllowsVpcAndNonVpcInstanceMemberships** *(boolean)* –

Indicates whether this option group can be applied to both VPC and non-VPC instances. The value `true` indicates the option group can be applied to both VPC and non-VPC instances.

* **VpcId** *(string)* –

If `AllowsVpcAndNonVpcInstanceMemberships` is `false`, this field is blank. If `AllowsVpcAndNonVpcInstanceMemberships` is `true` and this field is blank, then this option group can be applied to both VPC and non-VPC instances. If this field contains a value, then this option group can only be applied to instances that are in the VPC indicated by this field.

**delete_db_cluster** (**kwargs)**

The `delete_db_cluster` action deletes a previously provisioned DB cluster. A successful response from the web service indicates the request was received correctly. When you delete a DB cluster, all automated backups for that DB cluster are deleted and cannot be recovered. Manual DB cluster snapshots of the DB cluster to be deleted are not deleted.

For more information on Amazon Aurora, see Aurora on Amazon RDS in the Amazon RDS User Guide.

**Request Syntax**

```python
response = client.delete_db_cluster(
    DBClusterIdentifier='string',
    SkipFinalSnapshot=True|False,
    FinalDBSnapshotIdentifier='string'
)
```

**Parameters**

- **DBClusterIdentifier** *(string)* – The DB cluster identifier for the DB cluster to be deleted. This parameter isn’t case-sensitive.

  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **SkipFinalSnapshot** *(boolean)* – Determines whether a final DB cluster snapshot is created before the DB cluster is deleted. If `true` is specified, no DB cluster snapshot is created. If `false` is specified, a DB cluster snapshot is created before the DB cluster is deleted.

  **Note:** You must specify a `FinalDBSnapshotIdentifier` parameter if `SkipFinalSnapshot` is `false`.

  Default: `false`

- **FinalDBSnapshotIdentifier** *(string)* – The DB cluster snapshot identifier of the new DB cluster snapshot created when `SkipFinalSnapshot` is set to `false`.

  **Note:** Specifying this parameter and also setting the `SkipFinalSnapshot` parameter to `true` results in an error.

  Constraints:
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
Return type: dict

Returns:

Response Syntax:

```python
{
    'DBCluster': {
        'AllocatedStorage': 123,
        'AvailabilityZones': [ 'string',
        ],
        'BackupRetentionPeriod': 123,
        'CharacterSetName': 'string',
        'DatabaseName': 'string',
        'DBClusterIdentifier': 'string',
        'DBClusterParameterGroup': 'string',
        'DBSubnetGroup': 'string',
        'Status': 'string',
        'PercentProgress': 'string',
        'EarliestRestorableTime': datetime(2015, 1, 1),
        'Endpoint': 'string',
        'Engine': 'string',
        'EngineVersion': 'string',
        'LatestRestorableTime': datetime(2015, 1, 1),
        'Port': 123,
        'MasterUsername': 'string',
        'DBClusterOptionGroupMemberships': [ {
            'DBClusterOptionGroupName': 'string',
            'Status': 'string'
        },
        ],
        'PreferredBackupWindow': 'string',
        'PreferredMaintenanceWindow': 'string',
        'DBClusterMembers': [ {
            'DBInstanceIdentifier': 'string',
            'IsClusterWriter': True|False,
            'DBClusterParameterGroupStatus': 'string'
        },
        ],
        'VpcSecurityGroups': [ {
            'VpcSecurityGroupId': 'string',
            'Status': 'string'
        },
        ]
    }
}
```

Response Structure:

- `(dict)` –

Contains the result of a successful invocation of the following actions:

- CreateDBCluster
- DeleteDBCluster
- FailoverDBCluster
- ModifyDBCluster
– RestoreDBClusterFromSnapshot
This data type is used as a response element in the DescribeDBClusters action.

– **DBCluster (dict)** –

Contains the result of a successful invocation of the following actions:
* CreateDBCluster
* DeleteDBCluster
* FailoverDBCluster
* ModifyDBCluster
* RestoreDBClusterFromSnapshot

This data type is used as a response element in the DescribeDBClusters action.

* **AllocatedStorage (integer)** –
  Specifies the allocated storage size in gigabytes (GB).
* **AvailabilityZones (list)** –
  Provides the list of EC2 Availability Zones that instances in the DB cluster can be created in.
  · (string) –
* **BackupRetentionPeriod (integer)** –
  Specifies the number of days for which automatic DB snapshots are retained.
* **CharacterSetName (string)** –
  If present, specifies the name of the character set that this cluster is associated with.
* **DatabaseName (string)** –
  Contains the name of the initial database of this DB cluster that was provided at create time, if one was specified when the DB cluster was created. This same name is returned for the life of the DB cluster.
* **DBClusterIdentifier (string)** –
  Contains a user-supplied DB cluster identifier. This identifier is the unique key that identifies a DB cluster.
* **DBClusterParameterGroup (string)** –
  Specifies the name of the DB cluster parameter group for the DB cluster.
* **DBSubnetGroup (string)** –
  Specifies information on the subnet group associated with the DB cluster, including the name, description, and subnets in the subnet group.
* **Status (string)** –
  Specifies the current state of this DB cluster.
* **PercentProgress (string)** –
  Specifies the progress of the operation as a percentage.
* **EarliestRestorableTime (datetime)** –
  Specifies the earliest time to which a database can be restored with point-in-time restore.
* **Endpoint (string)** –
Specifies the connection endpoint for the primary instance of the DB cluster.

* **Engine (string)** –

  Provides the name of the database engine to be used for this DB cluster.

* **EngineVersion (string)** –

  Indicates the database engine version.

* **LatestRestorableTime (datetime)** –

  Specifies the latest time to which a database can be restored with point-in-time restore.

* **Port (integer)** –

  Specifies the port that the database engine is listening on.

* **MasterUsername (string)** –

  Contains the master username for the DB cluster.

* **DBClusterOptionGroupMemberships (list)** –

  Provides the list of option group memberships for this DB cluster.

    · **(dict)** –

      Contains status information for a DB cluster option group.

      · **DBClusterOptionGroupName (string)** –

        Specifies the name of the DB cluster option group.

      · **Status (string)** –

        Specifies the status of the DB cluster option group.

* **PreferredBackupWindow (string)** –

  Specifies the daily time range during which automated backups are created if automated backups are enabled, as determined by the BackupRetentionPeriod.

* **PreferredMaintenanceWindow (string)** –

  Specifies the weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).

* **DBClusterMembers (list)** –

  Provides the list of instances that make up the DB cluster.

    · **(dict)** –

      Contains information about an instance that is part of a DB cluster.

      · **DBInstanceIdentifier (string)** –

        Specifies the instance identifier for this member of the DB cluster.

      · **IsClusterWriter (boolean)** –

        Value that is true if the cluster member is the primary instance for the DB cluster and false otherwise.

      · **DBClusterParameterGroupStatus (string)** –

        Specifies the status of the DB cluster parameter group for this member of the DB cluster.

* **VpcSecurityGroups (list)** –
Provides a list of VPC security groups that the DB cluster belongs to.

- **dict** –
  
  This data type is used as a response element for queries on VPC security group membership.

- **VpcSecurityGroupId (string)** –
  
  The name of the VPC security group.

- **Status (string)** –
  
  The status of the VPC security group.

**delete_db_cluster_parameter_group (**kwargs**)**

Deletes a specified DB cluster parameter group. The DB cluster parameter group to be deleted cannot be associated with any DB clusters.

For more information on Amazon Aurora, see **Aurora on Amazon RDS** in the **Amazon RDS User Guide**.

**Request Syntax**

```python
response = client.delete_db_cluster_parameter_group(
    DBClusterParameterGroupName='string'
)
```

**Parameters**

- **DBClusterParameterGroupName (string)** – [REQUIRED]
  
  The name of the DB cluster parameter group.

  Constraints:
  - Must be the name of an existing DB cluster parameter group.
  - You cannot delete a default DB cluster parameter group.
  - Cannot be associated with any DB clusters.

**Returns**

None

**delete_db_cluster_snapshot (**kwargs**)**

Deletes a DB cluster snapshot. If the snapshot is being copied, the copy operation is terminated.

**Note:** The DB cluster snapshot must be in the **available** state to be deleted.

For more information on Amazon Aurora, see **Aurora on Amazon RDS** in the **Amazon RDS User Guide**.

**Request Syntax**

```python
response = client.delete_db_cluster_snapshot(
    DBClusterSnapshotIdentifier='string'
)
```

**Parameters**

- **DBClusterSnapshotIdentifier (string)** – [REQUIRED]
  
  The identifier of the DB cluster snapshot to delete.

  Constraints: Must be the name of an existing DB cluster snapshot in the **available** state.

**Return type**

**dict**

**Returns**

None
{  
  'DBClusterSnapshot': {  
    'AvailabilityZones': [  
      'string',  
    ],  
    'DBClusterSnapshotIdentifier': 'string',  
    'DBClusterIdentifier': 'string',  
    'SnapshotCreateTime': datetime(2015, 1, 1),  
    'Engine': 'string',  
    'AllocatedStorage': 123,  
    'Status': 'string',  
    'Port': 123,  
    'VpcId': 'string',  
    'ClusterCreateTime': datetime(2015, 1, 1),  
    'MasterUsername': 'string',  
    'EngineVersion': 'string',  
    'LicenseModel': 'string',  
    'SnapshotType': 'string',  
    'PercentProgress': 123  
  }  
}  

Response Structure

- (dict) –

Contains the result of a successful invocation of the following actions:
- CreateDBClusterSnapshot
- DeleteDBClusterSnapshot

This data type is used as a response element in the DescribeDBClusterSnapshots action.

- DBClusterSnapshot (dict) –

Contains the result of a successful invocation of the following actions:
* CreateDBClusterSnapshot
* DeleteDBClusterSnapshot

This data type is used as a response element in the DescribeDBClusterSnapshots action.

* AvailabilityZones (list) –
  Provides the list of EC2 Availability Zones that instances in the DB cluster snapshot can be restored in.
  * (string) –

* DBClusterSnapshotIdentifier (string) –
  Specifies the identifier for the DB cluster snapshot.

* DBClusterIdentifier (string) –
  Specifies the DB cluster identifier of the DB cluster that this DB cluster snapshot was created from.

* SnapshotCreateTime (datetime) –
  Provides the time when the snapshot was taken, in Universal Coordinated Time (UTC).

* Engine (string) –
  Specifies the name of the database engine.

* AllocatedStorage (integer) –
  Specifies the allocated storage size in gigabytes (GB).
* **Status** *(string)*  –  
  Specifies the status of this DB cluster snapshot.

* **Port** *(integer)*  –  
  Specifies the port that the DB cluster was listening on at the time of the snapshot.

* **VpcId** *(string)*  –  
  Provides the VPC ID associated with the DB cluster snapshot.

* **ClusterCreateTime** *(datetime)*  –  
  Specifies the time when the DB cluster was created, in Universal Coordinated Time (UTC).

* **MasterUsername** *(string)*  –  
  Provides the master username for the DB cluster snapshot.

* **EngineVersion** *(string)*  –  
  Provides the version of the database engine for this DB cluster snapshot.

* **LicenseModel** *(string)*  –  
  Provides the license model information for this DB cluster snapshot.

* **SnapshotType** *(string)*  –  
  Provides the type of the DB cluster snapshot.

* **PercentProgress** *(integer)*  –  
  Specifies the percentage of the estimated data that has been transferred.

### delete_db_instance(**kwargs**)

The `delete_db_instance` action deletes a previously provisioned DB instance. A successful response from the web service indicates the request was received correctly. When you delete a DB instance, all automated backups for that instance are deleted and cannot be recovered. Manual DB snapshots of the DB instance to be deleted are not deleted.

If a final DB snapshot is requested the status of the RDS instance will be “deleting” until the DB snapshot is created. The API action `DescribeDBInstance` is used to monitor the status of this operation. The action cannot be canceled or reverted once submitted.

Note that when a DB instance is in a failure state and has a status of ‘failed’, ‘incompatible-restore’, or ‘incompatible-network’, it can only be deleted when the SkipFinalSnapshot parameter is set to “true”.

### Request Syntax

```python
response = client.delete_db_instance(
    DBInstanceIdentifier='string',
    SkipFinalSnapshot=True|False,
    FinalDBSnapshotIdentifier='string'
)
```

### Parameters

- **DBInstanceIdentifier** *(string)*  –  [REQUIRED]

  The DB instance identifier for the DB instance to be deleted. This parameter isn’t case-sensitive.

  **Constraints:**
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
• **SkipFinalSnapshot** *(boolean)* – Determines whether a final DB snapshot is created before the DB instance is deleted. If `true` is specified, no DBSnapshot is created. If `false` is specified, a DB snapshot is created before the DB instance is deleted.

Note that when a DB instance is in a failure state and has a status of ‘failed’, ‘incompatible-restore’, or ‘incompatible-network’, it can only be deleted when the SkipFinalSnapshot parameter is set to “true”.

Specify `true` when deleting a Read Replica.

Note: The FinalDBSnapshotIdentifier parameter must be specified if SkipFinalSnapshot is `false`.

Default: `false`

• **FinalDBSnapshotIdentifier** *(string)* – The DBSnapshotIdentifier of the new DBSnapshot created when SkipFinalSnapshot is set to `false`.

Note: Specifying this parameter and also setting the SkipFinalSnapshot parameter to `true` results in an error.

Constraints:
- Must be 1 to 255 alphanumeric characters
- First character must be a letter
- Cannot end with a hyphen or contain two consecutive hyphens
- Cannot be specified when deleting a Read Replica.

Return type: `dict`

Returns:

**Response Syntax**

```json
{
    'DBInstance': {
        'DBInstanceIdentifier': 'string',
        'DBInstanceClass': 'string',
        'Engine': 'string',

Response Structure
• (dict) –
     Contains the result of a successful invocation of the following actions:
     – CreateDBInstance
     – DeleteDBInstance
     – ModifyDBInstance
     This data type is used as a response element in the DescribeDBInstances action.
     – **DBInstance** (dict) –
       Contains the result of a successful invocation of the following actions:
       * CreateDBInstance
       * DeleteDBInstance
       * ModifyDBInstance
       This data type is used as a response element in the DescribeDBInstances action.
     * **DBInstanceIdentifier** (string) –
       Contains a user-supplied database identifier. This identifier is the unique key that identifies a DB instance.
     * **DBInstanceClass** (string) –
       Contains the name of the compute and memory capacity class of the DB instance.
     * **Engine** (string) –
       Provides the name of the database engine to be used for this DB instance.
     * **DBInstanceStatus** (string) –
       Specifies the current state of this database.
     * **MasterUsername** (string) –
Contains the master username for the DB instance.

* **DBName** *(string)* –

The meaning of this parameter differs according to the database engine you use. For example, this value returns either MySQL or PostgreSQL information when returning values from CreateDBInstanceReadReplica since Read Replicas are only supported for MySQL and PostgreSQL.

**MySQL, SQL Server, PostgreSQL**

Contains the name of the initial database of this instance that was provided at create time, if one was specified when the DB instance was created. This same name is returned for the life of the DB instance.

Type: String

**Oracle**

Contains the Oracle System ID (SID) of the created DB instance. Not shown when the returned parameters do not apply to an Oracle DB instance.

* **Endpoint** *(dict)* –

Specifies the connection endpoint.

  · **Address** *(string)* –

    Specifies the DNS address of the DB instance.

  · **Port** *(integer)* –

    Specifies the port that the database engine is listening on.

* **AllocatedStorage** *(integer)* –

Specifies the allocated storage size specified in gigabytes.

* **InstanceCreateTime** *(datetime)* –

Provides the date and time the DB instance was created.

* **PreferredBackupWindow** *(string)* –

 Specifies the daily time range during which automated backups are created if automated backups are enabled, as determined by the BackupRetentionPeriod.

* **BackupRetentionPeriod** *(integer)* –

Specifies the number of days for which automatic DB snapshots are retained.

* **DBSecurityGroups** *(list)* –

Provides List of DB security group elements containing only DBSecurityGroup.Name and DBSecurityGroup.Status subelements.

  · *(dict)* –

    This data type is used as a response element in the following actions:

    · ModifyDBInstance
    · RebootDBInstance
    · RestoreDBInstanceFromDBSnapshot
    · RestoreDBInstanceToPointInTime

    * **DBSecurityGroupName** *(string)* –

      The name of the DB security group.
· **Status** *(string)* –
  The status of the DB security group.

* **VpcSecurityGroups** *(list)* –
  Provides List of VPC security group elements that the DB instance belongs to.
  · *(dict)* –
    This data type is used as a response element for queries on VPC security group membership.
    · **VpcSecurityGroupId** *(string)* –
      The name of the VPC security group.
    · **Status** *(string)* –
      The status of the VPC security group.

* **DBParameterGroups** *(list)* –
  Provides the list of DB parameter groups applied to this DB instance.
  · *(dict)* –
    The status of the DB parameter group.
    This data type is used as a response element in the following actions:
    · CreateDBInstance
    · CreateDBInstanceReadReplica
    · DeleteDBInstance
    · ModifyDBInstance
    · RebootDBInstance
    · RestoreDBInstanceFromDBSnapshot
    · **DBParameterGroupName** *(string)* –
      The name of the DP parameter group.
    · **ParameterApplyStatus** *(string)* –
      The status of parameter updates.

* **AvailabilityZone** *(string)* –
  Specifies the name of the Availability Zone the DB instance is located in.

* **DBSubnetGroup** *(dict)* –
  Specifies information on the subnet group associated with the DB instance, including the name, description, and subnets in the subnet group.
  · **DBSubnetGroupName** *(string)* –
    Specifies the name of the DB subnet group.
  · **DBSubnetGroupDescription** *(string)* –
    Provides the description of the DB subnet group.
  · **VpcId** *(string)* –
    Provides the VpcId of the DB subnet group.
  · **SubnetGroupStatus** *(string)* –
    Provides the status of the DB subnet group.
  · **Subnets** *(list)* –
Contains a list of Subnet elements.

- **(dict)**
  - This data type is used as a response element in the DescribeDBSubnetGroups action.
- **SubnetIdentifier (string)**
  - Specifies the identifier of the subnet.
- **SubnetAvailabilityZone (dict)**
  - Contains Availability Zone information.
  - This data type is used as an element in the following data type:
    - **OrderableDBInstanceOption**
    - **Name (string)**
      - The name of the availability zone.
    - **SubnetStatus (string)**
      - Specifies the status of the subnet.
- **PreferredMaintenanceWindow (string)**
  - Specifies the weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).
- **PendingModifiedValues (dict)**
  - Specifies that changes to the DB instance are pending. This element is only included when changes are pending. Specific changes are identified by subelements.
    - **DBInstanceClass (string)**
      - Contains the new `DBInstanceClass` for the DB instance that will be applied or is in progress.
    - **AllocatedStorage (integer)**
      - Contains the new `AllocatedStorage` size for the DB instance that will be applied or is in progress.
    - **MasterUserPassword (string)**
      - Contains the pending or in-progress change of the master credentials for the DB instance.
    - **Port (integer)**
      - Specifies the pending port for the DB instance.
    - **BackupRetentionPeriod (integer)**
      - Specifies the pending number of days for which automated backups are retained.
    - **MultiAZ (boolean)**
      - Indicates that the Single-AZ DB instance is to change to a Multi-AZ deployment.
    - **EngineVersion (string)**
      - Indicates the database engine version.
    - **Iops (integer)**
      - Specifies the new Provisioned IOPS value for the DB instance that will be applied or is being applied.
    - **DBInstanceIdentifier (string)**
Contains the new `DBInstanceIdentifier` for the DB instance that will be applied or is in progress.

- **StorageType** *(string)*
  Specifies the storage type to be associated with the DB instance.

- **CACertificateIdentifier** *(string)*
  Specifies the identifier of the CA certificate for the DB instance.

- **LatestRestorableTime** *(datetime)*
  Specifies the latest time to which a database can be restored with point-in-time restore.

- **MultiAZ** *(boolean)*
  Specifies if the DB instance is a Multi-AZ deployment.

- **EngineVersion** *(string)*
  Indicates the database engine version.

- **AutoMinorVersionUpgrade** *(boolean)*
  Indicates that minor version patches are applied automatically.

- **ReadReplicaSourceDBInstanceIdentifier** *(string)*
  Contains the identifier of the source DB instance if this DB instance is a Read Replica.

- **ReadReplicaDBInstanceIdentifiers** *(list)*
  Contains one or more identifiers of the Read Replicas associated with this DB instance.

- **LicenseModel** *(string)*
  License model information for this DB instance.

- **Iops** *(integer)*
  Specifies the Provisioned IOPS (I/O operations per second) value.

- **OptionGroupMemberships** *(list)*
  Provides the list of option group memberships for this DB instance.

- **CharacterSetName** *(string)*
  If present, specifies the name of the character set that this instance is associated with.

- **SecondaryAvailabilityZone** *(string)*
  If present, specifies the name of the secondary Availability Zone for a DB instance with multi-AZ support.

- **PubliclyAccessible** *(boolean)*
Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.

Default: The default behavior varies depending on whether a VPC has been requested or not. The following list shows the default behavior in each case.

- Default VPC: true
- VPC: false

If no DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be publicly accessible. If a specific DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be private.

* `StatusInfos (list)` –

The status of a Read Replica. If the instance is not a Read Replica, this will be blank.

- (dict) –
  
  Provides a list of status information for a DB instance.

  - `StatusType (string)` –
    
    This value is currently “read replication.”

  - `Normal (boolean)` –
    
    Boolean value that is true if the instance is operating normally, or false if the instance is in an error state.

  - `Status (string)` –
    
    Status of the DB instance. For a StatusType of read replica, the values can be replicating, error, stopped, or terminated.

  - `Message (string)` –
    
    Details of the error if there is an error for the instance. If the instance is not in an error state, this value is blank.

* `StorageType (string)` –

Specifies the storage type associated with DB instance.

* `TdeCredentialArn (string)` –

The ARN from the Key Store with which the instance is associated for TDE encryption.

* `DbInstancePort (integer)` –

Specifies the port that the DB instance listens on. If the DB instance is part of a DB cluster, this can be a different port than the DB cluster port.

* `DBClusterIdentifier (string)` –

If the DB instance is a member of a DB cluster, contains the name of the DB cluster that the DB instance is a member of.

* `StorageEncrypted (boolean)` –

Specifies whether the DB instance is encrypted.

* `KmsKeyId (string)` –
If `StorageEncrypted` is true, the KMS key identifier for the encrypted DB instance.

* **DbiResourceId** *(string)* –

If `StorageEncrypted` is true, the region-unique, immutable identifier for the encrypted DB instance. This identifier is found in AWS CloudTrail log entries whenever the KMS key for the DB instance is accessed.

* **CACertificateIdentifier** *(string)* –

The identifier of the CA certificate for this DB instance.

* **DomainMemberships** *(list)* –

The Active Directory Domain membership records associated with the DB instance.

  * *(dict)* –

    An Active Directory Domain membership record associated with the DB instance.

  * **Domain** *(string)* –

    The identifier of the Active Directory Domain.

  * **Status** *(string)* –

    The status of the DB instance’s Active Directory Domain membership (e.g. joined, pending-join, failed etc).

  * **Connectivity** *(string)* –

    The observed connectivity of the Active Directory Domain.

* **CopyTagsToSnapshot** *(boolean)* –

This property is not currently implemented.

```
def delete_db_parameter_group(**kwargs)
    Deletes a specified DBParameterGroup. The DBParameterGroup to be deleted cannot be associated with any DB instances.
```

**Request Syntax**

```
response = client.delete_db_parameter_group(
    DBParameterGroupName='string'
)
```

**Parameters**  

`DBParameterGroupName` *(string)* – [REQUIRED]

The name of the DB parameter group.

**Constraints:**

* Must be the name of an existing DB parameter group
* You cannot delete a default DB parameter group
* Cannot be associated with any DB instances

**Returns**  

None

```
def delete_db_security_group(**kwargs)
    Deletes a DB security group.
```

**Note:** The specified DB security group must not be associated with any DB instances.

**Request Syntax**
response = client.delete_db_security_group(
    DBSecurityGroupName='string'
)

**Parameters**  
**DBSecurityGroupName** *(string)* – [REQUIRED]  
The name of the DB security group to delete.

**Note:** You cannot delete the default DB security group.

Constraints:  
- Must be 1 to 255 alphanumeric characters  
- First character must be a letter  
- Cannot end with a hyphen or contain two consecutive hyphens  
- Must not be “Default”  
- Cannot contain spaces

**Returns**  
None

disable_db_snapshot(**kwargs)**
Deletes a DBSnapshot. If the snapshot is being copied, the copy operation is terminated.

**Note:** The DBSnapshot must be in the *available* state to be deleted.

**Request Syntax**

response = client.delete_db_snapshot(
    DBSnapshotIdentifier='string'
)

**Parameters**  
**DBSnapshotIdentifier** *(string)* – [REQUIRED]  
The DBSnapshot identifier.

Constraints: Must be the name of an existing DB snapshot in the *available* state.

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'DBSnapshot': {
        'DBSnapshotIdentifier': 'string',
        'DBInstanceIdentifier': 'string',
        'SnapshotCreateTime': datetime(2015, 1, 1),
        'Engine': 'string',
        'AllocatedStorage': 123,
        'Status': 'string',
        'Port': 123,
        'AvailabilityZone': 'string',
        'VpcId': 'string',
        'InstanceCreateTime': datetime(2015, 1, 1),
        'MasterUsername': 'string',
        'EngineVersion': 'string',
        'LicenseModel': 'string',
        'SnapshotType': 'string',
        'Iops': 123,
        'OptionGroupName': 'string',
```
Response Structure

- (dict) –

Contains the result of a successful invocation of the following actions:
- CreateDBSnapshot
- DeleteDBSnapshot

This data type is used as a response element in the DescribeDBSnapshots action.

- DBSnapshot (dict) –

Contains the result of a successful invocation of the following actions:
- CreateDBSnapshot
- DeleteDBSnapshot

This data type is used as a response element in the DescribeDBSnapshots action.

- DBSnapshotIdentifier (string) –
  Specifies the identifier for the DB snapshot.

- DBInstanceIdentifier (string) –
  Specifies the DB instance identifier of the DB instance this DB snapshot was created from.

- SnapshotCreateTime (datetime) –
  Provides the time when the snapshot was taken, in Universal Coordinated Time (UTC).

- Engine (string) –
  Specifies the name of the database engine.

- AllocatedStorage (integer) –
  Specifies the allocated storage size in gigabytes (GB).

- Status (string) –
  Specifies the status of this DB snapshot.

- Port (integer) –
  Specifies the port that the database engine was listening on at the time of the snapshot.

- AvailabilityZone (string) –
  Specifies the name of the Availability Zone the DB instance was located in at the time of the DB snapshot.

- VpcId (string) –
  Provides the VPC ID associated with the DB snapshot.

- InstanceCreateTime (datetime) –
  Specifies the time when the snapshot was taken, in Universal Coordinated Time (UTC).

- MasterUsername (string) –
Provides the master username for the DB snapshot.

* **EngineVersion** *(string)*

Specifies the version of the database engine.

* **LicenseModel** *(string)*

License model information for the restored DB instance.

* **SnapshotType** *(string)*

Provides the type of the DB snapshot.

* **Iops** *(integer)*

Specifies the Provisioned IOPS (I/O operations per second) value of the DB instance at the time of the snapshot.

* **OptionGroupName** *(string)*

Provides the option group name for the DB snapshot.

* **PercentProgress** *(integer)*

The percentage of the estimated data that has been transferred.

* **SourceRegion** *(string)*

The region that the DB snapshot was created in or copied from.

* **SourceDBSnapshotIdentifier** *(string)*

The DB snapshot Arn that the DB snapshot was copied from. It only has value in case of cross customer or cross region copy.

* **StorageType** *(string)*

Specifies the storage type associated with DB Snapshot.

* **TdeCredentialArn** *(string)*

The ARN from the Key Store with which to associate the instance for TDE encryption.

* **Encrypted** *(boolean)*

Specifies whether the DB snapshot is encrypted.

* **KmsKeyId** *(string)*

If Encrypted is true, the KMS key identifier for the encrypted DB snapshot.

**delete_db_subnet_group**( **kwargs** )

Deletes a DB subnet group.

**Note:** The specified database subnet group must not be associated with any DB instances.

**Request Syntax**

```python
response = client.delete_db_subnet_group(
    DBSubnetGroupName='string'
)
```

**Parameters**

- **DBSubnetGroupName** *(string)* – [REQUIRED]
  
  The name of the database subnet group to delete.

**Note:** You cannot delete the default subnet group.

**Constraints:**

- Must be 1 to 255 alphanumeric characters
• First character must be a letter
• Cannot end with a hyphen or contain two consecutive hyphens

Returns None

delete_event_subscription(**kwargs)
Deletes an RDS event notification subscription.

Request Syntax

response = client.delete_event_subscription(
    SubscriptionName='string'
)

Parameters SubscriptionName (string) – [REQUIRED]
The name of the RDS event notification subscription you want to delete.

Return type dict

Response Syntax

{
    'EventSubscription': {
        'CustomerAwsId': 'string',
        'CustSubscriptionId': 'string',
        'SnsTopicArn': 'string',
        'Status': 'string',
        'SubscriptionCreationTime': 'string',
        'SourceType': 'string',
        'SourceIdsList': [
            'string',
        ],
        'EventCategoriesList': [
            'string',
        ],
        'Enabled': True|False
    }
}

Response Structure

* (dict) –

Contains the results of a successful invocation of the DescribeEventSubscriptions action.

  – EventSubscription (dict) –

Contains the results of a successful invocation of the DescribeEventSubscriptions action.

* CustomerAwsId (string) –
The AWS customer account associated with the RDS event notification subscription.

* CustSubscriptionId (string) –
The RDS event notification subscription Id.

* SnsTopicArn (string) –
The topic ARN of the RDS event notification subscription.

* Status (string) –
The status of the RDS event notification subscription.
Constraints:
Can be one of the following: creating | modifying | deleting | active | no-permission | topic-not-exist
The status “no-permission” indicates that RDS no longer has permission to post to the SNS topic. The status “topic-not-exist” indicates that the topic was deleted after the subscription was created.
* **SubscriptionCreationTime** *(string)* –
The time the RDS event notification subscription was created.
* **SourceType** *(string)* –
The source type for the RDS event notification subscription.
* **SourceIdsList** *(list)* –
A list of source IDs for the RDS event notification subscription.
  · *(string)* –
* **EventCategoriesList** *(list)* –
A list of event categories for the RDS event notification subscription.
  · *(string)* –
* **Enabled** *(boolean)* –
A Boolean value indicating if the subscription is enabled. True indicates the subscription is enabled.

delete_option_group(**kwargs)
Deletes an existing option group.

Request Syntax

```python
response = client.delete_option_group(
    OptionGroupName='string'
)
```

Parameters
**OptionGroupName** *(string)* – [REQUIRED]
The name of the option group to be deleted.

Note: You cannot delete default option groups.

Returns None
describe_account_attributes()
Lists all of the attributes for a customer account. The attributes include Amazon RDS quotas for the account, such as the number of DB instances allowed. The description for a quota includes the quota name, current usage toward that quota, and the quota’s maximum value.

This command does not take any parameters.

Request Syntax

```python
response = client.describe_account_attributes()
```

Return type dict

Returns

Response Syntax
{  
    'AccountQuotas': [  
        {  
            'AccountQuotaName': 'string',  
            'Used': 123,  
            'Max': 123  
        },  
    ]  
}

Response Structure

- (dict) –
  Data returned by the DescribeAccountAttributes action.
  - AccountQuotas (list) –
    A list of AccountQuota objects. Within this list, each quota has a name, a count of usage toward the quota maximum, and a maximum value for the quota.
    - (dict) –
      Describes a quota for an AWS account, for example, the number of DB instances allowed.
      - AccountQuotaName (string) –
        The name of the Amazon RDS quota for this AWS account.
      - Used (integer) –
        The amount currently used toward the quota maximum.
      - Max (integer) –
        The maximum allowed value for the quota.

describe_certificates(**kwargs)
Lists the set of CA certificates provided by Amazon RDS for this AWS account.

Request Syntax

response = client.describe_certificates(
    CertificateIdentifier='string',
    Filters=[
        {'Name': 'string',
         'Values': [  
             'string',
         ]}
    ],
    MaxRecords=123,
    Marker='string'
)

Parameters

- CertificateIdentifier (string) – The user-supplied certificate identifier. If this parameter is specified, information for only the identified certificate is returned. This parameter isn’t case-sensitive.

  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
• **Filters** *(list)* – This parameter is not currently supported.
  - *(dict)* –
    - **Name** *(string)* – [REQUIRED]
      This parameter is not currently supported.
    - **Values** *(list)* – [REQUIRED]
      This parameter is not currently supported.
  - *(string)* –

• **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified `MaxRecords` value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.
  
  Default: 100

  Constraints: Minimum 20, maximum 100.

• **Marker** *(string)* – An optional pagination token provided by a previous `DescribeCertificates` request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

**Return type** dict

**Returns**

**Response Syntax**

```
{
  'Certificates': [
    {
      'CertificateIdentifier': 'string',
      'CertificateType': 'string',
      'Thumbprint': 'string',
      'ValidFrom': datetime(2015, 1, 1),
      'ValidTill': datetime(2015, 1, 1)
    },
    ],
  'Marker': 'string'
}
```

**Response Structure**

- *(dict)* –
  
  Data returned by the `DescribeCertificates` action.

  - **Certificates** *(list)* –
    
    The list of Certificate objects for the AWS account.

    - *(dict)* –
      
      A CA certificate for an AWS account.

      - **CertificateIdentifier** *(string)* –
        
        The unique key that identifies a certificate.

      - **CertificateType** *(string)* –
        
        The type of the certificate.

      - **Thumbprint** *(string)* –
        
        The thumbprint of the certificate.

      - **ValidFrom** *(datetime)* –
        
        The starting date from which the certificate is valid.
describe_db_cluster_parameter_groups(**kwargs)

Returns a list of DBClusterParameterGroup descriptions. If a DBClusterParameterGroupName parameter is specified, the list will contain only the description of the specified DB cluster parameter group.

For more information on Amazon Aurora, see Aurora on Amazon RDS in the Amazon RDS User Guide.

Request Syntax

response = client.describe_db_cluster_parameter_groups(
    DBClusterParameterGroupName='string',
    Filters=[
        {
            'Name': 'string',
            'Values': ['string',]
        },
    ],
    MaxRecords=123,
    Marker='string'
)

Parameters

- **DBClusterParameterGroupName (string)** – The name of a specific DB cluster parameter group to return details for.
  
  Constraints:
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **Filters (list)** – This parameter is not currently supported.
  - (dict) –
    - **Name (string)** – [REQUIRED]
      
      This parameter is not currently supported.
    - **Values (list)** – [REQUIRED]
      
      This parameter is not currently supported.
    - (string) –

- **MaxRecords (integer)** – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.
  
  Default: 100

  Constraints: Minimum 20, maximum 100.

- **Marker (string)** – An optional pagination token provided by a previous DescribeDBClusterParameterGroups request. If this parameter is
specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Marker': 'string',
    'DBClusterParameterGroups': [
        {
            'DBClusterParameterGroupName': 'string',
            'DBParameterGroupFamily': 'string',
            'Description': 'string'
        },
        ...
    ]
}
```

**Response Structure**

- *(dict)* –
  - **Marker** *(string)* –
    An optional pagination token provided by a previous `DescribeDBClusterParameterGroups` request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.
  - **DBClusterParameterGroups** *(list)* –
    A list of DB cluster parameter groups.
    - *(dict)* –
      Contains the result of a successful invocation of the `CreateDBClusterParameterGroup` action.
      This data type is used as a request parameter in the `DeleteDBClusterParameterGroup` action, and as a response element in the `DescribeDBClusterParameterGroups` action.
      - **DBClusterParameterGroupName** *(string)* –
        Provides the name of the DB cluster parameter group.
      - **DBParameterGroupFamily** *(string)* –
        Provides the name of the DB parameter group family that this DB cluster parameter group is compatible with.
      - **Description** *(string)* –
        Provides the customer-specified description for this DB cluster parameter group.

**describe_db_cluster_parameters**(**kwargs**)

Returns the detailed parameter list for a particular DB cluster parameter group.

For more information on Amazon Aurora, see [Aurora on Amazon RDS](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/) in the *Amazon RDS User Guide*.

**Request Syntax**

```python
response = client.describe_db_cluster_parameters(
    DBClusterParameterGroupName='string',
    Source='string',
    Filters=[
```
```json
{
    'Name': 'string',
    'Values': [
        'string',
    ],
},
MaxRecords=123,
Marker='string'
}
```

### Parameters

- **DBClusterParameterGroupName** *(string)* – [REQUIRED]
  
  The name of a specific DB cluster parameter group to return parameter details for.
  
  **Constraints:**
  
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **Source** *(string)* – A value that indicates to return only parameters for a specific source. Parameter sources can be engine, service, or customer.

- **Filters** *(list)* – This parameter is not currently supported.
  
  - *(dict)* –
  
    - **Name** *(string)* – [REQUIRED]
      
      This parameter is not currently supported.
    
    - **Values** *(list)* – [REQUIRED]
      
      This parameter is not currently supported.

- **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.
  
  Default: 100

  **Constraints:** Minimum 20, maximum 100.

- **Marker** *(string)* – An optional pagination token provided by a previous DescribeDBClusterParameters request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

### Return type

**dict**

### Returns

**Response Syntax**

```json
{
    'Parameters': [
        
    ]
}
```
Response Structure

- (dict) –

  Provides details about a DB cluster parameter group including the parameters in
  the DB cluster parameter group.

  - Parameters (list) –

    Provides a list of parameters for the DB cluster parameter group.

    - (dict) –

      This data type is used as a request parameter in the ModifyDBPa-
     rameterGroup and ResetDBParameterGroup actions.

      This data type is used as a response element in the De-
     scribeEngineDefaultParameters and DescribeDBParameters ac-
      tions.

      - ParameterName (string) –

        Specifies the name of the parameter.

      - ParameterValue (string) –

        Specifies the value of the parameter.

      - Description (string) –

        Provides a description of the parameter.

      - Source (string) –

        Indicates the source of the parameter value.

      - ApplyType (string) –

        Specifies the engine specific parameters type.

      - DataType (string) –

        Specifies the valid data type for the parameter.

      - AllowedValues (string) –

        Specifies the valid range of values for the parameter.

      - IsModifiable (boolean) –

        Indicates whether (true) or not (false) the parameter can
        be modified. Some parameters have security or operational
        implications that prevent them from being changed.

      - MinimumEngineVersion (string) –

        The earliest engine version to which the parameter can apply.

      - ApplyMethod (string) –

        Indicates when to apply parameter updates.

    - Marker (string) –

      An optional pagination token provided by a previous DescribeDBClus-
      terParameters request. If this parameter is specified, the response in-
includes only records beyond the marker, up to the value specified by MaxRecords.

**describe_db_cluster_snapshots(**kwargs)**

Returns information about DB cluster snapshots. This API supports pagination.

For more information on Amazon Aurora, see Aurora on Amazon RDS in the Amazon RDS User Guide.

**Request Syntax**

```python
response = client.describe_db_cluster_snapshots(
    DBClusterIdentifier='string',
    DBClusterSnapshotIdentifier='string',
    SnapshotType='string',
    Filters=[
        {
            'Name': 'string',
            'Values': [ 'string',
        ]
    ],
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**

- **DBClusterIdentifier (string)** – A DB cluster identifier to retrieve the list of DB cluster snapshots for. This parameter cannot be used in conjunction with the DBClusterSnapshotIdentifier parameter. This parameter is not case-sensitive.

  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **DBClusterSnapshotIdentifier (string)** – A specific DB cluster snapshot identifier to describe. This parameter cannot be used in conjunction with the DBClusterIdentifier parameter. This value is stored as a lowercase string.

  Constraints:
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens
  - If this is the identifier of an automated snapshot, the SnapshotType parameter must also be specified.

- **SnapshotType (string)** – The type of DB cluster snapshots that will be returned. Values can be **automated** or **manual**. If this parameter is not specified, the returned results will include all snapshot types.

- **Filters (list)** – This parameter is not currently supported.
  - *(dict)*
    - **Name (string)** – [REQUIRED]
      - This parameter is not currently supported.
    - **Values (list)** – [REQUIRED]
      - This parameter is not currently supported.
    - *(string)*
• **MaxRecords** (*integer*) – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.

    Default: 100

    Constraints: Minimum 20, maximum 100.

• **Marker** (*string*) – An optional pagination token provided by a previous DescribeDBClusterSnapshots request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Marker': 'string',
    'DBClusterSnapshots': [
        {
            'AvailabilityZones': ['string'],
            'DBClusterSnapshotIdentifier': 'string',
            'DBClusterIdentifier': 'string',
            'SnapshotCreateTime': datetime(2015, 1, 1),
            'Engine': 'string',
            'AllocatedStorage': 123,
            'Status': 'string',
            'Port': 123,
            'VpcId': 'string',
            'ClusterCreateTime': datetime(2015, 1, 1),
            'MasterUsername': 'string',
            'EngineVersion': 'string',
            'LicenseModel': 'string',
            'SnapshotType': 'string',
            'PercentProgress': 123
        },
        ...
    ]
}
```

**Response Structure**

• *(dict)* – Provides a list of DB cluster snapshots for the user as the result of a call to the DescribeDBClusterSnapshots action.

  – **Marker** (*string*) –

    An optional pagination token provided by a previous DescribeDBClusterSnapshots request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

  – **DBClusterSnapshots** (*list*) –

    Provides a list of DB cluster snapshots for the user.

    • *(dict)* –
Contains the result of a successful invocation of the following actions:
- CreateDBClusterSnapshot
- DeleteDBClusterSnapshot
This data type is used as a response element in the DescribeDBClusterSnapshots action.

- **AvailabilityZones** *(list)*
  Provides the list of EC2 Availability Zones that instances in the DB cluster snapshot can be restored in.

- **DBClusterSnapshotIdentifier** *(string)*
  Specifies the identifier for the DB cluster snapshot.

- **DBClusterIdentifier** *(string)*
  Specifies the DB cluster identifier of the DB cluster that this DB cluster snapshot was created from.

- **SnapshotCreateTime** *(datetime)*
  Provides the time when the snapshot was taken, in Universal Coordinated Time (UTC).

- **Engine** *(string)*
  Specifies the name of the database engine.

- **AllocatedStorage** *(integer)*
  Specifies the allocated storage size in gigabytes (GB).

- **Status** *(string)*
  Specifies the status of this DB cluster snapshot.

- **Port** *(integer)*
  Specifies the port that the DB cluster was listening on at the time of the snapshot.

- **VpcId** *(string)*
  Provides the VPC ID associated with the DB cluster snapshot.

- **ClusterCreateTime** *(datetime)*
  Specifies the time when the DB cluster was created, in Universal Coordinated Time (UTC).

- **MasterUsername** *(string)*
  Provides the master username for the DB cluster snapshot.

- **EngineVersion** *(string)*
  Provides the version of the database engine for this DB cluster snapshot.

- **LicenseModel** *(string)*
  Provides the license model information for this DB cluster snapshot.

- **SnapshotType** *(string)*
  Provides the type of the DB cluster snapshot.

- **PercentProgress** *(integer)*
  Specifies the percentage of the estimated data that has been transferred.
**describe_db_clusters**(**kwargs)**

Returns information about provisioned Aurora DB clusters. This API supports pagination.

For more information on Amazon Aurora, see Aurora on Amazon RDS in the Amazon RDS User Guide.

**Request Syntax**

```python
response = client.describe_db_clusters(  
    DBClusterIdentifier='string',  
    Filters=[  
        {'Name': 'string',  
        'Values': [  
            'string',  
        ]  
    },  
    MaxRecords=123,  
    Marker='string'
)
```

**Parameters**

- **DBClusterIdentifier** *(string)* – The user-supplied DB cluster identifier. If this parameter is specified, information from only the specific DB cluster is returned. This parameter isn’t case-sensitive.
  - Constraints:
    - Must contain from 1 to 63 alphanumeric characters or hyphens
    - First character must be a letter
    - Cannot end with a hyphen or contain two consecutive hyphens
- **Filters** *(list)* – This parameter is not currently supported.
  - *(dict)* –
    - **Name** *(string)* – [REQUIRED]
      - This parameter is not currently supported.
    - **Values** *(list)* – [REQUIRED]
      - This parameter is not currently supported.
- **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.
  - Default: 100
  - Constraints: Minimum 20, maximum 100.
- **Marker** *(string)* – An optional pagination token provided by a previous DescribeDBClusters request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'Marker': 'string',
    'DBClusters': [
        
    ]
}
```
Response Structure

- **(dict)** –
  
  Contains the result of a successful invocation of the DescribeDBClusters action.

  - **Marker (string)** –
    
    A pagination token that can be used in a subsequent DescribeDBClusters request.

  - **DBClusters (list)** –
    
    Contains a list of DB clusters for the user.

    - **(dict)** –
      
      Contains the result of a successful invocation of the following actions:
· CreateDBCluster
· DeleteDBCluster
· FailoverDBCluster
· ModifyDBCluster
· RestoreDBClusterFromSnapshot

This data type is used as a response element in the DescribeDBClusters action.

· **AllocatedStorage** *(integer)* –
  Specifies the allocated storage size in gigabytes (GB).

· **AvailabilityZones** *(list)* –
  Provides the list of EC2 Availability Zones that instances in the DB cluster can be created in.

· **BackupRetentionPeriod** *(integer)* –
  Specifies the number of days for which automatic DB snapshots are retained.

· **CharacterSetName** *(string)* –
  If present, specifies the name of the character set that this cluster is associated with.

· **DatabaseName** *(string)* –
  Contains the name of the initial database of this DB cluster that was provided at create time, if one was specified when the DB cluster was created. This same name is returned for the life of the DB cluster.

· **DBClusterIdentifier** *(string)* –
  Contains a user-supplied DB cluster identifier. This identifier is the unique key that identifies a DB cluster.

· **DBClusterParameterGroup** *(string)* –
  Specifies the name of the DB cluster parameter group for the DB cluster.

· **DBSubnetGroup** *(string)* –
  Specifies information on the subnet group associated with the DB cluster, including the name, description, and subnets in the subnet group.

· **Status** *(string)* –
  Specifies the current state of this DB cluster.

· **PercentProgress** *(string)* –
  Specifies the progress of the operation as a percentage.

· **EarliestRestorableTime** *(datetime)* –
  Specifies the earliest time to which a database can be restored with point-in-time restore.

· **Endpoint** *(string)* –
  Specifies the connection endpoint for the primary instance of the DB cluster.

· **Engine** *(string)* –
  Provides the name of the database engine to be used for this DB cluster.
· **EngineVersion** *(string)* –
  Indicates the database engine version.

· **LatestRestorableTime** *(datetime)* –
  Specifies the latest time to which a database can be restored
  with point-in-time restore.

· **Port** *(integer)* –
  Specifies the port that the database engine is listening on.

· **MasterUsername** *(string)* –
  Contains the master username for the DB cluster.

· **DBClusterOptionGroupMemberships** *(list)* –
  Provides the list of option group memberships for this DB
  cluster.

  · *(dict)* –
    Contains status information for a DB cluster option group.

· **DBClusterOptionGroupName** *(string)* –
  Specifies the name of the DB cluster option group.

· **Status** *(string)* –
  Specifies the status of the DB cluster option group.

· **PreferredBackupWindow** *(string)* –
  Specifies the daily time range during which automated back-
  ups are created if automated backups are enabled, as deter-
  mined by the *BackupRetentionPeriod*.

· **PreferredMaintenanceWindow** *(string)* –
  Specifies the weekly time range during which system mainte-
  nance can occur, in Universal Coordinated Time (UTC).

· **DBClusterMembers** *(list)* –
  Provides the list of instances that make up the DB cluster.

  · *(dict)* –
    Contains information about an instance that is part of a DB
    cluster.

· **DBInstanceIdentifier** *(string)* –
  Specifies the instance identifier for this member of the DB
  cluster.

· **IsClusterWriter** *(boolean)* –
  Value that is *true* if the cluster member is the primary in-
  stance for the DB cluster and *false* otherwise.

· **DBClusterParameterGroupStatus** *(string)* –
  Specifies the status of the DB cluster parameter group for this
  member of the DB cluster.

· **VpcSecurityGroups** *(list)* –
  Provides a list of VPC security groups that the DB cluster
  belongs to.

  · *(dict)* –
    This data type is used as a response element for queries on
    VPC security group membership.
· VpcSecurityGroupId (string) –
The name of the VPC security group.
· Status (string) –
The status of the VPC security group.

describe_db_engine_versions(**kwargs)
Returns a list of the available DB engines.

Request Syntax

response = client.describe_db_engine_versions(
    Engine='string',
    EngineVersion='string',
    DBParameterGroupFamily='string',
    Filters=[
        {'Name': 'string',
         'Values': [  
            'string',
         ]
        },
    ],
    MaxRecords=123,
    Marker='string',
    DefaultOnly=True|False,
    ListSupportedCharacterSets=True|False
)

Parameters

- **Engine (string)** – The database engine to return.
- **EngineVersion (string)** – The database engine version to return.
  
  Example: 5.1.49
- **DBParameterGroupFamily (string)** – The name of a specific DB parameter group family to return details for.

  Constraints:
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens
- **Filters (list)** – Not currently supported.
  
  - (dict) –
    * **Name (string)** – [REQUIRED]
      
      This parameter is not currently supported.
    * **Values (list)** – [REQUIRED]
      
      This parameter is not currently supported.
- **MaxRecords (integer)** – The maximum number of records to include in the response. If more than the MaxRecords value is available, a pagination token called a marker is included in the response so that the following results can be retrieved.

  Default: 100

  Constraints: Minimum 20, maximum 100.
• **Marker** *(string)* – An optional pagination token provided by a previous request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by **MaxRecords**.

• **DefaultOnly** *(boolean)* – Indicates that only the default version of the specified engine or engine and major version combination is returned.

• **ListSupportedCharacterSets** *(boolean)* – If this parameter is specified, and if the requested engine supports the **CharacterSetName** parameter for **CreateDBInstance**, the response includes a list of supported character sets for each engine version.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Marker': 'string',
    'DBEngineVersions': [
        {
            'Engine': 'string',
            'EngineVersion': 'string',
            'DBParameterGroupFamily': 'string',
            'DBEngineDescription': 'string',
            'DBEngineVersionDescription': 'string',
            'DefaultCharacterSet': {
                'CharacterSetName': 'string',
                'CharacterSetDescription': 'string'
            },
            'SupportedCharacterSets': [
                {
                    'CharacterSetName': 'string',
                    'CharacterSetDescription': 'string'
                },
            ],
        },
    ],
}
```

**Response Structure**

• *(dict)* – Contains the result of a successful invocation of the **DescribeDBEngineVersions** action.

  • **Marker** *(string)* – An optional pagination token provided by a previous request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by **MaxRecords**.

  • **DBEngineVersions** *(list)* – A list of **DBEngineVersion** elements.

    • *(dict)* – This data type is used as a response element in the action **DescribeDBEngineVersions**.

      • **Engine** *(string)* – The name of the database engine.

      • **EngineVersion** *(string)* –
The version number of the database engine.

- **DBParameterGroupFamily** *(string)* –
  The name of the DB parameter group family for the database engine.

- **DBEngineDescription** *(string)* –
  The description of the database engine.

- **DBEngineVersionDescription** *(string)* –
  The description of the database engine version.

- **DefaultCharacterSet** *(dict)* –
  The default character set for new instances of this engine version, if the `CharacterSetName` parameter of the `CreateDBInstance` API is not specified.

- **CharacterSetSetName** *(string)* –
  The name of the character set.

- **CharacterSetDescription** *(string)* –
  The description of the character set.

- **SupportedCharacterSets** *(list)* –
  A list of the character sets supported by this engine for the `CharacterSetName` parameter of the `CreateDBInstance` API.

- **(dict)** –
  This data type is used as a response element in the action `DescribeDBEngineVersions`.

- **CharacterSetName** *(string)* –
  The name of the character set.

- **CharacterSetDescription** *(string)* –
  The description of the character set.

describe_db_instances(**kwargs)**

Returns information about provisioned RDS instances. This API supports pagination.

**Request Syntax**

```python
response = client.describe_db_instances(
    DBInstanceIdentifier='string',
    Filters=[
        {'Name': 'string',
         'Values': ['string'],
        },
    ],
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**

- **DBInstanceIdentifier** *(string)* – The user-supplied instance identifier. If this parameter is specified, information from only the specific DB instance is returned. This parameter isn’t case-sensitive.
Constraints:
- Must contain from 1 to 63 alphanumeric characters or hyphens
- First character must be a letter
- Cannot end with a hyphen or contain two consecutive hyphens

- **Filters** (list) – This parameter is not currently supported.
  - *(dict)* –
    - **Name** *(string)* – [REQUIRED]
      This parameter is not currently supported.
    - **Values** *(list)* – [REQUIRED]
      This parameter is not currently supported.

- **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified `MaxRecords` value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.
  
  Default: 100
  
  Constraints: Minimum 20, maximum 100.

- **Marker** *(string)* – An optional pagination token provided by a previous `DescribeDBInstances` request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

**Return type** dict

**Returns** dict

**Response Syntax**

```json
{
  'Marker': 'string',
  'DBInstances': [
    {
      'DBInstanceIdentifier': 'string',
      'DBInstanceClass': 'string',
      'Engine': 'string',
      'DBInstanceStatus': 'string',
      'MasterUsername': 'string',
      'DBName': 'string',
      'Endpoint': {
        'Address': 'string',
        'Port': 123
      },

'PubliclyAccessible': True|False,
'StatusInfos': [}
Response Structure

- (dict) –
  Contains the result of a successful invocation of the DescribeDBInstances action.

  - Marker (string) –
    An optional pagination token provided by a previous request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

  - DBInstances (list) –
    A list of DBInstance instances.

    * (dict) –
      Contains the result of a successful invocation of the following actions:
      - CreateDBInstance
      - DeleteDBInstance
      - ModifyDBInstance

    This data type is used as a response element in the DescribeDBInstances action.

    - DBInstanceIdentifier (string) –
      Contains a user-supplied database identifier. This identifier is the unique key that identifies a DB instance.

    - DBInstanceClass (string) –
      Contains the name of the compute and memory capacity class of the DB instance.

    - Engine (string) –
      Provides the name of the database engine to be used for this
DB instance.
- **DBInstanceStatus** *(string)* –
  Specifies the current state of this database.
- **MasterUsername** *(string)* –
  Contains the master username for the DB instance.
- **DBName** *(string)* –
  The meaning of this parameter differs according to the
database engine you use. For example, this value returns ei-
ther MySQL or PostgreSQL information when returning val-
ues from CreateDBInstanceReadReplica since Read Replicas
are only supported for MySQL and PostgreSQL.

  **MySQL, SQL Server, PostgreSQL**
  Contains the name of the initial database of this instance that
  was provided at create time, if one was specified when the DB
  instance was created. This same name is returned for the life
  of the DB instance.

  Type: String
- **Oracle**
  Contains the Oracle System ID (SID) of the created DB in-
  stance. Not shown when the returned parameters do not apply
to an Oracle DB instance.
- **Endpoint** *(dict)* –
  Specifies the connection endpoint.
- **Address** *(string)* –
  Specifies the DNS address of the DB instance.
- **Port** *(integer)* –
  Specifies the port that the database engine is listening on.
- **AllocatedStorage** *(integer)* –
  Specifies the allocated storage size specified in gigabytes.
- **InstanceCreateTime** *(datetime)* –
  Provides the date and time the DB instance was created.
- **PreferredBackupWindow** *(string)* –
  Specifies the daily time range during which automated back-
  ups are created if automated backups are enabled, as deter-
  mined by the **BackupRetentionPeriod**.
- **BackupRetentionPeriod** *(integer)* –
  Specifies the number of days for which automatic DB snap-
  shots are retained.
- **DBSecurityGroups** *(list)* –
  Provides List of DB security group elements con-
taining only DBSecurityGroup.Name and
DBSecurityGroup.Status subelements.

  *(dict)* –
  This data type is used as a response element in the following
actions:
- ModifyDBInstance
- RebootDBInstance
- RestoreDBInstanceFromDBSnapshot
- RestoreDBInstanceToPointInTime
- **DBSecurityGroupName** *(string)* –
  The name of the DB security group.
- **Status** *(string)* –
  The status of the DB security group.
- **VpcSecurityGroups** *(list)* –
  Provides List of VPC security group elements that the DB instance belongs to.
  *(dict)* –
  This data type is used as a response element for queries on VPC security group membership.
- **VpcSecurityGroupId** *(string)* –
  The name of the VPC security group.
- **Status** *(string)* –
  The status of the VPC security group.
- **DBParameterGroups** *(list)* –
  Provides the list of DB parameter groups applied to this DB instance.
  *(dict)* –
  The status of the DB parameter group.
  This data type is used as a response element in the following actions:
- CreateDBInstance
- CreateDBInstanceReadReplica
- DeleteDBInstance
- ModifyDBInstance
- RebootDBInstance
- RestoreDBInstanceFromDBSnapshot
- **DBParameterGroupName** *(string)* –
  The name of the DP parameter group.
- **ParameterApplyStatus** *(string)* –
  The status of parameter updates.
- **AvailabilityZone** *(string)* –
  Specifies the name of the Availability Zone the DB instance is located in.
- **DBSubnetGroup** *(dict)* –
  Specifies information on the subnet group associated with the DB instance, including the name, description, and subnets in the subnet group.
- **DBSubnetGroupName** *(string)* –
  Specifies the name of the DB subnet group.
- **DBSubnetGroupDescription** *(string)* –
  Provides the description of the DB subnet group.
- **VpcId** *(string)* –
  Provides the VpcId of the DB subnet group.
· **SubnetGroupStatus** *(string)* –
  Provides the status of the DB subnet group.
· **Subnets** *(list)* –
  Contains a list of Subnet elements.
· **(dict)** –
  This data type is used as a response element in the DescribeDBSubnetGroups action.
· **SubnetIdentifier** *(string)* –
  Specifies the identifier of the subnet.
· **SubnetAvailabilityZone** *(dict)* –
  Contains Availability Zone information.
  This data type is used as an element in the following data type:
  · **OrderableDBInstanceOption**
  · **Name** *(string)* –
    The name of the availability zone.
· **SubnetStatus** *(string)* –
  Specifies the status of the subnet.
· **PreferredMaintenanceWindow** *(string)* –
  Specifies the weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).
· **PendingModifiedValues** *(dict)* –
  Specifies that changes to the DB instance are pending. This element is only included when changes are pending. Specific changes are identified by subelements.
· **DBInstanceClass** *(string)* –
  Contains the new **DBInstanceClass** for the DB instance that will be applied or is in progress.
· **AllocatedStorage** *(integer)* –
  Contains the new **AllocatedStorage** size for the DB instance that will be applied or is in progress.
· **MasterUserPassword** *(string)* –
  Contains the pending or in-progress change of the master credentials for the DB instance.
· **Port** *(integer)* –
  Specifies the pending port for the DB instance.
· **BackupRetentionPeriod** *(integer)* –
  Specifies the pending number of days for which automated backups are retained.
· **MultiAZ** *(boolean)* –
  Indicates that the Single-AZ DB instance is to change to a Multi-AZ deployment.
· **EngineVersion** *(string)* –
  Indicates the database engine version.
· **Iops** *(integer)* –
Specifies the new Provisioned IOPS value for the DB instance that will be applied or is being applied.

- **DBInstanceIdentifier (string)** –
  
  Contains the new `DBInstanceIdentifier` for the DB instance that will be applied or is in progress.

- **StorageType (string)** –
  
  Specifies the storage type to be associated with the DB instance.

- **CACertificateIdentifier (string)** –
  
  Specifies the identifier of the CA certificate for the DB instance.

- **LatestRestorableTime (datetime)** –
  
  Specifies the latest time to which a database can be restored with point-in-time restore.

- **MultiAZ (boolean)** –
  
  Specifies if the DB instance is a Multi-AZ deployment.

- **EngineVersion (string)** –
  
  Indicates the database engine version.

- **AutoMinorVersionUpgrade (boolean)** –
  
  Indicates that minor version patches are applied automatically.

- **ReadReplicaSourceDBInstanceIdentifier (string)** –
  
  Contains the identifier of the source DB instance if this DB instance is a Read Replica.

- **ReadReplicaDBInstanceIdentifiers (list)** –
  
  Contains one or more identifiers of the Read Replicas associated with this DB instance.

- **LicenseModel (string)** –
  
  License model information for this DB instance.

- **Iops (integer)** –
  
  Specifies the Provisioned IOPS (I/O operations per second) value.

- **OptionGroupMemberships (list)** –
  
  Provides the list of option group memberships for this DB instance.

- **OptionGroupName (string)** –
  
  The name of the option group that the instance belongs to.

- **Status (string)** –
  
  The status of the DB instance’s option group membership (e.g. in-sync, pending, pending-maintenance, applying).

- **CharacterSetName (string)** –
If present, specifies the name of the character set that this instance is associated with.

- **SecondaryAvailabilityZone** *(string)* –

  If present, specifies the name of the secondary Availability Zone for a DB instance with multi-AZ support.

- **PubliclyAccessible** *(boolean)* –

  Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.

  Default: The default behavior varies depending on whether a VPC has been requested or not. The following list shows the default behavior in each case.

  - **Default VPC**: true
  - **VPC**: false

    If no DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be publicly accessible. If a specific DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be private.

- **StatusInfos** *(list)* –

  The status of a Read Replica. If the instance is not a Read Replica, this will be blank.

  - *(dict)* –

    Provides a list of status information for a DB instance.

    - **StatusType** *(string)* –

      This value is currently “read replication.”

    - **Normal** *(boolean)* –

      Boolean value that is true if the instance is operating normally, or false if the instance is in an error state.

    - **Status** *(string)* –

      Status of the DB instance. For a StatusType of read replica, the values can be replicating, error, stopped, or terminated.

    - **Message** *(string)* –

      Details of the error if there is an error for the instance. If the instance is not in an error state, this value is blank.

    - **StorageType** *(string)* –

      Specifies the storage type associated with DB instance.

    - **TdeCredentialArn** *(string)* –

      The ARN from the Key Store with which the instance is associated for TDE encryption.

    - **DbInstancePort** *(integer)* –

      Specifies the port that the DB instance listens on. If the DB instance is part of a DB cluster, this can be a different port than the DB cluster port.
· **DBClusterIdentifier** *(string)* –
  If the DB instance is a member of a DB cluster, contains the name of the DB cluster that the DB instance is a member of.

· **StorageEncrypted** *(boolean)* –
  Specifies whether the DB instance is encrypted.

· **KmsKeyId** *(string)* –
  If **StorageEncrypted** is true, the KMS key identifier for the encrypted DB instance.

· **DbiResourceId** *(string)* –
  If **StorageEncrypted** is true, the region-unique, immutable identifier for the encrypted DB instance. This identifier is found in AWS CloudTrail log entries whenever the KMS key for the DB instance is accessed.

· **CACertificateIdentifier** *(string)* –
  The identifier of the CA certificate for this DB instance.

· **DomainMemberships** *(list)* –
  The Active Directory Domain membership records associated with the DB instance.

· *(dict)* –
  An Active Directory Domain membership record associated with the DB instance.

· **Domain** *(string)* –
  The identifier of the Active Directory Domain.

· **Status** *(string)* –
  The status of the DB instance’s Active Directory Domain membership (e.g. joined, pending-join, failed etc).

· **Connectivity** *(string)* –
  The observed connectivity of the Active Directory Domain.

· **CopyTagsToSnapshot** *(boolean)* –
  This property is not currently implemented.

**describe_db_log_files** (**kwargs**)

Returns a list of DB log files for the DB instance.

**Request Syntax**

```python
response = client.describe_db_log_files(
    DBInstanceIdentifier='string',
    FilenameContains='string',
    FileLastWritten=123,
    FileSize=123,
    Filters=[
        {
            'Name': 'string',
            'Values': [ 'string', ]
        },
    ],
    MaxRecords=123,
)
```
Boto3 Documentation, Release 1.1.4

Marker='string'

Parameters

• **DBInstanceIdentifier** *(string)* – **[REQUIRED]**
  The customer-assigned name of the DB instance that contains the log files you want to list.
  Constraints:
  – Must contain from 1 to 63 alphanumeric characters or hyphens
  – First character must be a letter
  – Cannot end with a hyphen or contain two consecutive hyphens

• **FilenameContains** *(string)* – Filters the available log files for log file names that contain the specified string.

• **FileLastWritten** *(integer)* – Filters the available log files for files written since the specified date, in POSIX timestamp format with milliseconds.

• **FileSize** *(integer)* – Filters the available log files for files larger than the specified size.

• **Filters** *(list)* – This parameter is not currently supported.
  – *(dict)* –
    * **Name** *(string)* – **[REQUIRED]**
      This parameter is not currently supported.
    * **Values** *(list)* – **[REQUIRED]**
      This parameter is not currently supported.
    · *(string)* –

• **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.

• **Marker** *(string)* – The pagination token provided in the previous request. If this parameter is specified the response includes only records beyond the marker, up to MaxRecords.

Return type  dict

Returns

Response Syntax

```python
{
    'DescribeDBLogFiles': [
        {
            'LogFileName': 'string',
            'LastWritten': 123,
            'Size': 123
        },
    ],
    'Marker': 'string'
}
```

Response Structure

• *(dict)* –
  The response from a call to DescribeDBLogFiles .
  – **DescribeDBLogFiles** *(list)* –
    The DB log files returned.
* (dict) –
  This data type is used as a response element to DescribeDBLogFiles.
  
  · **LogFileName (string)**
    The name of the log file for the specified DB instance.
  · **LastWritten (integer)**
    A POSIX timestamp when the last log entry was written.
  · **Size (integer)**
    The size, in bytes, of the log file for the specified DB instance.
  
  – **Marker (string)**
    A pagination token that can be used in a subsequent DescribeDBLogFiles request.

**describe_db_parameter_groups(**kwargs)**

Returns a list of DBParameterGroup descriptions. If a DBParameterGroupName is specified, the list will contain only the description of the specified DB parameter group.

**Request Syntax**

```python
response = client.describe_db_parameter_groups(
    DBParameterGroupName='string',
    Filters=[
        {
            'Name': 'string',
            'Values': [ 'string',
            ]
        },
    ],
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**

- **DBParameterGroupName (string)** – The name of a specific DB parameter group to return details for.

  Constraints:
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **Filters (list)** – This parameter is not currently supported.
  
  - (dict) –
    * **Name (string)** – [REQUIRED]
      This parameter is not currently supported.
    * **Values (list)** – [REQUIRED]
      This parameter is not currently supported.

- **MaxRecords (integer)** – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.

  Default: 100
Constraints: Minimum 20, maximum 100.

- **Marker** (string) – An optional pagination token provided by a previous DescribeDBParameterGroups request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

**Return type**  dict

**Response Syntax**

```python
{
    'Marker': 'string',
    'DBParameterGroups': [
        {
            'DBParameterGroupName': 'string',
            'DBParameterGroupFamily': 'string',
            'Description': 'string'
        }
    ]
}
```

**Response Structure**

- *(dict)* –

  Contains the result of a successful invocation of the DescribeDBParameterGroups action.

  - **Marker** (string) –

    An optional pagination token provided by a previous request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

  - **DBParameterGroups** (list) –

    A list of DBParameterGroup instances.

      - *(dict)* –

        Contains the result of a successful invocation of the CreateDBParameterGroup action.

        This data type is used as a request parameter in the DeleteDBParameterGroup action, and as a response element in the DescribeDBParameterGroups action.

          - **DBParameterGroupName** (string) –

            Provides the name of the DB parameter group.

          - **DBParameterGroupFamily** (string) –

            Provides the name of the DB parameter group family that this DB parameter group is compatible with.

          - **Description** (string) –

            Provides the customer-specified description for this DB parameter group.

**describe_db_parameters** (**kwargs)

Returns the detailed parameter list for a particular DB parameter group.

**Request Syntax**
```
response = client.describe_db_parameters(
    DBParameterGroupName='string',
    Source='string',
    Filters=[
        {
            'Name': 'string',
            'Values': [ 'string',
        ],
    ],
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**

- **DBParameterGroupName** *(string)* – [REQUIRED]
  The name of a specific DB parameter group to return details for.
  Constraints:
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **Source** *(string)* – The parameter types to return.
  Default: All parameter types returned
  Valid Values: `user` | `system` | `engine-default`

- **Filters** *(list)* – This parameter is not currently supported.
  - *(dict)* –
    - **Name** *(string)* – [REQUIRED]
      This parameter is not currently supported.
    - **Values** *(list)* – [REQUIRED]
      This parameter is not currently supported.

- **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified `MaxRecords` value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.
  Default: 100
  Constraints: Minimum 20, maximum 100.

- **Marker** *(string)* – An optional pagination token provided by a previous `DescribeDBParameters` request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

**Return type** `dict`

**Response Syntax**

```json
{
    'Parameters': [
        {
            'ParameterName': 'string',
        ],
    }
}
```
'ParameterValue': 'string',
'Description': 'string',
'Source': 'string',
'ApplyType': 'string',
'DataType': 'string',
'AllowedValues': 'string',
'IsModifiable': True|False,
'MinimumEngineVersion': 'string',
'ApplyMethod': 'immediate'|'pending-reboot'
},

'Parameters': Parameters

A list of Parameter values.

* (dict) –

This data type is used as a request parameter in the ModifyDBParameterGroup and ResetDBParameterGroup actions.

This data type is used as a response element in the DescribeEngineDefaultParameters and DescribeDBParameters actions.

- **ParameterName** (string) –
  Specifies the name of the parameter.
- **ParameterValue** (string) –
  Specifies the value of the parameter.
- **Description** (string) –
  Provides a description of the parameter.
- **Source** (string) –
  Indicates the source of the parameter value.
- **ApplyType** (string) –
  Specifies the engine specific parameters type.
- **DataType** (string) –
  Specifies the valid data type for the parameter.
- **AllowedValues** (string) –
  Specifies the valid range of values for the parameter.
- **IsModifiable** (boolean) –
  Indicates whether (true) or not (false) the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.
- **MinimumEngineVersion** (string) –
  The earliest engine version to which the parameter can apply.
- **ApplyMethod** (string) –
  Indicates when to apply parameter updates.

Response Structure

- (dict) –

  Contains the result of a successful invocation of the DescribeDBParameters action.

- **Parameters** (list) –

  A list of Parameter values.

* (dict) –

  This data type is used as a request parameter in the ModifyDBParameterGroup and ResetDBParameterGroup actions.

  This data type is used as a response element in the DescribeEngineDefaultParameters and DescribeDBParameters actions.

  - **ParameterName** (string) –
    Specifies the name of the parameter.
  - **ParameterValue** (string) –
    Specifies the value of the parameter.
  - **Description** (string) –
    Provides a description of the parameter.
  - **Source** (string) –
    Indicates the source of the parameter value.
  - **ApplyType** (string) –
    Specifies the engine specific parameters type.
  - **DataType** (string) –
    Specifies the valid data type for the parameter.
  - **AllowedValues** (string) –
    Specifies the valid range of values for the parameter.
  - **IsModifiable** (boolean) –
    Indicates whether (true) or not (false) the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.
  - **MinimumEngineVersion** (string) –
    The earliest engine version to which the parameter can apply.
  - **ApplyMethod** (string) –
    Indicates when to apply parameter updates.
– **Marker** *(string)* –

An optional pagination token provided by a previous request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

`describe_db_security_groups(**kwargs)`

Returns a list of `DBSecurityGroup` descriptions. If a `DBSecurityGroupName` is specified, the list will contain only the descriptions of the specified DB security group.

**Request Syntax**

```python
response = client.describe_db_security_groups(
    DBSecurityGroupName='string',
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ]
        },
    ],
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**

- **DBSecurityGroupName** *(string)* – The name of the DB security group to return details for.
- **Filters** *(list)* – This parameter is not currently supported.
  
  - *(dict)* –
    - **Name** *(string)* – *[REQUIRED]*
      
      This parameter is not currently supported.
    - **Values** *(list)* – *[REQUIRED]*
      
      This parameter is not currently supported.
- **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified `MaxRecords` value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.

  Default: 100

  Constraints: Minimum 20, maximum 100.
- **Marker** *(string)* – An optional pagination token provided by a previous `DescribeDBSecurityGroups` request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'Marker': 'string',
    'DBSecurityGroups': [
        
    ]
}
```
'OwnerId': 'string',
'DBSecurityGroupName': 'string',
'DBSecurityGroupDescription': 'string',
'VpcId': 'string',
'EC2SecurityGroups': [
  {
    'Status': 'string',
    'EC2SecurityGroupName': 'string',
    'EC2SecurityGroupId': 'string',
    'EC2SecurityGroupOwnerId': 'string'
  },
},
'IPRanges': [
  {
    'Status': 'string',
    'CIDRIP': 'string'
  }
],
]
}

Response Structure

• (dict) –
  Contains the result of a successful invocation of the DescribeDBSecurityGroups action.
  
  – Marker (string) –
  An optional pagination token provided by a previous request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

  – DBSecurityGroups (list) –
  A list of DBSecurityGroup instances.
      *

  * (dict) –
  Contains the result of a successful invocation of the following actions:
      · DescribeDBSecurityGroups
      · AuthorizeDBSecurityGroupIngress
      · CreateDBSecurityGroup
      · RevokeDBSecurityGroupIngress

  This data type is used as a response element in the DescribeDBSecurityGroups action.

  · OwnerId (string) –
    Provides the AWS ID of the owner of a specific DB security group.

  · DBSecurityGroupName (string) –
    Specifies the name of the DB security group.

  · DBSecurityGroupDescription (string) –
    Provides the description of the DB security group.

  · VpcId (string) –
    Provides the VpcId of the DB security group.

  · EC2SecurityGroups (list) –
Contains a list of EC2SecurityGroup elements.

- (dict) –

  This data type is used as a response element in the following actions:
  - AuthorizeDBSecurityGroupIngress
  - DescribeDBSecurityGroups
  - RevokeDBSecurityGroupIngress

- **Status** (string) –

  Provides the status of the EC2 security group. Status can be “authorizing”, “authorized”, “revoking”, and “revoked”.

- **EC2SecurityGroupName** (string) –

  Specifies the name of the EC2 security group.

- **EC2SecurityGroupId** (string) –

  Specifies the id of the EC2 security group.

- **EC2SecurityGroupOwnerId** (string) –

  Specifies the AWS ID of the owner of the EC2 security group specified in the **EC2SecurityGroupName** field.

- **IPRanges** (list) –

  Contains a list of IPRange elements.

  - (dict) –

    This data type is used as a response element in the DescribeDBSecurityGroups action.

    - **Status** (string) –

      Specifies the status of the IP range. Status can be “authorizing”, “authorized”, “revoking”, and “revoked”.

    - **CIDRIP** (string) –

      Specifies the IP range.

**describe_db_snapshots**(**kwargs**)  

Returns information about DB snapshots. This API supports pagination.

**Request Syntax**

```python
response = client.describe_db_snapshots(
    DBInstanceIdentifier='string',
    DBSnapshotIdentifier='string',
    SnapshotType='string',
    Filters=[
        {
            'Name': 'string',
            'Values': ['string'],
        },
    ],
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**
• **DBInstanceIdentifier** *(string)* – A DB instance identifier to retrieve the list of DB snapshots for. This parameter cannot be used in conjunction with DBSnapshotIdentifier. This parameter is not case-sensitive.

Constraints:
– Must contain from 1 to 63 alphanumeric characters or hyphens
– First character must be a letter
– Cannot end with a hyphen or contain two consecutive hyphens

• **DBSnapshotIdentifier** *(string)* – A specific DB snapshot identifier to describe. This parameter cannot be used in conjunction with DBInstanceIdentifier. This value is stored as a lowercase string.

Constraints:
– Must be 1 to 255 alphanumeric characters.
– First character must be a letter.
– Cannot end with a hyphen or contain two consecutive hyphens.
– If this is the identifier of an automated snapshot, the **SnapshotType** parameter must also be specified.

• **SnapshotType** *(string)* – The type of snapshots that will be returned. Values can be “automated” or “manual.” If not specified, the returned results will include all snapshots types.

• **Filters** *(list)* – This parameter is not currently supported.
  – *(dict)* –
    * **Name** *(string)* – [REQUIRED]
      – This parameter is not currently supported.
    * **Values** *(list)* – [REQUIRED]
      – This parameter is not currently supported.

• **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.

  Default: 100

  Constraints: Minimum 20, maximum 100.

• **Marker** *(string)* – An optional pagination token provided by a previous DescribeDBSnapshots request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

Return type: dict

Returns

Response Syntax

```python
{
    'Marker': 'string',

Response Structure

• (dict) –
  Contains the result of a successful invocation of the DescribeDBSnapshots action.

  –_marker_ (string) –
    An optional pagination token provided by a previous request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

  – DBSnapshots (list) –
    A list of DBSnapshot instances.
  * (dict) –
    Contains the result of a successful invocation of the following actions:
    • CreateDBSnapshot
    • DeleteDBSnapshot
    This data type is used as a response element in the DescribeDBSnapshots action.
  • DBSnapshotIdentifier (string) –
    Specifies the identifier for the DB snapshot.
  • DBInstanceIdentifier (string) –
    Specifies the DB instance identifier of the DB instance this DB snapshot was created from.
  • SnapshotCreateTime (datetime) –
    Provides the time when the snapshot was taken, in Universal Coordinated Time (UTC).
  • Engine (string) –
    Specifies the name of the database engine.
  • AllocatedStorage (integer) –
    Specifies the allocated storage size in gigabytes (GB).
  • Status (string) –
Specifies the status of this DB snapshot.

- **Port (integer)** –
  Specifies the port that the database engine was listening on at the time of the snapshot.

- **AvailabilityZone (string)** –
  Specifies the name of the Availability Zone the DB instance was located in at the time of the DB snapshot.

- **VpcId (string)** –
  Provides the VPC ID associated with the DB snapshot.

- **InstanceCreateTime (datetime)** –
  Specifies the time when the snapshot was taken, in Universal Coordinated Time (UTC).

- **MasterUsername (string)** –
  Provides the master username for the DB snapshot.

- **EngineVersion (string)** –
  Specifies the version of the database engine.

- **LicenseModel (string)** –
  License model information for the restored DB instance.

- **SnapshotType (string)** –
  Provides the type of the DB snapshot.

- **Iops (integer)** –
  Specifies the Provisioned IOPS (I/O operations per second) value of the DB instance at the time of the snapshot.

- **OptionGroupName (string)** –
  Provides the option group name for the DB snapshot.

- **PercentProgress (integer)** –
  The percentage of the estimated data that has been transferred.

- **SourceRegion (string)** –
  The region that the DB snapshot was created in or copied from.

- **SourceDBSnapshotIdentifier (string)** –
  The DB snapshot Arn that the DB snapshot was copied from. It only has value in case of cross customer or cross region copy.

- **StorageType (string)** –
  Specifies the storage type associated with DB Snapshot.

- **TdeCredentialArn (string)** –
  The ARN from the Key Store with which to associate the instance for TDE encryption.

- **Encrypted (boolean)** –
  Specifies whether the DB snapshot is encrypted.

- **KmsKeyId (string)** –
  If Encrypted is true, the KMS key identifier for the encrypted DB snapshot.
**describe_db_subnet_groups** (**kwargs)**

Returns a list of DBSubnetGroup descriptions. If a DBSubnetGroupName is specified, the list will contain only the descriptions of the specified DBSubnetGroup.

For an overview of CIDR ranges, go to the *Wikipedia Tutorial*.

Request Syntax

```python
response = client.describe_db_subnet_groups(
    DBSubnetGroupName='string',
    Filters=[
        {
            'Name': 'string',
            'Values': ['string',
            ],
        },
    ],
    MaxRecords=123,
    Marker='string'
)
```

Parameters

- **DBSubnetGroupName** (*string*) – The name of the DB subnet group to return details for.
- **Filters** (*list*) – This parameter is not currently supported.
  - (dict) –
    - **Name** (*string*) – [REQUIRED]
      - This parameter is not currently supported.
    - **Values** (*list*) – [REQUIRED]
      - This parameter is not currently supported.
- **MaxRecords** (*integer*) – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.

  Default: 100

  Constraints: Minimum 20, maximum 100.
- **Marker** (*string*) – An optional pagination token provided by a previous DescribeDBSubnetGroups request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

Return type  **dict**

Returns

Response Syntax

```python
{
    'Marker': 'string',
    'DBSubnetGroups': [
        {
            'DBSubnetGroupName': 'string',
            'DBSubnetGroupDescription': 'string',
            'VpcId': 'string',
            'SubnetGroupStatus': 'string',
        },
    ]
}
```
'Subnets': [
    {
        'SubnetIdentifier': 'string',
        'SubnetAvailabilityZone': {
            'Name': 'string'
        },
        'SubnetStatus': 'string'
    },
    
},
]

Response Structure

- (dict) —
  Contains the result of a successful invocation of the DescribeDBSubnetGroups action.

  - Marker (string) —
    An optional pagination token provided by a previous request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

  - DBSubnetGroups (list) —
    A list of DBSubnetGroup instances.

    * (dict) —
      Contains the result of a successful invocation of the following actions:
      - CreateDBSubnetGroup
      - ModifyDBSubnetGroup
      - DescribeDBSubnetGroups
      - DeleteDBSubnetGroup
      This data type is used as a response element in the DescribeDBSubnetGroups action.

      - DBSubnetGroupName (string) —
        Specifies the name of the DB subnet group.

      - DBSubnetGroupDescription (string) —
        Provides the description of the DB subnet group.

      - VpcId (string) —
        Provides the VpcId of the DB subnet group.

      - SubnetGroupStatus (string) —
        Provides the status of the DB subnet group.

      - Subnets (list) —
        Contains a list of Subnet elements.

        * (dict) —
          This data type is used as a response element in the DescribeDBSubnetGroups action.

          - SubnetIdentifier (string) —
            Specifies the identifier of the subnet.

          - SubnetAvailabilityZone (dict) —
            Contains Availability Zone information.
This data type is used as an element in the following data type:
- OrderableDBInstanceOption
- Name (string) –
  The name of the availability zone.
- SubnetStatus (string) –
  Specifies the status of the subnet.

**describe_engine_default_cluster_parameters(**kwargs)

Returns the default engine and system parameter information for the cluster database engine.

For more information on Amazon Aurora, see Aurora on Amazon RDS in the Amazon RDS User Guide.

**Request Syntax**

```python
response = client.describe_engine_default_cluster_parameters(
    DBParameterGroupFamily='string',
    Filters=[
        {
            'Name': 'string',
            'Values': ['string'],
        },
    ],
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**

- **DBParameterGroupFamily (string)** – [REQUIRED]
  The name of the DB cluster parameter group family to return engine parameter information for.
- **Filters (list)** – This parameter is not currently supported.
  - (dict) –
    - **Name (string)** – [REQUIRED]
      This parameter is not currently supported.
    - **Values (list)** – [REQUIRED]
      This parameter is not currently supported.
- **MaxRecords (integer)** – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.
  Default: 100
  Constraints: Minimum 20, maximum 100.
- **Marker (string)** – An optional pagination token provided by a previous DescribeEngineDefaultClusterParameters request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

**Return type** dict

**Response Syntax**

3.1. Services 3411

{
    'EngineDefaults': {
        'DBParameterGroupFamily': 'string',
        'Marker': 'string',
        'Parameters': [
            {
                'ParameterName': 'string',
                'ParameterValue': 'string',
                'Description': 'string',
                'Source': 'string',
                'ApplyType': 'string',
                'DataType': 'string',
                'AllowedValues': 'string',
                'IsModifiable': True|False,
                'MinimumEngineVersion': 'string',
                'ApplyMethod': 'immediate'|'pending-reboot'
            },
        ]
    }
}

Response Structure
- (dict) –
  Contains the result of a successful invocation of the DescribeEngineDefaultParameters action.
  - EngineDefaults (dict) –
    Contains the result of a successful invocation of the DescribeEngineDefaultParameters action.
    * DBParameterGroupFamily (string) –
      Specifies the name of the DB parameter group family that the engine default parameters apply to.
    * Marker (string) –
      An optional pagination token provided by a previous EngineDefaults request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.
    * Parameters (list) –
      Contains a list of engine default parameters.
        * (dict) –
          This data type is used as a request parameter in the ModifyDBParameterGroup and ResetDBParameterGroup actions.
          This data type is used as a response element in the DescribeEngineDefaultParameters and DescribeDBParameters actions.
        * ParameterName (string) –
          Specifies the name of the parameter.
        * ParameterValue (string) –
          Specifies the value of the parameter.
        * Description (string) –
          Provides a description of the parameter.
· **Source** *(string)* —
  Indicates the source of the parameter value.

· **ApplyType** *(string)* —
  Specifies the engine specific parameters type.

· **DataType** *(string)* —
  Specifies the valid data type for the parameter.

· **AllowedValues** *(string)* —
  Specifies the valid range of values for the parameter.

· **IsModifiable** *(boolean)* —
  Indicates whether *(true)* or not *(false)* the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.

· **MinimumEngineVersion** *(string)* —
  The earliest engine version to which the parameter can apply.

· **ApplyMethod** *(string)* —
  Indicates when to apply parameter updates.

**describe_engine_default_parameters(** **kwargs** **)**

Returns the default engine and system parameter information for the specified database engine.

**Request Syntax**

```python
response = client.describe_engine_default_parameters(
    DBParameterGroupFamily='string',
    Filters=[
        {
            'Name': 'string',
            'Values': ['string',
                       'string'],
        },
    ],
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**

- **DBParameterGroupFamily** *(string)* — [REQUIRED]
  The name of the DB parameter group family.

- **Filters** *(list)* — Not currently supported.
  - *(dict)* —
    * **Name** *(string)* — [REQUIRED]
      This parameter is not currently supported.
    * **Values** *(list)* — [REQUIRED]
      This parameter is not currently supported.
  - *(string)* —

- **MaxRecords** *(integer)* — The maximum number of records to include in the response. If more records exist than the specified **MaxRecords** value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.

  Default: 100
Constraints: Minimum 20, maximum 100.

- **Marker** (*string*) – An optional pagination token provided by a previous `DescribeEngineDefaultParameters` request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

**Return type** dict

**Returns**

**Response Syntax**

```python
{}

'EngineDefaults': {
    'DBParameterGroupFamily': 'string',
    'Marker': 'string',
    'Parameters': [
        {
            'ParameterName': 'string',
            'ParameterValue': 'string',
            'Description': 'string',
            'Source': 'string',
            'ApplyType': 'string',
            'DataType': 'string',
            'AllowedValues': 'string',
            'IsModifiable': True|False,
            'MinimumEngineVersion': 'string',
            'ApplyMethod': 'immediate'|'pending-reboot'
        }],
    'ApplyMethod': 'immediate'|'pending-reboot'
}
```

**Response Structure**

- *(dict)* – Contains the result of a successful invocation of the `DescribeEngineDefaultParameters` action.
  - **EngineDefaults** *(dict)* – Contains the result of a successful invocation of the `DescribeEngineDefaultParameters` action.
    - **DBParameterGroupFamily** *(string)* – Specifies the name of the DB parameter group family that the engine default parameters apply to.
    - **Marker** *(string)* – An optional pagination token provided by a previous EngineDefaults request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.
    - **Parameters** *(list)* – Contains a list of engine default parameters.
      - *(dict)* –
        - This data type is used as a request parameter in the `ModifyDBParameterGroup` and `ResetDBParameterGroup` actions.
        - This data type is used as a response element in the `DescribeEngineDefaultParameters` and `DescribeDBParameters` actions.
actions.

- **ParameterName (string)** – Specifies the name of the parameter.
- **ParameterValue (string)** – Specifies the value of the parameter.
- **Description (string)** – Provides a description of the parameter.
- **Source (string)** – Indicates the source of the parameter value.
- **ApplyType (string)** – Specifies the engine specific parameters type.
- **DataType (string)** – Specifies the valid data type for the parameter.
- **AllowedValues (string)** – Specifies the valid range of values for the parameter.
- **IsModifiable (boolean)** – Indicates whether (true) or not (false) the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.
- **MinimumEngineVersion (string)** – The earliest engine version to which the parameter can apply.
- **ApplyMethod (string)** – Indicates when to apply parameter updates.

describe_event_categories (**kwargs)**

Displays a list of categories for all event source types, or, if specified, for a specified source type. You can see a list of the event categories and source types in the Events topic in the Amazon RDS User Guide.

**Request Syntax**

```python
response = client.describe_event_categories(
    SourceType='string',
    Filters=[
        {
            'Name': 'string',
            'Values': [ 'string',
            ]
        },
    ]
)
```

**Parameters**

- **SourceType (string)** – The type of source that will be generating the events.
  
  Valid values: db-instance | db-parameter-group | db-security-group | db-snapshot
- **Filters (list)** – This parameter is not currently supported.
  
  ```
  - (dict) –
    * Name (string) – [REQUIRED]
  ```
  
  This parameter is not currently supported.
* Values (list) – [REQUIRED]

This parameter is not currently supported.

Return type dict

Returns

Response Syntax

```python
{
    'EventCategoriesMapList': [
        {
            'SourceType': 'string',
            'EventCategories': [ 'string',
            ]
        },
    ]
}
```

Response Structure

* (dict) –

Data returned from the **DescribeEventCategories** action.

- **EventCategoriesMapList (list)** –

  A list of EventCategoriesMap data types.

  * (dict) –

    Contains the results of a successful invocation of the **DescribeEventCategories** action.

    - **SourceType (string)** –
      
      The source type that the returned categories belong to

    - **EventCategories (list)** –
      
      The event categories for the specified source type

    * (string) –

**describe_event_subscriptions (**kwargs**)**

Lists all the subscription descriptions for a customer account. The description for a subscription includes SubscriptionName, SNSTopicARN, CustomerID, SourceType, SourceID, CreationTime, and Status.

If you specify a SubscriptionName, lists the description for that subscription.

Request Syntax

```python
response = client.describe_event_subscriptions(
    SubscriptionName='string',
    Filters=[
        {
            'Name': 'string',
            'Values': [ 'string',
            ]
        },
    ],
    MaxRecords=123,
    Marker='string'
)
```
Parameters

• **SubscriptionName** *(string)* – The name of the RDS event notification subscription you want to describe.

• **Filters** *(list)* – This parameter is not currently supported.
  
  – *(dict)* –
    
    * **Name** *(string)* – [REQUIRED]
      This parameter is not currently supported.

    * **Values** *(list)* – [REQUIRED]
      This parameter is not currently supported.

• **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified **MaxRecords** value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.

  Default: 100

  Constraints: Minimum 20, maximum 100.

• **Marker** *(string)* – An optional pagination token provided by a previous **DescribeOrderableDBInstanceOptions** request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by **MaxRecords**.

Return type  *dict*

Returns

Response Syntax

```
{  
'Marker': 'string',  
'EventSubscriptionsList': [  

 {  
'CustomerAwsId': 'string',  
'CustSubscriptionId': 'string',  
'SnsTopicArn': 'string',  
'Status': 'string',  
'SubscriptionCreationTime': 'string',  
'SourceType': 'string',  
'SourceIdsList': [  

 'string',  

 ],  
'EventCategoriesList': [  

 'string',  

 ],  
'Enabled': True|False  

 },  

 ]  
}
```

Response Structure

• *(dict)* –

  Data returned by the **DescribeEventSubscriptions** action.

  – **Marker** *(string)* –

    An optional pagination token provided by a previous **DescribeOrderableDBInstanceOptions** request. If this parameter is specified, the response
includes only records beyond the marker, up to the value specified by MaxRecords.

- **EventSubscriptionsList** *(list)*

  A list of EventSubscriptions data types.

  * *(dict)*

  Contains the results of a successful invocation of the DescribeEventSubscriptions action.

  - **CustomerAwsId** *(string)*

    The AWS customer account associated with the RDS event notification subscription.

  - **CustSubscriptionId** *(string)*

    The RDS event notification subscription Id.

  - **SnsTopicArn** *(string)*

    The topic ARN of the RDS event notification subscription.

  - **Status** *(string)*

    The status of the RDS event notification subscription.

    Constraints:

    Can be one of the following: creating | modifying | deleting | active | no-permission | topic-not-exist

    The status “no-permission” indicates that RDS no longer has permission to post to the SNS topic. The status “topic-not-exist” indicates that the topic was deleted after the subscription was created.

  - **SubscriptionCreationTime** *(string)*

    The time the RDS event notification subscription was created.

  - **SourceType** *(string)*

    The source type for the RDS event notification subscription.

  - **SourceIdsList** *(list)*

    A list of source IDs for the RDS event notification subscription.

    * *(string)*

  - **EventCategoriesList** *(list)*

    A list of event categories for the RDS event notification subscription.

    * *(string)*

  - **Enabled** *(boolean)*

    A Boolean value indicating if the subscription is enabled. True indicates the subscription is enabled.

**describe_events**(**kwargs**)

Returns events related to DB instances, DB security groups, DB snapshots, and DB parameter groups for the past 14 days. Events specific to a particular DB instance, DB security group, database snapshot, or DB parameter group can be obtained by providing the name as a parameter. By default, the past hour of events are returned.

**Request Syntax**
```python
response = client.describe_events(
    SourceIdentifier='string',
    SourceType='db-instance'|'db-parameter-group'|'db-security-group'|'db-snapshot',
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    Duration=123,
    EventCategories=['string'],
    Filters=[
        {'Name': 'string',
        'Values': ['string'],
    },
],
    MaxRecords=123,
    Marker='string'
)
```

### Parameters

- **SourceIdentifier** *(string)* – The identifier of the event source for which events will be returned. If not specified, then all sources are included in the response.

  Constraints:
  - If SourceIdentifier is supplied, SourceType must also be provided.
  - If the source type is DBInstance, then a DBInstanceIdentifier must be supplied.
  - If the source type is DBSecurityGroup, a DBSecurityGroupName must be supplied.
  - If the source type is DBParameterGroup, a DBParameterGroupName must be supplied.
  - If the source type is DBSnapshot, a DBSnapshotIdentifier must be supplied.
  - Cannot end with a hyphen or contain two consecutive hyphens.

- **SourceType** *(string)* – The event source to retrieve events for. If no value is specified, all events are returned.

- **StartTime** *(datetime)* – The beginning of the time interval to retrieve events for, specified in ISO 8601 format. For more information about ISO 8601, go to the ISO8601 Wikipedia page.

  Example: `2009-07-08T18:00Z`

- **EndTime** *(datetime)* – The end of the time interval for which to retrieve events, specified in ISO 8601 format. For more information about ISO 8601, go to the ISO8601 Wikipedia page.

  Example: `2009-07-08T18:00Z`

- **Duration** *(integer)* – The number of minutes to retrieve events for. Default: 60

- **EventCategories** *(list)* – A list of event categories that trigger notifications for a event notification subscription.

  - *(string)*

- **Filters** *(list)* – This parameter is not currently supported.

  - *(dict)*

     - **Name** *(string)* – [REQUIRED]
This parameter is not currently supported.

* Values (list) – [REQUIRED]

This parameter is not currently supported.

- (string) –

- MaxRecords (integer) – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.

Default: 100

Constraints: Minimum 20, maximum 100.

- Marker (string) – An optional pagination token provided by a previous DescribeEvents request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

Return type  dict

Returns

Response Syntax

```
{
    'Marker': 'string',
    'Events': [
        {
            'SourceIdentifier': 'string',
            'SourceType': 'db-instance'|'db-parameter-group'|'db-security-group'|'db-snapshot',
            'Message': 'string',
            'EventCategories': [
                'string',
            ],
            'Date': datetime(2015, 1, 1)
        },
    ]
}
```

Response Structure

- (dict) –

Contains the result of a successful invocation of the DescribeEvents action.

  - Marker (string) –

An optional pagination token provided by a previous Events request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

  - Events (list) –

A list of Event instances.

- (dict) –

This data type is used as a response element in the DescribeEvents action.

    - SourceIdentifier (string) –

Provides the identifier for the source of the event.

    - SourceType (string) –

Specifies the source type for this event.

    - Message (string) –

Provides the text of this event.
EventCategories (list) –
Specifies the category for the event.

(string) –

Date (datetime) –
Specifies the date and time of the event.

describe_option_group_options(**kwargs)
Describes all available options.

Request Syntax

response = client.describe_option_group_options(
    EngineName='string',
    MajorEngineVersion='string',
    Filters=[
        
        'Name': 'string',
        'Values': [ 'string',
        ]
    ],
    MaxRecords=123,
    Marker='string'
)

Parameters

- **EngineName (string) – [REQUIRED]**
  A required parameter. Options available for the given engine name will be described.

- **MajorEngineVersion (string) –** If specified, filters the results to include only options for the specified major engine version.

- **Filters (list) –** This parameter is not currently supported.
  - (dict) –
    * **Name (string) – [REQUIRED]**
      This parameter is not currently supported.
    * **Values (list) – [REQUIRED]**
      This parameter is not currently supported.

- **MaxRecords (integer) –** The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.
  
  Default: 100
  
  Constraints: Minimum 20, maximum 100.

- **Marker (string) –** An optional pagination token provided by a previous request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

Return type  dict

Returns

Response Syntax
{
  'OptionGroupOptions': [
    {
      'Name': 'string',
      'Description': 'string',
      'EngineName': 'string',
      'MajorEngineVersion': 'string',
      'MinimumRequiredMinorEngineVersion': 'string',
      'PortRequired': True|False,
      'DefaultPort': 123,
      'OptionsDependedOn': [

          'ApplyType': 'string',
          'AllowedValues': 'string',
          'IsModifiable': True|False
        }
      ],
    },
  ],
  'Marker': 'string'
}

Response Structure

• (dict) –
  – OptionGroupOptions (list) –
    List of available option group options.
    • (dict) –
      Available option.
        • Name (string) –
          The name of the option.
        • Description (string) –
          The description of the option.
        • EngineName (string) –
          The name of the engine that this option can be applied to.
        • MajorEngineVersion (string) –
          Indicates the major engine version that the option is available for.
        • MinimumRequiredMinorEngineVersion (string) –
          The minimum required engine version for the option to be applied.
        • PortRequired (boolean) –
          Specifies whether the option requires a port.
        • DefaultPort (integer) –
If the option requires a port, specifies the default port for the option.

- **OptionsDependedOn** *(list)*
  List of all options that are prerequisites for this option.
  
  - *(string)*
  - **Persistent** *(boolean)*
    
    A persistent option cannot be removed from the option group once the option group is used, but this option can be removed from the db instance while modifying the related data and assigning another option group without this option.

- **Permanent** *(boolean)*
  
  A permanent option cannot be removed from the option group once the option group is used, and it cannot be removed from the db instance after assigning an option group with this permanent option.

- **OptionGroupOptionSettings** *(list)*
  
  Specifies the option settings that are available (and the default value) for each option in an option group.
  
  - *(dict)*
    
    Option group option settings are used to display settings available for each option with their default values and other information. These values are used with the DescribeOptionGroupOptions action.
  
  - **SettingName** *(string)*
    
    The name of the option group option.
  
  - **SettingDescription** *(string)*
    
    The description of the option group option.
  
  - **DefaultValue** *(string)*
    
    The default value for the option group option.
  
  - **ApplyType** *(string)*
    
    The DB engine specific parameter type for the option group option.
  
  - **AllowedValues** *(string)*
    
    Indicates the acceptable values for the option group option.
  
  - **IsModifiable** *(boolean)*
    
    Boolean value where true indicates that this option group option can be changed from the default value.

- **Marker** *(string)*
  
  An optional pagination token provided by a previous request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

**describe_option_groups** (**kwargs)**

Describes the available option groups.

**Request Syntax**

```python
response = client.describe_option_groups(
    OptionGroupName='string',
)```
Parameters

- **OptionGroupName** (*string*) – The name of the option group to describe. Cannot be supplied together with EngineName or MajorEngineVersion.
- **Filters** (*list*) – This parameter is not currently supported.
  - *(dict)* –
    - **Name** (*string*) – [REQUIRED]
      This parameter is not currently supported.
    - **Values** (*list*) – [REQUIRED]
      This parameter is not currently supported.
  - *(string)* –
- **Marker** (*string*) – An optional pagination token provided by a previous DescribeOptionGroups request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.
- **MaxRecords** (*integer*) – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.

  Default: 100

  Constraints: Minimum 20, maximum 100.
- **EngineName** (*string*) – Filters the list of option groups to only include groups associated with a specific database engine.
- **MajorEngineVersion** (*string*) – Filters the list of option groups to only include groups associated with a specific database engine version. If specified, then EngineName must also be specified.

Return type  dict

Returns

Response Syntax

```json
{
    'OptionGroupsList': [
        {
            'OptionGroupName': 'string',
            'OptionGroupDescription': 'string',
            'EngineName': 'string',
            'MajorEngineVersion': 'string',
            'Options': [
                {
                    'OptionName': 'string',
                    'OptionDescription': 'string',
                },
            ],
        },
    ],
    'Marker': 'string',
    'MaxRecords': 123,
    'EngineName': 'string',
    'MajorEngineVersion': 'string',
}
```
'Persistent': True|False,
'Permanent': True|False,
'Port': 123,

  {
    'Name': 'string',
    'Value': 'string',
    'DefaultValue': 'string',
    'Description': 'string',
    'ApplyType': 'string',
    'DataType': 'string',
    'AllowedValues': 'string',
    'IsModifiable': True|False,
    'IsCollection': True|False
  },
],
'DBSecurityGroupMemberships': [
  {
    'DBSecurityGroupName': 'string',
    'Status': 'string'
  },
],
'VpcSecurityGroupMemberships': [
  {
    'VpcSecurityGroupId': 'string',
    'Status': 'string'
  }
],
'AllowsVpcAndNonVpcInstanceMemberships': True|False,
'VpcId': 'string'
}

Response Structure
• (dict) –
  List of option groups.
  – OptionGroupsList (list) –
    List of option groups.
    • (dict) –
      • OptionGroupName (string) –
        Specifies the name of the option group.
      • OptionGroupDescription (string) –
        Provides a description of the option group.
      • EngineName (string) –
        Indicates the name of the engine that this option group can be applied to.
      • MajorEngineVersion (string) –
        Indicates the major engine version associated with this option group.
      • Options (list) –
Indicates what options are available in the option group.

- *(dict)* –
  Option details.
  - **OptionName** *(string)* –
    The name of the option.
  - **OptionDescription** *(string)* –
    The description of the option.
  - **Persistent** *(boolean)* –
    Indicate if this option is persistent.
  - **Permanent** *(boolean)* –
    Indicate if this option is permanent.
  - **Port** *(integer)* –
    If required, the port configured for this option to use.
  - **OptionSettings** *(list)* –
    The option settings for this option.
    - *(dict)* –
      Option settings are the actual settings being applied or configured for that option. It is used when you modify an option group or describe option groups. For example, the NATIVE_NETWORK_ENCRYPTION option has a setting called SQLNET.ENCRYPTION_SERVER that can have several different values.
      - **Name** *(string)* –
        The name of the option that has settings that you can set.
      - **Value** *(string)* –
        The current value of the option setting.
      - **DefaultValue** *(string)* –
        The default value of the option setting.
      - **Description** *(string)* –
        The description of the option setting.
      - **ApplyType** *(string)* –
        The DB engine specific parameter type.
      - **DataType** *(string)* –
        The data type of the option setting.
      - **AllowedValues** *(string)* –
        The allowed values of the option setting.
      - **IsModifiable** *(boolean)* –
        A Boolean value that, when true, indicates the option setting can be modified from the default.
      - **IsCollection** *(boolean)* –
        Indicates if the option setting is part of a collection.
    - **DBSecurityGroupMemberships** *(list)* –
      If the option requires access to a port, then this DB security group allows access to the port.
This data type is used as a response element in the following actions:
- ModifyDBInstance
- RebootDBInstance
- RestoreDBInstanceFromDBSnapshot
- RestoreDBInstanceToPointInTime

**DBSecurityGroupName (string)** –

The name of the DB security group.

**Status (string)** –

The status of the DB security group.

**VpcSecurityGroupMemberships (list)** –

If the option requires access to a port, then this VPC security group allows access to the port.

This data type is used as a response element for queries on VPC security group membership.

**VpcSecurityGroupId (string)** –

The name of the VPC security group.

**Status (string)** –

The status of the VPC security group.

**AllowsVpcAndNonVpcInstanceMemberships (boolean)** –

Indicates whether this option group can be applied to both VPC and non-VPC instances. The value `true` indicates the option group can be applied to both VPC and non-VPC instances.

**VpcId (string)** –

If `AllowsVpcAndNonVpcInstanceMemberships` is `false`, this field is blank. If `AllowsVpcAndNonVpcInstanceMemberships` is `true` and this field is blank, then this option group can be applied to both VPC and non-VPC instances. If this field contains a value, then this option group can only be applied to instances that are in the VPC indicated by this field.

**Marker (string)** –

An optional pagination token provided by a previous request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

**describe_orderable_db_instance_options (**kwargs)**

Returns a list of orderable DB instance options for the specified engine.

**Request Syntax**

```python
def response = client.describe_orderable_db_instance_options(
    Engine='string',
    EngineVersion='string',
    DBInstanceClass='string',
    LicenseModel='string',
    Vpc=True|False,
    Filters=[
```
Parameters

- **Engine** *(string)* – [REQUIRED]
  The name of the engine to retrieve DB instance options for.

- **EngineVersion** *(string)* – The engine version filter value. Specify this parameter to show only the available offerings matching the specified engine version.

- **DBInstanceClass** *(string)* – The DB instance class filter value. Specify this parameter to show only the available offerings matching the specified DB instance class.

- **LicenseModel** *(string)* – The license model filter value. Specify this parameter to show only the available offerings matching the specified license model.

- **Vpc** *(boolean)* – The VPC filter value. Specify this parameter to show only the available VPC or non-VPC offerings.

- **Filters** *(list)* – This parameter is not currently supported.
  - *(dict)*
    - **Name** *(string)* – [REQUIRED]
      This parameter is not currently supported.
    - **Values** *(list)* – [REQUIRED]
      This parameter is not currently supported.

- **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified `MaxRecords` value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.

  Default: 100

  Constraints: Minimum 20, maximum 100.

- **Marker** *(string)* – An optional pagination token provided by a previous DescribeOrderableDBInstanceOptions request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

Return type  `dict`

Returns

**Response Syntax**

```python
{
'OrderableDBInstanceOptions': [
    {
      'Engine': 'string',
      'EngineVersion': 'string',
      'DBInstanceClass': 'string',
      'LicenseModel': 'string',
      'AvailabilityZones': [
```
Response Structure

- *(dict)* –
  Contains the result of a successful invocation of the DescribeOrderableDBInstanceOptions action.

  - **OrderableDBInstanceOptions** *(list)* –
    An OrderableDBInstanceOption structure containing information about orderable options for the DB instance.
    - *(dict)* –
      Contains a list of available options for a DB instance

      This data type is used as a response element in the DescribeOrderableDBInstanceOptions action.
      - **Engine** *(string)* –
        The engine type of the orderable DB instance.
      - **EngineVersion** *(string)* –
        The engine version of the orderable DB instance.
      - **DBInstanceClass** *(string)* –
        The DB instance class for the orderable DB instance.
      - **LicenseModel** *(string)* –
        The license model for the orderable DB instance.
      - **AvailabilityZones** *(list)* –
        A list of Availability Zones for the orderable DB instance.
      - *(dict)* –
        Contains Availability Zone information.

      This data type is used as an element in the following data type:
      - **OrderableDBInstanceOption**
        - **Name** *(string)* –
          The name of the availability zone.
        - **MultiAZCapable** *(boolean)* –
          Indicates whether this orderable DB instance is multi-AZ capable.
        - **ReadReplicaCapable** *(boolean)* –
          Indicates whether this orderable DB instance can have a Read Replica.
· **Vpc** *(boolean)* –

Indicates whether this is a VPC orderable DB instance.

· **SupportsStorageEncryption** *(boolean)* –

Indicates whether this orderable DB instance supports encrypted storage.

· **StorageType** *(string)* –

Indicates the storage type for this orderable DB instance.

· **SupportsIops** *(boolean)* –

Indicates whether this orderable DB instance supports provisioned IOPS.

· **Marker** *(string)* –

An optional pagination token provided by a previous OrderableDBInstanceOptions request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

describe_pending_maintenance_actions(**kwargs)**

Returns a list of resources (for example, DB instances) that have at least one pending maintenance action.

**Request Syntax**

```python
response = client.describe_pending_maintenance_actions(
    ResourceIdentifier='string',
    Filters=[
        {
            'Name': 'string',
            'Values': ['string'],
        },
    ],
    Marker='string',
    MaxRecords=123
)
```

**Parameters**

· **ResourceIdentifier** *(string)* – The ARN of a resource to return pending maintenance actions for.

· **Filters** *(list)* – A filter that specifies one or more resources to return pending maintenance actions for.

Supported filters:

- **db-instance-id** - Accepts DB instance identifiers and DB instance Amazon Resource Names (ARNs). The results list will only include pending maintenance actions for the DB instances identified by these ARNs.

- *(dict)* –
  * **Name** *(string)* – [REQUIRED]

  This parameter is not currently supported.

  * **Values** *(list)* – [REQUIRED]

  This parameter is not currently supported.

  · *(string)* –
• **Marker** *(string)* – An optional pagination token provided by a previous `DescribePendingMaintenanceActions` request. If this parameter is specified, the response includes only records beyond the marker, up to a number of records specified by `MaxRecords`.

• **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified `MaxRecords` value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.

  Default: 100

  Constraints: Minimum 20, maximum 100.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'PendingMaintenanceActions': [
        {
            'ResourceIdentifier': 'string',
            'PendingMaintenanceActionDetails': [
                {
                    'Action': 'string',
                    'AutoAppliedAfterDate': datetime(2015, 1, 1),
                    'ForcedApplyDate': datetime(2015, 1, 1),
                    'OptInStatus': 'string',
                    'CurrentApplyDate': datetime(2015, 1, 1),
                    'Description': 'string'
                },
                {
                    'Action': 'string',
                    'AutoAppliedAfterDate': datetime(2015, 1, 1),
                    'ForcedApplyDate': datetime(2015, 1, 1),
                    'OptInStatus': 'string',
                    'CurrentApplyDate': datetime(2015, 1, 1),
                    'Description': 'string'
                }
            ],
            'Marker': 'string'
        }
    ]
}
```

**Response Structure**

• *(dict)* – Data returned from the `DescribePendingMaintenanceActions` action.

  – **PendingMaintenanceActions** *(list)* –

    A list of the pending maintenance actions for the resource.

    * *(dict)* –

    Describes the pending maintenance actions for a resource.

    • **ResourceIdentifier** *(string)* –

      The ARN of the resource that has pending maintenance actions.

    • **PendingMaintenanceActionDetails** *(list)* –

      A list that provides details about the pending maintenance actions for the resource.

    * *(dict)* –

      Provides information about a pending maintenance action for a resource.

    • **Action** *(string)* –
The type of pending maintenance action that is available for the resource.

- **AutoAppliedAfterDate** (*datetime*)
  
  The date of the maintenance window when the action will be applied. The maintenance action will be applied to the resource during its first maintenance window after this date. If this date is specified, any next-maintenance opt-in requests are ignored.

- **ForcedApplyDate** (*datetime*)
  
  The date when the maintenance action will be automatically applied. The maintenance action will be applied to the resource on this date regardless of the maintenance window for the resource. If this date is specified, any immediate opt-in requests are ignored.

- **OptInStatus** (*string*)
  
  Indicates the type of opt-in request that has been received for the resource.

- **CurrentApplyDate** (*datetime*)
  
  The effective date when the pending maintenance action will be applied to the resource. This date takes into account opt-in requests received from the ApplyPendingMaintenanceAction API, the AutoAppliedAfterDate, and the ForcedApplyDate. This value is blank if an opt-in request has not been received and nothing has been specified as AutoAppliedAfterDate or ForcedApplyDate.

- **Description** (*string*)
  
  A description providing more detail about the maintenance action.

- **Marker** (*string*)
  
  An optional pagination token provided by a previous DescribePendingMaintenanceActions request. If this parameter is specified, the response includes only records beyond the marker, up to a number of records specified by MaxRecords.

describe_reserved_db_instances(**kwargs)**

Returns information about reserved DB instances for this account, or about a specified reserved DB instance.

**Request Syntax**

```
response = client.describe_reserved_db_instances(
    ReservedDBInstanceId='string',
    ReservedDBInstancesOfferingId='string',
    DBInstanceClass='string',
    Duration='string',
    ProductDescription='string',
    OfferingType='string',
    MultiAZ=True|False,
    Filters=[
        
            'Name': 'string',
            'Values': [ 'string',
```
Parameters

- **ReservedDBInstanceId (string)** – The reserved DB instance identifier filter value. Specify this parameter to show only the reservation that matches the specified reservation ID.
- **ReservedDBInstancesOfferingId (string)** – The offering identifier filter value. Specify this parameter to show only purchased reservations matching the specified offering identifier.
- **DBInstanceClass (string)** – The DB instance class filter value. Specify this parameter to show only those reservations matching the specified DB instances class.
- **Duration (string)** – The duration filter value, specified in years or seconds. Specify this parameter to show only reservations for this duration.
  
  Valid Values: 1 | 3 | 31536000 | 94608000
- **ProductDescription (string)** – The product description filter value. Specify this parameter to show only those reservations matching the specified product description.
- **OfferingType (string)** – The offering type filter value. Specify this parameter to show only the available offerings matching the specified offering type.
  
  Valid Values: "Partial Upfront" | "All Upfront" | "No Upfront"
- **MultiAZ (boolean)** – The Multi-AZ filter value. Specify this parameter to show only those reservations matching the specified Multi-AZ parameter.
- **Filters (list)** – This parameter is not currently supported.
  
  - (dict) –
    
    * **Name (string)** – [REQUIRED]
      
      This parameter is not currently supported.
    * **Values (list)** – [REQUIRED]
      
      This parameter is not currently supported.
    · (string) –

- **MaxRecords (integer)** – The maximum number of records to include in the response. If more than the MaxRecords value is available, a pagination token called a marker is included in the response so that the following results can be retrieved.
  
  Default: 100
  
  Constraints: Minimum 20, maximum 100.
- **Marker (string)** – An optional pagination token provided by a previous request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

Return type dict

Returns

Response Syntax
Response Structure

- (dict) –
  Contains the result of a successful invocation of the DescribeReservedDBInstances action.
  
  - Marker (string) –
    An optional pagination token provided by a previous request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.
  
  - ReservedDBInstances (list) –
    A list of reserved DB instances.
      - (dict) –
        This data type is used as a response element in the DescribeReservedDBInstances and PurchaseReservedDBInstancesOffering actions.
          - ReservedDBInstanceId (string) –
            The unique identifier for the reservation.
          - ReservedDBInstancesOfferingId (string) –
            The offering identifier.
          - DBInstanceClass (string) –
            The DB instance class for the reserved DB instance.
          - StartTime (datetime) –
            The time the reservation started.
          - Duration (integer) –
            The duration of the reservation in seconds.
- **FixedPrice** *(float)* –
  The fixed price charged for this reserved DB instance.
- **UsagePrice** *(float)* –
  The hourly price charged for this reserved DB instance.
- **CurrencyCode** *(string)* –
  The currency code for the reserved DB instance.
- **DBInstanceCount** *(integer)* –
  The number of reserved DB instances.
- **ProductDescription** *(string)* –
  The description of the reserved DB instance.
- **OfferingType** *(string)* –
  The offering type of this reserved DB instance.
- **MultiAZ** *(boolean)* –
  Indicates if the reservation applies to Multi-AZ deployments.
- **State** *(string)* –
  The state of the reserved DB instance.
- **RecurringCharges** *(list)* –
  The recurring price charged to run this reserved DB instance.

This data type is used as a response element in the DescribeReservedDBInstances and DescribeReservedDBInstancesOfferings actions.
- **RecurringChargeAmount** *(float)* –
  The amount of the recurring charge.
- **RecurringChargeFrequency** *(string)* –
  The frequency of the recurring charge.

**describe_reserved_db_instances_offerings(** **kwargs)**

Lists available reserved DB instance offerings.

**Request Syntax**

```python
response = client.describe_reserved_db_instances_offerings(
    ReservedDBInstancesOfferingId='string',
    DBInstanceClass='string',
    Duration='string',
    ProductDescription='string',
    OfferingType='string',
    MultiAZ=True|False,
    Filters=[
        {'Name': 'string',
         'Values': ['string',
                    ]},
    ],
    MaxRecords=123,
    Marker='string'
)
```
Parameters

- **ReservedDBInstancesOfferingId** *(string)* – The offering identifier filter value. Specify this parameter to show only the available offering that matches the specified reservation identifier.

  Example: 438012d3-4052-4cc7-b2e3-8d3372e0e706

- **DBInstanceClass** *(string)* – The DB instance class filter value. Specify this parameter to show only the available offerings matching the specified DB instance class.

- **Duration** *(string)* – Duration filter value, specified in years or seconds. Specify this parameter to show only reservations for this duration.

  Valid Values: 1 | 3 | 31536000 | 94608000

- **ProductDescription** *(string)* – Product description filter value. Specify this parameter to show only the available offerings matching the specified product description.

- **OfferingType** *(string)* – The offering type filter value. Specify this parameter to show only the available offerings matching the specified offering type.

  Valid Values: "Partial Upfront" | "All Upfront" | "No Upfront"

- **MultiAZ** *(boolean)* – The Multi-AZ filter value. Specify this parameter to show only the available offerings matching the specified Multi-AZ parameter.

- **Filters** *(list)* – This parameter is not currently supported.

  - *(dict)* –
    - **Name** *(string)* – [REQUIRED]
      This parameter is not currently supported.
    - **Values** *(list)* – [REQUIRED]
      This parameter is not currently supported.

- **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more than the MaxRecords value is available, a pagination token called a marker is included in the response so that the following results can be retrieved.

  Default: 100

  Constraints: Minimum 20, maximum 100.

- **Marker** *(string)* – An optional pagination token provided by a previous request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

Return type  dict

Returns

Response Syntax

```python
{
    'Marker': 'string',
    'ReservedDBInstancesOfferings': [
        {
            'ReservedDBInstancesOfferingId': 'string',
            'DBInstanceClass': 'string',
            'Duration': 123,
            'FixedPrice': 123.0,
            'UsagePrice': 123.0,
            'CurrencyCode': 'string',
        }
    ]
}
```
Response Structure

- **(dict)**
  Contains the result of a successful invocation of the DescribeReservedDBInstancesOfferings action.

  - **Marker (string)**
    An optional pagination token provided by a previous request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by **MaxRecords**.

  - **ReservedDBInstancesOfferings (list)**
    A list of reserved DB instance offerings.

    - **(dict)**
      This data type is used as a response element in the DescribeReservedDBInstancesOfferings action.

        - **ReservedDBInstancesOfferingId (string)**
          The offering identifier.

        - **DBInstanceClass (string)**
          The DB instance class for the reserved DB instance.

        - **Duration (integer)**
          The duration of the offering in seconds.

        - **FixedPrice (float)**
          The fixed price charged for this offering.

        - **UsagePrice (float)**
          The hourly price charged for this offering.

        - **CurrencyCode (string)**
          The currency code for the reserved DB instance offering.

        - **ProductDescription (string)**
          The database engine used by the offering.

        - **OfferingType (string)**
          The offering type.

        - **MultiAZ (boolean)**
          Indicates if the offering applies to Multi-AZ deployments.

        - **RecurringCharges (list)**
          The recurring price charged to run this reserved DB instance.

        - **(dict)**
          

3.1. Services
This data type is used as a response element in the DescribeReservedDBInstances and DescribeReservedDBInstancesOfferings actions.

- **RecurringChargeAmount** *(float)* –
  The amount of the recurring charge.

- **RecurringChargeFrequency** *(string)* –
  The frequency of the recurring charge.

**download_db_log_file_portion** (**kwargs**)

Downloads all or a portion of the specified log file, up to 1 MB in size.

**Request Syntax**

```python
response = client.download_db_log_file_portion(
    DBInstanceIdentifier='string',
    LogFileName='string',
    Marker='string',
    NumberOfLines=123
)
```

**Parameters**

- **DBInstanceIdentifier** *(string)* – [REQUIRED]
  The customer-assigned name of the DB instance that contains the log files you want to list.

  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **LogFileName** *(string)* – [REQUIRED]
  The name of the log file to be downloaded.

- **Marker** *(string)* – The pagination token provided in the previous request or “0”. If the Marker parameter is specified the response includes only records beyond the marker until the end of the file or up to NumberOfLines.

- **NumberOfLines** *(integer)* – The number of lines to download. If the number of lines specified results in a file over 1 MB in size, the file will be truncated at 1 MB in size.

  If the NumberOfLines parameter is specified, then the block of lines returned can be from the beginning or the end of the log file, depending on the value of the Marker parameter.

  - If neither Marker or NumberOfLines are specified, the entire log file is returned.
  - If NumberOfLines is specified and Marker is not specified, then the most recent lines from the end of the log file are returned.
  - If Marker is specified as “0”, then the specified number of lines from the beginning of the log file are returned.
  - You can download the log file in blocks of lines by specifying the size of the block using the NumberOfLines parameter, and by specifying a value of “0” for the Marker parameter in your first request. Include the Marker value returned in the response as the Marker value for the next request, continuing until the AdditionalDataPending response element returns false.

**Return type** *dict*
failover_db_cluster (**kwargs)

Forces a failover for a DB cluster.

A failover for a DB cluster promotes one of the read-only instances in the DB cluster to the master DB instance (the cluster writer) and deletes the current primary instance.

Amazon Aurora will automatically fail over to a read-only instance, if one exists, when the primary instance fails. You can force a failover when you want to simulate a failure of a DB instance for testing. Because each instance in a DB cluster has its own endpoint address, you will need to clean up and re-establish any existing connections that use those endpoint addresses when the failover is complete.

For more information on Amazon Aurora, see Aurora on Amazon RDS in the Amazon RDS User Guide.

Request Syntax

```python
response = client.failover_db_cluster(
    DBClusterIdentifier='string'
)
```

Parameters  

**DBClusterIdentifier** *(string)* – A DB cluster identifier to force a failover for.

This parameter is not case-sensitive.

Constraints:

- Must contain from 1 to 63 alphanumeric characters or hyphens
- First character must be a letter
- Cannot end with a hyphen or contain two consecutive hyphens

Return type  
dict

Returns

Response Syntax

```python
{
    'DBCluster': {
        'AllocatedStorage': 123,
        'AvailabilityZones': [
            'string',
            ...
        ],
        ...
    }
}
```
Response Structure

- `dict` –

Contains the result of a successful invocation of the following actions:

- CreateDBCluster
- DeleteDBCluster
- FailoverDBCluster
- ModifyDBCluster
- RestoreDBClusterFromSnapshot

This data type is used as a response element in the DescribeDBClusters action.

- `DBCluster` (dict) –

Contains the result of a successful invocation of the following actions:

- CreateDBCluster
- DeleteDBCluster
- FailoverDBCluster
- ModifyDBCluster
- RestoreDBClusterFromSnapshot
This data type is used as a response element in the DescribeDBClusters action.

* **AllocatedStorage** *(integer)* –
  
  Specifies the allocated storage size in gigabytes (GB).

* **AvailabilityZones** *(list)* –
  
  Provides the list of EC2 Availability Zones that instances in the DB cluster can be created in.
    
    · **(string)** –

* **BackupRetentionPeriod** *(integer)* –
  
  Specifies the number of days for which automatic DB snapshots are retained.

* **CharacterSetName** *(string)* –
  
  If present, specifies the name of the character set that this cluster is associated with.

* **DatabaseName** *(string)* –
  
  Contains the name of the initial database of this DB cluster that was provided at create time, if one was specified when the DB cluster was created. This same name is returned for the life of the DB cluster.

* **DBClusterIdentifier** *(string)* –
  
  Contains a user-supplied DB cluster identifier. This identifier is the unique key that identifies a DB cluster.

* **DBClusterParameterGroup** *(string)* –
  
  Specifies the name of the DB cluster parameter group for the DB cluster.

* **DBSubnetGroup** *(string)* –
  
  Specifies information on the subnet group associated with the DB cluster, including the name, description, and subnets in the subnet group.

* **Status** *(string)* –
  
  Specifies the current state of this DB cluster.

* **PercentProgress** *(string)* –
  
  Specifies the progress of the operation as a percentage.

* **EarliestRestorableTime** *(datetime)* –
  
  Specifies the earliest time to which a database can be restored with point-in-time restore.

* **Endpoint** *(string)* –
  
  Specifies the connection endpoint for the primary instance of the DB cluster.

* **Engine** *(string)* –
  
  Provides the name of the database engine to be used for this DB cluster.

* **EngineVersion** *(string)* –
  
  Indicates the database engine version.

* **LatestRestorableTime** *(datetime)* –
Specifies the latest time to which a database can be restored with point-in-time restore.

* **Port (integer)** –

  Specifies the port that the database engine is listening on.

* **MasterUsername (string)** –

  Contains the master username for the DB cluster.

* **DBClusterOptionGroupMemberships (list)** –

  Provides the list of option group memberships for this DB cluster.
  · **(dict)** –
    · Contains status information for a DB cluster option group.
    · **DBClusterOptionGroupName (string)** –
      · Specifies the name of the DB cluster option group.
    · **Status (string)** –
      · Specifies the status of the DB cluster option group.

* **PreferredBackupWindow (string)** –

  Specifies the daily time range during which automated backups are created if automated backups are enabled, as determined by the BackupRetentionPeriod.

* **PreferredMaintenanceWindow (string)** –

  Specifies the weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).

* **DBClusterMembers (list)** –

  Provides the list of instances that make up the DB cluster.
  · **(dict)** –
    · Contains information about an instance that is part of a DB cluster.
    · **DBInstanceIdentifier (string)** –
      · Specifies the instance identifier for this member of the DB cluster.
    · **IsClusterWriter (boolean)** –
      · Value that is true if the cluster member is the primary instance for the DB cluster and false otherwise.
    · **DBClusterParameterGroupStatus (string)** –
      · Specifies the status of the DB cluster parameter group for this member of the DB cluster.

* **VpcSecurityGroups (list)** –

  Provides a list of VPC security groups that the DB cluster belongs to.
  · **(dict)** –
    · This data type is used as a response element for queries on VPC security group membership.
    · **VpcSecurityGroupId (string)** –
      · The name of the VPC security group.
    · **Status (string)** –
      · The status of the VPC security group.
generate_presigned_url (ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)

Generate a presigned url given a client, its method, and arguments

Parameters

- **ClientMethod** (string) – The client method to presign for
- **Params** (dict) – The parameters normally passed to ClientMethod.
- **ExpiresIn** (int) – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** (string) – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns

The presigned url

get Paginator (operation_name)

Create a paginator for an operation.

Parameters **operation_name** (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get Paginator("create_foo")`.

Raises OperationNotPageableError Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

Return type L{botocore.paginate.Paginator}

Returns A paginator object.

get_waiter (waiter_name)

list_tags_for_resource (**kwargs)

Lists all tags on an Amazon RDS resource.

For an overview on tagging an Amazon RDS resource, see Tagging Amazon RDS Resources.

Request Syntax

```
response = client.list_tags_for_resource(
    ResourceName='string',
    Filters=[
        {'Name': 'string',
         'Values': ['string',
                    ],
         },
    ]
)
```

Parameters

- **ResourceName** (string) – [REQUIRED]

  The Amazon RDS resource with tags to be listed. This value is an Amazon Resource Name (ARN). For information about creating an ARN, see Constructing an RDS Amazon Resource Name (ARN).

- **Filters** (list) – This parameter is not currently supported.
  - (dict) –
    - **Name** (string) – [REQUIRED]
      - This parameter is not currently supported.
    - **Values** (list) – [REQUIRED]
      - This parameter is not currently supported.
Response Syntax

```python
{
    'TagList': [
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
}
```

Response Structure

- **(dict)** –
  - **TagList (list)** –
    List of tags returned by the ListTagsForResource operation.

- **(dict)** –
  Metadata assigned to an Amazon RDS resource consisting of a key-value pair.
  - **Key (string)** –
    A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘.’, ‘,’ ‘,’ ‘/’, ‘=’, ‘+’ ‘-’ (Java regex: “^([\p{L}\p{Z}\p{N}_.:/=\+\-]*$”).
  - **Value (string)** –
    A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘.’, ‘,’ ‘,’ ‘/’, ‘=’, ‘+’ ‘-’ (Java regex: “^([\p{L}\p{Z}\p{N}_.:/=\+\-]*$”).

`modify_db_cluster(**kwargs)`
Modify a setting for an Amazon Aurora DB cluster. You can change one or more database configuration parameters by specifying these parameters and the new values in the request. For more information on Amazon Aurora, see Aurora on Amazon RDS in the Amazon RDS User Guide.

**Request Syntax**

```python
response = client.modify_db_cluster(
    DBClusterIdentifier='string',
    NewDBClusterIdentifier='string',
    ApplyImmediately=True|False,
    BackupRetentionPeriod=123,
    DBClusterParameterGroupName='string',
    VpcSecurityGroupIds=[
        'string',
    ],
    Port=123,
    MasterUserPassword='string',
    OptionGroupName='string',
    PreferredBackupWindow='string',
)```
PreferredMaintenanceWindow='string'

Parameters

- **DBClusterIdentifier** (*string*) – The DB cluster identifier for the cluster being modified. This parameter is not case-sensitive.

  Constraints:
  - Must be the identifier for an existing DB cluster.
  - Must contain from 1 to 63 alphanumeric characters or hyphens.
  - First character must be a letter.
  - Cannot end with a hyphen or contain two consecutive hyphens.

- **NewDBClusterIdentifier** (*string*) – The new DB cluster identifier for the DB cluster when renaming a DB cluster. This value is stored as a lowercase string.

  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

  Example: my-cluster2

- **ApplyImmediately** (*boolean*) – A value that specifies whether the modifications in this request and any pending modifications are asynchronously applied as soon as possible, regardless of the PreferredMaintenanceWindow setting for the DB cluster.

  If this parameter is set to *false*, changes to the DB cluster are applied during the next maintenance window.

  Default: *false*

- **BackupRetentionPeriod** (*integer*) – The number of days for which automated backups are retained. Setting this parameter to a positive number enables backups. Setting this parameter to 0 disables automated backups.

  Default: 1

  Constraints:
  - Must be a value from 0 to 35

- **DBClusterParameterGroupName** (*string*) – The name of the DB cluster parameter group to use for the DB cluster.

- **VpcSecurityGroupIds** (*list*) – A list of VPC security groups that the DB cluster will belong to.

  - (*string*)

- **Port** (*integer*) – The port number on which the DB cluster accepts connections.

  Constraints: Value must be 1150–65535

  Default: The same port as the original DB cluster.

- **MasterUserPassword** (*string*) – The new password for the master database user. This password can contain any printable ASCII character except “/”, “””, or “@”.

  Constraints: Must contain from 8 to 41 characters.

- **OptionGroupName** (*string*) – A value that indicates that the DB cluster should be associated with the specified option group. Changing this parameter does not result in an outage except in the following case, and the change is applied during the next maintenance window unless the ApplyImmediately parameter is set to *true* for this request. If the parameter change results in an option group that enables OEM, this change can cause a brief (sub-second) period dur-
ing which new connections are rejected but existing connections are not interrupted.

Permanent options cannot be removed from an option group. The option group cannot be removed from a DB cluster once it is associated with a DB cluster.

- **PreferredBackupWindow** *(string)* – The daily time range during which automated backups are created if automated backups are enabled, using the `BackupRetentionPeriod` parameter.

  Default: A 30-minute window selected at random from an 8-hour block of time per region. To see the time blocks available, see *Adjusting the Preferred Maintenance Window* in the *Amazon RDS User Guide*.

  Constraints:
  - Must be in the format `hh24:mi-hh24:mi`.
  - Times should be in Universal Coordinated Time (UTC).
  - Must not conflict with the preferred maintenance window.
  - Must be at least 30 minutes.

- **PreferredMaintenanceWindow** *(string)* – The weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).

  Default: A 30-minute window selected at random from an 8-hour block of time per region, occurring on a random day of the week. To see the time blocks available, see *Adjusting the Preferred Maintenance Window* in the *Amazon RDS User Guide*.

  Valid Days: Mon, Tue, Wed, Thu, Fri, Sat, Sun

  Constraints: Minimum 30-minute window.

**Response Syntax**

```python
{
  'DBCluster': {
    'AllocatedStorage': 123,
    'AvailabilityZones': ['string'],
    'BackupRetentionPeriod': 123,
    'CharacterSetName': 'string',
    'DatabaseName': 'string',
    'DBClusterIdentifier': 'string',
    'DBClusterParameterGroup': 'string',
    'DBSubnetGroup': 'string',
    'Status': 'string',
    'PercentProgress': 'string',
    'EarliestRestorableTime': datetime(2015, 1, 1),
    'Endpoint': 'string',
    'Engine': 'string',
    'EngineVersion': 'string',
    'LatestRestorableTime': datetime(2015, 1, 1),
    'Port': 123,
    'MasterUsername': 'string',
    'DBClusterOptionGroupMemberships': [
      {
        'DBClusterOptionGroupName': 'string',
      }
  }
}
```
Response Structure

- **(dict)** –

  Contains the result of a successful invocation of the following actions:
  - CreateDBCluster
  - DeleteDBCluster
  - FailoverDBCluster
  - ModifyDBCluster
  - RestoreDBClusterFromSnapshot

This data type is used as a response element in the DescribeDBClusters action.

- **DBCluster (dict)** –

  Contains the result of a successful invocation of the following actions:
  - CreateDBCluster
  - DeleteDBCluster
  - FailoverDBCluster
  - ModifyDBCluster
  - RestoreDBClusterFromSnapshot

This data type is used as a response element in the DescribeDBClusters action.

* **AllocatedStorage (integer)** –

  Specifies the allocated storage size in gigabytes (GB).

* **AvailabilityZones (list)** –

  Provides the list of EC2 Availability Zones that instances in the DB cluster can be created in.

  - **(string)** –

  * **BackupRetentionPeriod (integer)** –

  Specifies the number of days for which automatic DB snapshots are retained.

  * **CharacterSetName (string)** –

  If present, specifies the name of the character set that this cluster is associated with.

  * **DatabaseName (string)** –
Contains the name of the initial database of this DB cluster that was provided at create time, if one was specified when the DB cluster was created. This same name is returned for the life of the DB cluster.

* **DBClusterIdentifier** *(string)* –

  Contains a user-supplied DB cluster identifier. This identifier is the unique key that identifies a DB cluster.

* **DBClusterParameterGroup** *(string)* –

  Specifies the name of the DB cluster parameter group for the DB cluster.

* **DBSubnetGroup** *(string)* –

  Specifies information on the subnet group associated with the DB cluster, including the name, description, and subnets in the subnet group.

* **Status** *(string)* –

  Specifies the current state of this DB cluster.

* **PercentProgress** *(string)* –

  Specifies the progress of the operation as a percentage.

* **EarliestRestorableTime** *(datetime)* –

  Specifies the earliest time to which a database can be restored with point-in-time restore.

* **Endpoint** *(string)* –

  Specifies the connection endpoint for the primary instance of the DB cluster.

* **Engine** *(string)* –

  Provides the name of the database engine to be used for this DB cluster.

* **EngineVersion** *(string)* –

  Indicates the database engine version.

* **LatestRestorableTime** *(datetime)* –

  Specifies the latest time to which a database can be restored with point-in-time restore.

* **Port** *(integer)* –

  Specifies the port that the database engine is listening on.

* **MasterUsername** *(string)* –

  Contains the master username for the DB cluster.

* **DBClusterOptionGroupMemberships** *(list)* –

  Provides the list of option group memberships for this DB cluster.

    · *(dict)* –

      Contains status information for a DB cluster option group.

    · **DBClusterOptionGroupName** *(string)* –

      Specifies the name of the DB cluster option group.

    · **Status** *(string)* –

      Specifies the status of the DB cluster option group.
* **PreferredBackupWindow** (*string*) –
  Specifies the daily time range during which automated backups are created if automated backups are enabled, as determined by the BackupRetentionPeriod.

* **PreferredMaintenanceWindow** (*string*) –
  Specifies the weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).

* **DBClusterMembers** (*list*) –
  Provides the list of instances that make up the DB cluster.
  · (dict) –
    Contains information about an instance that is part of a DB cluster.
  · **DBInstanceIdentifier** (*string*) –
    Specifies the instance identifier for this member of the DB cluster.
  · **IsClusterWriter** (*boolean*) –
    Value that is true if the cluster member is the primary instance for the DB cluster and false otherwise.
  · **DBClusterParameterGroupStatus** (*string*) –
    Specifies the status of the DB cluster parameter group for this member of the DB cluster.

* **VpcSecurityGroups** (*list*) –
  Provides a list of VPC security groups that the DB cluster belongs to.
  · (dict) –
    This data type is used as a response element for queries on VPC security group membership.
  · **VpcSecurityGroupId** (*string*) –
    The name of the VPC security group.
  · **Status** (*string*) –
    The status of the VPC security group.

**modify_db_cluster_parameter_group** (**kwargs**)
Modifies the parameters of a DB cluster parameter group. To modify more than one parameter, submit a list of the following: ParameterName, ParameterValue, and ApplyMethod. A maximum of 20 parameters can be modified in a single request.

For more information on Amazon Aurora, see [Aurora on Amazon RDS](https://docs.aws.amazon.com/AmazonRDS/latest/Aurora Concepts/aurora-concepts.html) in the [Amazon RDS User Guide](https://docs.aws.amazon.com/AmazonRDS/latest/RDS Concepts/aurora-concepts.html).

**Note:** Changes to dynamic parameters are applied immediately. Changes to static parameters require a reboot without failover to the DB cluster associated with the parameter group before the change can take effect.
Warning: After you create a DB cluster parameter group, you should wait at least 5 minutes before creating your first DB cluster that uses that DB cluster parameter group as the default parameter group. This allows Amazon RDS to fully complete the create action before the parameter group is used as the default for a new DB cluster. This is especially important for parameters that are critical when creating the default database for a DB cluster, such as the character set for the default database defined by the `character_set_database` parameter. You can use the `Parameter Groups` option of the Amazon RDS console or the `DescribeDBClusterParameters` command to verify that your DB cluster parameter group has been created or modified.

Request Syntax

```python
response = client.modify_db_cluster_parameter_group(
    DBClusterParameterGroupName='string',
    Parameters=[
        {
            'ParameterName': 'string',
            'ParameterValue': 'string',
            'Description': 'string',
            'Source': 'string',
            'ApplyType': 'string',
            'DataType': 'string',
            'AllowedValues': 'string',
            'IsModifiable': True|False,
            'MinimumEngineVersion': 'string',
            'ApplyMethod': 'immediate'|'pending-reboot'
        },
    ]
)
```

Parameters

- **DBClusterParameterGroupName** *(string) – [REQUIRED]*
  
  The name of the DB cluster parameter group to modify.

- **Parameters** *(list) – [REQUIRED]*
  
  A list of parameters in the DB cluster parameter group to modify.
  
  ```
  – (dict) –
  
  This data type is used as a request parameter in the ModifyDBParameterGroup and ResetDBParameterGroup actions.
  
  This data type is used as a response element in the DescribeEngineDefaultParameters and DescribeDBParameters actions.
  
  * **ParameterName** *(string) –*
    
    Specifies the name of the parameter.
  
  * **ParameterValue** *(string) –*
    
    Specifies the value of the parameter.
  
  * **Description** *(string) –*
    
    Provides a description of the parameter.
  
  * **Source** *(string) –*
    
    Indicates the source of the parameter value.
  
  * **ApplyType** *(string) –*
    
    Specifies the engine specific parameters type.
* **DataType (string)** –
  Specifies the valid data type for the parameter.
* **AllowedValues (string)** –
  Specifies the valid range of values for the parameter.
* **IsModifiable (boolean)** –
  Indicates whether (true) or not (false) the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.
* **MinimumEngineVersion (string)** –
  The earliest engine version to which the parameter can apply.
* **ApplyMethod (string)** –
  Indicates when to apply parameter updates.

**Return type**  dict
**Returns**

**Response Syntax**

```python
def response = client.modify_db_instance(**kwargs)
```

**Response Structure**

- *(dict)* –
  - **DBClusterParameterGroupName (string)** –
    The name of the DB cluster parameter group.
  
  **Constraints:**
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

  **Note:** This value is stored as a lowercase string.

**modify_db_instance(**kwargs)**
Modify settings for a DB instance. You can change one or more database configuration parameters by specifying these parameters and the new values in the request.

**Request Syntax**

```python
def response = client.modify_db_instance(
    DBInstanceIdentifier='string',
    AllocatedStorage=123,
    DBInstanceClass='string',
    DBSecurityGroups=[
        'string',
    ],
    VpcSecurityGroupIds=[
        'string',
    ],
    ApplyImmediately=True|False,
    MasterUserPassword='string',
    DBParameterGroupName='string',
    BackupRetentionPeriod=123,
    PreferredBackupWindow='string',
```

3.1. Services
Parameters

- **DBInstanceIdentifier** *(string)* – [REQUIRED]
  
  The DB instance identifier. This value is stored as a lowercase string.

  Constraints:
  - Must be the identifier for an existing DB instance
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **AllocatedStorage** *(integer)* – The new storage capacity of the RDS instance. Changing this setting does not result in an outage and the change is applied during the next maintenance window unless **ApplyImmediately** is set to true for this request.

  **MySQL**
  
  Default: Uses existing setting

  Valid Values: 5-6144

  Constraints: Value supplied must be at least 10% greater than the current value. Values that are not at least 10% greater than the existing value are rounded up so that they are 10% greater than the current value.

  Type: Integer

  **PostgreSQL**
  
  Default: Uses existing setting

  Valid Values: 5-6144

  Constraints: Value supplied must be at least 10% greater than the current value. Values that are not at least 10% greater than the existing value are rounded up so that they are 10% greater than the current value.

  Type: Integer

  **Oracle**
  
  Default: Uses existing setting

  Valid Values: 10-6144

  Constraints: Value supplied must be at least 10% greater than the current value. Values that are not at least 10% greater than the existing value are rounded up so that they are 10% greater than the current value.

  **SQL Server**
Cannot be modified.

If you choose to migrate your DB instance from using standard storage to using Provisioned IOPS, or from using Provisioned IOPS to using standard storage, the process can take time. The duration of the migration depends on several factors such as database load, storage size, storage type (standard or Provisioned IOPS), amount of IOPS provisioned (if any), and the number of prior scale storage operations. Typical migration times are under 24 hours, but the process can take up to several days in some cases. During the migration, the DB instance will be available for use, but might experience performance degradation. While the migration takes place, nightly backups for the instance will be suspended. No other Amazon RDS operations can take place for the instance, including modifying the instance, rebooting the instance, deleting the instance, creating a Read Replica for the instance, and creating a DB snapshot of the instance.

- **DBInstanceClass** *(string)* – The new compute and memory capacity of the DB instance. To determine the instance classes that are available for a particular DB engine, use the DescribeOrderableDBInstanceOptions action.

  Passing a value for this setting causes an outage during the change and is applied during the next maintenance window, unless `ApplyImmediately` is specified as `true` for this request.

  Default: Uses existing setting

  Valid Values: `db.t1.micro` | `db.m1.small` | `db.m1.medium` | `db.m1.large` | `db.m1.xlarge` | `db.m2.xlarge` | `db.m2.2xlarge` | `db.m2.4xlarge` | `db.m3.medium` | `db.m3.large` | `db.m3.xlarge` | `db.m3.2xlarge` | `db.r3.large` | `db.r3.xlarge` | `db.r3.2xlarge` | `db.r3.4xlarge` | `db.r3.8xlarge` | `db.t2.micro` | `db.t2.large` | `db.t2.medium`

- **DBSecurityGroups** *(list)* – A list of DB security groups to authorize on this DB instance. Changing this setting does not result in an outage and the change is asynchronously applied as soon as possible.

  Constraints:
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

  *(string)*

- **VpcSecurityGroupIds** *(list)* – A list of EC2 VPC security groups to authorize on this DB instance. This change is asynchronously applied as soon as possible.

  Constraints:
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

  *(string)*

- **ApplyImmediately** *(boolean)* – Specifies whether the modifications in this request and any pending modifications are asynchronously applied as soon as possible, regardless of the PreferredMaintenanceWindow setting for the DB instance.

  If this parameter is set to `false`, changes to the DB instance are applied during the next maintenance window. Some parameter changes can cause an outage and will be applied on the next call to RebootDBInstance, or the next failure reboot.
Review the table of parameters in Modifying a DB Instance and Using the Apply Immediately Parameter to see the impact that setting ApplyImmediatelly to true or false has for each modified parameter and to determine when the changes will be applied.

Default: false

- **MasterUserPassword** (string) – The new password for the DB instance master user. Can be any printable ASCII character except “/”, ““”, or “@”.

Changing this parameter does not result in an outage and the change is asynchronously applied as soon as possible. Between the time of the request and the completion of the request, the MasterUserPassword element exists in the PendingModifiedValues element of the operation response.

Default: Uses existing setting

Constraints: Must be 8 to 41 alphanumeric characters (MySQL), 8 to 30 alphanumeric characters (Oracle), or 8 to 128 alphanumeric characters (SQL Server).

**Note:** Amazon RDS API actions never return the password, so this action provides a way to regain access to a primary instance user if the password is lost. This includes restoring privileges that might have been accidentally revoked.

- **DBParameterGroupName** (string) – The name of the DB parameter group to apply to the DB instance. Changing this setting does not result in an outage. The parameter group name itself is changed immediately, but the actual parameter changes are not applied until you reboot the instance without failover. The db instance will NOT be rebooted automatically and the parameter changes will NOT be applied during the next maintenance window.

Default: Uses existing setting

Constraints: The DB parameter group must be in the same DB parameter group family as this DB instance.

- **BackupRetentionPeriod** (integer) – The number of days to retain automated backups. Setting this parameter to a positive number enables backups. Setting this parameter to 0 disables automated backups.

Changing this parameter can result in an outage if you change from 0 to a non-zero value or from a non-zero value to 0. These changes are applied during the next maintenance window unless the ApplyImmediately parameter is set to true for this request. If you change the parameter from one non-zero value to another non-zero value, the change is asynchronously applied as soon as possible.

Default: Uses existing setting

Constraints:
- Must be a value from 0 to 35
- Can be specified for a MySQL Read Replica only if the source is running MySQL 5.6
- Can be specified for a PostgreSQL Read Replica only if the source is running PostgreSQL 9.3.5
- Cannot be set to 0 if the DB instance is a source to Read Replicas

- **PreferredBackupWindow** (string) – The daily time range during which automated backups are created if automated backups are enabled, as determined by the BackupRetentionPeriod parameter. Changing this parameter does not result in an outage and the change is asynchronously applied as soon as possible.
Constraints:
- Must be in the format hh24:mi-hh24:mi
- Times should be in Universal Time Coordinated (UTC)
- Must not conflict with the preferred maintenance window
- Must be at least 30 minutes

- **PreferredMaintenanceWindow (string)** – The weekly time range (in UTC) during which system maintenance can occur, which might result in an outage. Changing this parameter does not result in an outage, except in the following situation, and the change is asynchronously applied as soon as possible. If there are pending actions that cause a reboot, and the maintenance window is changed to include the current time, then changing this parameter will cause a reboot of the DB instance. If moving this window to the current time, there must be at least 30 minutes between the current time and end of the window to ensure pending changes are applied.

  Default: Uses existing setting
  Valid Days: Mon | Tue | Wed | Thu | Fri | Sat | Sun
  Constraints: Must be at least 30 minutes

- **MultiAZ (boolean)** – Specifies if the DB instance is a Multi-AZ deployment. Changing this parameter does not result in an outage and the change is applied during the next maintenance window unless the ApplyImmediately parameter is set to true for this request.

  Constraints: Cannot be specified if the DB instance is a Read Replica. This parameter cannot be used with SQL Server DB instances. Multi-AZ for SQL Server DB instances is set using the Mirroring option in an option group associated with the DB instance.

- **EngineVersion (string)** – The version number of the database engine to upgrade to. Changing this parameter results in an outage and the change is applied during the next maintenance window unless the ApplyImmediately parameter is set to true for this request.

  For major version upgrades, if a non-default DB parameter group is currently in use, a new DB parameter group in the DB parameter group family for the new engine version must be specified. The new DB parameter group can be the default for that DB parameter group family.

  For a list of valid engine versions, see CreateDBInstance.

- **AllowMajorVersionUpgrade (boolean)** – Indicates that major version upgrades are allowed. Changing this parameter does not result in an outage and the change is asynchronously applied as soon as possible.

  Constraints: This parameter must be set to true when specifying a value for the EngineVersion parameter that is a different major version than the DB instance’s current version.

- **AutoMinorVersionUpgrade (boolean)** – Indicates that minor version upgrades will be applied automatically to the DB instance during the maintenance window. Changing this parameter does not result in an outage except in the following case and the change is asynchronously applied as soon as possible. An outage will result if this parameter is set to true during the maintenance window, and a newer minor version is available, and RDS has enabled auto patching for that engine version.

- **Iops (integer)** – The new Provisioned IOPS (I/O operations per second) value for the RDS instance. Changing this setting does not result in an outage.
and the change is applied during the next maintenance window unless the `ApplyImmediately` parameter is set to `true` for this request.

Default: Uses existing setting

Constraints: Value supplied must be at least 10% greater than the current value. Values that are not at least 10% greater than the existing value are rounded up so that they are 10% greater than the current value. If you are migrating from Provisioned IOPS to standard storage, set this value to 0. The DB instance will require a reboot for the change in storage type to take effect.

**SQL Server**

Setting the IOPS value for the SQL Server database engine is not supported.

Type: Integer

If you choose to migrate your DB instance from using standard storage to using Provisioned IOPS, or from using Provisioned IOPS to using standard storage, the process can take time. The duration of the migration depends on several factors such as database load, storage size, storage type (standard or Provisioned IOPS), amount of IOPS provisioned (if any), and the number of prior scale storage operations. Typical migration times are under 24 hours, but the process can take up to several days in some cases. During the migration, the DB instance will be available for use, but might experience performance degradation. While the migration takes place, nightly backups for the instance will be suspended. No other Amazon RDS operations can take place for the instance, including modifying the instance, rebooting the instance, deleting the instance, creating a Read Replica for the instance, and creating a DB snapshot of the instance.

- **OptionGroupName** *(string)* – Indicates that the DB instance should be associated with the specified option group. Changing this parameter does not result in an outage except in the following case and the change is applied during the next maintenance window unless the `ApplyImmediately` parameter is set to `true` for this request. If the parameter change results in an option group that enables OEM, this change can cause a brief (sub-second) period during which new connections are rejected but existing connections are not interrupted.

Permanent options, such as the TDE option for Oracle Advanced Security TDE, cannot be removed from an option group, and that option group cannot be removed from a DB instance once it is associated with a DB instance.

- **NewDBInstanceIdentifier** *(string)* – The new DB instance identifier for the DB instance when renaming a DB instance. When you change the DB instance identifier, an instance reboot will occur immediately if you set `ApplyImmediately` to `true`, or will occur during the next maintenance window if `ApplyImmediately` to `false`. This value is stored as a lowercase string.

Constraints:
- Must contain from 1 to 63 alphanumeric characters or hyphens
- First character must be a letter
- Cannot end with a hyphen or contain two consecutive hyphens

- **StorageType** *(string)* – Specifies the storage type to be associated with the DB instance.

  Valid values: `standard` | `gp2` | `io1`

  If you specify `io1`, you must also include a value for the `Iops` parameter.

Default: `io1` if the `Iops` parameter is specified; otherwise `standard`

- **TdeCredentialArn** *(string)* – The ARN from the Key Store with which to associate the instance for TDE encryption.
• **TdeCredentialPassword** *(string)* – The password for the given ARN from the Key Store in order to access the device.

• **CACertificateIdentifier** *(string)* – Indicates the certificate that needs to be associated with the instance.

• **Domain** *(string)* – Specify the Active Directory Domain to move the instance to.

  The specified Active Directory Domain must be created prior to this operation. Currently only SQL Server instance can be created in a Domain

• **CopyTagsToSnapshot** *(boolean)* – This property is not currently implemented.

**Return type** `dict`

**Returns**

**Response Structure**

- *(dict)* –

  Contains the result of a successful invocation of the following actions:
  - CreateDBInstance
  - DeleteDBInstance
  - ModifyDBInstance

  This data type is used as a response element in the DescribeDBInstances action.

- **DBInstance** *(dict)* –

  Contains the result of a successful invocation of the following actions:
  - CreateDBInstance
  - DeleteDBInstance
  - ModifyDBInstance

  This data type is used as a response element in the DescribeDBInstances action.

- **DBInstanceIdentifier** *(string)* –

  Contains a user-supplied database identifier. This identifier is the unique key that identifies a DB instance.

- **DBInstanceClass** *(string)* –

  Contains the name of the compute and memory capacity class of the DB instance.

- **Engine** *(string)* –

  Provides the name of the database engine to be used for this DB instance.

- **DBInstanceStatus** *(string)* –

  Specifies the current state of this database.

- **MasterUsername** *(string)* –

  Contains the master username for the DB instance.

- **DBName** *(string)* –

  The meaning of this parameter differs according to the database engine you use. For example, this value returns either MySQL or PostgreSQL information when returning values from CreateDBInstanceReadReplica since Read Replicas are only supported for MySQL and PostgreSQL.

  **MySQL, SQL Server, PostgreSQL**

  Contains the name of the initial database of this instance that was provided at create time, if one was specified when the DB instance was created. This same name is returned for the life of the DB instance.

  Type: String

  **Oracle**

  Contains the Oracle System ID (SID) of the created DB instance. Not shown when the returned parameters do not apply to an Oracle.
DB instance.

* **Endpoint (dict)** –

  Specifies the connection endpoint.

  ‧ **Address (string)** –

    Specifies the DNS address of the DB instance.

  ‧ **Port (integer)** –

    Specifies the port that the database engine is listening on.

* **AllocatedStorage (integer)** –

  Specifies the allocated storage size specified in gigabytes.

* **InstanceCreateTime (datetime)** –

  Provides the date and time the DB instance was created.

* **PreferredBackupWindow (string)** –

  Specifies the daily time range during which automated backups are created if automated backups are enabled, as determined by the `BackupRetentionPeriod`.

* **BackupRetentionPeriod (integer)** –

  Specifies the number of days for which automatic DB snapshots are retained.

* **DBSecurityGroups (list)** –

  Provides List of DB security group elements containing only `DBSecurityGroup.Name` and `DBSecurityGroup.Status` subelements.

  ‧ **(dict)** –

    This data type is used as a response element in the following actions:

    ‧ ModifyDBInstance
    ‧ RebootDBInstance
    ‧ RestoreDBInstanceFromDBSnapshot
    ‧ RestoreDBInstanceToPointInTime
    ‧ **DBSecurityGroupName (string)** –

    The name of the DB security group.

    ‧ **Status (string)** –

    The status of the DB security group.

* **VpcSecurityGroups (list)** –

  Provides List of VPC security group elements that the DB instance belongs to.

  ‧ **(dict)** –

    This data type is used as a response element for queries on VPC security group membership.

    ‧ **VpcSecurityGroupId (string)** –

    The name of the VPC security group.

    ‧ **Status (string)** –

    The status of the VPC security group.

* **DBParameterGroups (list)** –

  Provides the list of DB parameter groups applied to this DB instance.
· (dict) –

  The status of the DB parameter group.

  This data type is used as a response element in the following actions:
· CreateDBInstance
· CreateDBInstanceReadReplica
· DeleteDBInstance
· ModifyDBInstance
· RebootDBInstance
· RestoreDBInstanceFromDBSnapshot

· DBParameterGroupName (string) –

  The name of the DP parameter group.

· ParameterApplyStatus (string) –

  The status of parameter updates.

* AvailabilityZone (string) –

  Specifies the name of the Availability Zone the DB instance is located in.

* DBSubnetGroup (dict) –

  Specifies information on the subnet group associated with the DB instance, including the name, description, and subnets in the subnet group.

  · DBSubnetGroupName (string) –

    Specifies the name of the DB subnet group.

  · DBSubnetGroupDescription (string) –

    Provides the description of the DB subnet group.

  · VpcId (string) –

    Provides the VpcId of the DB subnet group.

  · SubnetGroupStatus (string) –

    Provides the status of the DB subnet group.

  · Subnets (list) –

    Contains a list of Subnet elements.

  · (dict) –

    This data type is used as a response element in the DescribeDBSubnetGroups action.

  · SubnetIdentifier (string) –

    Specifies the identifier of the subnet.

  · SubnetAvailabilityZone (dict) –

    Contains Availability Zone information.

    This data type is used as an element in the following data type:
· OrderableDBInstanceOption

  · Name (string) –

    The name of the availability zone.

  · SubnetStatus (string) –

    Specifies the status of the subnet.
* **PreferredMaintenanceWindow** *(string)* –
  Specifies the weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).

* **PendingModifiedValues** *(dict)* –
  Specifies that changes to the DB instance are pending. This element is only included when changes are pending. Specific changes are identified by subelements.
  - **DBInstanceClass** *(string)* –
    Contains the new `DBInstanceClass` for the DB instance that will be applied or is in progress.
  - **AllocatedStorage** *(integer)* –
    Contains the new `AllocatedStorage` size for the DB instance that will be applied or is in progress.
  - **MasterUserPassword** *(string)* –
    Contains the pending or in-progress change of the master credentials for the DB instance.
  - **Port** *(integer)* –
    Specifies the pending port for the DB instance.
  - **BackupRetentionPeriod** *(integer)* –
    Specifies the pending number of days for which automated backups are retained.
  - **MultiAZ** *(boolean)* –
    Indicates that the Single-AZ DB instance is to change to a Multi-AZ deployment.
  - **EngineVersion** *(string)* –
    Indicates the database engine version.
  - **Iops** *(integer)* –
    Specifies the new Provisioned IOPS value for the DB instance that will be applied or is being applied.
  - **DBInstanceIdentifier** *(string)* –
    Contains the new `DBInstanceIdentifier` for the DB instance that will be applied or is in progress.
  - **StorageType** *(string)* –
    Specifies the storage type to be associated with the DB instance.
  - **CACertificateIdentifier** *(string)* –
    Specifies the identifier of the CA certificate for the DB instance.

* **LatestRestorableTime** *(datetime)* –
  Specifies the latest time to which a database can be restored with point-in-time restore.

* **MultiAZ** *(boolean)* –
  Specifies if the DB instance is a Multi-AZ deployment.

* **EngineVersion** *(string)* –
  Indicates the database engine version.
* AutoMinorVersionUpgrade (boolean) –
Indicates that minor version patches are applied automatically.

* ReadReplicaSourceDBInstanceIdentifier (string) –
Contains the identifier of the source DB instance if this DB instance is a Read Replica.

* ReadReplicaDBInstanceIdentifiers (list) –
Contains one or more identifiers of the Read Replicas associated with this DB instance.
  · (string) –

* LicenseModel (string) –
License model information for this DB instance.

* Iops (integer) –
Specifies the Provisioned IOPS (I/O operations per second) value.

* OptionGroupMemberships (list) –
Provides the list of option group memberships for this DB instance.
  · (dict) –
    Provides information on the option groups the DB instance is a member of.
    · OptionGroupName (string) –
      The name of the option group that the instance belongs to.
    · Status (string) –
      The status of the DB instance’s option group membership (e.g. in-sync, pending, pending-maintenance, applying).

* CharacterSetName (string) –
If present, specifies the name of the character set that this instance is associated with.

* SecondaryAvailabilityZone (string) –
If present, specifies the name of the secondary Availability Zone for a DB instance with multi-AZ support.

* PubliclyAccessible (boolean) –
Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.

Default: The default behavior varies depending on whether a VPC has been requested or not. The following list shows the default behavior in each case.
  · Default VPC: true
  · VPC: false
If no DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be publicly accessible. If a specific DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be private.

* StatusInfos (list) –
The status of a Read Replica. If the instance is not a Read Replica, this will be blank.

- **(dict)** –
  Provides a list of status information for a DB instance.
  - **StatusType (string)** –
    This value is currently “read replication.”
  - **Normal (boolean)** –
    Boolean value that is true if the instance is operating normally, or false if the instance is in an error state.
  - **Status (string)** –
    Status of the DB instance. For a StatusType of read replica, the values can be replicating, error, stopped, or terminated.
  - **Message (string)** –
    Details of the error if there is an error for the instance. If the instance is not in an error state, this value is blank.

- **StorageType (string)** –
  Specifies the storage type associated with DB instance.

- **TdeCredentialArn (string)** –
  The ARN from the Key Store with which the instance is associated for TDE encryption.

- **DbInstancePort (integer)** –
  Specifies the port that the DB instance listens on. If the DB instance is part of a DB cluster, this can be a different port than the DB cluster port.

- **DBClusterIdentifier (string)** –
  If the DB instance is a member of a DB cluster, contains the name of the DB cluster that the DB instance is a member of.

- **StorageEncrypted (boolean)** –
  Specifies whether the DB instance is encrypted.

- **KmsKeyId (string)** –
  If StorageEncrypted is true, the KMS key identifier for the encrypted DB instance.

- **DbiResourceId (string)** –
  If StorageEncrypted is true, the region-unique, immutable identifier for the encrypted DB instance. This identifier is found in AWS CloudTrail log entries whenever the KMS key for the DB instance is accessed.

- **CACertificateIdentifier (string)** –
  The identifier of the CA certificate for this DB instance.

- **DomainMemberships (list)** –
  The Active Directory Domain membership records associated with the DB instance.
  - **(dict)** –
    An Active Directory Domain membership record associated with the DB instance.
- **Domain** *(string)* –
  The identifier of the Active Directory Domain.

- **Status** *(string)* –
  The status of the DB instance’s Active Directory Domain membership (e.g. joined, pending-join, failed etc).

- **Connectivity** *(string)* –
  The observed connectivity of the Active Directory Domain.

- **CopyTagsToSnapshot** *(boolean)* –
  This property is not currently implemented.

### modify_db_parameter_group(**kwargs)

Modifies the parameters of a DB parameter group. To modify more than one parameter, submit a list of the following: `ParameterName`, `ParameterValue`, and `ApplyMethod`. A maximum of 20 parameters can be modified in a single request.

**Note:** Changes to dynamic parameters are applied immediately. Changes to static parameters require a reboot without failover to the DB instance associated with the parameter group before the change can take effect.

**Warning:** After you modify a DB parameter group, you should wait at least 5 minutes before creating your first DB instance that uses that DB parameter group as the default parameter group. This allows Amazon RDS to fully complete the modify action before the parameter group is used as the default for a new DB instance. This is especially important for parameters that are critical when creating the default database for a DB instance, such as the character set for the default database defined by the `character_set_database` parameter. You can use the `Parameter Groups` option of the Amazon RDS console or the `DescribeDBParameters` command to verify that your DB parameter group has been created or modified.

### Request Syntax

```python
response = client.modify_db_parameter_group(
    DBParameterGroupName='string',
    Parameters=[
        {
            'ParameterName': 'string',
            'ParameterValue': 'string',
            'Description': 'string',
            'Source': 'string',
            'ApplyType': 'string',
            'DataType': 'string',
            'AllowedValues': 'string',
            'IsModifiable': True|False,
            'MinimumEngineVersion': 'string',
            'ApplyMethod': 'immediate'|'pending-reboot'
        },
    ]
)
```

### Parameters

- **DBParameterGroupName** *(string)* – [REQUIRED]
  The name of the DB parameter group.

  Constraints:
– Must be the name of an existing DB parameter group
– Must be 1 to 255 alphanumeric characters
– First character must be a letter
– Cannot end with a hyphen or contain two consecutive hyphens

• **Parameters** *(list) – [REQUIRED]*

An array of parameter names, values, and the apply method for the parameter update. At least one parameter name, value, and apply method must be supplied; subsequent arguments are optional. A maximum of 20 parameters can be modified in a single request.

Valid Values (for the application method): immediate | pending-reboot

**Note:** You can use the immediate value with dynamic parameters only. You can use the pending-reboot value for both dynamic and static parameters, and changes are applied when you reboot the DB instance without failover.

– *(dict) –*

This data type is used as a request parameter in the ModifyDBParameterGroup and ResetDBParameterGroup actions.

This data type is used as a response element in the DescribeEngineDefaultParameters and DescribeDBParameters actions.

* **ParameterName** *(string)* –

  Specifies the name of the parameter.

* **ParameterValue** *(string)* –

  Specifies the value of the parameter.

* **Description** *(string)* –

  Provides a description of the parameter.

* **Source** *(string)* –

  Indicates the source of the parameter value.

* **ApplyType** *(string)* –

  Specifies the engine specific parameters type.

* **DataType** *(string)* –

  Specifies the valid data type for the parameter.

* **AllowedValues** *(string)* –

  Specifies the valid range of values for the parameter.

* **IsModifiable** *(boolean)* –

  Indicates whether (true) or not (false) the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.

* **MinimumEngineVersion** *(string)* –

  The earliest engine version to which the parameter can apply.

* **ApplyMethod** *(string)* –

  Indicates when to apply parameter updates.
Boto3 Documentation, Release 1.1.4

Response Structure

- (dict) – Contains the result of a successful invocation of the ModifyDBParameterGroup or ResetDBParameterGroup action.
  - **DBParameterGroupName** *(string)* – Provides the name of the DB parameter group.

modify_db_subnet_group(**kwargs)

Modifies an existing DB subnet group. DB subnet groups must contain at least one subnet in at least two AZs in the region.

Request Syntax

```python
response = client.modify_db_subnet_group(
    DBSubnetGroupName='string',
    DBSubnetGroupDescription='string',
    SubnetIds=[
        'string',
    ]
)
```

Parameters

- **DBSubnetGroupName** *(string)* – [REQUIRED]
  The name for the DB subnet group. This value is stored as a lowercase string.
  Constraints: Must contain no more than 255 alphanumeric characters or hyphens. Must not be “Default”.
  Example: mySubnetgroup

- **DBSubnetGroupDescription** *(string)* – The description for the DB subnet group.

- **SubnetIds** *(list)* – [REQUIRED]
  The EC2 subnet IDs for the DB subnet group.
  - *(string)* –

Return type  dict

Returns

Response Syntax

```python
{
    'DBSubnetGroup': {
        'DBSubnetGroupName': 'string',
        'DBSubnetGroupDescription': 'string',
        'VpcId': 'string',
        'SubnetGroupStatus': 'string',
        'Subnets': [
            {
                'SubnetIdentifier': 'string',
                'SubnetAvailabilityZone': {
                    'Name': 'string'
                }
            },
        ]
    }
}
```
Response Structure

- (dict) –
  
  Contains the result of a successful invocation of the following actions:
  - CreateDBSubnetGroup
  - ModifyDBSubnetGroup
  - DescribeDBSubnetGroups
  - DeleteDBSubnetGroup
  
  This data type is used as a response element in the DescribeDBSubnetGroups action.

  - DBSubnetGroup (dict) –
    
    Contains the result of a successful invocation of the following actions:
    * CreateDBSubnetGroup
    * ModifyDBSubnetGroup
    * DescribeDBSubnetGroups
    * DeleteDBSubnetGroup
    
    This data type is used as a response element in the DescribeDBSubnetGroups action.

    * DBSubnetGroupName (string) –
      
      Specifies the name of the DB subnet group.

    * DBSubnetGroupDescription (string) –
      
      Provides the description of the DB subnet group.

    * VpcId (string) –
      
      Provides the VpcId of the DB subnet group.

    * SubnetGroupStatus (string) –
      
      Provides the status of the DB subnet group.

    * Subnets (list) –
      
      Contains a list of Subnet elements.

      * (dict) –
        
        This data type is used as a response element in the DescribeDBSubnetGroups action.

      * SubnetIdentifier (string) –
        
        Specifies the identifier of the subnet.

      * SubnetAvailabilityZone (dict) –
        
        Contains Availability Zone information.

        This data type is used as an element in the following data type:

        * OrderableDBInstanceOption

        * Name (string) –
          
          The name of the availability zone.

        * SubnetStatus (string) –
          
          Specifies the status of the subnet.
**modify_event_subscription(**\*kwargs\*)

Modifies an existing RDS event notification subscription. Note that you cannot modify the source identifiers using this call; to change source identifiers for a subscription, use the AddSourceIdentifierToSubscription and RemoveSourceIdentifierFromSubscription calls.

You can see a list of the event categories for a given SourceType in the Events topic in the Amazon RDS User Guide or by using the DescribeEventCategories action.

**Request Syntax**

```python
response = client.modify_eventSubscription(
    SubscriptionName='string',
    SnsTopicArn='string',
    SourceType='string',
    EventCategories=[
        'string',
    ],
    Enabled=True|False
)
```

**Parameters**

- **SubscriptionName** *(string)* – [REQUIRED]
  
  The name of the RDS event notification subscription.

- **SnsTopicArn** *(string)* – The Amazon Resource Name (ARN) of the SNS topic created for event notification. The ARN is created by Amazon SNS when you create a topic and subscribe to it.

- **SourceType** *(string)* – The type of source that will be generating the events. For example, if you want to be notified of events generated by a DB instance, you would set this parameter to db-instance. If this value is not specified, all events are returned.

  Valid values: db-instance | db-parameter-group | db-security-group | db-snapshot

- **EventCategories** *(list)* – A list of event categories for a SourceType that you want to subscribe to. You can see a list of the categories for a given SourceType in the Events topic in the Amazon RDS User Guide or by using the DescribeEventCategories action.

  - *(string)* –

- **Enabled** *(boolean)* – A Boolean value; set to true to activate the subscription.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'EventSubscription': {
        'CustomerAwsId': 'string',
        'CustSubscriptionId': 'string',
        'SnsTopicArn': 'string',
        'Status': 'string',
        'SubscriptionCreationTime': 'string',
        'SourceType': 'string',
        'SourceIdsList': [
            'string',
        ],
        'EventCategoriesList': [
            'string',
        ],
    }
}
```
Response Structure

- (dict) –

Contains the results of a successful invocation of the DescribeEventSubscriptions action.

- EventSubscription (dict) –

Contains the results of a successful invocation of the DescribeEventSubscriptions action.

* CustomerAwsId (string) –

The AWS customer account associated with the RDS event notification subscription.

* CustSubscriptionId (string) –

The RDS event notification subscription Id.

* SnsTopicArn (string) –

The topic ARN of the RDS event notification subscription.

* Status (string) –

The status of the RDS event notification subscription.

Constraints:

Can be one of the following: creating | modifying | deleting | active | no-permission | topic-not-exist

The status “no-permission” indicates that RDS no longer has permission to post to the SNS topic. The status “topic-not-exist” indicates that the topic was deleted after the subscription was created.

* SubscriptionCreationTime (string) –

The time the RDS event notification subscription was created.

* SourceType (string) –

The source type for the RDS event notification subscription.

* SourceIdsList (list) –

A list of source IDs for the RDS event notification subscription.

  · (string) –

* EventCategoriesList (list) –

A list of event categories for the RDS event notification subscription.

  · (string) –

* Enabled (boolean) –

A Boolean value indicating if the subscription is enabled. True indicates the subscription is enabled.

modify_option_group (**kwargs)

Modifies an existing option group.

Request Syntax
response = client.modify_option_group(
    OptionGroupName='string',
    OptionsToInclude=[
        {
            'OptionName': 'string',
            'Port': 123,
            'DBSecurityGroupMemberships': [
                'string',
            ],
            'VpcSecurityGroupMemberships': [
                'string',
            ],
            'OptionSettings': [
                {
                    'Name': 'string',
                    'Value': 'string',
                    'DefaultValue': 'string',
                    'Description': 'string',
                    'ApplyType': 'string',
                    'DataType': 'string',
                    'AllowedValues': 'string',
                    'IsModifiable': True|False,
                    'IsCollection': True|False,
                },
            ]
        },
    ],
    OptionsToRemove=[
        'string',
    ],
    ApplyImmediately=True|False
)

Parameters

- **OptionGroupName (string)** – [REQUIRED]

The name of the option group to be modified.

Permanent options, such as the TDE option for Oracle Advanced Security TDE, cannot be removed from an option group, and that option group cannot be removed from a DB instance once it is associated with a DB instance.

- **OptionsToInclude (list)** – Options in this list are added to the option group or, if already present, the specified configuration is used to update the existing configuration.
  - **(dict)** – A list of all available options
    - **OptionName (string)** – [REQUIRED]
      The configuration of options to include in a group.
    - **Port (integer)** – The optional port for the option.
    - **DBSecurityGroupMemberships (list)** – A list of DBSecurityGroupMembership name strings used for this option.
    - **VpcSecurityGroupMemberships (list)** –
A list of VpcSecurityGroupMembership name strings used for this option.
· (string) –

* OptionSettings (list) –
The option settings to include in an option group.
· (dict) –

  Option settings are the actual settings being applied or configured for that option. It is used when you modify an option group or describe option groups. For example, the NATIVE_NETWORK_ENCRYPTION option has a setting called SQLNET.ENCRYPTION_SERVER that can have several different values.
· Name (string) –
The name of the option that has settings that you can set.
· Value (string) –
The current value of the option setting.
· DefaultValue (string) –
The default value of the option setting.
· Description (string) –
The description of the option setting.
· ApplyType (string) –
The DB engine specific parameter type.
· DataType (string) –
The data type of the option setting.
· AllowedValues (string) –
The allowed values of the option setting.
· IsModifiable (boolean) –
  A Boolean value that, when true, indicates the option setting can be modified from the default.
· IsCollection (boolean) –
  Indicates if the option setting is part of a collection.

* OptionsToRemove (list) – Options in this list are removed from the option group.
  – (string) –

* ApplyImmediately (boolean) – Indicates whether the changes should be applied immediately, or during the next maintenance window for each instance associated with the option group.

Return type  dict

Returns

Response Syntax

```py
{
    'OptionGroup': {
        'OptionGroupName': 'string',
        'OptionGroupDescription': 'string',
        'EngineName': 'string',
        'MajorEngineVersion': 'string',
        'Options': [
```
Response Structure

- (dict) -
  - OptionGroup (dict) -
    - OptionGroupName (string) -
      Specifies the name of the option group.
    - OptionGroupDescription (string) -
      Provides a description of the option group.
    - EngineName (string) -
      Indicates the name of the engine that this option group can be applied to.
    - MajorEngineVersion (string) -
      Indicates the major engine version associated with this option group.
    - Options (list) -
      Indicates what options are available in the option group.
        - (dict) -
          Option details.
- **OptionName** *(string)* –
  The name of the option.
- **OptionDescription** *(string)* –
  The description of the option.
- **Persistent** *(boolean)* –
  Indicate if this option is persistent.
- **Permanent** *(boolean)* –
  Indicate if this option is permanent.
- **Port** *(integer)* –
  If required, the port configured for this option to use.
- **OptionSettings** *(list)* –
  The option settings for this option.
  - *(dict)* –
    Option settings are the actual settings being applied or configured for that option. It is used when you modify an option group or describe option groups. For example, the NATIVE_NETWORK_ENCRYPTION option has a setting called SQLNET.ENCRYPTION_SERVER that can have several different values.
- **Name** *(string)* –
  The name of the option that has settings that you can set.
- **Value** *(string)* –
  The current value of the option setting.
- **DefaultValue** *(string)* –
  The default value of the option setting.
- **Description** *(string)* –
  The description of the option setting.
- **ApplyType** *(string)* –
  The DB engine specific parameter type.
- **DataType** *(string)* –
  The data type of the option setting.
- **AllowedValues** *(string)* –
  The allowed values of the option setting.
- **IsModifiable** *(boolean)* –
  A Boolean value that, when true, indicates the option setting can be modified from the default.
- **IsCollection** *(boolean)* –
  Indicates if the option setting is part of a collection.
- **DBSecurityGroupMemberships** *(list)* –
  If the option requires access to a port, then this DB security group allows access to the port.
  - *(dict)* –
    This data type is used as a response element in the following actions:
    - ModifyDBInstance
- ReBootDBInstance
- RestoreDBInstanceFromDBSnapshot
- RestoreDBInstanceToPointInTime
- **DBSecurityGroupName (string)** –
  The name of the DB security group.
- **Status (string)** –
  The status of the DB security group.
- **VpcSecurityGroupMemberships (list)** –
  If the option requires access to a port, then this VPC security group allows access to the port.
- **(dict)** –
  This data type is used as a response element for queries on VPC security group membership.
- **VpcSecurityGroupId (string)** –
  The name of the VPC security group.
- **Status (string)** –
  The status of the VPC security group.
- **AllowVpcAndNonVpcInstanceMemberships (boolean)** –
  Indicates whether this option group can be applied to both VPC and non-VPC instances. The value true indicates the option group can be applied to both VPC and non-VPC instances.
- **VpcId (string)** –
  If **AllowVpcAndNonVpcInstanceMemberships** is false, this field is blank. If **AllowVpcAndNonVpcInstanceMemberships** is true and this field is blank, then this option group can be applied to both VPC and non-VPC instances. If this field contains a value, then this option group can only be applied to instances that are in the VPC indicated by this field.

**promote_read_replica(**kwargs**)**

Promotes a Read Replica DB instance to a standalone DB instance.

**Note:** We recommend that you enable automated backups on your Read Replica before promoting the Read Replica. This ensures that no backup is taken during the promotion process. Once the instance is promoted to a primary instance, backups are taken based on your backup settings.

**Request Syntax**

```python
response = client.promote_read_replica(
    DBInstanceIdentifier='string',
    BackupRetentionPeriod=123,
    PreferredBackupWindow='string'
)
```

**Parameters**

- **DBInstanceIdentifier (string)** – [REQUIRED]
  The DB instance identifier. This value is stored as a lowercase string.
  Constraints:
  - Must be the identifier for an existing Read Replica DB instance
  - Must contain from 1 to 63 alphanumeric characters or hyphens
• First character must be a letter
• Cannot end with a hyphen or contain two consecutive hyphens
Example: mydbinstance

• **BackupRetentionPeriod** *(integer)* – The number of days to retain automated backups. Setting this parameter to a positive number enables backups. Setting this parameter to 0 disables automated backups.

  Default: 1

  Constraints:
  – Must be a value from 0 to 8

• **PreferredBackupWindow** *(string)* – The daily time range during which automated backups are created if automated backups are enabled, using the `BackupRetentionPeriod` parameter.

  Default: A 30-minute window selected at random from an 8-hour block of time per region. To see the time blocks available, see Adjusting the Preferred Maintenance Window in the Amazon RDS User Guide.

  Constraints:
  – Must be in the format `hh24:mi-hh24:mi`.
  – Times should be in Universal Coordinated Time (UTC).
  – Must not conflict with the preferred maintenance window.
  – Must be at least 30 minutes.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'DBInstance': {
        'DBInstanceIdentifier': 'string',
        'DBInstanceClass': 'string',

Response Structure

- **(dict)** –

  Contains the result of a successful invocation of the following actions:
  - CreateDBInstance
  - DeleteDBInstance
  - ModifyDBInstance

  This data type is used as a response element in the DescribeDBInstances action.

- **DBInstance (dict)** –

  Contains the result of a successful invocation of the following actions:
  * CreateDBInstance
  * DeleteDBInstance
  * ModifyDBInstance

  This data type is used as a response element in the DescribeDBInstances action.

  - **DBInstanceIdentifier (string)** –
    Contains a user-supplied database identifier. This identifier is the unique key that identifies a DB instance.

  - **DBInstanceClass (string)** –
    Contains the name of the compute and memory capacity class of the DB instance.

  - **Engine (string)** –
    Provides the name of the database engine to be used for this DB instance.

  - **DBInstanceStatus (string)** –
    Specifies the current state of this database.

  - **MasterUsername (string)** –
    Contains the master username for the DB instance.

  - **DBName (string)** –
    The meaning of this parameter differs according to the database
engine you use. For example, this value returns either MySQL or PostgreSQL information when returning values from CreateDBInstanceReadReplica since Read Replicas are only supported for MySQL and PostgreSQL.

MySQL, SQL Server, PostgreSQL
Contains the name of the initial database of this instance that was provided at create time, if one was specified when the DB instance was created. This same name is returned for the life of the DB instance.

**Type:** String

Oracle
Contains the Oracle System ID (SID) of the created DB instance. Not shown when the returned parameters do not apply to an Oracle DB instance.

* **Endpoint** *(dict)* –

  Specifies the connection endpoint.
  - **Address** *(string)* –
    Specifies the DNS address of the DB instance.
  - **Port** *(integer)* –
    Specifies the port that the database engine is listening on.

* **AllocatedStorage** *(integer)* –

  Specifies the allocated storage size specified in gigabytes.

* **InstanceCreateTime** *(datetime)* –

  Provides the date and time the DB instance was created.

* **PreferredBackupWindow** *(string)* –

  Specifies the daily time range during which automated backups are created if automated backups are enabled, as determined by the BackupRetentionPeriod.

* **BackupRetentionPeriod** *(integer)* –

  Specifies the number of days for which automatic DB snapshots are retained.

* **DBSecurityGroups** *(list)* –

  Provides List of DB security group elements containing only DBSecurityGroup.Name and DBSecurityGroup.Status subelements.
  - *(dict)* –
    This data type is used as a response element in the following actions:
    - ModifyDBInstance
    - RebootDBInstance
    - RestoreDBInstanceFromDBSnapshot
    - RestoreDBInstanceToPointInTime
    - **DBSecurityGroupName** *(string)* –
      The name of the DB security group.
    - **Status** *(string)* –
      The status of the DB security group.

* **VpcSecurityGroups** *(list)* –
Provides List of VPC security group elements that the DB instance belongs to.

- **(dict)** –

  This data type is used as a response element for queries on VPC security group membership.

- **VpcSecurityGroupId (string)** –

  The name of the VPC security group.

- **Status (string)** –

  The status of the VPC security group.

* **DBParameterGroups (list)** –

Provides the list of DB parameter groups applied to this DB instance.

- **(dict)** –

  The status of the DB parameter group.

  This data type is used as a response element in the following actions:

  - CreateDBInstance
  - CreateDBInstanceReadReplica
  - DeleteDBInstance
  - ModifyDBInstance
  - RebootDBInstance
  - RestoreDBInstanceFromDBSnapshot

- **DBParameterGroupName (string)** –

  The name of the DP parameter group.

- **ParameterApplyStatus (string)** –

  The status of parameter updates.

* **AvailabilityZone (string)** –

  Specifies the name of the Availability Zone the DB instance is located in.

* **DBSubnetGroup (dict)** –

  Specifies information on the subnet group associated with the DB instance, including the name, description, and subnets in the subnet group.

  - **DBSubnetGroupName (string)** –

    Specifies the name of the DB subnet group.

  - **DBSubnetGroupDescription (string)** –

    Provides the description of the DB subnet group.

  - **VpcId (string)** –

    Provides the VpcId of the DB subnet group.

  - **SubnetGroupStatus (string)** –

    Provides the status of the DB subnet group.

  - **Subnets (list)** –

    Contains a list of Subnet elements.

  - **(dict)** –

    This data type is used as a response element in the DescribeDBSubnetGroups action.
· **SubnetIdentifier** *(string)* –
  Specifies the identifier of the subnet.
· **SubnetAvailabilityZone** *(dict)* –
  Contains Availability Zone information.
  This data type is used as an element in the following data type:
· **OrderableDBInstanceOption**
· **Name** *(string)* –
  The name of the availability zone.
· **SubnetStatus** *(string)* –
  Specifies the status of the subnet.

* **PreferredMaintenanceWindow** *(string)* –
  Specifies the weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).

* **PendingModifiedValues** *(dict)* –
  Specifies that changes to the DB instance are pending. This element is only included when changes are pending. Specific changes are identified by subelements.
· **DBInstanceClass** *(string)* –
  Contains the new `DBInstanceClass` for the DB instance that will be applied or is in progress.
· **AllocatedStorage** *(integer)* –
  Contains the new `AllocatedStorage` size for the DB instance that will be applied or is in progress.
· **MasterUserPassword** *(string)* –
  Contains the pending or in-progress change of the master credentials for the DB instance.
· **Port** *(integer)* –
  Specifies the pending port for the DB instance.
· **BackupRetentionPeriod** *(integer)* –
  Specifies the pending number of days for which automated backups are retained.
· **MultiAZ** *(boolean)* –
  Indicates that the Single-AZ DB instance is to change to a Multi-AZ deployment.
· **EngineVersion** *(string)* –
  Indicates the database engine version.
· **Iops** *(integer)* –
  Specifies the new Provisioned IOPS value for the DB instance that will be applied or is being applied.
· **DBInstanceIdentifier** *(string)* –
  Contains the new `DBInstanceIdentifier` for the DB instance that will be applied or is in progress.
· **StorageType** *(string)* –
  Specifies the storage type to be associated with the DB instance.
· **CACertificateIdentifier** *(string)* –
  Specifies the identifier of the CA certificate for the DB instance.

* **LatestRestorableTime** *(datetime)* –
  Specifies the latest time to which a database can be restored with point-in-time restore.

* **MultiAZ** *(boolean)* –
  Specifies if the DB instance is a Multi-AZ deployment.

* **EngineVersion** *(string)* –
  Indicates the database engine version.

* **AutoMinorVersionUpgrade** *(boolean)* –
  Indicates that minor version patches are applied automatically.

* **ReadReplicaSourceDBInstanceIdentifier** *(string)* –
  Contains the identifier of the source DB instance if this DB instance is a Read Replica.

* **ReadReplicaDBInstanceIdentifiers** *(list)* –
  Contains one or more identifiers of the Read Replicas associated with this DB instance.

* **LicenseModel** *(string)* –
  License model information for this DB instance.

* **Iops** *(integer)* –
  Specifies the Provisioned IOPS (I/O operations per second) value.

* **OptionGroupMemberships** *(list)* –
  Provides the list of option group memberships for this DB instance.
  · *(dict)* –
    Provides information on the option groups the DB instance is a member of.
  · **OptionGroupName** *(string)* –
    The name of the option group that the instance belongs to.
  · **Status** *(string)* –
    The status of the DB instance’s option group membership (e.g. in-sync, pending, pending-maintenance, applying).

* **CharacterSetName** *(string)* –
  If present, specifies the name of the character set that this instance is associated with.

* **SecondaryAvailabilityZone** *(string)* –
  If present, specifies the name of the secondary Availability Zone for a DB instance with multi-AZ support.

* **PubliclyAccessible** *(boolean)* –
  Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.
Default: The default behavior varies depending on whether a VPC has been requested or not. The following list shows the default behavior in each case.

- **Default VPC**: true
- **VPC**: false

If no DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be publicly accessible. If a specific DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be private.

* **StatusInfos (list)** –

The status of a Read Replica. If the instance is not a Read Replica, this will be blank.

- **(dict)** –
  - Provides a list of status information for a DB instance.
    - **StatusType (string)** –
      - This value is currently “read replication.”
    - **Normal (boolean)** –
      - Boolean value that is true if the instance is operating normally, or false if the instance is in an error state.
    - **Status (string)** –
      - Status of the DB instance. For a StatusType of read replica, the values can be replicating, error, stopped, or terminated.
    - **Message (string)** –
      - Details of the error if there is an error for the instance. If the instance is not in an error state, this value is blank.

* **StorageType (string)** –

Specifies the storage type associated with DB instance.

* **TdeCredentialArn (string)** –

The ARN from the Key Store with which the instance is associated for TDE encryption.

* **DbInstancePort (integer)** –

Specifies the port that the DB instance listens on. If the DB instance is part of a DB cluster, this can be a different port than the DB cluster port.

* **DBClusterIdentifier (string)** –

If the DB instance is a member of a DB cluster, contains the name of the DB cluster that the DB instance is a member of.

* **StorageEncrypted (boolean)** –

Specifies whether the DB instance is encrypted.

* **KmsKeyId (string)** –

If StorageEncrypted is true, the KMS key identifier for the encrypted DB instance.

* **DbiResourceId (string)** –

If StorageEncrypted is true, the region-unique, immutable identifier for the encrypted DB instance. This identifier is found
in AWS CloudTrail log entries whenever the KMS key for the DB instance is accessed.

* **CACertificateIdentifier (string)** –
  
The identifier of the CA certificate for this DB instance.

* **DomainMemberships (list)** –
  
The Active Directory Domain membership records associated with the DB instance.
  
  · **(dict)** –
    
    An Active Directory Domain membership record associated with the DB instance.
    
    · **Domain (string)** –
      
      The identifier of the Active Directory Domain.
    
    · **Status (string)** –
      
      The status of the DB instance’s Active Directory Domain membership (e.g. joined, pending-join, failed etc).
    
    · **Connectivity (string)** –
      
      The observed connectivity of the Active Directory Domain.

* **CopyTagsToSnapshot (boolean)** –
  
  This property is not currently implemented.

```python
purchase_reserved_db_instances_offering(**kwargs)
```

Purchases a reserved DB instance offering.

**Request Syntax**

```python
response = client.purchase_reserved_db_instances_offering(
    ReservedDBInstancesOfferingId='string',
    ReservedDBInstanceId='string',
    DBInstanceCount=123,
    Tags=[
        {'Key': 'string',
         'Value': 'string'}
    ]
)
```

**Parameters**

- **ReservedDBInstancesOfferingId (string)** – [REQUIRED]
  
  The ID of the Reserved DB instance offering to purchase.

  Example: 438012d3-4052-4cc7-b2e3-8d3372e0e706

- **ReservedDBInstanceId (string)** – Customer-specified identifier to track this reservation.

  Example: myreservationID

- **DBInstanceCount (integer)** – The number of instances to reserve.

  Default: 1

- **Tags (list)** – A list of tags.

  - **(dict)** –
    
    Metadata assigned to an Amazon RDS resource consisting of a key-value pair.
**Key**: (string) –

A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, _, ., /, =, +, - (Java regex: “^([\p{L}\p{Z}\p{N}_.:/=\+\-]*)$”).

**Value**: (string) –

A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, _, ., /, =, +, - (Java regex: “^([\p{L}\p{Z}\p{N}_.:/=\+\-]*)$”).

**Return type**: dict

**Returns**

**Response Syntax**

```python
{
    'ReservedDBInstance': {
        'ReservedDBInstanceId': 'string',
        'ReservedDBInstancesOfferingId': 'string',
        'DBInstanceClass': 'string',
        'StartTime': datetime(2015, 1, 1),
        'Duration': 123,
        'FixedPrice': 123.0,
        'UsagePrice': 123.0,
        'CurrencyCode': 'string',
        'DBInstanceCount': 123,
        'ProductDescription': 'string',
        'OfferingType': 'string',
        'MultiAZ': True|False,
        'State': 'string',
        'RecurringCharges': [  
            {'RecurringChargeAmount': 123.0,  
             'RecurringChargeFrequency': 'string'},  
        ],
    }
}
```

**Response Structure**

* (dict) –

This data type is used as a response element in the DescribeReservedDBInstances and PurchaseReservedDBInstancesOffering actions.

– **ReservedDBInstance**: (dict) –

This data type is used as a response element in the DescribeReservedDBInstances and PurchaseReservedDBInstancesOffering actions.

* **ReservedDBInstanceId**: (string) –

The unique identifier for the reservation.

* **ReservedDBInstancesOfferingId**: (string) –

The offering identifier.
The DB instance class for the reserved DB instance.

* **StartTime** *(datetime)* –
  The time the reservation started.

* **Duration** *(integer)* –
  The duration of the reservation in seconds.

* **FixedPrice** *(float)* –
  The fixed price charged for this reserved DB instance.

* **UsagePrice** *(float)* –
  The hourly price charged for this reserved DB instance.

* **CurrencyCode** *(string)* –
  The currency code for the reserved DB instance.

* **DBInstanceCount** *(integer)* –
  The number of reserved DB instances.

* **ProductDescription** *(string)* –
  The description of the reserved DB instance.

* **OfferingType** *(string)* –
  The offering type of this reserved DB instance.

* **MultiAZ** *(boolean)* –
  Indicates if the reservation applies to Multi-AZ deployments.

* **State** *(string)* –
  The state of the reserved DB instance.

* **RecurringCharges** *(list)* –
  The recurring price charged to run this reserved DB instance.

  · *(dict)* –
    This data type is used as a response element in the
    DescribeReservedDBInstances and DescribeReservedDBInst-
    ancesOfferings actions.

  · **RecurringChargeAmount** *(float)* –
    The amount of the recurring charge.

  · **RecurringChargeFrequency** *(string)* –
    The frequency of the recurring charge.

**reboot_db_instance**( **kwargs)**

Rebooting a DB instance restarts the database engine service. A reboot also applies to the DB instance any modifications to the associated DB parameter group that were pending. Rebooting a DB instance results in a momentary outage of the instance, during which the DB instance status is set to rebooting. If the RDS instance is configured for MultiAZ, it is possible that the reboot will be conducted through a failover. An Amazon RDS event is created when the reboot is completed.

If your DB instance is deployed in multiple Availability Zones, you can force a failover from one AZ to the other during the reboot. You might force a failover to test the availability of your DB instance deployment or to restore operations to the original AZ after a failover occurs.

The time required to reboot is a function of the specific database engine’s crash recovery process. To improve the reboot time, we recommend that you reduce database activities as much as possible during the reboot process to reduce rollback activity for in-transit transactions.

**Request Syntax**
response = client.reboot_db_instance(
    DBInstanceIdentifier='string',
    ForceFailover=True|False
)

Parameters

- **DBInstanceIdentifier** *(string) – [REQUIRED]*
  The DB instance identifier. This parameter is stored as a lowercase string.
  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **ForceFailover** *(boolean)* – When true, the reboot will be conducted through a MultiAZ failover.
  Constraint: You cannot specify true if the instance is not configured for MultiAZ.

Return type  dict

Returns

Response Syntax

```json
{
    'DBInstance': {
        'DBInstanceIdentifier': 'string',

Response Structure

- (dict) –

Contains the result of a successful invocation of the following actions:
- CreateDBInstance
- DeleteDBInstance
- ModifyDBInstance

This data type is used as a response element in the DescribeDBInstances action.

- DBInstance (dict) –

Contains the result of a successful invocation of the following actions:
- CreateDBInstance
- DeleteDBInstance
- ModifyDBInstance

This data type is used as a response element in the DescribeDBInstances action.

- DBInstanceIdentifier (string) –

Contains a user-supplied database identifier. This identifier is the unique key that identifies a DB instance.

- DBInstanceClass (string) –

Contains the name of the compute and memory capacity class of the DB instance.

- Engine (string) –

Provides the name of the database engine to be used for this DB instance.

- DBInstanceStatus (string) –

Specifies the current state of this database.

- MasterUsername (string) –

Contains the master username for the DB instance.

- DBName (string) –

The meaning of this parameter differs according to the database engine you use. For example, this value returns either MySQL or PostgreSQL information when returning values from CreateDBInstanceReadReplica since Read Replicas are only supported for MySQL and PostgreSQL.
MySQL, SQL Server, PostgreSQL
Contains the name of the initial database of this instance that was
provided at create time, if one was specified when the DB instance
was created. This same name is returned for the life of the DB
instance.
Type: String
Oracle
Contains the Oracle System ID (SID) of the created DB instance.
Not shown when the returned parameters do not apply to an Oracle
DB instance.
* Endpoint (dict) –
  Specifies the connection endpoint.
    · Address (string) –
      Specifies the DNS address of the DB instance.
    · Port (integer) –
      Specifies the port that the database engine is listening on.
* AllocatedStorage (integer) –
  Specifies the allocated storage size specified in gigabytes.
* InstanceCreateTime (datetime) –
  Provides the date and time the DB instance was created.
* PreferredBackupWindow (string) –
  Specifies the daily time range during which automated backups are
  created if automated backups are enabled, as determined by the
  BackupRetentionPeriod.
* BackupRetentionPeriod (integer) –
  Specifies the number of days for which automatic DB snapshots are
  retained.
* DBSecurityGroups (list) –
  Provides List of DB security group elements containing only
  DBSecurityGroup.Name and
  DBSecurityGroup.Status subelements.
    · (dict) –
      This data type is used as a response element in the following
      actions:
        · ModifyDBInstance
        · RebootDBInstance
        · RestoreDBInstanceFromDBSnapshot
        · RestoreDBInstanceToPointInTime
    · DBSecurityGroupName (string) –
      The name of the DB security group.
    · Status (string) –
      The status of the DB security group.
* VpcSecurityGroups (list) –
  Provides List of VPC security group elements that the DB instance
  belongs to.
    · (dict) –
This data type is used as a response element for queries on VPC security group membership.

- **VpcSecurityGroupId** *(string)* –
  The name of the VPC security group.
- **Status** *(string)* –
  The status of the VPC security group.

* **DBParameterGroups** *(list)* –
  Provides the list of DB parameter groups applied to this DB instance.
  - *(dict)* –
    The status of the DB parameter group.
  This data type is used as a response element in the following actions:
  - CreateDBInstance
  - CreateDBInstanceReadReplica
  - DeleteDBInstance
  - ModifyDBInstance
  - RebootDBInstance
  - RestoreDBInstanceFromDBSnapshot
  - **DBParameterGroupName** *(string)* –
    The name of the DP parameter group.
  - **ParameterApplyStatus** *(string)* –
    The status of parameter updates.

* **AvailabilityZone** *(string)* –
  Specifies the name of the Availability Zone the DB instance is located in.

* **DBSubnetGroup** *(dict)* –
  Specifies information on the subnet group associated with the DB instance, including the name, description, and subnets in the subnet group.
  - **DBSubnetGroupName** *(string)* –
    Specifies the name of the DB subnet group.
  - **DBSubnetGroupDescription** *(string)* –
    Provides the description of the DB subnet group.
  - **VpcId** *(string)* –
    Provides the VpcId of the DB subnet group.
  - **SubnetGroupStatus** *(string)* –
    Provides the status of the DB subnet group.
  - **Subnets** *(list)* –
    Contains a list of Subnet elements.
  - *(dict)* –
    This data type is used as a response element in the DescribeDBSubnetGroups action.
  - **SubnetIdentifier** *(string)* –
    Specifies the identifier of the subnet.
- **SubnetAvailabilityZone** *(dict)* –
  Contains Availability Zone information.
  
  This data type is used as an element in the following data type:
- **OrderableDBInstanceOption**
- **Name** *(string)* –
  The name of the availability zone.
- **SubnetStatus** *(string)* –
  Specifies the status of the subnet.

- **PreferredMaintenanceWindow** *(string)* –
  Specifies the weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).

- **PendingModifiedValues** *(dict)* –
  Specifies that changes to the DB instance are pending. This element is only included when changes are pending. Specific changes are identified by subelements.
  - **DBInstanceClass** *(string)* –
    Contains the new *DBInstanceClass* for the DB instance that will be applied or is in progress.
  - **AllocatedStorage** *(integer)* –
    Contains the new *AllocatedStorage* size for the DB instance that will be applied or is in progress.
  - **MasterUserPassword** *(string)* –
    Contains the pending or in-progress change of the master credentials for the DB instance.
  - **Port** *(integer)* –
    Specifies the pending port for the DB instance.
  - **BackupRetentionPeriod** *(integer)* –
    Specifies the pending number of days for which automated backups are retained.
  - **MultiAZ** *(boolean)* –
    Indicates that the Single-AZ DB instance is to change to a Multi-AZ deployment.
  - **EngineVersion** *(string)* –
    Indicates the database engine version.
  - **Iops** *(integer)* –
    Specifies the new Provisioned IOPS value for the DB instance that will be applied or is being applied.
  - **DBInstanceIdentifier** *(string)* –
    Contains the new *DBInstanceIdentifier* for the DB instance that will be applied or is in progress.
  - **StorageType** *(string)* –
    Specifies the storage type to be associated with the DB instance.
  - **CACertificateIdentifier** *(string)* –
Specifies the identifier of the CA certificate for the DB instance.

* **LatestRestorableTime** *(datetime)*
  Specifies the latest time to which a database can be restored with point-in-time restore.

* **MultiAZ** *(boolean)*
  Specifies if the DB instance is a Multi-AZ deployment.

* **EngineVersion** *(string)*
  Indicates the database engine version.

* **AutoMinorVersionUpgrade** *(boolean)*
  Indicates that minor version patches are applied automatically.

* **ReadReplicaSourceDBInstanceIdentifier** *(string)*
  Contains the identifier of the source DB instance if this DB instance is a Read Replica.

* **ReadReplicaDBInstanceIdentifiers** *(list)*
  Contains one or more identifiers of the Read Replicas associated with this DB instance.

* **LicenseModel** *(string)*
  License model information for this DB instance.

* **Iops** *(integer)*
  Specifies the Provisioned IOPS (I/O operations per second) value.

* **OptionGroupMemberships** *(list)*
  Provides the list of option group memberships for this DB instance.

  * **gender** *(dict)*
    Provides information on the option groups the DB instance is a member of.

  * **OptionGroupName** *(string)*
    The name of the option group that the instance belongs to.

  * **Status** *(string)*
    The status of the DB instance’s option group membership (e.g. in-sync, pending, pending-maintenance, applying).

* **CharacterSetName** *(string)*
  If present, specifies the name of the character set that this instance is associated with.

* **SecondaryAvailabilityZone** *(string)*
  If present, specifies the name of the secondary Availability Zone for a DB instance with multi-AZ support.

* **PubliclyAccessible** *(boolean)*
  Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.
Default: The default behavior varies depending on whether a VPC has been requested or not. The following list shows the default behavior in each case.

- **Default VPC:** true
- **VPC:** false

If no DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be publicly accessible. If a specific DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be private.

* **StatusInfos (list)** –

The status of a Read Replica. If the instance is not a Read Replica, this will be blank.

  - (dict) –
    - Provides a list of status information for a DB instance.
    - **StatusType (string)** –
      - This value is currently “read replication.”
    - **Normal (boolean)** –
      - Boolean value that is true if the instance is operating normally, or false if the instance is in an error state.
    - **Status (string)** –
      - Status of the DB instance. For a StatusType of read replica, the values can be replicating, error, stopped, or terminated.
    - **Message (string)** –
      - Details of the error if there is an error for the instance. If the instance is not in an error state, this value is blank.

* **StorageType (string)** –

  Specifies the storage type associated with DB instance.

* **TdeCredentialArn (string)** –

  The ARN from the Key Store with which the instance is associated for TDE encryption.

* **DbInstancePort (integer)** –

  Specifies the port that the DB instance listens on. If the DB instance is part of a DB cluster, this can be a different port than the DB cluster port.

* **DBClusterIdentifier (string)** –

  If the DB instance is a member of a DB cluster, contains the name of the DB cluster that the DB instance is a member of.

* **StorageEncrypted (boolean)** –

  Specifies whether the DB instance is encrypted.

* **KmsKeyId (string)** –

  If StorageEncrypted is true, the KMS key identifier for the encrypted DB instance.

* **DbiResourceId (string)** –

  If StorageEncrypted is true, the region-unique, immutable identifier for the encrypted DB instance. This identifier is found

3494 Chapter 3. API Reference
in AWS CloudTrail log entries whenever the KMS key for the DB instance is accessed.

* **CACertificateIdentifier (string)** –
  The identifier of the CA certificate for this DB instance.

* **DomainMemberships (list)** –
  The Active Directory Domain membership records associated with the DB instance.
  
  · (dict) –
    An Active Directory Domain membership record associated with the DB instance.
    
    · **Domain (string)** –
      The identifier of the Active Directory Domain.
    
    · **Status (string)** –
      The status of the DB instance’s Active Directory Domain membership (e.g. joined, pending-join, failed etc).
    
    · **Connectivity (string)** –
      The observed connectivity of the Active Directory Domain.

* **CopyTagsToSnapshot (boolean)** –
  This property is not currently implemented.

remove_source_identifier_from_subscription(**kwargs)
Removes a source identifier from an existing RDS event notification subscription.

**Request Syntax**

```python
response = client.remove_source_identifier_from_subscription(
    SubscriptionName='string',
    SourceIdentifier='string'
)
```

**Parameters**

- **SubscriptionName (string)** – [REQUIRED]
  The name of the RDS event notification subscription you want to remove a source identifier from.

- **SourceIdentifier (string)** – [REQUIRED]
  The source identifier to be removed from the subscription, such as the DB instance identifier for a DB instance or the name of a security group.

**Return type**

**dict**

**Returns**

**Response Syntax**

```json
{
    'EventSubscription': {
        'CustomerAwsId': 'string',
        'CustSubscriptionId': 'string',
        'SnsTopicArn': 'string',
        'Status': 'string',
        'SubscriptionCreationTime': 'string',
        'SourceType': 'string',
        'SourceIdsList': [
            'string',
        ]
    }
}
```
Response Structure

• (dict) –
  Contains the results of a successful invocation of the DescribeEventSubscriptions action.

  – EventSubscription (dict) –
    Contains the results of a successful invocation of the DescribeEventSubscriptions action.
    * CustomerAwsId (string) –
      The AWS customer account associated with the RDS event notification subscription.
    * CustSubscriptionId (string) –
      The RDS event notification subscription Id.
    * SnsTopicArn (string) –
      The topic ARN of the RDS event notification subscription.
    * Status (string) –
      The status of the RDS event notification subscription.
    Constraints:
    Can be one of the following: creating | modifying | deleting | active | no-permission | topic-not-exist
    The status “no-permission” indicates that RDS no longer has permission to post to the SNS topic. The status “topic-not-exist” indicates that the topic was deleted after the subscription was created.
    * SubscriptionCreationTime (string) –
      The time the RDS event notification subscription was created.
    * SourceType (string) –
      The source type for the RDS event notification subscription.
    * SourceIdsList (list) –
      A list of source IDs for the RDS event notification subscription.
      * (string) –
    * EventCategoriesList (list) –
      A list of event categories for the RDS event notification subscription.
      * (string) –
    * Enabled (boolean) –
      A Boolean value indicating if the subscription is enabled. True indicates the subscription is enabled.

remove_tags_from_resource(**kwargs)
Removes metadata tags from an Amazon RDS resource.
For an overview on tagging an Amazon RDS resource, see Tagging Amazon RDS Resources.

Request Syntax

```python
response = client.remove_tags_from_resource(
    ResourceName='string',
    TagKeys=[
        'string',
    ]
)
```

Parameters

- **ResourceName** *(string)* – [REQUIRED]
  
  The Amazon RDS resource the tags will be removed from. This value is an Amazon Resource Name (ARN). For information about creating an ARN, see Constructing an RDS Amazon Resource Name (ARN).

- **TagKeys** *(list)* – [REQUIRED]
  
  The tag key (name) of the tag to be removed.

Returns

None

reset_db_cluster_parameter_group(**kwargs)

Modifies the parameters of a DB cluster parameter group to the default value. To reset specific parameters submit a list of the following: ParameterName and ApplyMethod. To reset the entire DB cluster parameter group, specify the DBClusterParameterGroupName and ResetAllParameters parameters.

When resetting the entire group, dynamic parameters are updated immediately and static parameters are set to pending-reboot to take effect on the next DB instance restart or RebootDBInstance request. You must call RebootDBInstance for every DB instance in your DB cluster that you want the updated static parameter to apply to.

For more information on Amazon Aurora, see Aurora on Amazon RDS in the Amazon RDS User Guide.

Request Syntax

```python
response = client.reset_db_cluster_parameter_group(
    DBClusterParameterGroupName='string',
    ResetAllParameters=True|False,
    Parameters=[
        {
            'ParameterName': 'string',
            'ParameterValue': 'string',
            'Description': 'string',
            'Source': 'string',
            'ApplyType': 'string',
            'DataType': 'string',
            'AllowedValues': 'string',
            'IsModifiable': True|False,
            'MinimumEngineVersion': 'string',
            'ApplyMethod': 'immediate'|'pending-reboot'
        },
    ]
)
```

Parameters
• **DBClusterParameterGroupName** *(string)* – **[REQUIRED]**
  
The name of the DB cluster parameter group to reset.

• **ResetAllParameters** *(boolean)* – A value that is set to `true` to reset all parameters in the DB cluster parameter group to their default values, and `false` otherwise. You cannot use this parameter if there is a list of parameter names specified for the `Parameters` parameter.

• **Parameters** *(list)* – A list of parameter names in the DB cluster parameter group to reset to the default values. You cannot use this parameter if the `ResetAllParameters` parameter is set to `true`.

  – *(dict)* –

  This data type is used as a request parameter in the `ModifyDBParameterGroup` and `ResetDBParameterGroup` actions.

  This data type is used as a response element in the `DescribeEngineDefaultParameters` and `DescribeDBParameters` actions.

  * **ParameterName** *(string)* –
    
    Specifies the name of the parameter.

  * **ParameterValue** *(string)* –
    
    Specifies the value of the parameter.

  * **Description** *(string)* –
    
    Provides a description of the parameter.

  * **Source** *(string)* –
    
    Indicates the source of the parameter value.

  * **ApplyType** *(string)* –
    
    Specifies the engine specific parameters type.

  * **DataType** *(string)* –
    
    Specifies the valid data type for the parameter.

  * **AllowedValues** *(string)* –
    
    Specifies the valid range of values for the parameter.

  * **IsModifiable** *(boolean)* –
    
    Indicates whether (`true`) or not (`false`) the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.

  * **MinimumEngineVersion** *(string)* –
    
    The earliest engine version to which the parameter can apply.

  * **ApplyMethod** *(string)* –
    
    Indicates when to apply parameter updates.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'DBClusterParameterGroupName': 'string'
}
```

**Response Structure**

• *(dict)* –
– **DBClusterParameterGroupName** *(string)* –

The name of the DB cluster parameter group.

Constraints:
* Must be 1 to 255 alphanumeric characters
* First character must be a letter
* Cannot end with a hyphen or contain two consecutive hyphens

**Note:** This value is stored as a lowercase string.

**reset_db_parameter_group** (**kwargs**)
Modifies the parameters of a DB parameter group to the engine/system default value. To reset specific parameters submit a list of the following: ParameterName and ApplyMethod. To reset the entire DB parameter group, specify the DBParameterGroup name and ResetAllParameters parameters. When resetting the entire group, dynamic parameters are updated immediately and static parameters are set to pending-reboot to take effect on the next DB instance restart or RebootDBInstance request.

**Request Syntax**

```python
response = client.reset_db_parameter_group(
    DBParameterGroupName='string',
    ResetAllParameters=True|False,
    Parameters=[
        {
            'ParameterName': 'string',
            'ParameterValue': 'string',
            'Description': 'string',
            'Source': 'string',
            'ApplyType': 'string',
            'DataType': 'string',
            'AllowedValues': 'string',
            'IsModifiable': True|False,
            'MinimumEngineVersion': 'string',
            'ApplyMethod': 'immediate'|'pending-reboot'
        },
    ]
)
```

**Parameters**

- **DBParameterGroupName** *(string)* – REQUIRED

  The name of the DB parameter group.

  Constraints:
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **ResetAllParameters** *(boolean)* – Specifies whether *(true)* or not *(false)* to reset all parameters in the DB parameter group to default values.

  Default: true

- **Parameters** *(list)* – An array of parameter names, values, and the apply method for the parameter update. At least one parameter name, value, and apply method must be supplied; subsequent arguments are optional. A maximum of 20 parameters can be modified in a single request.

  MySQL
Valid Values (for Apply method): immediate | pending-reboot

You can use the immediate value with dynamic parameters only. You can use the pending-reboot value for both dynamic and static parameters, and changes are applied when DB instance reboots.

Oracle

Valid Values (for Apply method): pending-reboot

- (dict) –

This data type is used as a request parameter in the ModifyDBParameterGroup and ResetDBParameterGroup actions.

This data type is used as a response element in the DescribeEngineDefaultParameters and DescribeDBParameters actions.

* ParameterName (string) –
  Specifies the name of the parameter.
* ParameterValue (string) –
  Specifies the value of the parameter.
* Description (string) –
  Provides a description of the parameter.
* Source (string) –
  Indicates the source of the parameter value.
* ApplyType (string) –
  Specifies the engine specific parameters type.
* DataType (string) –
  Specifies the valid data type for the parameter.
* AllowedValues (string) –
  Specifies the valid range of values for the parameter.
* IsModifiable (boolean) –
  Indicates whether (true) or not (false) the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.
* MinimumEngineVersion (string) –
  The earliest engine version to which the parameter can apply.
* ApplyMethod (string) –
  Indicates when to apply parameter updates.

Return type  dict

Returns

Response Syntax

```
{
    'DBParameterGroupName': 'string'
}
```

Response Structure

- (dict) –

Contains the result of a successful invocation of the ModifyDBParameterGroup or ResetDBParameterGroup action.
– **DBParameterGroupName** *(string)* –

Provides the name of the DB parameter group.

```python
restore_db_cluster_from_snapshot(**kwargs)
```

Creates a new DB cluster from a DB cluster snapshot. The target DB cluster is created from the source DB cluster restore point with the same configuration as the original source DB cluster, except that the new DB cluster is created with the default security group.

For more information on Amazon Aurora, see [Aurora on Amazon RDS](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/) in the *Amazon RDS User Guide*.

### Request Syntax

```python
response = client.restore_db_cluster_from_snapshot(
    AvailabilityZones=[
        'string',
    ],
    DBClusterIdentifier='string',
    SnapshotIdentifier='string',
    Engine='string',
    EngineVersion='string',
    Port=123,
    DBSubnetGroupName='string',
    DatabaseName='string',
    OptionGroupName='string',
    VpcSecurityGroupIds=[
        'string',
    ],
    Tags=[
        {'Key': 'string',
         'Value': 'string'}
    ],
)
```

### Parameters

- **AvailabilityZones** *(list)* – Provides the list of EC2 Availability Zones that instances in the restored DB cluster can be created in.
  
  - *(string)* –

- **DBClusterIdentifier** *(string)* – [REQUIRED]

  The name of the DB cluster to create from the DB cluster snapshot. This parameter isn’t case-sensitive.

  Constraints:
  
  - Must contain from 1 to 255 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

  Example: my-snapshot-id

- **SnapshotIdentifier** *(string)* – [REQUIRED]

  The identifier for the DB cluster snapshot to restore from.

  Constraints:
  
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **Engine** *(string)* – [REQUIRED]
The database engine to use for the new DB cluster.

Default: The same as source

Constraint: Must be compatible with the engine of the source

- **EngineVersion** *(string)* – The version of the database engine to use for the new DB cluster.

- **Port** *(integer)* – The port number on which the new DB cluster accepts connections.

  Constraints: Value must be 1150–65535

  Default: The same port as the original DB cluster.

- **DBSubnetGroupName** *(string)* – The name of the DB subnet group to use for the new DB cluster.

- **DatabaseName** *(string)* – The database name for the restored DB cluster.

- **OptionGroupName** *(string)* – The name of the option group to use for the restored DB cluster.

- **VpcSecurityGroupIds** *(list)* – A list of VPC security groups that the new DB cluster will belong to.
  - *(string)*

- **Tags** *(list)* – The tags to be assigned to the restored DB cluster.
  - *(dict)*

  Metadata assigned to an Amazon RDS resource consisting of a key-value pair.

  * **Key** *(string)* –

    A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘’, ‘/’, ‘\’, ‘=', ‘+’, ‘_’ (Java regex: “\p{L}[^\p{L}\p{Z}\p{N}\_\.:\=\+\-\*\?\^\$\}\{\}\[\]|\s]”).

  * **Value** *(string)* –

    A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘’, ‘/’, ‘\’, ‘=', ‘+’, ‘_’ (Java regex: “\p{L}[^\p{L}\p{Z}\p{N}\_\.:\=\+\-\*\?\^\$\}\{\}\[\]|\s]”)
Response Structure

- (dict) – Contains the result of a successful invocation of the following actions:
  - CreateDBCluster
  - DeleteDBCluster
  - FailoverDBCluster
  - ModifyDBCluster
  - RestoreDBClusterFromSnapshot

  This data type is used as a response element in the DescribeDBClusters action.

- DBCluster (dict) –

  Contains the result of a successful invocation of the following actions:
  - CreateDBCluster
  - DeleteDBCluster
  - FailoverDBCluster
  - ModifyDBCluster
  - RestoreDBClusterFromSnapshot

  This data type is used as a response element in the DescribeDBClusters action.

  - AllocatedStorage (integer) –

    Specifies the allocated storage size in gigabytes (GB).

  - AvailabilityZones (list) –

    Provides the list of EC2 Availability Zones that instances in the DB cluster can be created in.
- (string) –
  - BackupRetentionPeriod (integer) –
    Specifies the number of days for which automatic DB snapshots are
    retained.
  - CharacterSetName (string) –
    If present, specifies the name of the character set that this cluster is
    associated with.
  - DatabaseName (string) –
    Contains the name of the initial database of this DB cluster that was
    provided at create time, if one was specified when the DB cluster
    was created. This same name is returned for the life of the DB
    cluster.
  - DBClusterIdentifier (string) –
    Contains a user-supplied DB cluster identifier. This identifier is the
    unique key that identifies a DB cluster.
  - DBClusterParameterGroup (string) –
    Specifies the name of the DB cluster parameter group for the DB
    cluster.
  - DBSubnetGroup (string) –
    Specifies information on the subnet group associated with the DB
    cluster, including the name, description, and subnets in the subnet
    group.
  - Status (string) –
    Specifies the current state of this DB cluster.
  - PercentProgress (string) –
    Specifies the progress of the operation as a percentage.
  - EarliestRestorableTime (datetime) –
    Specifies the earliest time to which a database can be restored with
    point-in-time restore.
  - Endpoint (string) –
    Specifies the connection endpoint for the primary instance of the
    DB cluster.
  - Engine (string) –
    Provides the name of the database engine to be used for this DB
    cluster.
  - EngineVersion (string) –
    Indicates the database engine version.
  - LatestRestorableTime (datetime) –
    Specifies the latest time to which a database can be restored with
    point-in-time restore.
  - Port (integer) –
    Specifies the port that the database engine is listening on.
  - MasterUsername (string) –
    Contains the master username for the DB cluster.
  - DBClusterOptionGroupMemberships (list) –
    Provides the list of option group memberships for this DB cluster.
Boto3 Documentation, Release 1.1.4

- *(dict)* –
  Contains status information for a DB cluster option group.
  - **DBClusterOptionGroupName** *(string)* –
    Specifies the name of the DB cluster option group.
  - **Status** *(string)* –
    Specifies the status of the DB cluster option group.

- **PreferredBackupWindow** *(string)* –
  Specifies the daily time range during which automated backups are created if automated backups are enabled, as determined by the **BackupRetentionPeriod**.

- **PreferredMaintenanceWindow** *(string)* –
  Specifies the weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).

- **DBClusterMembers** *(list)* –
  Provides the list of instances that make up the DB cluster.
  - *(dict)* –
    Contains information about an instance that is part of a DB cluster.
    - **DBInstanceIdentifier** *(string)* –
      Specifies the instance identifier for this member of the DB cluster.
    - **IsClusterWriter** *(boolean)* –
      Value that is **true** if the cluster member is the primary instance for the DB cluster and **false** otherwise.
    - **DBClusterParameterGroupStatus** *(string)* –
      Specifies the status of the DB cluster parameter group for this member of the DB cluster.

- **VpcSecurityGroups** *(list)* –
  Provides a list of VPC security groups that the DB cluster belongs to.
  - *(dict)* –
    This data type is used as a response element for queries on VPC security group membership.
    - **VpcSecurityGroupId** *(string)* –
      The name of the VPC security group.
    - **Status** *(string)* –
      The status of the VPC security group.

**restore_db_cluster_to_point_in_time(**kwargs)**

Restores a DB cluster to an arbitrary point in time. Users can restore to any point in time before **LatestRestorableTime** for up to **BackupRetentionPeriod** days. The target DB cluster is created from the source DB cluster with the same configuration as the original DB cluster, except that the new DB cluster is created with the default DB security group.

For more information on Amazon Aurora, see **Aurora on Amazon RDS** in the **Amazon RDS User Guide**.

**Request Syntax**
response = client.restore_db_cluster_to_point_in_time(
    DBClusterIdentifier='string',
    SourceDBClusterIdentifier='string',
    RestoreToTime=datetime(2015, 1, 1),
    UseLatestRestorableTime=True|False,
    Port=123,
    DBSubnetGroupName='string',
    OptionGroupName='string',
    VpcSecurityGroupIds=['string'],
    Tags=[
        {'Key': 'string',
         'Value': 'string'},
    ],
)

Parameters

- **DBClusterIdentifier (string)** – [REQUIRED]

  The name of the new DB cluster to be created.

  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **SourceDBClusterIdentifier (string)** – [REQUIRED]

  The identifier of the source DB cluster from which to restore.

  Constraints:
  - Must be the identifier of an existing database instance
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **RestoreToTime (datetime)** – The date and time to restore the DB cluster to.

  Valid Values: Value must be a time in Universal Coordinated Time (UTC) format

  Constraints:
  - Must be before the latest restorable time for the DB instance
  - Cannot be specified if UseLatestRestorableTime parameter is true
  - Example: 2015-03-07T23:45:00Z

- **UseLatestRestorableTime (boolean)** – A value that is set to true to restore the DB cluster to the latest restorable backup time, and false otherwise.

  Default: false

  Constraints: Cannot be specified if RestoreToTime parameter is provided.

- **Port (integer)** – The port number on which the new DB cluster accepts connections.

  Constraints: Value must be 1150-65535

  Default: The same port as the original DB cluster.

- **DBSubnetGroupName (string)** – The DB subnet group name to use for the new DB cluster.
• **OptionGroupName** *(string)* – The name of the option group for the new DB cluster.

• **VpcSecurityGroupIds** *(list)* – A list of VPC security groups that the new DB cluster belongs to.
  - *(string)*

• **Tags** *(list)* – A list of tags.
  - *(dict)*

  Metadata assigned to an Amazon RDS resource consisting of a key-value pair.

  * **Key** *(string)* –

    A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘ ’, ‘=’, ‘+’, ‘.’ (Java regex: “^[\p{L}\p{Z}\p{N}_.:/=+\-]*$”).

  * **Value** *(string)* –

    A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘ ’, ‘=’, ‘+’, ‘.’ (Java regex: “^[\p{L}\p{Z}\p{N}_.:/=+\-]*$”).

**Return type** *dict*

**Returns**

**Response Syntax**

```json
{
  'DBCluster': {
    'AllocatedStorage': 123,
    'AvailabilityZones': [
      'string',
    ],
    'BackupRetentionPeriod': 123,
    'CharacterSetName': 'string',
    'DatabaseName': 'string',
    'DBClusterIdentifier': 'string',
    'DBClusterParameterGroup': 'string',
    'DBSubnetGroup': 'string',
    'Status': 'string',
    'PercentProgress': 'string',

        'DBClusterOptionGroupName': 'string',
        'Status': 'string'
      },
    ],
    'PreferredBackupWindow': 'string',
    'PreferredMaintenanceWindow': 'string',
  }
}
```
Response Structure

- (dict)

Contains the result of a successful invocation of the following actions:
- CreateDBCluster
- DeleteDBCluster
- FailoverDBCluster
- ModifyDBCluster
- RestoreDBClusterFromSnapshot

This data type is used as a response element in the DescribeDBClusters action.

- DBCluster (dict)

Contains the result of a successful invocation of the following actions:
- CreateDBCluster
- DeleteDBCluster
- FailoverDBCluster
- ModifyDBCluster
- RestoreDBClusterFromSnapshot

This data type is used as a response element in the DescribeDBClusters action.

- AllocatedStorage (integer)

  Specifies the allocated storage size in gigabytes (GB).

- AvailabilityZones (list)

  Provides the list of EC2 Availability Zones that instances in the DB cluster can be created in.

  - (string)

- BackupRetentionPeriod (integer)

  Specifies the number of days for which automatic DB snapshots are retained.

- CharacterSetName (string)

  If present, specifies the name of the character set that this cluster is associated with.

- DatabaseName (string)

  Contains the name of the initial database of this DB cluster that was provided at create time, if one was specified when the DB cluster was created. This same name is returned for the life of the DB cluster.
* **DBClusterIdentifier** *(string)* –
  Contains a user-supplied DB cluster identifier. This identifier is the
  unique key that identifies a DB cluster.

* **DBClusterParameterGroup** *(string)* –
  Specifies the name of the DB cluster parameter group for the DB
  cluster.

* **DBSubnetGroup** *(string)* –
  Specifies information on the subnet group associated with the DB
  cluster, including the name, description, and subnets in the subnet
  group.

* **Status** *(string)* –
  Specifies the current state of this DB cluster.

* **PercentProgress** *(string)* –
  Specifies the progress of the operation as a percentage.

* **EarliestRestorableTime** *(datetime)* –
  Specifies the earliest time to which a database can be restored with
  point-in-time restore.

* **Endpoint** *(string)* –
  Specifies the connection endpoint for the primary instance of the
  DB cluster.

* **Engine** *(string)* –
  Provides the name of the database engine to be used for this DB
  cluster.

* **EngineVersion** *(string)* –
  Indicates the database engine version.

* **LatestRestorableTime** *(datetime)* –
  Specifies the latest time to which a database can be restored with
  point-in-time restore.

* **Port** *(integer)* –
  Specifies the port that the database engine is listening on.

* **MasterUsername** *(string)* –
  Contains the master username for the DB cluster.

* **DBClusterOptionGroupMemberships** *(list)* –
  Provides the list of option group memberships for this DB cluster.
    · **(dict)** –
      Contains status information for a DB cluster option group.
        · **DBClusterOptionGroupName** *(string)* –
          Specifies the name of the DB cluster option group.
        · **Status** *(string)* –
          Specifies the status of the DB cluster option group.

* **PreferredBackupWindow** *(string)* –
  Specifies the daily time range during which automated backups are
  created if automated backups are enabled, as determined by the
  BackupRetentionPeriod.
* **PreferredMaintenanceWindow** *(string)* –
  Specifies the weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).

* **DBClusterMembers** *(list)* –
  Provides the list of instances that make up the DB cluster.
  · *(dict)* –
    Contains information about an instance that is part of a DB cluster.
    · **DBInstanceIdentifier** *(string)* –
      Specifies the instance identifier for this member of the DB cluster.
    · **IsClusterWriter** *(boolean)* –
      Value that is `true` if the cluster member is the primary instance for the DB cluster and `false` otherwise.
    · **DBClusterParameterGroupStatus** *(string)* –
      Specifies the status of the DB cluster parameter group for this member of the DB cluster.

* **VpcSecurityGroups** *(list)* –
  Provides a list of VPC security groups that the DB cluster belongs to.
  · *(dict)* –
    This data type is used as a response element for queries on VPC security group membership.
    · **VpcSecurityGroupId** *(string)* –
      The name of the VPC security group.
    · **Status** *(string)* –
      The status of the VPC security group.

**restore_db_instance_from_db_snapshot** (**kwargs)**

Creates a new DB instance from a DB snapshot. The target database is created from the source database restore point with the most of original configuration, but in a system chosen availability zone with the default security group, the default subnet group, and the default DB parameter group. By default, the new DB instance is created as a single-AZ deployment except when the instance is a SQL Server instance that has an option group that is associated with mirroring; in this case, the instance becomes a mirrored AZ deployment and not a single-AZ deployment.

If your intent is to replace your original DB instance with the new, restored DB instance, then rename your original DB instance before you call the RestoreDBInstanceFromDBSnapshot action. RDS does not allow two DB instances with the same name. Once you have renamed your original DB instance with a different identifier, then you can pass the original name of the DB instance as the DBInstanceIdentifier in the call to the RestoreDBInstanceFromDBSnapshot action. The result is that you will replace the original DB instance with the DB instance created from the snapshot.

**Request Syntax**

```python
response = client.restore_db_instance_from_db_snapshot(
    DBInstanceIdentifier='string',
    DBSnapshotIdentifier='string',
    DBInstanceClass='string',
    Port=123,
    AvailabilityZone='string',
)```
DBSubnetGroupName='string', MultiAZ=True|False, PubliclyAccessible=True|False, AutoMinorVersionUpgrade=True|False, LicenseModel='string', DBName='string', Engine='string', Iops=123, OptionGroupName='string', Tags=[
   
   'Key': 'string',
   'Value': 'string'
],
StorageType='string', TdeCredentialArn='string', TdeCredentialPassword='string', VpcSecurityGroupIds=[
   'string',
],
DBSecurityGroups=[
   'string',
],
Domain='string', CopyTagsToSnapshot=True|False

Parameters

- **DBInstanceIdentifier** *(string)* – [REQUIRED]
  
  Name of the DB instance to create from the DB snapshot. This parameter isn’t case-sensitive.
  
  Constraints:
  - Must contain from 1 to 255 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens
  
  Example: my-snapshot-id

- **DBSnapshotIdentifier** *(string)* – [REQUIRED]
  
  The identifier for the DB snapshot to restore from.
  
  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **DBInstanceClass** *(string)* – The compute and memory capacity of the Amazon RDS DB instance.

  Valid Values:  
  
  
<p>| | | | | | | |</p>
<table>

</tbody>
</table>

- **Port** *(integer)* – The port number on which the database accepts connections.
Default: The same port as the original DB instance

Constraints: Value must be 1150-65535

- **AvailabilityZone** (*string*) – The EC2 Availability Zone that the database instance will be created in.
  
  Default: A random, system-chosen Availability Zone.
  
  Constraint: You cannot specify the AvailabilityZone parameter if the MultiAZ parameter is set to true.
  
  Example: us-east-1a

- **DBSubnetGroupName** (*string*) – The DB subnet group name to use for the new instance.

- **MultiAZ** (*boolean*) – Specifies if the DB instance is a Multi-AZ deployment.
  
  Constraint: You cannot specify the AvailabilityZone parameter if the MultiAZ parameter is set to true.

- **PubliclyAccessible** (*boolean*) – Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.
  
  Default: The default behavior varies depending on whether a VPC has been requested or not. The following list shows the default behavior in each case.
  
  - Default VPC: true
  - VPC: false
  
  If no DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be publicly accessible.
  
  If a specific DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be private.

- **AutoMinorVersionUpgrade** (*boolean*) – Indicates that minor version upgrades will be applied automatically to the DB instance during the maintenance window.

- **LicenseModel** (*string*) – License model information for the restored DB instance.
  
  Default: Same as source.
  
  Valid values: license-included | bring-your-own-license | general-public-license

- **DBName** (*string*) – The database name for the restored DB instance.
  
  Note: This parameter doesn’t apply to the MySQL engine.

- **Engine** (*string*) – The database engine to use for the new instance.
  
  Default: The same as source
  
  Constraint: Must be compatible with the engine of the source
  
  Valid Values: MySQL | oracle-se1 | oracle-se | oracle-ee | sqlserver-ee | sqlserver-se | sqlserver-ex | sqlserver-web | postgres

- **Iops** (*integer*) – Specifies the amount of provisioned IOPS for the DB instance, expressed in I/O operations per second. If this parameter is not specified, the IOPS value will be taken from the backup. If this parameter is set to 0, the new instance will be converted to a non-PIOPS instance, which will take additional time, though your DB instance will be available for connections before the conversion starts.
Constraints: Must be an integer greater than 1000.

**SQL Server**

Setting the IOPS value for the SQL Server database engine is not supported.

- **OptionGroupName** *(string)* – The name of the option group to be used for the restored DB instance.

Permanent options, such as the TDE option for Oracle Advanced Security TDE, cannot be removed from an option group, and that option group cannot be removed from a DB instance once it is associated with a DB instance

- **Tags** *(list)* – A list of tags.
  - *(dict)* –

  Metadata assigned to an Amazon RDS resource consisting of a key-value pair.

  * **Key** *(string)* –

    A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘ ’, ‘\ ’, ‘/’, ‘\ ’, ‘=’, ‘+’, ‘\ ’ (Java regex: “^([\p{L}\p{Z}\p{N}_.:/=+\-]*)$”).

  * **Value** *(string)* –

    A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘ ’, ‘\ ’, ‘/’, ‘\ ’, ‘=’, ‘+’, ‘\ ’ (Java regex: “^([\p{L}\p{Z}\p{N}_.:/=+\-]*)$”).

- **StorageType** *(string)* – Specifies the storage type to be associated with the DB instance.

  Valid values: *standard | gp2 | iol*

If you specify iol, you must also include a value for the Iops parameter.

Default: iol if the Iops parameter is specified; otherwise standard

- **TdeCredentialArn** *(string)* – The ARN from the Key Store with which to associate the instance for TDE encryption.

- **TdeCredentialPassword** *(string)* – The password for the given ARN from the Key Store in order to access the device.

- **VpcSecurityGroupIds** *(list)* – A list of EC2 VPC security groups to associate with this DB instance.

  Default: The default EC2 VPC security group for the DB subnet group’s VPC.

  - *(string)* –

- **DBSecurityGroups** *(list)* – A list of DB security groups to associate with this DB instance.

  Default: The default DB security group for the database engine.

  - *(string)* –

- **Domain** *(string)* – Specify the Active Directory Domain to restore the instance in.

- **CopyTagsToSnapshot** *(boolean)* – This property is not currently implemented.

**Return type** dict

**Returns**

Response Structure

- (dict) -

Contains the result of a successful invocation of the following actions:

- CreateDBInstance
- DeleteDBInstance
– ModifyDBInstance
This data type is used as a response element in the DescribeDBInstances action.

– DBInstance (dict) –
Contains the result of a successful invocation of the following actions:
* CreateDBInstance
* DeleteDBInstance
* ModifyDBInstance
This data type is used as a response element in the DescribeDBInstances action.

* DBInstanceIdentifier (string) –
Contains a user-supplied database identifier. This identifier is the unique key that identifies a DB instance.

* DBInstanceClass (string) –
Contains the name of the compute and memory capacity class of the DB instance.

* Engine (string) –
Provides the name of the database engine to be used for this DB instance.

* DBInstanceStatus (string) –
Specifies the current state of this database.

* MasterUsername (string) –
Contains the master username for the DB instance.

* DBName (string) –
The meaning of this parameter differs according to the database engine you use. For example, this value returns either MySQL or PostgreSQL information when returning values from CreateDBInstanceReadReplica since Read Replicas are only supported for MySQL and PostgreSQL.

 MySQL, SQL Server, PostgreSQL
Contains the name of the initial database of this instance that was provided at create time, if one was specified when the DB instance was created. This same name is returned for the life of the DB instance.

Type: String

 Oracle
Contains the Oracle System ID (SID) of the created DB instance. Not shown when the returned parameters do not apply to an Oracle DB instance.

* Endpoint (dict) –
Specifies the connection endpoint.
  · Address (string) –
    Specifies the DNS address of the DB instance.
  · Port (integer) –
    Specifies the port that the database engine is listening on.

* AllocatedStorage (integer) –
Specifies the allocated storage size specified in gigabytes.

* InstanceCreateTime (datetime) –
Provides the date and time the DB instance was created.

* **PreferredBackupWindow** *(string)* –

Specifies the daily time range during which automated backups are created if automated backups are enabled, as determined by the BackupRetentionPeriod.

* **BackupRetentionPeriod** *(integer)* –

Specifies the number of days for which automatic DB snapshots are retained.

* **DBSecurityGroups** *(list)* –

Provides List of DB security group elements containing only DBSecurityGroup.Name and DBSecurityGroup.Status subelements.

  - *(dict)* –

    This data type is used as a response element in the following actions:
    - ModifyDBInstance
    - RebootDBInstance
    - RestoreDBInstanceFromDBSnapshot
    - RestoreDBInstanceToPointInTime
    - **DBSecurityGroupName** *(string)* –

      The name of the DB security group.
    - **Status** *(string)* –

      The status of the DB security group.

* **VpcSecurityGroups** *(list)* –

Provides List of VPC security group elements that the DB instance belongs to.

  - *(dict)* –

    This data type is used as a response element for queries on VPC security group membership.
    - **VpcSecurityGroupId** *(string)* –

      The name of the VPC security group.
    - **Status** *(string)* –

      The status of the VPC security group.

* **DBParameterGroups** *(list)* –

Provides the list of DB parameter groups applied to this DB instance.

  - *(dict)* –

    The status of the DB parameter group.

    This data type is used as a response element in the following actions:
    - CreateDBInstance
    - CreateDBInstanceReadReplica
    - DeleteDBInstance
    - ModifyDBInstance
    - RebootDBInstance
    - RestoreDBInstanceFromDBSnapshot
- **DBParameterGroupName** (string) –
  The name of the DP parameter group.
- **ParameterApplyStatus** (string) –
  The status of parameter updates.

* **AvailabilityZone** (string) –
  Specifies the name of the Availability Zone the DB instance is located in.

* **DBSubnetGroup** (dict) –
  Specifies information on the subnet group associated with the DB instance, including the name, description, and subnets in the subnet group.
  - **DBSubnetGroupName** (string) –
    Specifies the name of the DB subnet group.
  - **DBSubnetGroupDescription** (string) –
    Provides the description of the DB subnet group.
  - **VpcId** (string) –
    Provides the VpcId of the DB subnet group.
  - **SubnetGroupStatus** (string) –
    Provides the status of the DB subnet group.
  - **Subnets** (list) –
    Contains a list of Subnet elements.
    - (dict) –
      This data type is used as a response element in the DescribeDBSubnetGroups action.
  - **SubnetIdentifier** (string) –
    Specifies the identifier of the subnet.
  - **SubnetAvailabilityZone** (dict) –
    Contains Availability Zone information.
    This data type is used as an element in the following data type:
    - **OrderableDBInstanceOption**
      - **Name** (string) –
        The name of the availability zone.
    - **SubnetStatus** (string) –
      Specifies the status of the subnet.

* **PreferredMaintenanceWindow** (string) –
  Specifies the weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).

* **PendingModifiedValues** (dict) –
  Specifies that changes to the DB instance are pending. This element is only included when changes are pending. Specific changes are identified by subelements.
  - **DBInstanceClass** (string) –
    Contains the new DBInstanceClass for the DB instance that will be applied or is in progress.
- **AllocatedStorage (integer)** –
  
  Contains the new AllocatedStorage size for the DB instance that will be applied or is in progress.

- **MasterUserPassword (string)** –
  
  Contains the pending or in-progress change of the master credentials for the DB instance.

- **Port (integer)** –
  
  Specifies the pending port for the DB instance.

- **BackupRetentionPeriod (integer)** –
  
  Specifies the pending number of days for which automated backups are retained.

- **MultiAZ (boolean)** –
  
  Indicates that the Single-AZ DB instance is to change to a Multi-AZ deployment.

- **EngineVersion (string)** –
  
  Indicates the database engine version.

- **Iops (integer)** –
  
  Specifies the new Provisioned IOPS value for the DB instance that will be applied or is being applied.

- **DBInstanceIdentifier (string)** –
  
  Contains the new DBInstanceIdentifier for the DB instance that will be applied or is in progress.

- **StorageType (string)** –
  
  Specifies the storage type to be associated with the DB instance.

- **CACertificateIdentifier (string)** –
  
  Specifies the identifier of the CA certificate for the DB instance.

- **LatestRestorableTime (datetime)** –
  
  Specifies the latest time to which a database can be restored with point-in-time restore.

- **MultiAZ (boolean)** –
  
  Specifies if the DB instance is a Multi-AZ deployment.

- **EngineVersion (string)** –
  
  Indicates the database engine version.

- **AutoMinorVersionUpgrade (boolean)** –
  
  Indicates that minor version patches are applied automatically.

- **Read Replica Source DB Instance Identifier (string)** –
  
  Contains the identifier of the source DB instance if this DB instance is a Read Replica.

- **Read Replica DB Instance Identifiers (list)** –
  
  Contains one or more identifiers of the Read Replicas associated with this DB instance.
* **LicenseModel** *(string)* –
  License model information for this DB instance.

* **Iops** *(integer)* –
  Specifies the Provisioned IOPS (I/O operations per second) value.

* **OptionGroupMemberships** *(list)* –
  Provides the list of option group memberships for this DB instance.
  · **(dict)** –
    Provides information on the option groups the DB instance is a member of.
    · **OptionGroupName** *(string)* –
      The name of the option group that the instance belongs to.
    · **Status** *(string)* –
      The status of the DB instance’s option group membership (e.g. in-sync, pending, pending-maintenance, applying).

* **CharacterSetName** *(string)* –
  If present, specifies the name of the character set that this instance is associated with.

* **SecondaryAvailabilityZone** *(string)* –
  If present, specifies the name of the secondary Availability Zone for a DB instance with multi-AZ support.

* **PubliclyAccessible** *(boolean)* –
  Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.

Default: The default behavior varies depending on whether a VPC has been requested or not. The following list shows the default behavior in each case.
  · **Default VPC**: true
  · **VPC**: false

If no DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be publicly accessible. If a specific DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be private.

* **StatusInfos** *(list)* –
  The status of a Read Replica. If the instance is not a Read Replica, this will be blank.
  · *(dict)* –
    Provides a list of status information for a DB instance.
    · **StatusType** *(string)* –
      This value is currently “read replication.”
    · **Normal** *(boolean)* –
      Boolean value that is true if the instance is operating normally, or false if the instance is in an error state.
· **Status** *(string)* –
  Status of the DB instance. For a StatusType of read replica, the values can be replicating, error, stopped, or terminated.
· **Message** *(string)* –
  Details of the error if there is an error for the instance. If the instance is not in an error state, this value is blank.
· **StorageType** *(string)* –
  Specifies the storage type associated with DB instance.
· **TdeCredentialArn** *(string)* –
  The ARN from the Key Store with which the instance is associated for TDE encryption.
· **DbInstancePort** *(integer)* –
  Specifies the port that the DB instance listens on. If the DB instance is part of a DB cluster, this can be a different port than the DB cluster port.
· **DBClusterIdentifier** *(string)* –
  If the DB instance is a member of a DB cluster, contains the name of the DB cluster that the DB instance is a member of.
· **StorageEncrypted** *(boolean)* –
  Specifies whether the DB instance is encrypted.
· **KmsKeyId** *(string)* –
  If StorageEncrypted is true, the KMS key identifier for the encrypted DB instance.
· **DbiResourceId** *(string)* –
  If StorageEncrypted is true, the region-unique, immutable identifier for the encrypted DB instance. This identifier is found in AWS CloudTrail log entries whenever the KMS key for the DB instance is accessed.
· **CACertificateIdentifier** *(string)* –
  The identifier of the CA certificate for this DB instance.
· **DomainMemberships** *(list)* –
  The Active Directory Domain membership records associated with the DB instance.
  · *(dict)* –
    An Active Directory Domain membership record associated with the DB instance.
    · **Domain** *(string)* –
      The identifier of the Active Directory Domain.
    · **Status** *(string)* –
      The status of the DB instance’s Active Directory Domain membership (e.g. joined, pending-join, failed etc).
    · **Connectivity** *(string)* –
      The observed connectivity of the Active Directory Domain.
· **CopyTagsToSnapshot** *(boolean)* –
  This property is not currently implemented.
**restore_db_instance_to_point_in_time(**kwargs)**

Restores a DB instance to an arbitrary point-in-time. Users can restore to any point in time before the LatestRestorableTime for up to BackupRetentionPeriod days. The target database is created with the most of original configuration, but in a system chosen availability zone with the default security group, the default subnet group, and the default DB parameter group. By default, the new DB instance is created as a single-AZ deployment except when the instance is a SQL Server instance that has an option group that is associated with mirroring; in this case, the instance becomes a mirrored deployment and not a single-AZ deployment.

**Request Syntax**

```python
response = client.restore_db_instance_to_point_in_time(
    SourceDBInstanceIdentifier='string',
    TargetDBInstanceIdentifier='string',
    RestoreTime=datetime(2015, 1, 1),
    UseLatestRestorableTime=True|False,
    DBInstanceClass='string',
    Port=123,
    AvailabilityZone='string',
    DBSubnetGroupName='string',
    MultiAZ=True|False,
    PubliclyAccessible=True|False,
    AutoMinorVersionUpgrade=True|False,
    LicenseModel='string',
    DBName='string',
    Engine='string',
    Iops=123,
    OptionGroupName='string',
    CopyTagsToSnapshot=True|False,
    Tags=[
        {'Key': 'string',
         'Value': 'string'},
    ],
    StorageType='string',
    TdeCredentialArn='string',
    TdeCredentialPassword='string',
    VpcSecurityGroupIds=[
        'string',
    ],
    DBSecurityGroups=[
        'string',
    ],
    Domain='string'
)
```

**Parameters**

- **SourceDBInstanceIdentifier (string)**  – [REQUIRED]

  The identifier of the source DB instance from which to restore.

  Constraints:
  - Must be the identifier of an existing database instance
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **TargetDBInstanceIdentifier (string)**  – [REQUIRED]
The name of the new database instance to be created.

Constraints:
- Must contain from 1 to 63 alphanumeric characters or hyphens
- First character must be a letter
- Cannot end with a hyphen or contain two consecutive hyphens

• **RestoreTime** *(datetime)* – The date and time to restore from.

Valid Values: Value must be a time in Universal Coordinated Time (UTC) format

Constraints:
- Must be before the latest restorable time for the DB instance
- Cannot be specified if UseLatestRestorableTime parameter is true

Example: 2009-09-07T23:45:00Z

• **UseLatestRestorableTime** *(boolean)* – Specifies whether (true) or not (false) the DB instance is restored from the latest backup time.

Default: false

Constraints: Cannot be specified if RestoreTime parameter is provided.

• **DBInstanceClass** *(string)* – The compute and memory capacity of the Amazon RDS DB instance.

Valid Values: `db.t1.micro | db.m1.small | db.m1.medium | db.m1.large | db.m2.xlarge | db.m3.xlarge | db.m3.large | db.r3.xlarge | db.r3.large | db.r3.2xlarge | db.r3.4xlarge | db.r3.8xlarge | db.t2.micro | db.t2.small | db.t2.medium`

Default: The same DBInstanceClass as the original DB instance.

• **Port** *(integer)* – The port number on which the database accepts connections.

Constraints: Value must be `1150-65535`

Default: The same port as the original DB instance.

• **AvailabilityZone** *(string)* – The EC2 Availability Zone that the database instance will be created in.

Default: A random, system-chosen Availability Zone.

Constraint: You cannot specify the AvailabilityZone parameter if the MultiAZ parameter is set to true.

Example: `us-east-1a`

• **DBSubnetGroupName** *(string)* – The DB subnet group name to use for the new instance.

• **MultiAZ** *(boolean)* – Specifies if the DB instance is a Multi-AZ deployment.

Constraint: You cannot specify the AvailabilityZone parameter if the MultiAZ parameter is set to true.

• **PubliclyAccessible** *(boolean)* – Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.

Default: The default behavior varies depending on whether a VPC has been requested or not. The following list shows the default behavior in each case.

- **Default VPC:** true
- **VPC**: false

If no DB subnet group has been specified as part of the request and the Publicly-Accessible value has not been set, the DB instance will be publicly accessible. If a specific DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be private.

- **AutoMinorVersionUpgrade** *(boolean)* – Indicates that minor version upgrades will be applied automatically to the DB instance during the maintenance window.

- **LicenseModel** *(string)* – License model information for the restored DB instance.

  Default: Same as source.

  Valid values: license-included | bring-your-own-license | general-public-license

- **DBName** *(string)* – The database name for the restored DB instance.

  Note: This parameter is not used for the MySQL engine.

- **Engine** *(string)* – The database engine to use for the new instance.

  Default: The same as source

  Constraint: Must be compatible with the engine of the source

  Valid Values: MySQL | oracle-se1 | oracle-se | oracle-ee | sqlserver-ee | sqlserver-se | sqlserver-ex | sqlserver-web | postgres

- **Iops** *(integer)* – The amount of Provisioned IOPS (input/output operations per second) to be initially allocated for the DB instance.

  Constraints: Must be an integer greater than 1000.

**SQL Server**

Setting the IOPS value for the SQL Server database engine is not supported.

- **OptionGroupName** *(string)* – The name of the option group to be used for the restored DB instance.

  Permanent options, such as the TDE option for Oracle Advanced Security TDE, cannot be removed from an option group, and that option group cannot be removed from a DB instance once it is associated with a DB instance

- **CopyTagsToSnapshot** *(boolean)* – This property is not currently implemented.

- **Tags** *(list)* – A list of tags.

  - *(dict)* – Metadata assigned to an Amazon RDS resource consisting of a key-value pair.

    - **Key** *(string)* – A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘=’, ‘+’, ‘-’ (Java regex: “^([\p{L}\p{Z}\p{N}_.:/=+-]+$)”).

    - **Value** *(string)* – A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with “aws:” or “rds:”. The string can only contain only the set of Unicode letters, digits, white-space, ‘_’, ‘.’, ‘/’, ‘=’, ‘+’, ‘-’ (Java regex: “^([\p{L}\p{Z}\p{N}_.:/=+-]+$)”).
• **StorageType** *(string)* – Specifies the storage type to be associated with the DB instance.

Valid values: `standard` | `gp2` | `io1`

If you specify `io1`, you must also include a value for the `Iops` parameter.

Default: `io1` if the `Iops` parameter is specified; otherwise `standard`

• **TdeCredentialArn** *(string)* – The ARN from the Key Store with which to associate the instance for TDE encryption.

• **TdeCredentialPassword** *(string)* – The password for the given ARN from the Key Store in order to access the device.

• **VpcSecurityGroupIds** *(list)* – A list of EC2 VPC security groups to associate with this DB instance.

Default: The default EC2 VPC security group for the DB subnet group’s VPC.

• **DBSecurityGroups** *(list)* – A list of DB security groups to associate with this DB instance.

Default: The default DB security group for the database engine.

• **Domain** *(string)* – Specify the Active Directory Domain to restore the instance in.

Return type: `dict`

Returns

Response Syntax

```json

```
Response Structure

• (dict) –
  Contains the result of a successful invocation of the following actions:
  – CreateDBInstance
  – DeleteDBInstance
  – ModifyDBInstance
This data type is used as a response element in the DescribeDBInstances action.

– DBInstance (dict) –
  Contains the result of a successful invocation of the following actions:
  * CreateDBInstance
  * DeleteDBInstance
  * ModifyDBInstance
This data type is used as a response element in the DescribeDBInstances action.
  * DBInstanceIdentifier (string) –
    Contains a user-supplied database identifier. This identifier is the unique key that identifies a DB instance.
  * DBInstanceClass (string) –
    Contains the name of the compute and memory capacity class of the DB instance.
  * Engine (string) –
    Provides the name of the database engine to be used for this DB instance.
  * DBInstanceStatus (string) –
    Specifies the current state of this database.
  * MasterUsername (string) –
    Contains the master username for the DB instance.
  * DBName (string) –
    The meaning of this parameter differs according to the database
engine you use. For example, this value returns either MySQL or PostgreSQL information when returning values from CreateDBInstanceRestoreReplica since Read Replicas are only supported for MySQL and PostgreSQL.

**MySQL, SQL Server, PostgreSQL**

Contains the name of the initial database of this instance that was provided at create time, if one was specified when the DB instance was created. This same name is returned for the life of the DB instance.

Type: String

**Oracle**

Contains the Oracle System ID (SID) of the created DB instance. Not shown when the returned parameters do not apply to an Oracle DB instance.

* **Endpoint** *(dict)*

  Specifies the connection endpoint.

  * **Address** *(string)*
    
    Specifies the DNS address of the DB instance.

  * **Port** *(integer)*
    
    Specifies the port that the database engine is listening on.

* **AllocatedStorage** *(integer)*

  Specifies the allocated storage size specified in gigabytes.

* **InstanceCreateTime** *(datetime)*

  Provides the date and time the DB instance was created.

* **PreferredBackupWindow** *(string)*

  Specifies the daily time range during which automated backups are created if automated backups are enabled, as determined by the BackupRetentionPeriod.

* **BackupRetentionPeriod** *(integer)*

  Specifies the number of days for which automatic DB snapshots are retained.

* **DBSecurityGroups** *(list)*

  Provides List of DB security group elements containing only DBSecurityGroup.Name and DBSecurityGroup.Status subelements.

  * **(dict)**
    
    This data type is used as a response element in the following actions:

    * ModifyDBInstance
    * RebootDBInstance
    * RestoreDBInstanceFromDBSnapshot
    * RestoreDBInstanceToPointInTime
    * **DBSecurityGroupName** *(string)*
      
      The name of the DB security group.

    * **Status** *(string)*
      
      The status of the DB security group.

* **VpcSecurityGroups** *(list)*
Provides List of VPC security group elements that the DB instance belongs to.

- *(dict)* –
  
  This data type is used as a response element for queries on VPC security group membership.
  - **VpcSecurityGroupId** *(string)* –
    
    The name of the VPC security group.
  - **Status** *(string)* –
    
    The status of the VPC security group.

* **DBParameterGroups** *(list)* –

Provides the list of DB parameter groups applied to this DB instance.

- *(dict)* –
  
  The status of the DB parameter group.

  This data type is used as a response element in the following actions:
  - CreateDBInstance
  - CreateDBInstanceReadReplica
  - DeleteDBInstance
  - ModifyDBInstance
  - RebootDBInstance
  - RestoreDBInstanceFromDBSnapshot
  - **DBParameterGroupName** *(string)* –
    
    The name of the DP parameter group.
  - **ParameterApplyStatus** *(string)* –
    
    The status of parameter updates.

* **AvailabilityZone** *(string)* –

  Specifies the name of the Availability Zone the DB instance is located in.

* **DBSubnetGroup** *(dict)* –

  Specifies information on the subnet group associated with the DB instance, including the name, description, and subnets in the subnet group.

  - **DBSubnetGroupName** *(string)* –
    
    Specifies the name of the DB subnet group.
  - **DBSubnetGroupDescription** *(string)* –
    
    Provides the description of the DB subnet group.
  - **VpcId** *(string)* –
    
    Provides the VpcId of the DB subnet group.
  - **SubnetGroupStatus** *(string)* –
    
    Provides the status of the DB subnet group.
  - **Subnets** *(list)* –
    
    Contains a list of Subnet elements.
  - *(dict)* –
    
    This data type is used as a response element in the DescribeDBSubnetGroups action.
- **SubnetIdentifier** *(string)* –
  Specifies the identifier of the subnet.
- **SubnetAvailabilityZone** *(dict)* –
  Contains Availability Zone information.
  This data type is used as an element in the following data type:
  - **OrderableDBInstanceOption**
    - **Name** *(string)* –
      The name of the availability zone.
    - **SubnetStatus** *(string)* –
      Specifies the status of the subnet.
- **PreferredMaintenanceWindow** *(string)* –
  Specifies the weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).
- **PendingModifiedValues** *(dict)* –
  Specifies that changes to the DB instance are pending. This element is only included when changes are pending. Specific changes are identified by subelements.
  - **DBInstanceClass** *(string)* –
    Contains the new DBInstanceClass for the DB instance that will be applied or is in progress.
  - **AllocatedStorage** *(integer)* –
    Contains the new AllocatedStorage size for the DB instance that will be applied or is in progress.
  - **MasterUserPassword** *(string)* –
    Contains the pending or in-progress change of the master credentials for the DB instance.
  - **Port** *(integer)* –
    Specifies the pending port for the DB instance.
  - **BackupRetentionPeriod** *(integer)* –
    Specifies the pending number of days for which automated backups are retained.
  - **MultiAZ** *(boolean)* –
    Indicates that the Single-AZ DB instance is to change to a Multi-AZ deployment.
  - **EngineVersion** *(string)* –
    Indicates the database engine version.
  - **Iops** *(integer)* –
    Specifies the new Provisioned IOPS value for the DB instance that will be applied or is being applied.
  - **DBInstanceIdentifier** *(string)* –
    Contains the new DBInstanceIdentifier for the DB instance that will be applied or is in progress.
  - **StorageType** *(string)* –
    Specifies the storage type to be associated with the DB instance.
· **CACertificateIdentifier** *(string)* –
  Specifies the identifier of the CA certificate for the DB instance.

* **LatestRestorableTime** *(datetime)* –
  Specifies the latest time to which a database can be restored with point-in-time restore.

* **MultiAZ** *(boolean)* –
  Specifies if the DB instance is a Multi-AZ deployment.

* **EngineVersion** *(string)* –
  Indicates the database engine version.

* **AutoMinorVersionUpgrade** *(boolean)* –
  Indicates that minor version patches are applied automatically.

* **ReadReplicaSourceDBInstanceIdentifier** *(string)* –
  Contains the identifier of the source DB instance if this DB instance is a Read Replica.

* **ReadReplicaDBInstanceIdentifiers** *(list)* –
  Contains one or more identifiers of the Read Replicas associated with this DB instance.
  · *(string)* –

* **LicenseModel** *(string)* –
  License model information for this DB instance.

* **Iops** *(integer)* –
  Specifies the Provisioned IOPS (I/O operations per second) value.

* **OptionGroupMemberships** *(list)* –
  Provides the list of option group memberships for this DB instance.
  · *(dict)* –
    Provides information on the option groups the DB instance is a member of.
  · **OptionGroupName** *(string)* –
    The name of the option group that the instance belongs to.
  · **Status** *(string)* –
    The status of the DB instance’s option group membership (e.g. in-sync, pending, pending-maintenance, applying).

* **CharacterSetName** *(string)* –
  If present, specifies the name of the character set that this instance is associated with.

* **SecondaryAvailabilityZone** *(string)* –
  If present, specifies the name of the secondary Availability Zone for a DB instance with multi-AZ support.

* **PubliclyAccessible** *(boolean)* –
  Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.
Default: The default behavior varies depending on whether a VPC has been requested or not. The following list shows the default behavior in each case.

- **Default VPC:** true
- **VPC:** false

If no DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be publicly accessible. If a specific DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be private.

* **StatusInfos (list)** –

  The status of a Read Replica. If the instance is not a Read Replica, this will be blank.

  - *(dict)* –
    - Provides a list of status information for a DB instance.
    - **StatusType (string)** –
      - This value is currently “read replication.”
    - **Normal (boolean)** –
      - Boolean value that is true if the instance is operating normally, or false if the instance is in an error state.
    - **Status (string)** –
      - Status of the DB instance. For a StatusType of read replica, the values can be replicating, error, stopped, or terminated.
    - **Message (string)** –
      - Details of the error if there is an error for the instance. If the instance is not in an error state, this value is blank.

* **StorageType (string)** –

  Specifies the storage type associated with DB instance.

* **TdeCredentialArn (string)** –

  The ARN from the Key Store with which the instance is associated for TDE encryption.

* **DbInstancePort (integer)** –

  Specifies the port that the DB instance listens on. If the DB instance is part of a DB cluster, this can be a different port than the DB cluster port.

* **DBClusterIdentifier (string)** –

  If the DB instance is a member of a DB cluster, contains the name of the DB cluster that the DB instance is a member of.

* **StorageEncrypted (boolean)** –

  Specifies whether the DB instance is encrypted.

* **KmsKeyId (string)** –

  If StorageEncrypted is true, the KMS key identifier for the encrypted DB instance.

* **DbiResourceId (string)** –

  If StorageEncrypted is true, the region-unique, immutable identifier for the encrypted DB instance. This identifier is found
in AWS CloudTrail log entries whenever the KMS key for the DB instance is accessed.

* **CACertificateIdentifier** *(string)* –
  The identifier of the CA certificate for this DB instance.

* **DomainMemberships** *(list)* –
  The Active Directory Domain membership records associated with the DB instance.
    
    *(dict)* –
    An Active Directory Domain membership record associated with the DB instance.
    
    **Domain** *(string)* –
    The identifier of the Active Directory Domain.
    
    **Status** *(string)* –
    The status of the DB instance’s Active Directory Domain membership (e.g. joined, pending-join, failed etc).
    
    **Connectivity** *(string)* –
    The observed connectivity of the Active Directory Domain.

* **CopyTagsToSnapshot** *(boolean)* –
  This property is not currently implemented.

---

**revoke_db_security_group_ingress** (**kwargs**)

Revolves ingress from a DBSecurityGroup for previously authorized IP ranges or EC2 or VPC Security Groups. Required parameters for this API are one of CIDRIP, EC2SecurityGroupId for VPC, or (EC2SecurityGroupOwnerld and either EC2SecurityGroupName or EC2SecurityGroupId).

**Request Syntax**

```python
response = client.revoke_db_security_group_ingress(
    DBSecurityGroupName='string',
    CIDRIP='string',
    EC2SecurityGroupName='string',
    EC2SecurityGroupId='string',
    EC2SecurityGroupOwnerld='string'
)
```

**Parameters**

- **DBSecurityGroupName** *(string)* – [REQUIRED]
  The name of the DB security group to revoke ingress from.

- **CIDRIP** *(string)* – The IP range to revoke access from. Must be a valid CIDR range. If CIDRIP is specified, EC2SecurityGroupName, EC2SecurityGroupId and EC2SecurityGroupOwnerld cannot be provided.

- **EC2SecurityGroupName** *(string)* – The name of the EC2 security group to revoke access from. For VPC DB security groups, EC2SecurityGroupId must be provided. Otherwise, EC2SecurityGroupOwnerld and either EC2SecurityGroupName or EC2SecurityGroupId must be provided.

- **EC2SecurityGroupId** *(string)* – The id of the EC2 security group to revoke access from. For VPC DB security groups, EC2SecurityGroupId must be provided. Otherwise, EC2SecurityGroupOwnerld and either EC2SecurityGroupName or EC2SecurityGroupId must be provided.

- **EC2SecurityGroupOwnerld** *(string)* – The AWS Account Number of the owner of the EC2 security group specified in the EC2SecurityGroupName
parameter. The AWS Access Key ID is not an acceptable value. For VPC DB security groups, \texttt{EC2SecurityGroupId} must be provided. Otherwise, \texttt{EC2SecurityGroupOwnerId} and either \texttt{EC2SecurityGroupName} or \texttt{EC2SecurityGroupId} must be provided.

Return type: dict

Returns

Response Syntax

```
{
  'DBSecurityGroup': {
    'OwnerId': 'string',
    'DBSecurityGroupName': 'string',
    'DBSecurityGroupDescription': 'string',
    'VpcId': 'string',
    'EC2SecurityGroups': [
      {
        'Status': 'string',
        'EC2SecurityGroupName': 'string',
        'EC2SecurityGroupId': 'string',
        'EC2SecurityGroupOwnerId': 'string'
      },
    ],
    'IPRanges': [
      {
        'Status': 'string',
        'CIDRIP': 'string'
      },
    ]
  }
}
```

Response Structure

- (dict) –

Contains the result of a successful invocation of the following actions:
- DescribeDBSecurityGroups
- AuthorizeDBSecurityGroupIngress
- CreateDBSecurityGroup
- RevokeDBSecurityGroupIngress

This data type is used as a response element in the DescribeDBSecurityGroups action.

- DBSecurityGroup (dict) –

Contains the result of a successful invocation of the following actions:
- DescribeDBSecurityGroups
- AuthorizeDBSecurityGroupIngress
- CreateDBSecurityGroup
- RevokeDBSecurityGroupIngress

This data type is used as a response element in the DescribeDBSecurityGroups action.

- OwnerId (string) –

Provides the AWS ID of the owner of a specific DB security group.

- DBSecurityGroupName (string) –

Specifies the name of the DB security group.

- DBSecurityGroupDescription (string) –
Provides the description of the DB security group.

* **VpcId** *(string)* –

  Provides the VpcId of the DB security group.

* **EC2SecurityGroups** *(list)* –

  Contains a list of EC2SecurityGroup elements.
  
  - *(dict)* –
    
    This data type is used as a response element in the following actions:
    
    - AuthorizeDBSecurityGroupIngress
    - DescribeDBSecurityGroups
    - RevokeDBSecurityGroupIngress
    
    - **Status** *(string)* –
      
      Provides the status of the EC2 security group. Status can be “authorizing”, “authorized”, “revoking”, and “revoked”.

    - **EC2SecurityGroupName** *(string)* –
      
      Specifies the name of the EC2 security group.

    - **EC2SecurityGroupId** *(string)* –
      
      Specifies the id of the EC2 security group.

    - **EC2SecurityGroupOwnerId** *(string)* –
      
      Specifies the AWS ID of the owner of the EC2 security group specified in the EC2SecurityGroupName field.

* **IPRanges** *(list)* –

  Contains a list of IPRange elements.
  
  - *(dict)* –
    
    This data type is used as a response element in the DescribeDBSecurityGroups action.

    - **Status** *(string)* –
      
      Specifies the status of the IP range. Status can be “authorizing”, “authorized”, “revoking”, and “revoked”.

    - **CIDRIP** *(string)* –
      
      Specifies the IP range.

### Paginators

The available paginators are:

- RDSPaginatorDescribeDBEngineVersions
- RDSPaginatorDescribeDBInstances
- RDSPaginatorDescribeDBLogFiles
- RDSPaginatorDescribeDBParameterGroups
- RDSPaginatorDescribeDBParameters
- RDSPaginatorDescribeDBSecurityGroups
- RDSPaginatorDescribeDBSnapshots
- RDSPaginatorDescribeDBSubnetGroups
class RDS.Paginator.DescribeDBEngineVersions

class RDS.Paginator.DescribeDBEngineVersions

    paginator = client.get_paginator('describe_db_engine_versions')

    paginate(**kwargs)

    Returns an iterator that will paginate through responses from
    RDS.Client.describe_db_engine_versions().

    Request Syntax

    response_iterator = paginator.paginate(
        Engine='string',
        EngineVersion='string',
        DBParameterGroupFamily='string',
        Filters=[
            {  
                'Name': 'string',
                'Values': ['string'],
            },
        ],
        DefaultOnly=True|False,
        ListSupportedCharacterSets=True|False,
        PaginationConfig={
            'MaxItems': 123,
            'PageSize': 123,
            'StartingToken': 'string'
        }
    )

    Parameters

    • **Engine** *(string)* – The database engine to return.
    • **EngineVersion** *(string)* – The database engine version to return.
        Example: 5.1.49
    • **DBParameterGroupFamily** *(string)* – The name of a specific DB parameter
        group family to return details for.
        Constraints:
        – Must be 1 to 255 alphanumeric characters
        – First character must be a letter
        – Cannot end with a hyphen or contain two consecutive hyphens
• **Filters** *(list)* – Not currently supported.
  
  · *(dict)* –
    * Name *(string)* – *[REQUIRED]*
      
      This parameter is not currently supported.
    
    * Values *(list)* – *[REQUIRED]*
      
      This parameter is not currently supported.
  
  · *(string)* –

• **DefaultOnly** *(boolean)* – Indicates that only the default version of the specified engine or engine and major version combination is returned.

• **ListSupportedCharacterSets** *(boolean)* – If this parameter is specified, and if the requested engine supports the CharacterSetName parameter for CreateDBInstance, the response includes a list of supported character sets for each engine version.

• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  · MaxItems *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a **NextToken** will be provided in the output that you can use to resume pagination.
  
  · PageSize *(integer)* –
    
    The size of each page.
  
  · StartingToken *(string)* –
    
    A token to specify where to start paginating. This is the **NextToken** from a previous response.

Return type  dict

Returns

Response Syntax

```
{
    'DBEngineVersions': [  
        {
            'Engine': 'string',
            'EngineVersion': 'string',
            'DBParameterGroupFamily': 'string',
            'DBEngineDescription': 'string',
            'DBEngineVersionDescription': 'string',
            'DefaultCharacterSet': {  
                'CharacterSetName': 'string',
                'CharacterSetDescription': 'string'
            },
            'SupportedCharacterSets': [  
                {
                    'CharacterSetName': 'string',
                    'CharacterSetDescription': 'string'
                },
            ],
        },
    ],
    'NextToken': 'string'
}
```

Response Structure
Contains the result of a successful invocation of the DescribeDBEngineVersions action.

- **DBEngineVersions (list)** –
  
  A list of DBEngineVersion elements.
  
  * (dict) –

  This data type is used as a response element in the action DescribeDBEngineVersions.

  - **Engine (string)** –
    
    The name of the database engine.

  - **EngineVersion (string)** –
    
    The version number of the database engine.

  - **DBParameterGroupFamily (string)** –
    
    The name of the DB parameter group family for the database engine.

  - **DBEngineDescription (string)** –
    
    The description of the database engine.

  - **DBEngineVersionDescription (string)** –
    
    The description of the database engine version.

  - **DefaultCharacterSet (dict)** –
    
    The default character set for new instances of this engine version, if the CharacterSetName parameter of the CreateDBInstance API is not specified.

    - **CharacterSetName (string)** –
      
      The name of the character set.

    - **CharacterSetDescription (string)** –
      
      The description of the character set.

    - **SupportedCharacterSets (list)** –
      
      A list of the character sets supported by this engine for the CharacterSetName parameter of the CreateDBInstance API.

    * (dict) –

      This data type is used as a response element in the action DescribeDBEngineVersions.

    - **CharacterSetName (string)** –
      
      The name of the character set.

    - **CharacterSetDescription (string)** –
      
      The description of the character set.

- **NextToken (string)** –

  A token to resume pagination.

```python
class RDS.Paginator.DescribeDBInstances

    paginator = client.get_paginator('describe_db_instances')
```
**paginate(**kwargs**)

Creates an iterator that will paginate through responses from `RDS.Client.describe_db_instances()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    DBInstanceIdentifier='string',
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ]
        },
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **DBInstanceIdentifier** *(string)* – The user-supplied instance identifier. If this parameter is specified, information from only the specific DB instance is returned. This parameter isn’t case-sensitive.
  
  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens
- **Filters** *(list)* – This parameter is not currently supported.
  
  - *(dict)* –
    * **Name** *(string)* – [REQUIRED]
      
      This parameter is not currently supported.
    * **Values** *(list)* – [REQUIRED]
      
      This parameter is not currently supported.
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  - **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –
    
    The size of each page.
  - **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** dict

**Returns**

**Response Syntax**
{
    'DBInstances': [

        }
    }
}
Response Structure

- `dict` – Contains the result of a successful invocation of the DescribeDBInstances action.
- **DBInstances** *(list)* —

  A list of DBInstance instances.

  * *(dict)* —

    Contains the result of a successful invocation of the following actions:
    - CreateDBInstance
    - DeleteDBInstance
    - ModifyDBInstance

  This data type is used as a response element in the DescribeDBInstances action.

    - **DBInstanceIdentifier** *(string)* —

      Contains a user-supplied database identifier. This identifier is the unique key that identifies a DB instance.

    - **DBInstanceClass** *(string)* —

      Contains the name of the compute and memory capacity class of the DB instance.

    - **Engine** *(string)* —

      Provides the name of the database engine to be used for this DB instance.

    - **DBInstanceStatus** *(string)* —

      Specifies the current state of this database.

    - **MasterUsername** *(string)* —

      Contains the master username for the DB instance.

    - **DBName** *(string)* —

      The meaning of this parameter differs according to the database engine you use. For example, this value returns either MySQL or PostgreSQL information when returning values from CreateDBInstanceReadReplica since Read Replicas are only supported for MySQL and PostgreSQL.

      - **MySQL, SQL Server, PostgreSQL**

        Contains the name of the initial database of this instance that was provided at create time, if one was specified when the DB instance was created. This same name is returned for the life of the DB instance.

        Type: String

        - **Oracle**

          Contains the Oracle System ID (SID) of the created DB instance. Not shown when the returned parameters do not apply to an Oracle DB instance.

        - **Endpoint** *(dict)* —

          Specifies the connection endpoint.

        - **Address** *(string)* —

          Specifies the DNS address of the DB instance.

        - **Port** *(integer)* —

          Specifies the port that the database engine is listening on.

        - **AllocatedStorage** *(integer)* —

          Specifies the allocated storage size specified in gigabytes.
- **InstanceCreateTime** (*datetime*) –
  Provides the date and time the DB instance was created.
- **PreferredBackupWindow** (*string*) –
  Specifies the daily time range during which automated backups are created if automated backups are enabled, as determined by the **BackupRetentionPeriod**.
- **BackupRetentionPeriod** (*integer*) –
  Specifies the number of days for which automatic DB snapshots are retained.
- **DBSecurityGroups** (*list*) –
  Provides List of DB security group elements containing only **DBSecurityGroup.Name** and **DBSecurityGroup.Status** subelements.
  - **(dict)** –
    This data type is used as a response element in the following actions:
    - ModifyDBInstance
    - RebootDBInstance
    - RestoreDBInstanceFromDBSnapshot
    - RestoreDBInstanceToPointInTime
    - **DBSecurityGroupName** (*string*) –
      The name of the DB security group.
    - **Status** (*string*) –
      The status of the DB security group.
- **VpcSecurityGroups** (*list*) –
  Provides List of VPC security group elements that the DB instance belongs to.
  - **(dict)** –
    This data type is used as a response element for queries on VPC security group membership.
  - **VpcSecurityGroupId** (*string*) –
    The name of the VPC security group.
  - **Status** (*string*) –
    The status of the VPC security group.
- **DBParameterGroups** (*list*) –
  Provides the list of DB parameter groups applied to this DB instance.
  - **(dict)** –
    The status of the DB parameter group.
    This data type is used as a response element in the following actions:
    - CreateDBInstance
    - CreateDBInstanceReadReplica
    - DeleteDBInstance
    - ModifyDBInstance
    - RebootDBInstance
    - RestoreDBInstanceFromDBSnapshot
- **DBParameterGroupName** *(string)* –
  The name of the DP parameter group.
- **ParameterApplyStatus** *(string)* –
  The status of parameter updates.
- **AvailabilityZone** *(string)* –
  Specifies the name of the Availability Zone the DB instance is located in.
- **DBSubnetGroup** *(dict)* –
  Specifies information on the subnet group associated with the DB instance, including the name, description, and subnets in the subnet group.
- **DBSubnetGroupName** *(string)* –
  Specifies the name of the DB subnet group.
- **DBSubnetGroupDescription** *(string)* –
  Provides the description of the DB subnet group.
- **VpcId** *(string)* –
  Provides the VpcId of the DB subnet group.
- **SubnetGroupStatus** *(string)* –
  Provides the status of the DB subnet group.
- **Subnets** *(list)* –
  Contains a list of Subnet elements.
- **SubnetIdentifier** *(string)* –
  Specifies the identifier of the subnet.
- **SubnetAvailabilityZone** *(dict)* –
  Contains Availability Zone information.
  This data type is used as an element in the following data type:
- **OrderableDBInstanceOption**
  - **Name** *(string)* –
    The name of the availability zone.
- **PreferredMaintenanceWindow** *(string)* –
  Specifies the weekly time range during which system maintenance can occur, in Universal Coordinated Time (UTC).
- **PendingModifiedValues** *(dict)* –
  Specifies that changes to the DB instance are pending. This element is only included when changes are pending. Specific changes are identified by subelements.
- **DBInstanceClass** *(string)* –
  Contains the new **DBInstanceClass** for the DB instance that will be applied or is in progress.
- **AllocatedStorage** *(integer)* –
  Contains the new `AllocatedStorage` size for the DB instance that will be applied or is in progress.
- **MasterUserPassword** *(string)* –
  Contains the pending or in-progress change of the master credentials for the DB instance.
- **Port** *(integer)* –
  Specifies the pending port for the DB instance.
- **BackupRetentionPeriod** *(integer)* –
  Specifies the pending number of days for which automated backups are retained.
- **MultiAZ** *(boolean)* –
  Indicates that the Single-AZ DB instance is to change to a Multi-AZ deployment.
- **EngineVersion** *(string)* –
  Indicates the database engine version.
- **Iops** *(integer)* –
  Specifies the new Provisioned IOPS value for the DB instance that will be applied or is being applied.
- **DBInstanceIdentifier** *(string)* –
  Contains the new `DBInstanceIdentifier` for the DB instance that will be applied or is in progress.
- **StorageType** *(string)* –
  Specifies the storage type to be associated with the DB instance.
- **CACertificateIdentifier** *(string)* –
  Specifies the identifier of the CA certificate for the DB instance.
- **LatestRestorableTime** *(datetime)* –
  Specifies the latest time to which a database can be restored with point-in-time restore.
- **MultiAZ** *(boolean)* –
  Specifies if the DB instance is a Multi-AZ deployment.
- **EngineVersion** *(string)* –
  Indicates the database engine version.
- **AutoMinorVersionUpgrade** *(boolean)* –
  Indicates that minor version patches are applied automatically.
- **ReadReplicaSourceDBInstanceIdentifier** *(string)* –
  Contains the identifier of the source DB instance if this DB instance is a Read Replica.
- **ReadReplicaDBInstanceIdentifiers** *(list)* –
  Contains one or more identifiers of the Read Replicas associated with this DB instance.
- **LicenseModel** *(string)* –
  License model information for this DB instance.
- **Iops** *(integer)* –
  Specifies the Provisioned IOPS (I/O operations per second) value.
- **OptionGroupMemberships** *(list)* –
  Provides the list of option group memberships for this DB instance.
  *(dict)* –
  Provides information on the option groups the DB instance is a member of.
- **OptionGroupName** *(string)* –
  The name of the option group that the instance belongs to.
- **Status** *(string)* –
  The status of the DB instance’s option group membership (e.g. in-sync, pending, pending-maintenance, applying).
- **CharacterSetName** *(string)* –
  If present, specifies the name of the character set that this instance is associated with.
- **SecondaryAvailabilityZone** *(string)* –
  If present, specifies the name of the secondary Availability Zone for a DB instance with multi-AZ support.
- **PubliclyAccessible** *(boolean)* –
  Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.

Default: The default behavior varies depending on whether a VPC has been requested or not. The following list shows the default behavior in each case.

- **Default VPC**: true
- **VPC**: false

  If no DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be publicly accessible. If a specific DB subnet group has been specified as part of the request and the PubliclyAccessible value has not been set, the DB instance will be private.
- **StatusInfos** *(list)* –
  The status of a Read Replica. If the instance is not a Read Replica, this will be blank.
  *(dict)* –
  Provides a list of status information for a DB instance.
- **StatusType** *(string)* –
  This value is currently “read replication.”
- **Normal** *(boolean)* –
Boolean value that is true if the instance is operating normally, or false if the instance is in an error state.

- **Status** *(string)* –

  Status of the DB instance. For a StatusType of read replica, the values can be replicating, error, stopped, or terminated.

- **Message** *(string)* –

  Details of the error if there is an error for the instance. If the instance is not in an error state, this value is blank.

- **StorageType** *(string)* –

  Specifies the storage type associated with DB instance.

- **TdeCredentialArn** *(string)* –

  The ARN from the Key Store with which the instance is associated for TDE encryption.

- **DbInstancePort** *(integer)* –

  Specifies the port that the DB instance listens on. If the DB instance is part of a DB cluster, this can be a different port than the DB cluster port.

- **DBClusterIdentifier** *(string)* –

  If the DB instance is a member of a DB cluster, contains the name of the DB cluster that the DB instance is a member of.

- **StorageEncrypted** *(boolean)* –

  Specifies whether the DB instance is encrypted.

- **KmsKeyId** *(string)* –

  If StorageEncrypted is true, the KMS key identifier for the encrypted DB instance.

- **DbiResourceId** *(string)* –

  If StorageEncrypted is true, the region-unique, immutable identifier for the encrypted DB instance. This identifier is found in AWS CloudTrail log entries whenever the KMS key for the DB instance is accessed.

- **CACertificateIdentifier** *(string)* –

  The identifier of the CA certificate for this DB instance.

- **DomainMemberships** *(list)* –

  The Active Directory Domain membership records associated with the DB instance.

  - *(dict)* –

    An Active Directory Domain membership record associated with the DB instance.

  - **Domain** *(string)* –

    The identifier of the Active Directory Domain.

  - **Status** *(string)* –

    The status of the DB instance’s Active Directory Domain membership (e.g. joined, pending-join, failed etc).

  - **Connectivity** *(string)* –

    The observed connectivity of the Active Directory Domain.
CopyTagsToSnapshot (boolean) –

This property is not currently implemented.

NextToken (string) –

A token to resume pagination.

class RDS.Paginator.DescribeDBLogFiles

paginator = client.get_paginator('describe_db_log_files')

paginate(**kwargs)

Creates an iterator that will paginate through responses from RDS.Client.describe_db_log_files().

Request Syntax

response_iterator = paginator.paginate(
    DBInstanceIdentifier='string',
    FilenameContains='string',
    FileLastWritten=123,
    FileSize=123,
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ]
        },
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **DBInstanceIdentifier (string) – [REQUIRED]**
  The customer-assigned name of the DB instance that contains the log files you want to list.

  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **FilenameContains (string) –** Filters the available log files for log file names that contain the specified string.

- **FileLastWritten (integer) –** Filters the available log files for files written since the specified date, in POSIX timestamp format with milliseconds.

- **FileSize (integer) –** Filters the available log files for files larger than the specified size.

- **Filters (list) –** This parameter is not currently supported.
  - (dict) –
    - **Name (string) – [REQUIRED]**
      This parameter is not currently supported.
Values (list) – [REQUIRED]

This parameter is not currently supported.

PaginationConfig (dict) – A dictionary that provides parameters to control pagination.

- MaxItems (integer) –
  The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

- PageSize (integer) –
  The size of each page.

- StartingToken (string) –
  A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict

Returns

Response Syntax

```python
{
    'DescribeDBLogFiles': [
        {
            'LogFileName': 'string',
            'LastWritten': 123,
            'Size': 123
        },
        ...
    ],
    'NextToken': 'string'
}
```

Response Structure

- (dict) –
  The response from a call to DescribeDBLogFiles.

  - DescribeDBLogFiles (list) –
    The DB log files returned.

    - (dict) –
      This data type is used as a response element to DescribeDBLogFiles.

      - LogFileName (string) –
        The name of the log file for the specified DB instance.

      - LastWritten (integer) –
        A POSIX timestamp when the last log entry was written.

      - Size (integer) –
        The size, in bytes, of the log file for the specified DB instance.

      - NextToken (string) –
        A token to resume pagination.

class RDS.Paginator.DescribeDBParameterGroups
paginator = client.get_paginator('describe_db_parameter_groups')

paginate(**kwargs)

Creates an iterator that will paginate through responses from RDS.Client.describe_db_parameter_groups().

Request Syntax

response_iterator = paginator.paginate(
    DBParameterGroupName='string',
    Filters=[
        {
            'Name': 'string',
            'Values': ['string',
                ]
        },
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **DBParameterGroupName** *(string)* – The name of a specific DB parameter group to return details for.

  Constraints:
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **Filters** *(list)* – This parameter is not currently supported.
  - *(dict)* –
    - **Name** *(string)* – [REQUIRED]
      - This parameter is not currently supported.
    - **Values** *(list)* – [REQUIRED]
      - *(string)* –

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* –
    - The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –
    - The size of each page.
  - **StartingToken** *(string)* –
    - A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  **dict**
Returns

Response Syntax

```json
{
    'DBParameterGroups': [
        {
            'DBParameterGroupName': 'string',
            'DBParameterGroupFamily': 'string',
            'Description': 'string'
        },
        
        
    ],
    'NextToken': 'string'
}
```

Response Structure

- (dict) –
  Contains the result of a successful invocation of the DescribeDBParameterGroups action.

  - DBParameterGroups (list) –
    A list of DBParameterGroup instances.
    - (dict) –
      Contains the result of a successful invocation of the CreateDBParameterGroup action.

      This data type is used as a request parameter in the DeleteDBParameterGroup action, and as a response element in the DescribeDBParameterGroups action.

      - DBParameterGroupName (string) –
        Provides the name of the DB parameter group.
      - DBParameterGroupFamily (string) –
        Provides the name of the DB parameter group family that this DB parameter group is compatible with.
      - Description (string) –
        Provides the customer-specified description for this DB parameter group.

  - NextToken (string) –
    A token to resume pagination.

```python
class RDS.Paginator.DescribeDBParameters

    paginator = client.get_paginator('describe_db_parameters')
```

paginate(**kwargs)

Creates an iterator that will paginate through responses from RDS.Client.describe_db_parameters().

Request Syntax

```python
response_iterator = paginator.paginate(
    DBParameterGroupName='string',
    Source='string',
)```
Parameters

- **DBParameterGroupName (string)** – [REQUIRED]
  
  The name of a specific DB parameter group to return details for.
  
  Constraints:
  
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **Source (string)** – The parameter types to return.

  Default: All parameter types returned

  Valid Values: user | system | engine-default

- **Filters (list)** – This parameter is not currently supported.

  - *(dict)* –
    
    - **Name (string)** – [REQUIRED]
      
      This parameter is not currently supported.
    
    - **Values (list)** – [REQUIRED]
      
      This parameter is not currently supported.

- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.

  - **MaxItems (integer)** –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  
  - **PageSize (integer)** –
    
    The size of each page.
  
  - **StartingToken (string)** –
    
    A token to specify where to start paginating. This is the `NextToken` from a previous response.
'ParameterName': 'string',
'ParameterValue': 'string',
'Description': 'string',
'Source': 'string',
'ApplyType': 'string',
'DataType': 'string',
'AllowedValues': 'string',
'IsModifiable': True|False,
'MinimumEngineVersion': 'string',
'ApplyMethod': 'immediate'|'pending-reboot'
}
,
,
'NextToken': 'string'
}

Response Structure

- *(dict)* –
  Contains the result of a successful invocation of the DescribeDBParameters action.
  - **Parameters**(list) –
    A list of Parameter values.
    - *(dict)* –
      This data type is used as a request parameter in the ModifyDBParameterGroup and ResetDBParameterGroup actions.
      This data type is used as a response element in the DescribeEngineDefaultParameters and DescribeDBParameters actions.
      - **ParameterName**(string) –
        Specifies the name of the parameter.
      - **ParameterValue**(string) –
        Specifies the value of the parameter.
      - **Description**(string) –
        Provides a description of the parameter.
      - **Source**(string) –
        Indicates the source of the parameter value.
      - **ApplyType**(string) –
        Specifies the engine specific parameters type.
      - **DataType**(string) –
        Specifies the valid data type for the parameter.
      - **AllowedValues**(string) –
        Specifies the valid range of values for the parameter.
      - **IsModifiable**(boolean) –
        Indicates whether (true) or not (false) the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.
      - **MinimumEngineVersion**(string) –
        The earliest engine version to which the parameter can apply.
- **ApplyMethod** *(string)* – Indicates when to apply parameter updates.

- **NextToken** *(string)* – A token to resume pagination.

```python
class RDS.Paginator.DescribeDBSecurityGroups

paginator = client.get_paginator('describe_db_security_groups')

paginate(**kwargs)

    Creates an iterator that will paginate through responses from 
    RDS.Client.describe_db_security_groups().

Request Syntax

```python
response_iterator = paginator.paginate(
    DBSecurityGroupName='string',
    Filters={[  
        'Name': 'string',
        'Values': [  
            'string',
        ]
    },  
    PaginationConfig={  
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    })
```

### Parameters

- **DBSecurityGroupName** *(string)* – The name of the DB security group to return details for.
- **Filters** *(list)* – This parameter is not currently supported.
  - *(dict)* –
    - *(string)* – [REQUIRED]
      - This parameter is not currently supported.
    - **Values** *(list)* – [REQUIRED]
      - This parameter is not currently supported.
  - *(string)* –
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* – The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* – The size of each page.
A token to specify where to start paginating. This is the NextToken from a previous response.

Return type: dict

Returns

Response Syntax

```python
{
    'DBSecurityGroups': [
        {
            'OwnerId': 'string',
            'DBSecurityGroupName': 'string',
            'DBSecurityGroupDescription': 'string',
            'VpcId': 'string',
            'EC2SecurityGroups': [
                {
                    'Status': 'string',
                    'EC2SecurityGroupName': 'string',
                    'EC2SecurityGroupId': 'string',
                    'EC2SecurityGroupOwnerId': 'string'
                }
            ],
            'IPRanges': [
                {
                    'Status': 'string',
                    'CIDRIP': 'string'
                }
            ],
            'NextToken': 'string'
        }
    ],
}
```

Response Structure

- **(dict)** –
  Contains the result of a successful invocation of the DescribeDBSecurityGroups action.

  - **DBSecurityGroups (list)** –
    A list of DBSecurityGroup instances.

  - **(dict)** –
    Contains the result of a successful invocation of the following actions:
    - DescribeDBSecurityGroups
    - AuthorizeDBSecurityGroupIngress
    - CreateDBSecurityGroup
    - RevokeDBSecurityGroupIngress

  This data type is used as a response element in the DescribeDBSecurityGroups action.

  - **OwnerId (string)** –
    Provides the AWS ID of the owner of a specific DB security group.

  - **DBSecurityGroupName (string)** –
    Specifies the name of the DB security group.

  - **DBSecurityGroupDescription (string)** –
Provides the description of the DB security group.

- **VpcId (string)** –
  Provides the VpcId of the DB security group.

- **EC2SecurityGroups (list)** –
  Contains a list of EC2SecurityGroup elements.
  - **(dict)** –
    This data type is used as a response element in the following actions:
    - AuthorizeDBSecurityGroupIngress
    - DescribeDBSecurityGroups
    - RevokeDBSecurityGroupIngress
    - **Status (string)** –
      Provides the status of the EC2 security group. Status can be “authorizing”, “authorized”, “revoking”, and “revoked”.

- **EC2SecurityGroupName (string)** –
  Specifies the name of the EC2 security group.

- **EC2SecurityGroupId (string)** –
  Specifies the id of the EC2 security group.

- **EC2SecurityGroupOwnerId (string)** –
  Specifies the AWS ID of the owner of the EC2 security group specified in the EC2SecurityGroupName field.

- **IPRanges (list)** –
  Contains a list of IPRange elements.
  - **(dict)** –
    This data type is used as a response element in the DescribeDBSecurityGroups action.
    - **Status (string)** –
      Specifies the status of the IP range. Status can be “authorizing”, “authorized”, “revoking”, and “revoked”.
    - **CIDRIP (string)** –
      Specifies the IP range.

- **NextToken (string)** –
  A token to resume pagination.

class RDS.Paginator.DescribeDBSnapshots

    paginator = client.get_paginator('describe_db_snapshots')

    paginate(**kwargs)
    Creates an iterator that will paginate through responses from RDS.Client.describe_db_snapshots().

    Request Syntax

    response_iterator = paginator.paginate(
        DBInstanceIdentifier='string',
        DBSnapshotIdentifier='string',
        SnapshotType='string',
        **kwargs)

3556 Chapter 3. API Reference
Parameters

- **DBInstanceIdentifier** *(string)* – A DB instance identifier to retrieve the list of DB snapshots for. This parameter cannot be used in conjunction with **DBSnapshotIdentifier**. This parameter is not case-sensitive.

  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **DBSnapshotIdentifier** *(string)* – A specific DB snapshot identifier to describe. This parameter cannot be used in conjunction with **DBInstanceIdentifier**. This value is stored as a lowercase string.

  Constraints:
  - Must be 1 to 255 alphanumeric characters.
  - First character must be a letter.
  - Cannot end with a hyphen or contain two consecutive hyphens.
  - If this is the identifier of an automated snapshot, the **SnapshotType** parameter must also be specified.

- **SnapshotType** *(string)* – The type of snapshots that will be returned. Values can be “automated” or “manual.” If not specified, the returned results will include all snapshots types.

- **Filters** *(list)* – This parameter is not currently supported.
  - *(dict)*  
    - *(string)* – [REQUIRED]
      This parameter is not currently supported.
    - *(list)* – [REQUIRED]
      This parameter is not currently supported.

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a **NextToken** will be provided in the output that you can use to resume pagination.

  - **PageSize** *(integer)* –
    The size of each page.

  - **StartingToken** *(string)* –
A token to specify where to start paginating. This is the NextToken from a previous response.

Return type: dict

Returns:

Response Syntax:

```python
{
    'DBSnapshots': [
        {
            'DBSnapshotIdentifier': 'string',
            'DBInstanceIdentifier': 'string',
            'SnapshotCreateTime': datetime(2015, 1, 1),
            'Engine': 'string',
            'AllocatedStorage': 123,
            'Status': 'string',
            'Port': 123,
            'AvailabilityZone': 'string',
            'VpcId': 'string',
            'InstanceCreateTime': datetime(2015, 1, 1),
            'MasterUsername': 'string',
            'EngineVersion': 'string',
            'LicenseModel': 'string',
            'SnapshotType': 'string',
            'Iops': 123,
            'OptionGroupName': 'string',
            'PercentProgress': 123,
            'SourceRegion': 'string',
            'SourceDBSnapshotIdentifier': 'string',
            'StorageType': 'string',
            'TdeCredentialArn': 'string',
            'Encrypted': True|False,
            'KmsKeyId': 'string'
        },
    ],
    'NextToken': 'string'
}
```

Response Structure:
- (dict) –
  Contains the result of a successful invocation of the DescribeDBSnapshots action.
  - DBSnapshots (list) –
    A list of DBSnapshot instances.
    * (dict) –
      Contains the result of a successful invocation of the following actions:
      - CreateDBSnapshot
      - DeleteDBSnapshot
      This data type is used as a response element in the DescribeDBSnapshots action.
      - DBSnapshotIdentifier (string) –
        Specifies the identifier for the DB snapshot.
      - DBInstanceIdentifier (string) –
Specifies the DB instance identifier of the DB instance this DB snapshot was created from.

- **SnapshotsCreateTime** *(datetime)* –

  Provides the time when the snapshot was taken, in Universal Coordinated Time (UTC).

- **Engine** *(string)* –

  Specifies the name of the database engine.

- **AllocatedStorage** *(integer)* –

  Specifies the allocated storage size in gigabytes (GB).

- **Status** *(string)* –

  Specifies the status of this DB snapshot.

- **Port** *(integer)* –

  Specifies the port that the database engine was listening on at the time of the snapshot.

- **AvailabilityZone** *(string)* –

  Specifies the name of the Availability Zone the DB instance was located in at the time of the DB snapshot.

- **VpcId** *(string)* –

  Provides the VPC ID associated with the DB snapshot.

- **InstanceCreateTime** *(datetime)* –

  Specifies the time when the snapshot was taken, in Universal Coordinated Time (UTC).

- **MasterUsername** *(string)* –

  Provides the master username for the DB snapshot.

- **EngineVersion** *(string)* –

  Specifies the version of the database engine.

- **LicenseModel** *(string)* –

  License model information for the restored DB instance.

- **SnapshotType** *(string)* –

  Provides the type of the DB snapshot.

- **Iops** *(integer)* –

  Specifies the Provisioned IOPS (I/O operations per second) value of the DB instance at the time of the snapshot.

- **OptionGroupName** *(string)* –

  Provides the option group name for the DB snapshot.

- **PercentProgress** *(integer)* –

  The percentage of the estimated data that has been transferred.

- **SourceRegion** *(string)* –

  The region that the DB snapshot was created in or copied from.

- **SourceDBSnapshotIdentifier** *(string)* –

  The DB snapshot Arn that the DB snapshot was copied from. It only has value in case of cross customer or cross region copy.
- **StorageType (string)** –
  Specifies the storage type associated with DB Snapshot.

- **TdeCredentialArn (string)** –
  The ARN from the Key Store with which to associate the instance for TDE encryption.

- **Encrypted (boolean)** –
  Specifies whether the DB snapshot is encrypted.

- **KmsKeyId (string)** –
  If Encrypted is true, the KMS key identifier for the encrypted DB snapshot.

- **NextToken (string)** –
  A token to resume pagination.

```python
class RDS.Paginator.DescribeDBSubnetGroups

paginator = client.get_paginator('describe_db_subnet_groups')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `RDS.Client.describe_db_subnet_groups()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    DBSubnetGroupName='string',
    Filters=[
        {
            'Name': 'string',
            'Values': ['string',
                        'string',
            ]
        },
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **DBSubnetGroupName (string)** – The name of the DB subnet group to return details for.
- **Filters (list)** – This parameter is not currently supported.
  - (dict) –
    - **Name (string)** – [REQUIRED]
      This parameter is not currently supported.
    - **Values (list)** – [REQUIRED]
      This parameter is not currently supported.
  - (string) –
- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
– **MaxItems** (integer) –

The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.

– **PageSize** (integer) –

The size of each page.

– **StartingToken** (string) –

A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'DBSubnetGroups': [
        {
            'DBSubnetGroupName': 'string',
            'DBSubnetGroupDescription': 'string',
            'VpcId': 'string',
            'SubnetGroupStatus': 'string',
            'Subnets': [
                {
                    'SubnetIdentifier': 'string',
                    'SubnetAvailabilityZone': {
                        'Name': 'string'
                    },
                    'SubnetStatus': 'string'
                }
            ],
            'NextToken': 'string'
        }
    ]
}
```

**Response Structure**

* `(dict)` –

Contains the result of a successful invocation of the DescribeDBSubnetGroups action.

– **DBSubnetGroups** (list) –

A list of DBSubnetGroup instances.

* `(dict)` –

Contains the result of a successful invocation of the following actions:

- CreateDBSubnetGroup
- ModifyDBSubnetGroup
- DescribeDBSubnetGroups
- DeleteDBSubnetGroup

This data type is used as a response element in the DescribeDBSubnetGroups action.

- **DBSubnetGroupName** (string) –

  Specifies the name of the DB subnet group.
- **DBSubnetGroupDescription** *(string)* —
  Provides the description of the DB subnet group.

- **VpcId** *(string)* —
  Provides the VpcId of the DB subnet group.

- **SubnetGroupStatus** *(string)* —
  Provides the status of the DB subnet group.

- **Subnets** *(list)* —
  Contains a list of Subnet elements.

  *(dict)* —
  This data type is used as a response element in the DescribeDBSubnetGroups action.

- **SubnetIdentifier** *(string)* —
  Specifies the identifier of the subnet.

- **SubnetAvailabilityZone** *(dict)* —
  Contains Availability Zone information.
  This data type is used as an element in the following data type:

  - **OrderableDBInstanceOption**
    - **Name** *(string)* —
      The name of the availability zone.
    - **SubnetStatus** *(string)* —
      Specifies the status of the subnet.

- **NextToken** *(string)* —
  A token to resume pagination.

```python
class RDS.Paginator.DescribeEngineDefaultParameters

paginator = client.get_paginator('describe_engine_default_parameters')

paginate(**kwargs)

response_iterator = paginator.paginate(
    DBParameterGroupFamily='string',
    Filters=[
        {'Name': 'string',
         'Values': ['string'],
      },
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```
Parameters

- **DBParameterGroupFamily** *(string)* – [REQUIRED]
  
  The name of the DB parameter group family.

- **Filters** *(list)* – Not currently supported.
  
  - *(dict)* –
    
    * **Name** *(string)* – [REQUIRED]
      
      This parameter is not currently supported.
    
    * **Values** *(list)* – [REQUIRED]
      
      This parameter is not currently supported.

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  - **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  
  - **PageSize** *(integer)* –
    
    The size of each page.
  
  - **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

Return type  `dict`

Returns

Response Syntax

```json
{
  'EngineDefaults': {
    'DBParameterGroupFamily': 'string',
    'Marker': 'string',
    'Parameters': [
      {
        'ParameterName': 'string',
        'ParameterValue': 'string',
        'Description': 'string',
        'Source': 'string',
        'ApplyType': 'string',
        'DataType': 'string',
        'AllowedValues': 'string',
        'IsModifiable': True|False,
        'MinimumEngineVersion': 'string',
        'ApplyMethod': 'immediate'|'pending-reboot'
      },
    ],
  },
  'NextToken': 'string'
}
```

Response Structure

- *(dict)* –
Contains the result of a successful invocation of the DescribeEngineDefaultParameters action.

- **EngineDefaults** *(dict)* –

  Contains the result of a successful invocation of the DescribeEngineDefaultParameters action.

- **DBParameterGroupFamily** *(string)* –

  Specifies the name of the DB parameter group family that the engine default parameters apply to.

- **Marker** *(string)* –

  An optional pagination token provided by a previous EngineDefaults request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by **MaxRecords**.

- **Parameters** *(list)* –

  Contains a list of engine default parameters.

  - *(dict)* –

    This data type is used as a request parameter in the ModifyDBParameterGroup and ResetDBParameterGroup actions.

    This data type is used as a response element in the DescribeEngineDefaultParameters and DescribeDBParameters actions.

    - **ParameterName** *(string)* –

      Specifies the name of the parameter.

    - **ParameterValue** *(string)* –

      Specifies the value of the parameter.

    - **Description** *(string)* –

      Provides a description of the parameter.

    - **Source** *(string)* –

      Indicates the source of the parameter value.

    - **ApplyType** *(string)* –

      Specifies the engine specific parameters type.

    - **DataType** *(string)* –

      Specifies the valid data type for the parameter.

    - **AllowedValues** *(string)* –

      Specifies the valid range of values for the parameter.

    - **IsModifiable** *(boolean)* –

      Indicates whether *(true)* or not *(false)* the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.

    - **MinimumEngineVersion** *(string)* –

      The earliest engine version to which the parameter can apply.

    - **ApplyMethod** *(string)* –

      Indicates when to apply parameter updates.

- **NextToken** *(string)* –

  A token to resume pagination.
class RDS.Paginator.DescribeEventSubscriptions

paginator = client.get_paginator('describe_event_subscriptions')

paginate(**kwargs)
    Creates an iterator that will paginate through responses from RDS.Client.describe_event_subscriptions().

Request Syntax

response_iterator = paginator.paginate(
    SubscriptionName='string',
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **SubscriptionName** *(string)* – The name of the RDS event notification subscription you want to describe.
- **Filters** *(list)* – This parameter is not currently supported.
  - *(dict)* –
    - **Name** *(string)* – [REQUIRED]
      This parameter is not currently supported.
    - **Values** *(list)* – [REQUIRED]
      This parameter is not currently supported.
  - *(string)* –
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –
    The size of each page.
  - **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict

Returns

Response Syntax
{  
    'EventSubscriptionsList': [  
        {  
            'CustomerAwsId': 'string',  
            'CustSubscriptionId': 'string',  
            'SnsTopicArn': 'string',  
            'Status': 'string',  
            'SubscriptionCreationTime': 'string',  
            'SourceType': 'string',  
            'SourceIdsList': [  
                'string',  
            ],  
            'EventCategoriesList': [  
                'string',  
            ],  
            'Enabled': True|False  
        },  
    ],  
    'NextToken': 'string'  
}  

Response Structure  
• (dict) –  
  Data returned by the DescribeEventSubscriptions action.  
  – EventSubscriptionsList (list) –  
    A list of EventSubscriptions data types.  
    * (dict) –  
      Contains the results of a successful invocation of the DescribeEventSubscriptions action.  
      • CustomerAwsId (string) –  
        The AWS customer account associated with the RDS event notification subscription.  
      • CustSubscriptionId (string) –  
        The RDS event notification subscription Id.  
      • SnsTopicArn (string) –  
        The topic ARN of the RDS event notification subscription.  
      • Status (string) –  
        The status of the RDS event notification subscription.  
        Constraints:  
        Can be one of the following: creating | modifying | deleting | active | no-permission | topic-not-exist  
        The status “no-permission” indicates that RDS no longer has permission to post to the SNS topic. The status “topic-not-exist” indicates that the topic was deleted after the subscription was created.  
      • SubscriptionCreationTime (string) –  
        The time the RDS event notification subscription was created.  
      • SourceType (string) –  
        The source type for the RDS event notification subscription.
- **SourceIdsList** (list) –
  A list of source IDs for the RDS event notification subscription.
  - **(string)** –
- **EventCategoriesList** (list) –
  A list of event categories for the RDS event notification subscription.
  - **(string)** –
  - **Enabled** (boolean) –
    A Boolean value indicating if the subscription is enabled.
    True indicates the subscription is enabled.
- **NextToken** (string) –
  A token to resume pagination.

```python
class RDS.Paginator.DescribeEvents

paginator = client.get_paginator('describe_events')
paginate(**kwargs)
```

**Request Syntax**

```python
response_iterator = paginator.paginate(
    SourceIdentifier='string',
    SourceType='db-instance'|'db-parameter-group'|'db-security-group'|'db-snapshot',
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    Duration=123,
    EventCategories=[
        'string',
    ],
    Filters=[
        {'Name': 'string',
        'Values': [
            'string',
        ]},
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **SourceIdentifier** (string) – The identifier of the event source for which events will be returned. If not specified, then all sources are included in the response.

  Constraints:
  - If SourceIdentifier is supplied, SourceType must also be provided.
  - If the source type is DBInstance, then a DBInstanceIdentifier must be supplied.
- If the source type is `DBSecurityGroup`, a `DBSecurityGroupName` must be supplied.
- If the source type is `DBParameterGroup`, a `DBParameterGroupName` must be supplied.
- If the source type is `DBSnapshot`, a `DBSnapshotIdentifier` must be supplied.
- Cannot end with a hyphen or contain two consecutive hyphens.

**SourceType** *(string)* – The event source to retrieve events for. If no value is specified, all events are returned.

**StartTime** *(datetime)* – The beginning of the time interval to retrieve events for, specified in ISO 8601 format. For more information about ISO 8601, go to the ISO8601 Wikipedia page.

Example: 2009-07-08T18:00Z

**EndTime** *(datetime)* – The end of the time interval for which to retrieve events, specified in ISO 8601 format. For more information about ISO 8601, go to the ISO8601 Wikipedia page.

Example: 2009-07-08T18:00Z

**Duration** *(integer)* – The number of minutes to retrieve events for.

Default: 60

**EventCategories** *(list)* – A list of event categories that trigger notifications for a event notification subscription.

  • *(string)*

**Filters** *(list)* – This parameter is not currently supported.

  • *(dict)*

  • **Name** *(string)* – [REQUIRED]
    This parameter is not currently supported.

  • **Values** *(list)* – [REQUIRED]
    This parameter is not currently supported.

• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

  • **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

  • **PageSize** *(integer)* –
    The size of each page.

  • **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** `dict`

**Response Syntax**

```py
{
    'Events': [
        {'SourceIdentifier': 'string',
         'SourceType': 'db-instance'|'db-parameter-group'|'db-security-group'|'db-snapshot',
         'Message': 'string',
        }
    ]
}
```
Response Structure

- *(dict)* –
  Contains the result of a successful invocation of the DescribeEvents action.
  - **Events** *(list)* –
    A list of Event instances.
    * *(dict)* –
      This data type is used as a response element in the DescribeEvents action.
      - **SourceIdentifier** *(string)* –
        Provides the identifier for the source of the event.
      - **SourceType** *(string)* –
        Specifies the source type for this event.
      - **Message** *(string)* –
        Provides the text of this event.
      - **EventCategories** *(list)* –
        Specifies the category for the event.
      - *(string)* –
      - **Date** *(datetime)* –
        Specifies the date and time of the event.
  - **NextToken** *(string)* –
    A token to resume pagination.

```python
class RDS.Paginator.DescribeOptionGroupOptions

paginator = client.get_paginator('describe_option_group_options')
paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `RDS.Client.describe_option_group_options()`.

Request Syntax

```python
response_iterator = paginator.paginate(
    EngineName='string',
    MajorEngineVersion='string',
    Filters=[
        
            'Name': 'string',
            'Values': [ 
            'string',
            ]
    ]
```
Boto3 Documentation, Release 1.1.4

},
],
PaginationConfig={
  'MaxItems': 123,
  'PageSize': 123,
  'StartingToken': 'string'
}
}

Parameters

- **EngineName (string) – [REQUIRED]**
  A required parameter. Options available for the given engine name will be described.

- **MajorEngineVersion (string) –** If specified, filters the results to include only options for the specified major engine version.

- **Filters (list) –** This parameter is not currently supported.
  - (dict) –
    - **Name (string) – [REQUIRED]**
      This parameter is not currently supported.
    - **Values (list) – [REQUIRED]**
      This parameter is not currently supported.

- **PaginationConfig (dict) –** A dictionary that provides parameters to control pagination.
  - **MaxItems (integer) –**
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize (integer) –**
    The size of each page.
  - **StartingToken (string) –**
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

Return type  dict

Returns

Response Syntax

```python

{
  'OptionGroupOptions': [
  
  
  ],
  'Name': 'string',
  'Description': 'string',
  'EngineName': 'string',
  'MajorEngineVersion': 'string',
  'MinimumRequiredMinorEngineVersion': 'string',
  'PortRequired': True|False,
  'DefaultPort': 123,
  'OptionsDependedOn': [
  
  ],
  'Persistent': True|False,
  'Permanent': True|False,
```

3570 Chapter 3. API Reference
'OptionGroupOptionSettings': [ 
  { 
    'SettingName': 'string',
    'SettingDescription': 'string',
    'DefaultValue': 'string',
    'ApplyType': 'string',
    'AllowedValues': 'string',
    'IsModifiable': True|False
  },
  
  
},
],

'NextToken': 'string'

Response Structure
• (dict) –
  – OptionGroupOptions (list) –
    List of available option group options.
    • (dict) – 
      Available option.
      • Name (string) –
        The name of the option.
      • Description (string) –
        The description of the option.
      • EngineName (string) –
        The name of the engine that this option can be applied to.
      • MajorEngineVersion (string) –
        Indicates the major engine version that the option is available for.
      • MinimumRequiredMinorEngineVersion (string) –
        The minimum required engine version for the option to be applied.
      • PortRequired (boolean) –
        Specifies whether the option requires a port.
      • DefaultPort (integer) –
        If the option requires a port, specifies the default port for the option.
      • OptionsDependedOn (list) –
        List of all options that are prerequisites for this option.
        • (string) –
          • Persistent (boolean) –
            A persistent option cannot be removed from the option group once the option group is used, but this option can be removed from the db instance while modifying the related data and assigning another option group without this option.
          • Permanent (boolean) –
            A permanent option cannot be removed from the option group once the option group is used, and it cannot be removed from
the db instance after assigning an option group with this permanent option.

- **OptionGroupOptionSettings (list)** –

  Specifies the option settings that are available (and the default value) for each option in an option group.

- **(dict)** –

  Option group option settings are used to display settings available for each option with their default values and other information. These values are used with the DescribeOptionGroupOptions action.

- **SettingName (string)** –

  The name of the option group option.

- **SettingDescription (string)** –

  The description of the option group option.

- **DefaultValue (string)** –

  The default value for the option group option.

- **ApplyType (string)** –

  The DB engine specific parameter type for the option group option.

- **AllowedValues (string)** –

  Indicates the acceptable values for the option group option.

- **IsModifiable (boolean)** –

  Boolean value where true indicates that this option group option can be changed from the default value.

- **NextToken (string)** –

  A token to resume pagination.

```python
class RDS.Paginator.DescribeOptionGroups

paginator = client.get_paginator('describe_option_groups')

paginate(**kwargs)

Creates an iterator that will paginate through responses from RDS.Client.describe_option_groups().

Request Syntax

response_iterator = paginator.paginate(
    OptionGroupName='string',
    Filters=[
        {'Name': 'string',
         'Values': ['string',
                    'string'],
        },
    ],
    EngineName='string',
    MajorEngineVersion='string',
    PaginationConfig={
```
'MaxItems': 123,
'PageSize': 123,
'StartingToken': 'string'
}
}

Parameters

- **OptionGroupName** (**string**) – The name of the option group to describe. Cannot be supplied together with EngineName or MajorEngineVersion.
- **Filters** (**list**) – This parameter is not currently supported.
  - (dict)
    - **Name** (**string**) – [REQUIRED]
      This parameter is not currently supported.
    - **Values** (**list**) – [REQUIRED]
      This parameter is not currently supported.
  - (string)
    
- **EngineName** (**string**) – Filters the list of option groups to only include groups associated with a specific database engine.
- **MajorEngineVersion** (**string**) – Filters the list of option groups to only include groups associated with a specific database engine version. If specified, then EngineName must also be specified.
- **PaginationConfig** (**dict**) – A dictionary that provides parameters to control pagination.
  - **MaxItems** (**integer**) – The total number of items to return. If the total number of items available is more than the value specified in max-items then a **NextToken** will be provided in the output that you can use to resume pagination.
  - **PageSize** (**integer**) – The size of each page.
  - **StartingToken** (**string**) – A token to specify where to start paginating. This is the **NextToken** from a previous response.

Returns

Return type **dict**

Returns

Response Syntax

```python
{
  'OptionGroupsList': [
    {
      'OptionGroupName': 'string',
      'OptionGroupDescription': 'string',
      'EngineName': 'string',
      'MajorEngineVersion': 'string',
      'Options': [
        {
          'OptionName': 'string',
          'OptionDescription': 'string',
          'Persistent': True|False,
          'Permanent': True|False,
          'Port': 123,
          'OptionSettings': [|
```
'Name': 'string',
'Value': 'string',
'DefaultValue': 'string',
'Description': 'string',
'ApplyType': 'string',
'DataType': 'string',
'AllowedValues': 'string',
'IsModifiable': True|False,
'IsCollection': True|False,

],
'DBSecurityGroupMemberships': [

],
'VpcSecurityGroupMemberships': [

],

'AllowsVpcAndNonVpcInstanceMemberships': True|False,
'VpcId': 'string',

],

'NextToken': 'string'

Response Structure

• (dict) – List of option groups.
  – OptionGroupsList (list) – List of option groups.
    * (dict) –
      • OptionGroupName (string) – Specifies the name of the option group.
      • OptionGroupDescription (string) – Provides a description of the option group.
      • EngineName (string) – Indicates the name of the engine that this option group can be applied to.
      • MajorEngineVersion (string) – Indicates the major engine version associated with this option group.
      • Options (list) – Indicates what options are available in the option group.
      • (dict) – Option details.
· **OptionName** *(string)* –
  The name of the option.

· **OptionDescription** *(string)* –
  The description of the option.

· **Persistent** *(boolean)* –
  Indicate if this option is persistent.

· **Permanent** *(boolean)* –
  Indicate if this option is permanent.

· **Port** *(integer)* –
  If required, the port configured for this option to use.

· **OptionSettings** *(list)* –
  The option settings for this option.

  · *(dict)* –

    Option settings are the actual settings being applied or configured for that option. It is used when you modify an option group or describe option groups. For example, the NATIVE_NETWORK_ENCRYPTION option has a setting called SQLNET.ENCRYPTION_SERVER that can have several different values.

· **Name** *(string)* –
  The name of the option that has settings that you can set.

· **Value** *(string)* –
  The current value of the option setting.

· **DefaultValue** *(string)* –
  The default value of the option setting.

· **Description** *(string)* –
  The description of the option setting.

· **ApplyType** *(string)* –
  The DB engine specific parameter type.

· **DataType** *(string)* –
  The data type of the option setting.

· **AllowedValues** *(string)* –
  The allowed values of the option setting.

· **IsModifiable** *(boolean)* –
  A Boolean value that, when true, indicates the option setting can be modified from the default.

· **IsCollection** *(boolean)* –
  Indicates if the option setting is part of a collection.

· **DBSecurityGroupMemberships** *(list)* –
  If the option requires access to a port, then this DB security group allows access to the port.

  · *(dict)* –

    This data type is used as a response element in the following actions:

    · ModifyDBInstance
- RebootDBInstance
- RestoreDBInstanceFromDBSnapshot
- RestoreDBInstanceToPointInTime
- **DBSecurityGroupName** *(string)* –
  The name of the DB security group.
- **Status** *(string)* –
  The status of the DB security group.
- **VpcSecurityGroupMemberships** *(list)* –
  If the option requires access to a port, then this VPC security group allows access to the port.
- *(dict)* –
  This data type is used as a response element for queries on VPC security group membership.
- **VpcSecurityGroupId** *(string)* –
  The name of the VPC security group.
- **Status** *(string)* –
  The status of the VPC security group.
- **AllowsVpcAndNonVpcInstanceMemberships** *(boolean)* –
  Indicates whether this option group can be applied to both VPC and non-VPC instances. The value `true` indicates the option group can be applied to both VPC and non-VPC instances.
- **VpcId** *(string)* –
  If `AllowsVpcAndNonVpcInstanceMemberships` is `false`, this field is blank. If `AllowsVpcAndNonVpcInstanceMemberships` is `true` and this field is blank, then this option group can be applied to both VPC and non-VPC instances. If this field contains a value, then this option group can only be applied to instances that are in the VPC indicated by this field.

- **NextToken** *(string)* –
  A token to resume pagination.

class RDS.Paginator.DescribeOrderableDBInstanceOptions

```python
pagi = client.get_paginator('describe_orderable_db_instance_options')

paginate(**kwargs)

Creates an iterator that will paginate through responses from RDS.Client.describe_orderable_db_instance_options().

Request Syntax

```python
response_iterator = pagi.paginate(
    Engine='string',
    EngineVersion='string',
    DBInstanceClass='string',
    LicenseModel='string',
    Vpc=True|False,
    Filters=[
    {  
```
Parameters

- **Engine** *(string)* – [REQUIRED]
  The name of the engine to retrieve DB instance options for.

- **EngineVersion** *(string)* – The engine version filter value. Specify this parameter to show only the available offerings matching the specified engine version.

- **DBInstanceClass** *(string)* – The DB instance class filter value. Specify this parameter to show only the available offerings matching the specified DB instance class.

- **LicenseModel** *(string)* – The license model filter value. Specify this parameter to show only the available offerings matching the specified license model.

- **Vpc** *(boolean)* – The VPC filter value. Specify this parameter to show only the available VPC or non-VPC offerings.

- **Filters** *(list)* – This parameter is not currently supported.
  
  - *(dict)* –
    
    - **Name** *(string)* – [REQUIRED]
      This parameter is not currently supported.
    
    - **Values** *(list)* – [REQUIRED]
      This parameter is not currently supported.

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

  - **PageSize** *(integer)* –
    The size of each page.

  - **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  **dict**

Returns

Response Syntax

```python
{
    'OrderableDBInstanceOptions': [
        {
            'Engine': 'string',
```
'EngineVersion': 'string',
'DBInstanceClass': 'string',
'LicenseModel': 'string',
'AvailabilityZones': [
    {
        'Name': 'string'
    }
],
'MultiAZCapable': True|False,
'ReadReplicaCapable': True|False,
'Vpc': True|False,
'SupportsStorageEncryption': True|False,
'StorageType': 'string',
'SupportsIops': True|False
},

'NextToken': 'string'

Response Structure

• (dict) –

Contains the result of a successful invocation of the DescribeOrderableDBInstanceOptions action.

– OrderableDBInstanceOptions (list) –

An OrderableDBInstanceOption structure containing information about orderable options for the DB instance.

• (dict) –

Contains a list of available options for a DB instance

This data type is used as a response element in the DescribeOrderableDBInstanceOptions action.

• Engine (string) –

The engine type of the orderable DB instance.

• EngineVersion (string) –

The engine version of the orderable DB instance.

• DBInstanceClass (string) –

The DB instance class for the orderable DB instance.

• LicenseModel (string) –

The license model for the orderable DB instance.

• AvailabilityZones (list) –

A list of Availability Zones for the orderable DB instance.

• (dict) –

Contains Availability Zone information.

This data type is used as an element in the following data type:

• OrderableDBInstanceOption

• Name (string) –

The name of the availability zone.

• MultiAZCapable (boolean) –

Indicates whether this orderable DB instance is multi-AZ capable.
- **ReadReplicaCapable** *(boolean)* – Indicates whether this orderable DB instance can have a Read Replica.
- **Vpc** *(boolean)* – Indicates whether this is a VPC orderable DB instance.
- **SupportsStorageEncryption** *(boolean)* – Indicates whether this orderable DB instance supports encrypted storage.
- **StorageType** *(string)* – Indicates the storage type for this orderable DB instance.
- **SupportsIops** *(boolean)* – Indicates whether this orderable DB instance supports provisioned IOPS.

- **NextToken** *(string)* – A token to resume pagination.

```python
class RDS.Paginator.DescribeReservedDBInstances

paginator = client.get_paginator('describeReservedDBInstances')

paginate(**kwargs)
    Creates an iterator that will paginate through responses from
    RDS.Client.describeReservedDBInstances().

    Request Syntax
    
    response_iterator = paginator.paginate(
        ReservedDBInstanceId='string',
        ReservedDBInstancesOfferingId='string',
        DBInstanceClass='string',
        Duration='string',
        ProductDescription='string',
        OfferingType='string',
        MultiAZ=True|False,
        Filters=[
            {'Name': 'string',
             'Values': [ 'string',
            ]},
        ],
        PaginationConfig={
            'MaxItems': 123,
            'pageSize': 123,
            'StartingToken': 'string'
        }
    )

Parameters

- **ReservedDBInstanceId** *(string)* – The reserved DB instance identifier filter value. Specify this parameter to show only the reservation that matches the specified reservation ID.
```
• **ReservedDBInstancesOfferingId** *(string)* – The offering identifier filter value. Specify this parameter to show only purchased reservations matching the specified offering identifier.

• **DBInstanceClass** *(string)* – The DB instance class filter value. Specify this parameter to show only those reservations matching the specified DB instances class.

• **Duration** *(string)* – The duration filter value, specified in years or seconds. Specify this parameter to show only reservations for this duration.

Valid Values: 1 | 3 | 31536000 | 94608000

• **ProductDescription** *(string)* – The product description filter value. Specify this parameter to show only those reservations matching the specified product description.

• **OfferingType** *(string)* – The offering type filter value. Specify this parameter to show only the available offerings matching the specified offering type.

Valid Values: "Partial Upfront" | "All Upfront" | "No Upfront"

• **MultiAZ** *(boolean)* – The Multi-AZ filter value. Specify this parameter to show only those reservations matching the specified Multi-AZ parameter.

• **Filters** *(list)* – This parameter is not currently supported.

  – *(dict)* –
    * **Name** *(string)* – [REQUIRED]
      This parameter is not currently supported.
    * **Values** *(list)* – [REQUIRED]
      This parameter is not currently supported.

• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

  – **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.

  – **PageSize** *(integer)* –
    The size of each page.

  – **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

Return type  `dict`

Returns

Response Syntax

```json
{
  'ReservedDBInstances': [
  
  ],
}
```
Response Structure

- **(dict)** –
  Contains the result of a successful invocation of the DescribeReservedDBInstances action.

  - **ReservedDBInstances (list)** –
    A list of reserved DB instances.

      - **(dict)** –
        This data type is used as a response element in the DescribeReservedDBInstances and PurchaseReservedDBInstancesOffering actions.

          - **ReservedDBInstanceId (string)** –
            The unique identifier for the reservation.

          - **ReservedDBInstancesOfferingId (string)** –
            The offering identifier.

          - **DBInstanceClass (string)** –
            The DB instance class for the reserved DB instance.

          - **StartTime (datetime)** –
            The time the reservation started.

          - **Duration (integer)** –
            The duration of the reservation in seconds.

          - **FixedPrice (float)** –
            The fixed price charged for this reserved DB instance.

          - **UsagePrice (float)** –
            The hourly price charged for this reserved DB instance.

          - **CurrencyCode (string)** –
            The currency code for the reserved DB instance.

          - **DBInstanceCount (integer)** –
            The number of reserved DB instances.

          - **ProductDescription (string)** –
            The description of the reserved DB instance.

          - **OfferingType (string)** –
The offering type of this reserved DB instance.

- **MultiAZ** *(boolean)* – Indicates if the reservation applies to Multi-AZ deployments.
- **State** *(string)* – The state of the reserved DB instance.
- **RecurringCharges** *(list)* – The recurring price charged to run this reserved DB instance.

  - **RecurringChargeAmount** *(float)* – The amount of the recurring charge.
  - **RecurringChargeFrequency** *(string)* – The frequency of the recurring charge.

- **NextToken** *(string)* – A token to resume pagination.

```python
class RDS.Paginator.DescribeReservedDBInstancesOfferings

paginator = client.get_paginator('describe_reserved_db_instances_offerings')
paginate(**kwargs)

Creates an iterator that will paginate through responses from
RDS.Client.describe_reserved_db_instances_offerings().
```

**Request Syntax**

```python
response_iterator = paginator.paginate(
    ReservedDBInstancesOfferingId='string',
    DBInstanceClass='string',
    Duration='string',
    ProductDescription='string',
    OfferingType='string',
    MultiAZ=True|False,
    Filters=[
        {
            'Name': 'string',
            'Values': [ 'string',
                        ]
        },
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**
• **ReservedDBInstancesOfferingId** *(string)* – The offering identifier filter value. Specify this parameter to show only the available offering that matches the specified reservation identifier.

Example: 438012d3-4052-4cc7-b2e3-8d3372e0e706

• **DBInstanceClass** *(string)* – The DB instance class filter value. Specify this parameter to show only the available offerings matching the specified DB instance class.

• **Duration** *(string)* – Duration filter value, specified in years or seconds. Specify this parameter to show only reservations for this duration.

Valid Values: 1 | 3 | 31536000 | 94608000

• **ProductDescription** *(string)* – Product description filter value. Specify this parameter to show only the available offerings matching the specified product description.

• **OfferingType** *(string)* – The offering type filter value. Specify this parameter to show only the available offerings matching the specified offering type.

Valid Values: "Partial Upfront" | "All Upfront" | "No Upfront"

• **MultiAZ** *(boolean)* – The Multi-AZ filter value. Specify this parameter to show only the available offerings matching the specified Multi-AZ parameter.

• **Filters** *(list)* – This parameter is not currently supported.

  (dict) –

  * **Name** *(string)* – [REQUIRED]
    
    This parameter is not currently supported.

  * **Values** *(list)* – [REQUIRED]
    
    This parameter is not currently supported.

  (string) –

• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

  (dict) –

  * **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NEXT_TOKEN will be provided in the output that you can use to resume pagination.

  * **PageSize** *(integer)* –
    
    The size of each page.

  * **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the NEXT_TOKEN from a previous response.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
'ReservedDBInstancesOfferings': [
{
'ReservedDBInstancesOfferingId': 'string',
'DBInstanceClass': 'string',
'Duration': 123,

'NextToken': 'string'

Response Structure

• (dict) –
  Contains the result of a successful invocation of the DescribeReservedDBInstancesOfferings action.
  – ReservedDBInstancesOfferings (list) –
    A list of reserved DB instance offerings.
    • (dict) –
      This data type is used as a response element in the DescribeReservedDBInstancesOfferings action.
      • ReservedDBInstancesOfferingId (string) –
        The offering identifier.
      • DBInstanceClass (string) –
        The DB instance class for the reserved DB instance.
      • Duration (integer) –
        The duration of the offering in seconds.
      • FixedPrice (float) –
        The fixed price charged for this offering.
      • UsagePrice (float) –
        The hourly price charged for this offering.
      • CurrencyCode (string) –
        The currency code for the reserved DB instance offering.
      • ProductDescription (string) –
        The database engine used by the offering.
      • OfferingType (string) –
        The offering type.
      • MultiAZ (boolean) –
        Indicates if the offering applies to Multi-AZ deployments.
      • RecurringCharges (list) –
        The recurring price charged to run this reserved DB instance.
      • (dict) –
        This data type is used as a response element in the DescribeReservedDBInstances and DescribeReservedDBInstancesOfferings actions.
- **RecurringChargeAmount** *(float)* –
  The amount of the recurring charge.
- **RecurringChargeFrequency** *(string)* –
  The frequency of the recurring charge.
- **NextToken** *(string)* –
  A token to resume pagination.

```python
class RDS.Paginator.DownloadDBLogFilePortion

paginator = client.get_paginator('download_db_log_file_portion')
paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `RDS.Client.download_db_log_file_portion()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    DBInstanceIdentifier='string',
    LogFileName='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **DBInstanceIdentifier** *(string)* – [REQUIRED]
  The customer-assigned name of the DB instance that contains the log files you want to list.
  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens
- **LogFileName** *(string)* – [REQUIRED]
  The name of the log file to be downloaded.
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –
    The size of each page.
  - **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** dict
Returns

Response Syntax

```python
{
    'LogFileData': 'string',
    'AdditionalDataPending': True|False,
    'NextToken': 'string'
}
```

Response Structure

- (dict) –
  - **LogFileData** *(string)* – Entries from the specified log file.
  - **AdditionalDataPending** *(boolean)* – Boolean value that if true, indicates there is more data to be downloaded.
  - **NextToken** *(string)* – A token to resume pagination.

Waiters

The available waiters are:

- `RDS.Waiter.DBInstanceAvailable`
- `RDS.Waiter.DBInstanceDeleted`
- `RDS.Waiter.DBSnapshotCompleted`

```python
class RDS.Waiter.DBInstanceAvailable

waiter = client.get_waiter('db_instance_available')

wait(**kwargs)
```

Polls `RDS.Client.describe_db_instances()` every 30 seconds until a successful state is reached. An error is returned after 60 failed checks.

Request Syntax

```python
waiter.wait(
    DBInstanceIdentifier='string',
    Filters=[
    {
        'Name': 'string',
        'Values': [ 'string',
    ],
    },
    MaxRecords=123,
    Marker='string'
)
```

Parameters
• **DBInstanceIdentifier** *(string)* – The user-supplied instance identifier. If this parameter is specified, information from only the specific DB instance is returned. This parameter isn’t case-sensitive.

Constraints:
– Must contain from 1 to 63 alphanumeric characters or hyphens
– First character must be a letter
– Cannot end with a hyphen or contain two consecutive hyphens

• **Filters** *(list)* – This parameter is not currently supported.

  – *(dict)*
    * **Name** *(string)* – [REQUIRED]
      This parameter is not currently supported.
    * **Values** *(list)* – [REQUIRED]
      This parameter is not currently supported.

• **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.

  Default: 100

Constraints: Minimum 20, maximum 100.

• **Marker** *(string)* – An optional pagination token provided by a previous DescribeDBInstances request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

**Returns** None

```python
class RDS.Waiter.DBInstanceDeleted

waiter = client.get_waiter('db_instance_deleted')

wait(**kwargs)
```

Polls `RDS.Client.describe_db_instances()` every 30 seconds until a successful state is reached. An error is returned after 60 failed checks.

**Request Syntax**

```python
waiter.wait(
    DBInstanceIdentifier='string',
    Filters=[
        {'Name': 'string',
         'Values': [ 'string',
         ]},
    ],
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**
• **DBInstanceIdentifier** (*string*) – The user-supplied instance identifier. If this parameter is specified, information from only the specific DB instance is returned. This parameter isn’t case-sensitive.

  Constraints:
  – Must contain from 1 to 63 alphanumeric characters or hyphens
  – First character must be a letter
  – Cannot end with a hyphen or contain two consecutive hyphens

• **Filters** (*list*) – This parameter is not currently supported.
  – (*dict*) –
    * **Name** (*string*) – [REQUIRED]
      This parameter is not currently supported.
    * **Values** (*list*) – [REQUIRED]
      This parameter is not currently supported.
  – (*string*) –

• **MaxRecords** (*integer*) – The maximum number of records to include in the response. If more records exist than the specified `MaxRecords` value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.

  Default: 100
  Constraints: Minimum 20, maximum 100.

• **Marker** (*string*) – An optional pagination token provided by a previous `DescribeDBInstances` request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

Returns None

class RDS.Waiter=DBSnapshotCompleted

waiter = client.get_waiter('db_snapshot_completed')

wait(**kwargs)

Polls `RDS.Client.describe_db_snapshots()` every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

waiter.wait(
    DBInstanceIdentifier='string',
    DBSnapshotIdentifier='string',
    SnapshotType='string',
    Filters=[
        {
            'Name': 'string',
            'Values': [ 'string',
        ]
    ],
    MaxRecords=123,
    Marker='string'
)

Parameters
• **DBInstanceIdentifier** *(string)* – A DB instance identifier to retrieve the list of DB snapshots for. This parameter cannot be used in conjunction with `DBSnapshotIdentifier`. This parameter is not case-sensitive.

  Constraints:
  – Must contain from 1 to 63 alphanumeric characters or hyphens
  – First character must be a letter
  – Cannot end with a hyphen or contain two consecutive hyphens

• **DBSnapshotIdentifier** *(string)* – A specific DB snapshot identifier to describe. This parameter cannot be used in conjunction with `DBInstanceIdentifier`. This value is stored as a lowercase string.

  Constraints:
  – Must be 1 to 255 alphanumeric characters.
  – First character must be a letter.
  – Cannot end with a hyphen or contain two consecutive hyphens.
  – If this is the identifier of an automated snapshot, the `SnapshotType` parameter must also be specified.

• **SnapshotType** *(string)* – The type of snapshots that will be returned. Values can be “automated” or “manual.” If not specified, the returned results will include all snapshots types.

• **Filters** *(list)* – This parameter is not currently supported.
  – *(dict)* –
    * **Name** *(string)* – [REQUIRED]
      This parameter is not currently supported.
    * **Values** *(list)* – [REQUIRED]
      This parameter is not currently supported.
  – *(string)* –

• **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified `MaxRecords` value, a pagination token called a marker is included in the response so that the remaining results can be retrieved.

  Default: 100

  Constraints: Minimum 20, maximum 100.

• **Marker** *(string)* – An optional pagination token provided by a previous `DescribeDBSnapshots` request. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

**Returns** None

- `describe_tags()`
**authorize_cluster_security_group_ingress(**"kwargs")**

Adds an inbound (ingress) rule to an Amazon Redshift security group. Depending on whether the application accessing your cluster is running on the Internet or an EC2 instance, you can authorize inbound access to either a Classless Interdomain Routing (CIDR) IP address range or an EC2 security group. You can add as many as 20 ingress rules to an Amazon Redshift security group.

**Note:** The EC2 security group must be defined in the AWS region where the cluster resides.

For an overview of CIDR blocks, see the Wikipedia article on Classless Inter-Domain Routing.

You must also associate the security group with a cluster so that clients running on these IP addresses or the EC2 instance are authorized to connect to the cluster. For information about managing security groups, go to Working with Security Groups in the Amazon Redshift Cluster Management Guide.

**Request Syntax**

```python
response = client.authorize_cluster_security_group_ingress(
    ClusterSecurityGroupName='string',
    CIDRIP='string',
    EC2SecurityGroupName='string',
    EC2SecurityGroupOwnerId='string'
)
```

**Parameters**

- **ClusterSecurityGroupName** *(string)* – [REQUIRED]
  
  The name of the security group to which the ingress rule is added.

- **CIDRIP** *(string)* – The IP range to be added the Amazon Redshift security group.

- **EC2SecurityGroupName** *(string)* – The EC2 security group to be added the Amazon Redshift security group.

- **EC2SecurityGroupOwnerId** *(string)* – The AWS account number of the owner of the security group specified by the EC2SecurityGroupName parameter. The AWS Access Key ID is not an acceptable value.

**Example:** 111122223333

**Return type** `dict`
Returns

Response Syntax

```
{
  'ClusterSecurityGroup': {
    'ClusterSecurityGroupName': 'string',
    'Description': 'string',
    'EC2SecurityGroups': [
      {
        'Status': 'string',
        'EC2SecurityGroupName': 'string',
        'EC2SecurityGroupOwnerId': 'string',
        'Tags': [
          {
            'Key': 'string',

            'Key': 'string',
            'Value': 'string'
          },
        ],
      },
    ],
    'Tags': [
      {
        'Key': 'string',
        'Value': 'string'
      },
    ],
  }
}
```

Response Structure

- (dict) –
  Describes a security group.
    - ClusterSecurityGroup (dict) –
      Describes a security group.
        * ClusterSecurityGroupName (string) –
          The name of the cluster security group to which the operation was applied.
        * Description (string) –
          A description of the security group.
        * EC2SecurityGroups (list) –
          A list of EC2 security groups that are permitted to access clusters associated with this cluster security group.
· (dict) –
  Describes an Amazon EC2 security group.
  · **Status (string)** –
    The status of the EC2 security group.
  · **EC2SecurityGroupName (string)** –
    The name of the EC2 Security Group.
  · **EC2SecurityGroupOwnerId (string)** –
    The AWS ID of the owner of the EC2 security group specified in the **EC2SecurityGroupName** field.
  · **Tags (list)** –
    The list of tags for the EC2 security group.
    · (dict) –
      A tag consisting of a name/value pair for a resource.
      · **Key (string)** –
        The key, or name, for the resource tag.
      · **Value (string)** –
        The value for the resource tag.

* **IPRanges (list)** –
  A list of IP ranges (CIDR blocks) that are permitted to access clusters associated with this cluster security group.
  · (dict) –
    Describes an IP range used in a security group.
    · **Status (string)** –
      The status of the IP range, for example, “authorized”.
    · **CIDRIP (string)** –
      The IP range in Classless Inter-Domain Routing (CIDR) notation.
    · **Tags (list)** –
      The list of tags for the IP range.
      · (dict) –
        A tag consisting of a name/value pair for a resource.
        · **Key (string)** –
          The key, or name, for the resource tag.
        · **Value (string)** –
          The value for the resource tag.

* **Tags (list)** –
  The list of tags for the cluster security group.
  · (dict) –
    A tag consisting of a name/value pair for a resource.
    · **Key (string)** –
      The key, or name, for the resource tag.
    · **Value (string)** –
      The value for the resource tag.
authorize_snapshot_access(**kwargs)

Authorizes the specified AWS customer account to restore the specified snapshot.

For more information about working with snapshots, go to Amazon Redshift Snapshots in the Amazon Redshift Cluster Management Guide.

Request Syntax

```python
response = client.authorize_snapshot_access(
    SnapshotIdentifier='string',
    SnapshotClusterIdentifier='string',
    AccountWithRestoreAccess='string'
)
```

**Parameters**

- **SnapshotIdentifier** *(string) – [REQUIRED]*
  The identifier of the snapshot the account is authorized to restore.

- **SnapshotClusterIdentifier** *(string)* – The identifier of the cluster the snapshot was created from. This parameter is required if your IAM user has a policy containing a snapshot resource element that specifies anything other than * for the cluster name.

- **AccountWithRestoreAccess** *(string) – [REQUIRED]*
  The identifier of the AWS customer account authorized to restore the specified snapshot.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'Snapshot': {
        'SnapshotIdentifier': 'string',
        'ClusterIdentifier': 'string',
        'SnapshotCreateTime': datetime(2015, 1, 1),
        'Status': 'string',
        'Port': 123,
        'AvailabilityZone': 'string',
        'ClusterCreateTime': datetime(2015, 1, 1),
        'MasterUsername': 'string',
        'ClusterVersion': 'string',
        'SnapshotType': 'string',
        'NodeType': 'string',
        'NumberOfNodes': 123,
        'DBName': 'string',
        'VpcId': 'string',
        'Encrypted': True|False,
        'KmsKeyId': 'string',
        'EncryptedWithHSM': True|False,
        'AccountsWithRestoreAccess': [
            {
                'AccountId': 'string'
            },
        ],
        'OwnerAccount': 'string',
        'TotalBackupSizeInMegaBytes': 123.0,
        'ActualIncrementalBackupSizeInMegaBytes': 123.0,
        'BackupProgressInMegaBytes': 123.0,
    }
}
```
Response Structure

- (dict) –
  Describes a snapshot.
  - Snapshot (dict) –
    Describes a snapshot.
      * SnapshotIdentifier (string) –
        The snapshot identifier that is provided in the request.
      * ClusterIdentifier (string) –
        The identifier of the cluster for which the snapshot was taken.
      * SnapshotCreateTime (datetime) –
        The time (UTC) when Amazon Redshift began the snapshot. A snapshot contains a copy of the cluster data as of this exact time.
      * Status (string) –
        The snapshot status. The value of the status depends on the API operation used.
        - CreateClusterSnapshot and CopyClusterSnapshot returns status as “creating”.
        - DescribeClusterSnapshots returns status as “creating”, “available”, “final snapshot”, or “failed”.
        - DeleteClusterSnapshot returns status as “deleted”.
      * Port (integer) –
        The port that the cluster is listening on.
      * AvailabilityZone (string) –
        The Availability Zone in which the cluster was created.
      * ClusterCreateTime (datetime) –
        The time (UTC) when the cluster was originally created.
      * MasterUsername (string) –
        The master user name for the cluster.
      * ClusterVersion (string) –
        The version ID of the Amazon Redshift engine that is running on the cluster.
      * SnapshotType (string) –
The snapshot type. Snapshots created using `CreateClusterSnapshot` and `CopyClusterSnapshot` will be of type “manual”.

- **NodeType** *(string)* – The node type of the nodes in the cluster.
- **NumberOfNodes** *(integer)* – The number of nodes in the cluster.
- **DBName** *(string)* – The name of the database that was created when the cluster was created.
- **VpcId** *(string)* – The VPC identifier of the cluster if the snapshot is from a cluster in a VPC. Otherwise, this field is not in the output.
- **Encrypted** *(boolean)* – If `true`, the data in the snapshot is encrypted at rest.
- **KmsKeyId** *(string)* – The AWS Key Management Service (KMS) key ID of the encryption key that was used to encrypt data in the cluster from which the snapshot was taken.
- **EncryptedWithHSM** *(boolean)* – A boolean that indicates whether the snapshot data is encrypted using the HSM keys of the source cluster. `true` indicates that the data is encrypted using HSM keys.
- **AccountsWithRestoreAccess** *(list)* – A list of the AWS customer accounts authorized to restore the snapshot. Returns `null` if no accounts are authorized. Visible only to the snapshot owner.
  - *(dict)* – Describes an AWS customer account authorized to restore a snapshot.
  - **AccountId** *(string)* – The identifier of an AWS customer account authorized to restore a snapshot.
- **OwnerAccount** *(string)* – For manual snapshots, the AWS customer account used to create or copy the snapshot. For automatic snapshots, the owner of the cluster. The owner can perform all snapshot actions, such as sharing a manual snapshot.
- **TotalBackupSizeInMegaBytes** *(float)* – The size of the complete set of backup data that would be used to restore the cluster.
- **ActualIncrementalBackupSizeInMegaBytes** *(float)* – The size of the incremental backup.
- **BackupProgressInMegaBytes** *(float)* – The number of megabytes that have been transferred to the snapshot backup.
- **CurrentBackupRateInMegaBytesPerSecond** *(float)* –
The number of megabytes per second being transferred to the snapshot backup. Returns 0 for a completed backup.

* EstimatedSecondsToCompletion (integer) –

The estimate of the time remaining before the snapshot backup will complete. Returns 0 for a completed backup.

* ElapsedTimeInSeconds (integer) –

The amount of time an in-progress snapshot backup has been running, or the amount of time it took a completed backup to finish.

* SourceRegion (string) –

The source region from which the snapshot was copied.

* Tags (list) –

The list of tags for the cluster snapshot.

* RestorableNodeTypes (list) –

The list of node types that this cluster snapshot is able to restore into.

---

**can_paginate** (operation_name)

Check if an operation can be paginated.

**Parameters**

* operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

**Returns**

True if the operation can be paginated, False otherwise.

**copy_cluster_snapshot** (**kwargs)**

Copies the specified automated cluster snapshot to a new manual cluster snapshot. The source must be an automated snapshot and it must be in the available state.

When you delete a cluster, Amazon Redshift deletes any automated snapshots of the cluster. Also, when the retention period of the snapshot expires, Amazon Redshift automatically deletes it. If you want to keep an automated snapshot for a longer period, you can make a manual copy of the snapshot. Manual snapshots are retained until you delete them.

For more information about working with snapshots, go to Amazon Redshift Snapshots in the Amazon Redshift Cluster Management Guide.

**Request Syntax**

response = client.copy_cluster_snapshot(
    SourceSnapshotIdentifier='string',
    SourceSnapshotClusterIdentifier='string',
    TargetSnapshotIdentifier='string'
)

**Parameters**
• **SourceSnapshotIdentifier** (*string*) – [REQUIRED]
  
  The identifier for the source snapshot.
  
  Constraints:
  – Must be the identifier for a valid automated snapshot whose state is available.

• **SourceSnapshotClusterIdentifier** (*string*) – The identifier of the cluster the source snapshot was created from. This parameter is required if your IAM user has a policy containing a snapshot resource element that specifies anything other than * for the cluster name.
  
  Constraints:
  – Must be the identifier for a valid cluster.

• **TargetSnapshotIdentifier** (*string*) – [REQUIRED]
  
  The identifier given to the new manual snapshot.
  
  Constraints:
  – Cannot be null, empty, or blank.
  – Must contain from 1 to 255 alphanumeric characters or hyphens.
  – First character must be a letter.
  – Cannot end with a hyphen or contain two consecutive hyphens.
  – Must be unique for the AWS account that is making the request.

Return type  
dict

Returns

Response Syntax

```json
{
    'Snapshot': {
        'SnapshotIdentifier': 'string',
        'ClusterIdentifier': 'string',
        'SnapshotCreateTime': datetime(2015, 1, 1),
        'Status': 'string',
        'Port': 123,
        'AvailabilityZone': 'string',
        'ClusterCreateTime': datetime(2015, 1, 1),
        'MasterUsername': 'string',
        'ClusterVersion': 'string',
        'SnapshotType': 'string',
        'NodeType': 'string',
        'NumberOfNodes': 123,
        'DBName': 'string',
        'VpcId': 'string',
        'Encrypted': True|False,
        'KmsKeyId': 'string',
        'EncryptedWithHSM': True|False,
        'AccountsWithRestoreAccess': [
            {
                'AccountId': 'string'
            },
        ],
        'OwnerAccount': 'string',
        'TotalBackupSizeInMegaBytes': 123.0,
        'ActualIncrementalBackupSizeInMegaBytes': 123.0,
        'BackupProgressInMegaBytes': 123.0,
        'CurrentBackupRateInMegaBytesPerSecond': 123.0,
        'EstimatedSecondsToCompletion': 123,
    }
}
```
Response Structure

- (dict) –
  Describes a snapshot.

  - Snapshot (dict) –
    Describes a snapshot.
    - SnapshotIdentifier (string) –
      The snapshot identifier that is provided in the request.
    - ClusterIdentifier (string) –
      The identifier of the cluster for which the snapshot was taken.
    - SnapshotCreateTime (datetime) –
      The time (UTC) when Amazon Redshift began the snapshot. A snapshot contains a copy of the cluster data as of this exact time.
    - Status (string) –
      The snapshot status. The value of the status depends on the API operation used:
      - CreateClusterSnapshot and CopyClusterSnapshot returns status as “creating”.
      - DescribeClusterSnapshots returns status as “creating”, “available”, “final snapshot”, or “failed”.
      - DeleteClusterSnapshot returns status as “deleted”.
    - Port (integer) –
      The port that the cluster is listening on.
    - AvailabilityZone (string) –
      The Availability Zone in which the cluster was created.
    - ClusterCreateTime (datetime) –
      The time (UTC) when the cluster was originally created.
    - MasterUsername (string) –
      The master user name for the cluster.
    - ClusterVersion (string) –
      The version ID of the Amazon Redshift engine that is running on the cluster.
    - SnapshotType (string) –
      The snapshot type. Snapshots created using CreateClusterSnapshot and CopyClusterSnapshot will be of type “manual”.

3.1. Services 3599
* **NodeType** *(string)* –
  The node type of the nodes in the cluster.

* **NumberOfNodes** *(integer)* –
  The number of nodes in the cluster.

* **DBName** *(string)* –
  The name of the database that was created when the cluster was created.

* **VpcId** *(string)* –
  The VPC identifier of the cluster if the snapshot is from a cluster in a VPC. Otherwise, this field is not in the output.

* **Encrypted** *(boolean)* –
  If true, the data in the snapshot is encrypted at rest.

* **KmsKeyId** *(string)* –
  The AWS Key Management Service (KMS) key ID of the encryption key that was used to encrypt data in the cluster from which the snapshot was taken.

* **EncryptedWithHSM** *(boolean)* –
  A boolean that indicates whether the snapshot data is encrypted using the HSM keys of the source cluster. true indicates that the data is encrypted using HSM keys.

* **AccountsWithRestoreAccess** *(list)* –
  A list of the AWS customer accounts authorized to restore the snapshot. Returns null if no accounts are authorized. Visible only to the snapshot owner.

  · **(dict)** –
    Describes an AWS customer account authorized to restore a snapshot.

  · **AccountId** *(string)* –
    The identifier of an AWS customer account authorized to restore a snapshot.

* **OwnerAccount** *(string)* –
  For manual snapshots, the AWS customer account used to create or copy the snapshot. For automatic snapshots, the owner of the cluster. The owner can perform all snapshot actions, such as sharing a manual snapshot.

* **TotalBackupSizeInMegaBytes** *(float)* –
  The size of the complete set of backup data that would be used to restore the cluster.

* **ActualIncrementalBackupSizeInMegaBytes** *(float)* –
  The size of the incremental backup.

* **BackupProgressInMegaBytes** *(float)* –
  The number of megabytes that have been transferred to the snapshot backup.

* **CurrentBackupRateInMegaBytesPerSecond** *(float)* –
  The number of megabytes per second being transferred to the snapshot backup. Returns 0 for a completed backup.
* **EstimatedSecondsToCompletion** *(integer)* –
  The estimate of the time remaining before the snapshot backup will complete. Returns 0 for a completed backup.

* **ElapsedTimeInSeconds** *(integer)* –
  The amount of time an in-progress snapshot backup has been running, or the amount of time it took a completed backup to finish.

* **SourceRegion** *(string)* –
  The source region from which the snapshot was copied.

* **Tags** *(list)* –
  The list of tags for the cluster snapshot.
  · **(dict)** –
    A tag consisting of a name/value pair for a resource.
    · **Key** *(string)* –
      The key, or name, for the resource tag.
    · **Value** *(string)* –
      The value for the resource tag.

* **RestorableNodeTypes** *(list)* –
  The list of node types that this cluster snapshot is able to restore into.
  · **(string)** –

customize_cluster(**kwargs)**

Creates a new cluster. To create the cluster in virtual private cloud (VPC), you must provide cluster subnet
group name. If you don’t provide a cluster subnet group name or the cluster security group parameter,
Amazon Redshift creates a non-VPC cluster, it associates the default cluster security group with the
cluster. For more information about managing clusters, go to Amazon Redshift Clusters in the Amazon
Redshift Cluster Management Guide.

**Request Syntax**

```python
response = client.create_cluster(
    DBName='string',
    ClusterIdentifier='string',
    ClusterType='string',
    NodeType='string',
    MasterUsername='string',
    MasterUserPassword='string',
    ClusterSecurityGroups=[
        'string',
    ],
    VpcSecurityGroupIds=[
        'string',
    ],
    ClusterSubnetGroupName='string',
    AvailabilityZone='string',
    PreferredMaintenanceWindow='string',
    ClusterParameterGroupName='string',
    AutomatedSnapshotRetentionPeriod=123,
    Port=123,
    ClusterVersion='string',
    AllowVersionUpgrade=True|False,
    NumberOfNodes=123,
)```

3.1. Services
Parameters

- **DBName** *(string)* – The name of the first database to be created when the cluster is created.

  To create additional databases after the cluster is created, connect to the cluster with a SQL client and use SQL commands to create a database. For more information, go to Create a Database in the Amazon Redshift Database Developer Guide.

  Default: dev

  Constraints:
  - Must contain 1 to 64 alphanumeric characters.
  - Must contain only lowercase letters.
  - Cannot be a word that is reserved by the service. A list of reserved words can be found in Reserved Words in the Amazon Redshift Database Developer Guide.

- **ClusterIdentifier** *(string)* – [REQUIRED]

  A unique identifier for the cluster. You use this identifier to refer to the cluster for any subsequent cluster operations such as deleting or modifying. The identifier also appears in the Amazon Redshift console.

  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens.
  - Alphabetic characters must be lowercase.
  - First character must be a letter.
  - Cannot end with a hyphen or contain two consecutive hyphens.
  - Must be unique for all clusters within an AWS account.

  Example: myexamplecluster

- **ClusterType** *(string)* – The type of the cluster. When cluster type is specified as `single-node`, the `NumberOfNodes` parameter is not required.

  Valid Values: multi-node | single-node

  Default: multi-node

- **NodeType** *(string)* – [REQUIRED]

  The node type to be provisioned for the cluster. For information about node types, go to Working with Clusters in the Amazon Redshift Cluster Management Guide.

  Valid Values: ds1.xlarge | ds1.8xlarge | ds2.xlarge | ds2.8xlarge | dc1.large | dc1.8xlarge.
• **MasterUsername** *(string)* – [REQUIRED]

The user name associated with the master user account for the cluster that is being created.

Constraints:
- Must be 1 - 128 alphanumeric characters.
- First character must be a letter.
- Cannot be a reserved word. A list of reserved words can be found in Reserved Words in the Amazon Redshift Database Developer Guide.

• **MasterUserPassword** *(string)* – [REQUIRED]

The password associated with the master user account for the cluster that is being created.

Constraints:
- Must be between 8 and 64 characters in length.
- Must contain at least one uppercase letter.
- Must contain at least one lowercase letter.
- Must contain one number.
- Can be any printable ASCII character (ASCII code 33 to 126) except ’ (single quote), “ (double quote), , /, @, or space.

• **ClusterSecurityGroups** *(list)* – A list of security groups to be associated with this cluster.

  Default: The default cluster security group for Amazon Redshift.

  – *(string)* –

• **VpcSecurityGroupIds** *(list)* – A list of Virtual Private Cloud (VPC) security groups to be associated with the cluster.

  Default: The default VPC security group is associated with the cluster.

  – *(string)* –

• **ClusterSubnetGroupName** *(string)* – The name of a cluster subnet group to be associated with this cluster.

  If this parameter is not provided the resulting cluster will be deployed outside virtual private cloud (VPC).

• **AvailabilityZone** *(string)* – The EC2 Availability Zone (AZ) in which you want Amazon Redshift to provision the cluster. For example, if you have several EC2 instances running in a specific Availability Zone, then you might want the cluster to be provisioned in the same zone in order to decrease network latency.

  Default: A random, system-chosen Availability Zone in the region that is specified by the endpoint.

  Example: us-east-1d

  Constraint: The specified Availability Zone must be in the same region as the current endpoint.

• **PreferredMaintenanceWindow** *(string)* – The weekly time range (in UTC) during which automated cluster maintenance can occur.

  Default: A 30-minute window selected at random from an 8-hour block of time per region, occurring on a random day of the week. For more information about the time blocks for each region, see Maintenance Windows in Amazon Redshift Cluster Management Guide.

  Valid Days: Mon | Tue | Wed | Thu | Fri | Sat | Sun
Constraints: Minimum 30-minute window.

- **ClusterParameterGroupName (string)** – The name of the parameter group to be associated with this cluster.

  Default: The default Amazon Redshift cluster parameter group. For information about the default parameter group, go to Working with Amazon Redshift Parameter Groups

  Constraints:
  - Must be 1 to 255 alphanumeric characters or hyphens.
  - First character must be a letter.
  - Cannot end with a hyphen or contain two consecutive hyphens.

- **AutomatedSnapshotRetentionPeriod (integer)** – The number of days that automated snapshots are retained. If the value is 0, automated snapshots are disabled. Even if automated snapshots are disabled, you can still create manual snapshots when you want with CreateClusterSnapshot.

  Default: 1

  Constraints: Must be a value from 0 to 35.

- **Port (integer)** – The port number on which the cluster accepts incoming connections.

  The cluster is accessible only via the JDBC and ODBC connection strings. Part of the connection string requires the port on which the cluster will listen for incoming connections.

  Default: 5439

  Valid Values: 1150-65535

- **ClusterVersion (string)** – The version of the Amazon Redshift engine software that you want to deploy on the cluster.

  The version selected runs on all the nodes in the cluster.

  Constraints: Only version 1.0 is currently available.

  Example: 1.0

- **AllowVersionUpgrade (boolean)** – If true, major version upgrades can be applied during the maintenance window to the Amazon Redshift engine that is running on the cluster.

  When a new major version of the Amazon Redshift engine is released, you can request that the service automatically apply upgrades during the maintenance window to the Amazon Redshift engine that is running on your cluster.

  Default: true

- **NumberOfNodes (integer)** – The number of compute nodes in the cluster.

  This parameter is required when the ClusterType parameter is specified as multi-node.

  For information about determining how many nodes you need, go to Working with Clusters in the Amazon Redshift Cluster Management Guide.

  If you don’t specify this parameter, you get a single-node cluster. When requesting a multi-node cluster, you must specify the number of nodes that you want in the cluster.

  Default: 1

  Constraints: Value must be at least 1 and no more than 100.
• PubliclyAccessible (boolean) – If true, the cluster can be accessed from a public network.
• Encrypted (boolean) – If true, the data in the cluster is encrypted at rest.
  Default: false
• HsmClientCertificateIdentifier (string) – Specifies the name of the HSM client certificate the Amazon Redshift cluster uses to retrieve the data encryption keys stored in an HSM.
• HsmConfigurationIdentifier (string) – Specifies the name of the HSM configuration that contains the information the Amazon Redshift cluster can use to retrieve and store keys in an HSM.
• ElasticIp (string) – The Elastic IP (EIP) address for the cluster.
  Constraints: The cluster must be provisioned in EC2-VPC and publicly-accessible through an Internet gateway. For more information about provisioning clusters in EC2-VPC, go to Supported Platforms to Launch Your Cluster in the Amazon Redshift Cluster Management Guide.
• Tags (list) – A list of tag instances.
  – (dict) –
    A tag consisting of a name/value pair for a resource.
    * Key (string) –
      The key, or name, for the resource tag.
    * Value (string) –
      The value for the resource tag.
• KmsKeyId (string) – The AWS Key Management Service (KMS) key ID of the encryption key that you want to use to encrypt data in the cluster.

Response Structure
• (dict) –
  Describes a cluster.
  – Cluster (dict) –
    Describes a cluster.
    * ClusterIdentifier (string) –
      The unique identifier of the cluster.
    * NodeType (string) –
      The node type for the nodes in the cluster.
    * ClusterStatus (string) –
      The current state of this cluster. Possible values include available, creating, deleting, rebooting, renaming, and resizing.
    * ModifyStatus (string) –
      The status of a modify operation, if any, initiated for the cluster.
    * MasterUsername (string) –
      The master user name for the cluster. This name is used to connect to the database that is specified in DBName.
    * DBName (string) –
      The name of the initial database that was created when the cluster was created. This same name is returned for the life of the cluster. If an initial database was not specified, a database named “dev” was created by default.
    * Endpoint (dict) –
      The connection endpoint.
        • Address (string) –
          The DNS address of the Cluster.
        • Port (integer) –
          The port that the database engine is listening on.
    * ClusterCreateTime (datetime) –
      The date and time that the cluster was created.
    * AutomatedSnapshotRetentionPeriod (integer) –
      The number of days that automatic cluster snapshots are retained.
ClusterSecurityGroups (list) –
A list of cluster security group that are associated with the cluster. Each security group is represented by an element that contains ClusterSecurityGroup.Name and ClusterSecurityGroup.Status subelements.

Cluster security groups are used when the cluster is not created in a VPC. Clusters that are created in a VPC use VPC security groups, which are listed by the VpcSecurityGroups parameter.

· (dict) –
  · Describes a security group.
  · ClusterSecurityGroupName (string) –
    · The name of the cluster security group.
  · Status (string) –
    · The status of the cluster security group.

VpcSecurityGroups (list) –
A list of Virtual Private Cloud (VPC) security groups that are associated with the cluster. This parameter is returned only if the cluster is in a VPC.

· (dict) –
  · Describes the members of a VPC security group.
  · VpcSecurityGroupId (string) –
  · Status (string) –

ClusterParameterGroups (list) –
The list of cluster parameter groups that are associated with this cluster. Each parameter group in the list is returned with its status.

· (dict) –
  · Describes the status of a parameter group.
  · ParameterGroupName (string) –
    · The name of the cluster parameter group.
  · ParameterApplyStatus (string) –
    · The status of parameter updates.
  · ClusterParameterStatusList (list) –
    · The list of parameter statuses.

For more information about parameters and parameter groups, go to Amazon Redshift Parameter Groups in the Amazon Redshift Cluster Management Guide.

· (dict) –
  · Describes the status of a parameter group.
  · ParameterName (string) –
    · The name of the parameter.
  · ParameterApplyStatus (string) –
    · The status of the parameter that indicates whether the parameter is in sync with the database, waiting for a cluster reboot, or encountered an error when being applied.

The following are possible statuses and descriptions.
in-sync: The parameter value is in sync with the database.
pending-reboot: The parameter value will be applied after the cluster reboots.
applying: The parameter value is being applied to the database.
invalid-parameter: Cannot apply the parameter value because it has an invalid value or syntax.
apply-deferred: The parameter contains static property changes. The changes are deferred until the cluster reboots.
apply-error: Cannot connect to the cluster. The parameter change will be applied after the cluster reboots.
unknown-error: Cannot apply the parameter change right now. The change will be applied after the cluster reboots.

ParameterApplyErrorDescription (string) –
The error that prevented the parameter from being applied to the database.

ClusterSubnetGroupName (string) –
The name of the subnet group that is associated with the cluster. This parameter is valid only when the cluster is in a VPC.

VpcId (string) –
The identifier of the VPC the cluster is in, if the cluster is in a VPC.

AvailabilityZone (string) –
The name of the Availability Zone in which the cluster is located.

PreferredMaintenanceWindow (string) –
The weekly time range (in UTC) during which system maintenance can occur.

PendingModifiedValues (dict) –
If present, changes to the cluster are pending. Specific pending changes are identified by subelements.

MasterUserPassword (string) –
The pending or in-progress change of the master user password for the cluster.

NodeType (string) –
The pending or in-progress change of the cluster’s node type.

NumberOfNodes (integer) –
The pending or in-progress change of the number of nodes in the cluster.

ClusterType (string) –
The pending or in-progress change of the cluster type.

ClusterVersion (string) –
The pending or in-progress change of the service version.

AutomatedSnapshotRetentionPeriod (integer) –
The pending or in-progress change of the automated snapshot retention period.

ClusterIdentifier (string) –
The pending or in-progress change of the new identifier for the cluster.

* **ClusterVersion** *(string)* –

The version ID of the Amazon Redshift engine that is running on the cluster.

* **AllowVersionUpgrade** *(boolean)* –

If `true`, major version upgrades will be applied automatically to the cluster during the maintenance window.

* **NumberOfNodes** *(integer)* –

The number of compute nodes in the cluster.

* **PubliclyAccessible** *(boolean)* –

If `true`, the cluster can be accessed from a public network.

* **Encrypted** *(boolean)* –

If `true`, data in the cluster is encrypted at rest.

* **RestoreStatus** *(dict)* –

Describes the status of a cluster restore action. Returns null if the cluster was not created by restoring a snapshot.

  · **Status** *(string)* –

    The status of the restore action. Returns starting, restoring, completed, or failed.

  · **CurrentRestoreRateInMegaBytesPerSecond** *(float)* –

    The number of megabytes per second being transferred from the backup storage. Returns the average rate for a completed backup.

  · **SnapshotSizeInMegaBytes** *(integer)* –

    The size of the set of snapshot data used to restore the cluster.

  · **ProgressInMegaBytes** *(integer)* –

    The number of megabytes that have been transferred from snapshot storage.

  · **ElapsedTimeInSeconds** *(integer)* –

    The amount of time an in-progress restore has been running, or the amount of time it took a completed restore to finish.

  · **EstimatedTimeToCompletionInSeconds** *(integer)* –

    The estimate of the time remaining before the restore will complete. Returns 0 for a completed restore.

* **HsmStatus** *(dict)* –

Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.

Values: active, applying

  · **HsmClientCertificateIdentifier** *(string)* –

    Specifies the name of the HSM client certificate the Amazon Redshift cluster uses to retrieve the data encryption keys stored in an HSM.

  · **HsmConfigurationIdentifier** *(string)* –

    Specifies the name of the HSM configuration that contains the information the Amazon Redshift cluster can use to retrieve
and store keys in an HSM.

- **Status** (string) –
  
  Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.

  Values: active, applying

- **ClusterSnapshotCopyStatus** (dict) –
  
  Returns the destination region and retention period that are configured for cross-region snapshot copy.
  
  - **DestinationRegion** (string) –
    
    The destination region that snapshots are automatically copied to when cross-region snapshot copy is enabled.
  
  - **RetentionPeriod** (integer) –
    
    The number of days that automated snapshots are retained in the destination region after they are copied from a source region.
  
  - **SnapshotCopyGrantName** (string) –
    
    The name of the snapshot copy grant.

- **ClusterPublicKey** (string) –
  
  The public key for the cluster.

- **ClusterNodes** (list) –
  
  The nodes in a cluster.
  
  - (dict) –
    
    The identifier of a node in a cluster.
  
  - **NodeRole** (string) –
    
    Whether the node is a leader node or a compute node.
  
  - **PrivateIPAddress** (string) –
    
    The private IP address of a node within a cluster.
  
  - **PublicIPAddress** (string) –
    
    The public IP address of a node within a cluster.

- **ElasticIpStatus** (dict) –
  
  Describes the status of the elastic IP (EIP) address.
  
  - **ElasticIp** (string) –
    
    The elastic IP (EIP) address for the cluster.
  
  - **Status** (string) –
    
    Describes the status of the elastic IP (EIP) address.

- **ClusterRevisionNumber** (string) –
  
  The specific revision number of the database in the cluster.

- **Tags** (list) –
  
  The list of tags for the cluster.
  
  - (dict) –
    
    A tag consisting of a name/value pair for a resource.
  
    - **Key** (string) –
      
      The key, or name, for the resource tag.
create_cluster_parameter_group (**kwargs)

Creates an Amazon Redshift parameter group.

Creating parameter groups is independent of creating clusters. You can associate a cluster with a parameter
group when you create the cluster. You can also associate an existing cluster with a parameter group after
the cluster is created by using ModifyCluster .

Parameters in the parameter group define specific behavior that applies to the databases you create on the
cluster. For more information about parameters and parameter groups, go to Amazon Redshift Parameter
Groups in the Amazon Redshift Cluster Management Guide .

Request Syntax

```python
response = client.create_cluster_parameter_group(
    ParameterGroupName='string',
    ParameterGroupFamily='string',
    Description='string',
    Tags=[
        {'Key': 'string', 'Value': 'string'},
    ],
)
```

Parameters

- **ParameterGroupName (string)** – [REQUIRED]
  
  The name of the cluster parameter group.

  Constraints:
  - Must be 1 to 255 alphanumeric characters or hyphens
  - First character must be a letter.
  - Cannot end with a hyphen or contain two consecutive hyphens.
  - Must be unique withing your AWS account.

  **Note:** This value is stored as a lower-case string.

- **ParameterGroupFamily (string)** – [REQUIRED]
  
  The Amazon Redshift engine version to which the cluster parameter group ap-
  plies. The cluster engine version determines the set of parameters.

  To get a list of valid parameter group family names, you can call DescribeClus-
terParameterGroups . By default, Amazon Redshift returns a list of all the pa-
parameter groups that are owned by your AWS account, including the default pa-
parameter groups for each Amazon Redshift engine version. The parameter group
family names associated with the default parameter groups provide you the valid
values. For example, a valid family name is “redshift-1.0”.

- **Description (string)** – [REQUIRED]
  
  A description of the parameter group.

- **Tags (list)** – A list of tag instances.
– (dict) –

A tag consisting of a name/value pair for a resource.

* Key (string) –
  
The key, or name, for the resource tag.

* Value (string) –
  
The value for the resource tag.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'ClusterParameterGroup': {
        'ParameterGroupName': 'string',
        'ParameterGroupFamily': 'string',
        'Description': 'string',
        'Tags': [
            {
                'Key': 'string',
                'Value': 'string'
            }
        ]
    }
}
```

**Response Structure**

* (dict) –

  Describes a parameter group.

  – **ClusterParameterGroup** (dict) –

    Describes a parameter group.

    * ParameterGroupName (string) –
      
The name of the cluster parameter group.

    * ParameterGroupFamily (string) –
      
The name of the cluster parameter group family that this cluster parameter group is compatible with.

    * Description (string) –
      
The description of the parameter group.

    * Tags (list) –
      
The list of tags for the cluster parameter group.

      · (dict) –
        
        A tag consisting of a name/value pair for a resource.

      · Key (string) –
        
The key, or name, for the resource tag.

      · Value (string) –
        
The value for the resource tag.

---

**create_cluster_security_group**(**kwargs**)

Creates a new Amazon Redshift security group. You use security groups to control access to non-VPC clusters.
For information about managing security groups, go to Amazon Redshift Cluster Security Groups in the Amazon Redshift Cluster Management Guide.

Request Syntax

```python
response = client.create_cluster_security_group(
    ClusterSecurityGroupName='string',
    Description='string',
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

Parameters

- **ClusterSecurityGroupName** *(string) – [REQUIRED]*
  
The name for the security group. Amazon Redshift stores the value as a lowercase string.

  Constraints:
  - Must contain no more than 255 alphanumeric characters or hyphens.
  - Must not be “Default”.
  - Must be unique for all security groups that are created by your AWS account.

  Example: `examplesecuritygroup`

- **Description** *(string) – [REQUIRED]*
  
  A description for the security group.

- **Tags** *(List)* – A list of tag instances.

  - *(dict)* – A tag consisting of a name/value pair for a resource.
    
    * **Key** *(string)* –
      
      The key, or name, for the resource tag.
    
    * **Value** *(string)* –
      
      The value for the resource tag.

Return type  dict

Returns

Response Syntax

```json
{
    'ClusterSecurityGroup': {
        'ClusterSecurityGroupName': 'string',
        'Description': 'string',
        'EC2SecurityGroups': [
            {
                'Status': 'string',
                'EC2SecurityGroupName': 'string',
                'EC2SecurityGroupOwnerId': 'string',
                'Tags': [
                    {
                        'Key': 'string',
                        'Value': 'string'
                    },
                ],
            },
        ],
    },
}
```
Response Structure

- (dict) –
  
  Describes a security group.
  
  - ClusterSecurityGroup (dict) –
    
    Describes a security group.
    
    * ClusterSecurityGroupName (string) –
      
      The name of the cluster security group to which the operation was applied.
    
    * Description (string) –
      
      A description of the security group.
    
    * EC2SecurityGroups (list) –
      
      A list of EC2 security groups that are permitted to access clusters associated with this cluster security group.
        
        - (dict) –
          
          Describes an Amazon EC2 security group.
        
        * Status (string) –
          
          The status of the EC2 security group.
        
        * EC2SecurityGroupName (string) –
          
          The name of the EC2 Security Group.
        
        * EC2SecurityGroupOwnerId (string) –
          
          The AWS ID of the owner of the EC2 security group specified in the EC2SecurityGroupName field.
        
        * Tags (list) –
          
          The list of tags for the EC2 security group.
        
        - (dict) –
          
          A tag consisting of a name/value pair for a resource.
Key (string) –
   The key, or name, for the resource tag.

Value (string) –
   The value for the resource tag.

* IPRanges (list) –
   A list of IP ranges (CIDR blocks) that are permitted to access clusters associated with
   this cluster security group.
   
   (dict) –
   Describes an IP range used in a security group.
   
   Status (string) –
   The status of the IP range, for example, “authorized”.
   
   CIDRIP (string) –
   The IP range in Classless Inter-Domain Routing (CIDR) notation.
   
   Tags (list) –
   The list of tags for the IP range.
   
   (dict) –
   A tag consisting of a name/value pair for a resource.
   
   Key (string) –
   The key, or name, for the resource tag.
   
   Value (string) –
   The value for the resource tag.

* Tags (list) –
   The list of tags for the cluster security group.
   
   (dict) –
   A tag consisting of a name/value pair for a resource.
   
   Key (string) –
   The key, or name, for the resource tag.
   
   Value (string) –
   The value for the resource tag.

create_cluster_snapshot (**kwargs)

Creates a manual snapshot of the specified cluster. The cluster must be in the available state.

For more information about working with snapshots, go to Amazon Redshift Snapshots in the Amazon
Redshift Cluster Management Guide.

Request Syntax

```python
response = client.create_cluster_snapshot(
    SnapshotIdentifier='string',
    ClusterIdentifier='string',
    Tags=[
        
            'Key': 'string',
            'Value': 'string'
        ]
)
```
Parameters

- **SnapshotIdentifier** *(string)*  – [REQUIRED]
  A unique identifier for the snapshot that you are requesting. This identifier must be unique for all snapshots within the AWS account.
  
  Constraints:
  - Cannot be null, empty, or blank
  - Must contain from 1 to 255 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

  Example: my-snapshot-id

- **ClusterIdentifier** *(string)*  – [REQUIRED]
  The cluster identifier for which you want a snapshot.

- **Tags** *(list)*  – A list of tag instances.
  - *(dict)*

    A tag consisting of a name/value pair for a resource.
    - **Key** *(string)*
      The key, or name, for the resource tag.
    - **Value** *(string)*
      The value for the resource tag.

Return type  dict

Returns

Response Syntax

```
{
    'Snapshot': {
        'SnapshotIdentifier': 'string',
        'ClusterIdentifier': 'string',
        'SnapshotCreateTime': datetime(2015, 1, 1),
        'Status': 'string',
        'Port': 123,
        'AvailabilityZone': 'string',
        'ClusterCreateTime': datetime(2015, 1, 1),
        'MasterUsername': 'string',
        'ClusterVersion': 'string',
        'SnapshotType': 'string',
        'NodeType': 'string',
        'NumberOfNodes': 123,
        'DBName': 'string',
        'VpcId': 'string',
        'Encrypted': True|False,
        'KmsKeyId': 'string',
        'EncryptedWithHSM': True|False,
        'AccountsWithRestoreAccess': [
            {
                'AccountId': 'string'
            },
        ],
        'OwnerAccount': 'string',
        'TotalBackupSizeInMegaBytes': 123.0,
        'ActualIncrementalBackupSizeInMegaBytes': 123.0,
        'BackupProgressInMegaBytes': 123.0,
        'CurrentBackupRateInMegaBytesPerSecond': 123.0,
        'EstimatedSecondsToCompletion': 123,
    },
}
{'ElapsedTimeInSeconds': 123,
'SourceRegion': 'string',
'Tags': [
    {'Key': 'string',
     'Value': 'string'
    },
],
'Restorables': [
    'string',
]
}

Response Structure
- (dict) –
  Describes a snapshot.
  - Snapshot (dict) –
    Describes a snapshot.
    * SnapshotIdentifier (string) –
      The snapshot identifier that is provided in the request.
    * ClusterIdentifier (string) –
      The identifier of the cluster for which the snapshot was taken.
    * SnapshotCreateTime (datetime) –
      The time (UTC) when Amazon Redshift began the snapshot. A snapshot contains a copy of the cluster data as of this exact time.
    * Status (string) –
      The snapshot status. The value of the status depends on the API operation used.
      · CreateClusterSnapshot and CopyClusterSnapshot returns status as “creating”.
      · DescribeClusterSnapshots returns status as “creating”, “available”, “final snapshot”, or “failed”.
      · DeleteClusterSnapshot returns status as “deleted”.
    * Port (integer) –
      The port that the cluster is listening on.
    * AvailabilityZone (string) –
      The Availability Zone in which the cluster was created.
    * ClusterCreateTime (datetime) –
      The time (UTC) when the cluster was originally created.
    * MasterUsername (string) –
      The master user name for the cluster.
    * ClusterVersion (string) –
      The version ID of the Amazon Redshift engine that is running on the cluster.
    * SnapshotType (string) –
      The snapshot type. Snapshots created using CreateClusterSnapshot and CopyClusterSnapshot will be of type “manual”.
* **NodeType** *(string)* –
  The node type of the nodes in the cluster.

* **NumberOfNodes** *(integer)* –
  The number of nodes in the cluster.

* **DBName** *(string)* –
  The name of the database that was created when the cluster was created.

* **VpcId** *(string)* –
  The VPC identifier of the cluster if the snapshot is from a cluster in a VPC. Otherwise, this field is not in the output.

* **Encrypted** *(boolean)* –
  If `true`, the data in the snapshot is encrypted at rest.

* **KmsKeyId** *(string)* –
  The AWS Key Management Service (KMS) key ID of the encryption key that was used to encrypt data in the cluster from which the snapshot was taken.

* **EncryptedWithHSM** *(boolean)* –
  A boolean that indicates whether the snapshot data is encrypted using the HSM keys of the source cluster. `true` indicates that the data is encrypted using HSM keys.

* **AccountsWithRestoreAccess** *(list)* –
  A list of the AWS customer accounts authorized to restore the snapshot. Returns `null` if no accounts are authorized. Visible only to the snapshot owner.
  · **(dict)** –
    Describes an AWS customer account authorized to restore a snapshot.
  · **AccountId** *(string)* –
    The identifier of an AWS customer account authorized to restore a snapshot.

* **OwnerAccount** *(string)* –
  For manual snapshots, the AWS customer account used to create or copy the snapshot. For automatic snapshots, the owner of the cluster. The owner can perform all snapshot actions, such as sharing a manual snapshot.

* **TotalBackupSizeInMegaBytes** *(float)* –
  The size of the complete set of backup data that would be used to restore the cluster.

* **ActualIncrementalBackupSizeInMegaBytes** *(float)* –
  The size of the incremental backup.

* **BackupProgressInMegaBytes** *(float)* –
  The number of megabytes that have been transferred to the snapshot backup.

* **CurrentBackupRateInMegaBytesPerSecond** *(float)* –
  The number of megabytes per second being transferred to the snapshot backup. Returns `0` for a completed backup.
* **EstimatedSecondsToCompletion** *(integer)* –
  The estimate of the time remaining before the snapshot backup will complete. Returns 0 for a completed backup.

* **ElapsedTimeInSeconds** *(integer)* –
  The amount of time an in-progress snapshot backup has been running, or the amount of time it took a completed backup to finish.

* **SourceRegion** *(string)* –
  The source region from which the snapshot was copied.

* **Tags** *(list)* –
  The list of tags for the cluster snapshot.
  · **(dict)** –
    A tag consisting of a name/value pair for a resource.
    · **Key** *(string)* –
      The key, or name, for the resource tag.
    · **Value** *(string)* –
      The value for the resource tag.

* **RestorableNodeTypes** *(list)* –
  The list of node types that this cluster snapshot is able to restore into.
  · **(string)** –

`create_cluster_subnet_group(**kwargs)`

Creates a new Amazon Redshift subnet group. You must provide a list of one or more subnets in your existing Amazon Virtual Private Cloud (Amazon VPC) when creating Amazon Redshift subnet group.

For information about subnet groups, go to Amazon Redshift Cluster Subnet Groups in the Amazon Redshift Cluster Management Guide.

**Request Syntax**

```python
response = client.create_cluster_subnet_group(
    ClusterSubnetGroupName='string',
    Description='string',
    SubnetIds=[
        'string',
    ],
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

**Parameters**

* **ClusterSubnetGroupName** *(string)* – [REQUIRED]
  The name for the subnet group. Amazon Redshift stores the value as a lowercase string.

  Constraints:
  – Must contain no more than 255 alphanumeric characters or hyphens.
  – Must not be “Default”.
Must be unique for all subnet groups that are created by your AWS account.

Example: examplesubnetgroup

- **Description** *(string)* – [REQUIRED]
  
  A description for the subnet group.

- **SubnetIds** *(list)* – [REQUIRED]
  
  An array of VPC subnet IDs. A maximum of 20 subnets can be modified in a single request.

- **Tags** *(list)* – A list of tag instances.

  - *(dict)* –
    
    A tag consisting of a name/value pair for a resource.

    - **Key** *(string)* –
      
      The key, or name, for the resource tag.

    - **Value** *(string)* –
      
      The value for the resource tag.

Return type: dict

Returns:

**Response Syntax**

```
{
  'ClusterSubnetGroup': {
    'ClusterSubnetGroupName': 'string',
    'Description': 'string',
    'VpcId': 'string',
    'SubnetGroupStatus': 'string',
    'Subnets': [
      {
        'SubnetIdentifier': 'string',
        'SubnetAvailabilityZone': {
          'Name': 'string'
        },
        'SubnetStatus': 'string'
      },
    ],
    'Tags': [
      {
        'Key': 'string',
        'Value': 'string'
      },
    ]
  }
}
```

**Response Structure**

- *(dict)* –

  Describes a subnet group.

  - **ClusterSubnetGroup** *(dict)* –

    Describes a subnet group.

    - **ClusterSubnetGroupName** *(string)* –

      The name of the cluster subnet group.
* Description (string) – 
The description of the cluster subnet group.
* VpcId (string) – 
The VPC ID of the cluster subnet group.
* SubnetGroupStatus (string) – 
The status of the cluster subnet group. Possible values are Complete, Incomplete and Invalid.
* Subnets (list) – 
A list of the VPC Subnet elements.
  · (dict) – 
    Describes a subnet.
  · SubnetIdentifier (string) – 
    The identifier of the subnet.
  · SubnetAvailabilityZone (dict) – 
    Describes an availability zone.
    · Name (string) – 
      The name of the availability zone.
    · SubnetStatus (string) – 
      The status of the subnet.
* Tags (list) – 
The list of tags for the cluster subnet group.
  · (dict) – 
    A tag consisting of a name/value pair for a resource.
    · Key (string) – 
      The key, or name, for the resource tag.
    · Value (string) – 
      The value for the resource tag.

create_event_subscription (**kwargs)

Creates an Amazon Redshift event notification subscription. This action requires an ARN (Amazon Resource Name) of an Amazon SNS topic created by either the Amazon Redshift console, the Amazon SNS console, or the Amazon SNS API. To obtain an ARN with Amazon SNS, you must create a topic in Amazon SNS and subscribe to the topic. The ARN is displayed in the SNS console.

You can specify the source type, and lists of Amazon Redshift source IDs, event categories, and event severities. Notifications will be sent for all events you want that match those criteria. For example, you can specify source type = cluster, source ID = my-cluster-1 and mycluster2, event categories = Availability, Backup, and severity = ERROR. The subscription will only send notifications for those ERROR events in the Availability and Backup categories for the specified clusters.

If you specify both the source type and source IDs, such as source type = cluster and source identifier = my-cluster-1, notifications will be sent for all the cluster events for my-cluster-1. If you specify a source type but do not specify a source identifier, you will receive notice of the events for the objects of that type in your AWS account. If you do not specify either the SourceType nor the SourceIdentifier, you will be notified of events generated from all Amazon Redshift sources belonging to your AWS account. You must specify a source type if you specify a source ID.

Request Syntax
response = client.create_event_subscription(
    SubscriptionName='string',
    SnsTopicArn='string',
    SourceType='string',
    SourceIds=[
        'string',
    ],
    EventCategories=[
        'string',
    ],
    Severity='string',
    Enabled=True|False,
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)

Parameters

• **SubscriptionName (string)** – [REQUIRED]

  The name of the event subscription to be created.

  Constraints:
  – Cannot be null, empty, or blank.
  – Must contain from 1 to 255 alphanumeric characters or hyphens.
  – First character must be a letter.
  – Cannot end with a hyphen or contain two consecutive hyphens.

• **SnsTopicArn (string)** – [REQUIRED]

  The Amazon Resource Name (ARN) of the Amazon SNS topic used to transmit
  the event notifications. The ARN is created by Amazon SNS when you create a
  topic and subscribe to it.

• **SourceType (string)** – The type of source that will be generating the events. For
  example, if you want to be notified of events generated by a cluster, you would
  set this parameter to cluster. If this value is not specified, events are returned for
  all Amazon Redshift objects in your AWS account. You must specify a source
  type in order to specify source IDs.

  Valid values: cluster, cluster-parameter-group, cluster-security-group, and
  cluster-snapshot.

• **SourceIds (list)** – A list of one or more identifiers of Amazon Redshift source
  objects. All of the objects must be of the same type as was specified in the source
  type parameter. The event subscription will return only events generated by the
  specified objects. If not specified, then events are returned for all objects within
  the source type specified.

  Example: my-cluster-1, my-cluster-2

  Example: my-snapshot-1, my-snapshot-2

• **EventCategories (list)** – Specifies the Amazon Redshift event categories to be
  published by the event notification subscription.

  Values: Configuration, Management, Monitoring, Security
• **Severity** (*string*) – Specifies the Amazon Redshift event severity to be published by the event notification subscription.

Values: ERROR, INFO

• **Enabled** (*boolean*) – A Boolean value; set to `true` to activate the subscription, set to `false` to create the subscription but not active it.

• **Tags** (*list*) – A list of tag instances.
  
  - (*dict*) –
    
    A tag consisting of a name/value pair for a resource.
    
    - **Key** (*string*) –
      
      The key, or name, for the resource tag.
    
    - **Value** (*string*) –
      
      The value for the resource tag.

Return type  
**dict**

Returns

**Response Syntax**

```python
{
    'EventSubscription': {
        'CustomerAwsId': 'string',
        'CustSubscriptionId': 'string',
        'SnsTopicArn': 'string',
        'Status': 'string',
        'SubscriptionCreationTime': datetime(2015, 1, 1),
        'SourceType': 'string',
        'SourceIdsList': [ 'string',
                          ],
        'EventCategoriesList': [ 'string',
                                ],
        'Severity': 'string',
        'Enabled': True|False,
        'Tags': [ { 'Key': 'string',
                    'Value': 'string'
                  },
                  ]
    }
}
```

**Response Structure**

- (*dict*) –
  
  - **EventSubscription** (*dict*) –
    
    - **CustomerAwsId** (*string*) –
      
      The AWS customer account associated with the Amazon Redshift event notification subscription.
    
    - **CustSubscriptionId** (*string*) –
      
      The name of the Amazon Redshift event notification subscription.
    
    - **SnsTopicArn** (*string*) –
      
      The Amazon Resource Name (ARN) of the Amazon SNS topic used by the event notification subscription.
* **Status** *(string)* –

The status of the Amazon Redshift event notification subscription.

Constraints:
- Can be one of the following: active | no-permission | topic-not-exist
- The status “no-permission” indicates that Amazon Redshift no longer has permission to post to the Amazon SNS topic.
- The status “topic-not-exist” indicates that the topic was deleted after the subscription was created.

* **SubscriptionCreationTime** *(datetime)* –

The date and time the Amazon Redshift event notification subscription was created.

* **SourceType** *(string)* –

The source type of the events returned the Amazon Redshift event notification, such as cluster, or cluster-snapshot.

* **SourceIdsList** *(list)* –

A list of the sources that publish events to the Amazon Redshift event notification subscription.

- *(string)* –

* **EventCategoriesList** *(list)* –

The list of Amazon Redshift event categories specified in the event notification subscription.

Values: Configuration, Management, Monitoring, Security

- *(string)* –

* **Severity** *(string)* –

The event severity specified in the Amazon Redshift event notification subscription.

Values: ERROR, INFO

* **Enabled** *(boolean)* –

A Boolean value indicating whether the subscription is enabled. `true` indicates the subscription is enabled.

* **Tags** *(list)* –

The list of tags for the event subscription.

- *(dict)* –

  A tag consisting of a name/value pair for a resource.

  - **Key** *(string)* –

    The key, or name, for the resource tag.

  - **Value** *(string)* –

    The value for the resource tag.

---

**create_hsm_client_certificate**(**kwargs**)

Creates an HSM client certificate that an Amazon Redshift cluster will use to connect to the client’s HSM in order to store and retrieve the keys used to encrypt the cluster databases.

The command returns a public key, which you must store in the HSM. In addition to creating the HSM certificate, you must create an Amazon Redshift HSM configuration that provides a cluster the information needed to store and use encryption keys in the HSM. For more information, go to Hardware Security Modules in the Amazon Redshift Cluster Management Guide.
Request Syntax

```python
response = client.create_hsm_client_certificate(
    HsmClientCertificateIdentifier='string',
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

**Parameters**

- **HsmClientCertificateIdentifier** (*string*) – [REQUIRED]
  
  The identifier to be assigned to the new HSM client certificate that the cluster will use to connect to the HSM to use the database encryption keys.

- **Tags** (*list*) – A list of tag instances.
  
  - (dict) –
    
    A tag consisting of a name/value pair for a resource.

    - **Key** (*string*) –
      
      The key, or name, for the resource tag.

    - **Value** (*string*) –
      
      The value for the resource tag.

**Return type**  dict

**Returns**

**Response Syntax**

```json
{
    'HsmClientCertificate': {
        'HsmClientCertificateIdentifier': 'string',
        'HsmClientCertificatePublicKey': 'string',
        'Tags': [
            {
                'Key': 'string',
                'Value': 'string'
            },
        ]
    }
}
```

**Response Structure**

- (dict) –

  Returns information about an HSM client certificate. The certificate is stored in a secure Hardware Storage Module (HSM), and used by the Amazon Redshift cluster to encrypt data files.

  - **HsmClientCertificate** (dict) –

    Returns information about an HSM client certificate. The certificate is stored in a secure Hardware Storage Module (HSM), and used by the Amazon Redshift cluster to encrypt data files.

    - **HsmClientCertificateIdentifier** (*string*) –

      The identifier of the HSM client certificate.
HsmClientCertificatePublicKey (string) –

The public key that the Amazon Redshift cluster will use to connect to the HSM. You must register the public key in the HSM.

Tags (list) –

The list of tags for the HSM client certificate.

- (dict) –

  A tag consisting of a name/value pair for a resource.

    - Key (string) –

      The key, or name, for the resource tag.

    - Value (string) –

      The value for the resource tag.

create_hsm_configuration(**kwargs)

Creates an HSM configuration that contains the information required by an Amazon Redshift cluster to store and use database encryption keys in a Hardware Security Module (HSM). After creating the HSM configuration, you can specify it as a parameter when creating a cluster. The cluster will then store its encryption keys in the HSM.

In addition to creating an HSM configuration, you must also create an HSM client certificate. For more information, go to Hardware Security Modules in the Amazon Redshift Cluster Management Guide.

Request Syntax

```python
response = client.create_hsm_configuration(
    HsmConfigurationIdentifier='string',
    Description='string',
    HsmIpAddress='string',
    HsmPartitionName='string',
    HsmPartitionPassword='string',
    HsmServerPublicCertificate='string',
    Tags= [
        { 'Key': 'string',
          'Value': 'string'
        },
    ],
)
```

Parameters

- HsmConfigurationIdentifier (string) – [REQUIRED]

  The identifier to be assigned to the new Amazon Redshift HSM configuration.

- Description (string) – [REQUIRED]

  A text description of the HSM configuration to be created.

- HsmIpAddress (string) – [REQUIRED]

  The IP address that the Amazon Redshift cluster must use to access the HSM.

- HsmPartitionName (string) – [REQUIRED]

  The name of the partition in the HSM where the Amazon Redshift clusters will store their database encryption keys.

- HsmPartitionPassword (string) – [REQUIRED]

  The password required to access the HSM partition.
• **HsmServerPublicCertificate** (*string*) – [REQUIRED]

The HSMs public certificate file. When using Cloud HSM, the file name is server.pem.

• **Tags** (*list*) – A list of tag instances.
  
  – (*dict*) –

  A tag consisting of a name/value pair for a resource.

  * **Key** (*string*) –

    The key, or name, for the resource tag.

  * **Value** (*string*) –

    The value for the resource tag.

**Return type**  
dict

**Returns**

**Response Syntax**

```
{
    'HsmConfiguration': {
        'HsmConfigurationIdentifier': 'string',
        'Description': 'string',
        'HsmIpAddress': 'string',
        'HsmPartitionName': 'string',
        'Tags': [
            {
                'Key': 'string',
                'Value': 'string'
            }
        ]
    }
}
```

**Response Structure**

• (*dict*) –

  Returns information about an HSM configuration, which is an object that describes to Amazon Redshift clusters the information they require to connect to an HSM where they can store database encryption keys.

  – **HsmConfiguration** (*dict*) –

    Returns information about an HSM configuration, which is an object that describes to Amazon Redshift clusters the information they require to connect to an HSM where they can store database encryption keys.

    * **HsmConfigurationIdentifier** (*string*) –

      The name of the Amazon Redshift HSM configuration.

    * **Description** (*string*) –

      A text description of the HSM configuration.

    * **HsmIpAddress** (*string*) –

      The IP address that the Amazon Redshift cluster must use to access the HSM.

    * **HsmPartitionName** (*string*) –

      The name of the partition in the HSM where the Amazon Redshift clusters will store their database encryption keys.
* Tags (list) –
  The list of tags for the HSM configuration.
  
  * (dict) –
    A tag consisting of a name/value pair for a resource.
    
    * Key (string) –
      The key, or name, for the resource tag.
    
    * Value (string) –
      The value for the resource tag.

create_snapshot_copy_grant (**kwargs)

Creates a snapshot copy grant that permits Amazon Redshift to use a customer master key (CMK) from AWS Key Management Service (AWS KMS) to encrypt copied snapshots in a destination region.

For more information about managing snapshot copy grants, go to Amazon Redshift Database Encryption in the Amazon Redshift Cluster Management Guide.

Request Syntax

```python
response = client.create_snapshot_copy_grant(
    SnapshotCopyGrantName='string',
    KmsKeyId='string',
    Tags=[
    
    
    ]
)
```

Parameters

- **SnapshotCopyGrantName (string)** – [REQUIRED]
  The name of the snapshot copy grant. This name must be unique in the region for the AWS account.

  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens.
  - Alphabetic characters must be lowercase.
  - First character must be a letter.
  - Cannot end with a hyphen or contain two consecutive hyphens.
  - Must be unique for all clusters within an AWS account.

- **KmsKeyId (string)** – The unique identifier of the customer master key (CMK) to which to grant Amazon Redshift permission. If no key is specified, the default key is used.

- **Tags (list)** – A list of tag instances.
  
  * (dict) –
  A tag consisting of a name/value pair for a resource.

  * Key (string) –
    The key, or name, for the resource tag.

  * Value (string) –
    The value for the resource tag.

Return type: dict
Returns

Response Syntax

```
{
    'SnapshotCopyGrant': {
        'SnapshotCopyGrantName': 'string',
        'KmsKeyId': 'string',
        'Tags': [
            {
                'Key': 'string',
                'Value': 'string'
            }
        ]
    }
}
```

Response Structure

- (dict) –
  The snapshot copy grant that grants Amazon Redshift permission to encrypt copied snapshots with the specified customer master key (CMK) from AWS KMS in the destination region.

  For more information about managing snapshot copy grants, go to Amazon Redshift Database Encryption in the Amazon Redshift Cluster Management Guide.

- SnapshotCopyGrant (dict) –
  The snapshot copy grant that grants Amazon Redshift permission to encrypt copied snapshots with the specified customer master key (CMK) from AWS KMS in the destination region.

  For more information about managing snapshot copy grants, go to Amazon Redshift Database Encryption in the Amazon Redshift Cluster Management Guide.

  - **SnapshotCopyGrantName** (string) –
    The name of the snapshot copy grant.

  - **KmsKeyId** (string) –
    The unique identifier of the customer master key (CMK) in AWS KMS to which Amazon Redshift is granted permission.

  - **Tags** (list) –
    A list of tag instances.
    - (dict) –
      A tag consisting of a name/value pair for a resource.
    
      - **Key** (string) –
        The key, or name, for the resource tag.

      - **Value** (string) –
        The value for the resource tag.

create_tags(**kwargs)**

Adds one or more tags to a specified resource.

A resource can have up to 10 tags. If you try to create more than 10 tags for a resource, you will receive an error and the attempt will fail.
If you specify a key that already exists for the resource, the value for that key will be updated with the new value.

**Request Syntax**

```python
response = client.create_tags(
    ResourceName='string',
    Tags=[
        {'Key': 'string',
         'Value': 'string'},
    ],
)
```

**Parameters**

- **ResourceName** *(string)* – [REQUIRED]
  
  The Amazon Resource Name (ARN) to which you want to add the tag or tags. For example, `arn:aws:redshift:us-east-1:123456789:cluster:t1`.

- **Tags** *(list)* – [REQUIRED]
  
  One or more name/value pairs to add as tags to the specified resource. Each tag name is passed in with the parameter `Key` and the corresponding value is passed in with the parameter `Value`. The `Key` and `Value` parameters are separated by a comma (,). Separate multiple tags with a space. For example, `--tags "Key"="owner","Value"="admin"
"Key"="environment","Value"="test"
"Key"="version","Value"="1.0"`
  
  - (dict) –
    
    A tag consisting of a name/value pair for a resource.
    
    * **Key** *(string)* –
      
      The key, or name, for the resource tag.
    
    * **Value** *(string)* –
      
      The value for the resource tag.

**Returns** None

**delete_cluster** (**kwargs)**

Deletes a previously provisioned cluster. A successful response from the web service indicates that the request was received correctly. Use DescribeClusters to monitor the status of the deletion. The delete operation cannot be canceled or reverted once submitted. For more information about managing clusters, go to Amazon Redshift Clusters in the Amazon Redshift Cluster Management Guide.

If you want to shut down the cluster and retain it for future use, set `SkipFinalClusterSnapshot` to `false` and specify a name for `FinalClusterSnapshotIdentifier`. You can later restore this snapshot to resume using the cluster. If a final cluster snapshot is requested, the status of the cluster will be “final-snapshot” while the snapshot is being taken, then it’s “deleting” once Amazon Redshift begins deleting the cluster.

For more information about managing clusters, go to Amazon Redshift Clusters in the Amazon Redshift Cluster Management Guide.

**Request Syntax**

```python
response = client.delete_cluster(
    ClusterIdentifier='string',
    SkipFinalClusterSnapshot=True|False,
```
Parameters

• **ClusterIdentifier** *(string)* – [REQUIRED]
  
  The identifier of the cluster to be deleted.
  
  Constraints:
  
  – Must contain lowercase characters.
  – Must contain from 1 to 63 alphanumeric characters or hyphens.
  – First character must be a letter.
  – Cannot end with a hyphen or contain two consecutive hyphens.

• **SkipFinalClusterSnapshot** *(boolean)* – Determines whether a final snapshot of the cluster is created before Amazon Redshift deletes the cluster. If `true`, a final cluster snapshot is not created. If `false`, a final cluster snapshot is created before the cluster is deleted.

  **Note:** The `FinalClusterSnapshotIdentifier` parameter must be specified if `SkipFinalClusterSnapshot` is `false`.

  Default: `false`

• **FinalClusterSnapshotIdentifier** *(string)* – The identifier of the final snapshot that is to be created immediately before deleting the cluster. If this parameter is provided, `SkipFinalClusterSnapshot` must be `false`.

  Constraints:
  
  – Must be 1 to 255 alphanumeric characters.
  – First character must be a letter.
  – Cannot end with a hyphen or contain two consecutive hyphens.

Return type: dict

Returns

Response Syntax

```json
{
    'Cluster': {
        'ClusterIdentifier': 'string',
        'NodeType': 'string',
        'ClusterStatus': 'string',

}]}
Response Structure

- **(dict)** –
  Describes a cluster.
  - **Cluster (dict)** –
    Describes a cluster.
    * **ClusterIdentifier (string)** –
      The unique identifier of the cluster.
    * **NodeType (string)** –
      The node type for the nodes in the cluster.
    * **ClusterStatus (string)** –
      The current state of this cluster. Possible values include available, creating, deleting, rebooting, renaming, and resizing.
    * **ModifyStatus (string)** –
      The status of a modify operation, if any, initiated for the cluster.
    * **MasterUsername (string)** –
      The master user name for the cluster. This name is used to connect to the database that is specified in **DBName**.
    * **DBName (string)** –
      The name of the initial database that was created when the cluster was created. This same name is returned for the life of the cluster. If an initial database was not specified, a database named “dev” was created by default.
    * **Endpoint (dict)** –
      The connection endpoint.
      - **Address (string)** –
        The DNS address of the Cluster.
      - **Port (integer)** –
        The port that the database engine is listening on.
    * **ClusterCreateTime (datetime)** –
      The date and time that the cluster was created.
* AutomatedSnapshotRetentionPeriod (integer) –
  The number of days that automatic cluster snapshots are retained.

* ClusterSecurityGroups (list) –
  A list of cluster security group that are associated with the cluster. Each security group is represented by an element that contains ClusterSecurityGroup.Name and ClusterSecurityGroup.Status subelements.

Cluster security groups are used when the cluster is not created in a VPC. Clusters that are created in a VPC use VPC security groups, which are listed by the VpcSecurityGroups parameter.

  · (dict) –
    Describes a security group.
    · ClusterSecurityGroupName (string) –
      The name of the cluster security group.
    · Status (string) –
      The status of the cluster security group.

* VpcSecurityGroups (list) –
  A list of Virtual Private Cloud (VPC) security groups that are associated with the cluster. This parameter is returned only if the cluster is in a VPC.

  · (dict) –
    Describes the members of a VPC security group.
    · VpcSecurityGroupId (string) –
    · Status (string) –

* ClusterParameterGroups (list) –
  The list of cluster parameter groups that are associated with this cluster. Each parameter group in the list is returned with its status.

  · (dict) –
    Describes the status of a parameter group.
    · ParameterGroupName (string) –
      The name of the cluster parameter group.
    · ParameterApplyStatus (string) –
      The status of parameter updates.
    · ClusterParameterStatusList (list) –
      The list of parameter statuses.

For more information about parameters and parameter groups, go to Amazon Redshift Parameter Groups in the Amazon Redshift Cluster Management Guide.

  · (dict) –
    Describes the status of a parameter group.
    · ParameterName (string) –
      The name of the parameter.
    · ParameterApplyStatus (string) –
      The status of the parameter that indicates whether the parameter is in sync with the database, waiting for a cluster reboot,
or encountered an error when being applied.

The following are possible statuses and descriptions:
- `in-sync`: The parameter value is in sync with the database.
- `pending-reboot`: The parameter value will be applied after the cluster reboots.
- `applying`: The parameter value is being applied to the database.
- `invalid-parameter`: Cannot apply the parameter value because it has an invalid value or syntax.
- `apply-deferred`: The parameter contains static property changes. The changes are deferred until the cluster reboots.
- `apply-error`: Cannot connect to the cluster. The parameter change will be applied after the cluster reboots.
- `unknown-error`: Cannot apply the parameter change right now. The change will be applied after the cluster reboots.

### ParameterApplyErrorDescription (string) –

The error that prevented the parameter from being applied to the database.

* **ClusterSubnetGroupName (string) –**

  The name of the subnet group that is associated with the cluster. This parameter is valid only when the cluster is in a VPC.

* **VpcId (string) –**

  The identifier of the VPC the cluster is in, if the cluster is in a VPC.

* **AvailabilityZone (string) –**

  The name of the Availability Zone in which the cluster is located.

* **PreferredMaintenanceWindow (string) –**

  The weekly time range (in UTC) during which system maintenance can occur.

* **PendingModifiedValues (dict) –**

  If present, changes to the cluster are pending. Specific pending changes are identified by subelements.

  - **MasterUserPassword (string) –**

    The pending or in-progress change of the master user password for the cluster.

  - **NodeType (string) –**

    The pending or in-progress change of the cluster’s node type.

  - **NumberOfNodes (integer) –**

    The pending or in-progress change of the number of nodes in the cluster.

  - **ClusterType (string) –**

    The pending or in-progress change of the cluster type.

  - **ClusterVersion (string) –**

    The pending or in-progress change of the service version.

  - **AutomatedSnapshotRetentionPeriod (integer) –**

    The pending or in-progress change of the automated snapshot retention period.
· **ClusterIdentifier** *(string)* –
  
  The pending or in-progress change of the new identifier for the cluster.

· **ClusterVersion** *(string)* –
  
  The version ID of the Amazon Redshift engine that is running on the cluster.

· **AllowVersionUpgrade** *(boolean)* –
  
  If `true`, major version upgrades will be applied automatically to the cluster during the maintenance window.

· **NumberOfNodes** *(integer)* –
  
  The number of compute nodes in the cluster.

· **PubliclyAccessible** *(boolean)* –
  
  If `true`, the cluster can be accessed from a public network.

· **Encrypted** *(boolean)* –
  
  If `true`, data in the cluster is encrypted at rest.

· **RestoreStatus** *(dict)* –
  
  Describes the status of a cluster restore action. Returns null if the cluster was not created by restoring a snapshot.

  · **Status** *(string)* –
    
    The status of the restore action. Returns starting, restoring, completed, or failed.

  · **CurrentRestoreRateInMegaBytesPerSecond** *(float)* –
    
    The number of megabytes per second being transferred from the backup storage. Returns the average rate for a completed backup.

  · **SnapshotSizeInMegaBytes** *(integer)* –
    
    The size of the set of snapshot data used to restore the cluster.

  · **ProgressInMegaBytes** *(integer)* –
    
    The number of megabytes that have been transferred from snapshot storage.

  · **ElapsedTimeInSeconds** *(integer)* –
    
    The amount of time an in-progress restore has been running, or the amount of time it took a completed restore to finish.

  · **EstimatedTimeToCompletionInSeconds** *(integer)* –
    
    The estimate of the time remaining before the restore will complete. Returns 0 for a completed restore.

· **HsmStatus** *(dict)* –
  
  Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.

  Values: active, applying

  · **HsmClientCertificateIdentifier** *(string)* –
    
    Specifies the name of the HSM client certificate the Amazon Redshift cluster uses to retrieve the data encryption keys stored in an HSM.

  · **HsmConfigurationIdentifier** *(string)* –
Specifies the name of the HSM configuration that contains the information the Amazon Redshift cluster can use to retrieve and store keys in an HSM.

- **Status** (string) –
  Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.
  Values: active, applying

  - **ClusterSnapshotCopyStatus** (dict) –
    Returns the destination region and retention period that are configured for cross-region snapshot copy.
    - **DestinationRegion** (string) –
      The destination region that snapshots are automatically copied to when cross-region snapshot copy is enabled.
    - **RetentionPeriod** (integer) –
      The number of days that automated snapshots are retained in the destination region after they are copied from a source region.
    - **SnapshotCopyGrantName** (string) –
      The name of the snapshot copy grant.

  - **ClusterPublicKey** (string) –
    The public key for the cluster.

  - **ClusterNodes** (list) –
    The nodes in a cluster.
    - **Node** (dict) –
      The identifier of a node in a cluster.
    - **NodeRole** (string) –
      Whether the node is a leader node or a compute node.
    - **PrivateIPAddress** (string) –
      The private IP address of a node within a cluster.
    - **PublicIPAddress** (string) –
      The public IP address of a node within a cluster.

  - **ElasticIpStatus** (dict) –
    Describes the status of the elastic IP (EIP) address.
    - **ElasticIp** (string) –
      The elastic IP (EIP) address for the cluster.
    - **Status** (string) –
      Describes the status of the elastic IP (EIP) address.

  - **ClusterRevisionNumber** (string) –
    The specific revision number of the database in the cluster.

  - **Tags** (list) –
    The list of tags for the cluster.
    - **Tag** (dict) –
      A tag consisting of a name/value pair for a resource.
- **Key** *(string)* –
  The key, or name, for the resource tag.
- **Value** *(string)* –
  The value for the resource tag.
- **KmsKeyId** *(string)* –
  The AWS Key Management Service (KMS) key ID of the encryption key used to encrypt data in the cluster.

**delete_cluster_parameter_group(** **kwargs**

Deletes a specified Amazon Redshift parameter group.

**Note:** You cannot delete a parameter group if it is associated with a cluster.

**Request Syntax**

```python
response = client.delete_cluster_parameter_group(
    ParameterGroupName='string'
)
```

**Parameters**  
**ParameterGroupName** *(string)* – [REQUIRED]

The name of the parameter group to be deleted.

**Constraints:**
- Must be the name of an existing cluster parameter group.
- Cannot delete a default cluster parameter group.

**Returns** None

**delete_cluster_security_group(** **kwargs**

Deletes an Amazon Redshift security group.

**Note:** You cannot delete a security group that is associated with any clusters. You cannot delete the default security group.

For information about managing security groups, go to Amazon Redshift Cluster Security Groups in the Amazon Redshift Cluster Management Guide.

**Request Syntax**

```python
response = client.delete_cluster_security_group(
    ClusterSecurityGroupName='string'
)
```

**Parameters**  
**ClusterSecurityGroupName** *(string)* – [REQUIRED]

The name of the cluster security group to be deleted.

**Returns** None

**delete_cluster_snapshot(** **kwargs**

Deletes the specified manual snapshot. The snapshot must be in the available state, with no other users authorized to access the snapshot.

Unlike automated snapshots, manual snapshots are retained even after you delete your cluster. Amazon Redshift does not delete your manual snapshots. You must delete manual snapshot explicitly to avoid getting charged. If other accounts are authorized to access the snapshot, you must revoke all of the authorizations before you can delete the snapshot.
Request Syntax

response = client.delete_cluster_snapshot(
    SnapshotIdentifier='string',
    SnapshotClusterIdentifier='string'
)

Parameters

- **SnapshotIdentifier** *(string)* – [REQUIRED]
  
The unique identifier of the manual snapshot to be deleted.
  
  Constraints: Must be the name of an existing snapshot that is in the available state.

- **SnapshotClusterIdentifier** *(string)* – The unique identifier of the cluster the snapshot was created from. This parameter is required if your IAM user has a policy containing a snapshot resource element that specifies anything other than * for the cluster name.
  
  Constraints: Must be the name of valid cluster.

Return type  dict

Returns

Response Syntax

```
{
    'Snapshot': {
        'SnapshotIdentifier': 'string',
        'ClusterIdentifier': 'string',
        'SnapshotCreateTime': datetime(2015, 1, 1),
        'Status': 'string',
        'Port': 123,
        'AvailabilityZone': 'string',
        'ClusterCreateTime': datetime(2015, 1, 1),
        'MasterUsername': 'string',
        'ClusterVersion': 'string',
        'SnapshotType': 'string',
        'NodeType': 'string',
        'NumberOfNodes': 123,
        'DBName': 'string',
        'VpcId': 'string',
        'Encrypted': True|False,
        'KmsKeyId': 'string',
        'EncryptedWithHSM': True|False,
        'AccountsWithRestoreAccess': [
            {
                'AccountId': 'string'
            },
        ],
        'OwnerAccount': 'string',
        'TotalBackupSizeInMegaBytes': 123.0,
        'ActualIncrementalBackupSizeInMegaBytes': 123.0,
        'BackupProgressInMegaBytes': 123.0,
        'CurrentBackupRateInMegaBytesPerSecond': 123.0,
        'EstimatedSecondsToCompletion': 123,
        'ElapsedTimeInSeconds': 123,
        'SourceRegion': 'string',
        'Tags': [
            {
            }
        ]
    }
}
```
Response Structure

- (dict) –
  Describes a snapshot.
  - **Snapshot** (dict) –
    Describes a snapshot.
    - **SnapshotIdentifier** *(string)* –
      The snapshot identifier that is provided in the request.
    - **ClusterIdentifier** *(string)* –
      The identifier of the cluster for which the snapshot was taken.
    - **SnapshotCreateTime** *(datetime)* –
      The time (UTC) when Amazon Redshift began the snapshot. A snapshot contains a copy of the cluster data as of this exact time.
    - **Status** *(string)* –
      The snapshot status. The value of the status depends on the API operation used.
      - CreateClusterSnapshot and CopyClusterSnapshot returns status as “creating”.
      - DescribeClusterSnapshots returns status as “creating”, “available”, “final snapshot”, or “failed”.
      - DeleteClusterSnapshot returns status as “deleted”.
    - **Port** *(integer)* –
      The port that the cluster is listening on.
    - **AvailabilityZone** *(string)* –
      The Availability Zone in which the cluster was created.
    - **ClusterCreateTime** *(datetime)* –
      The time (UTC) when the cluster was originally created.
    - **MasterUsername** *(string)* –
      The master user name for the cluster.
    - **ClusterVersion** *(string)* –
      The version ID of the Amazon Redshift engine that is running on the cluster.
    - **SnapshotType** *(string)* –
      The snapshot type. Snapshots created using CreateClusterSnapshot and CopyClusterSnapshot will be of type “manual”.
    - **NodeType** *(string)* –
      The node type of the nodes in the cluster.
    - **NumberOfNodes** *(integer)* –
The number of nodes in the cluster.

* **DBName** *(string)* –
  The name of the database that was created when the cluster was created.

* **VpcId** *(string)* –
  The VPC identifier of the cluster if the snapshot is from a cluster in a VPC. Otherwise, this field is not in the output.

* **Encrypted** *(boolean)* –
  If `true`, the data in the snapshot is encrypted at rest.

* **KmsKeyId** *(string)* –
  The AWS Key Management Service (KMS) key ID of the encryption key that was used to encrypt data in the cluster from which the snapshot was taken.

* **EncryptedWithHSM** *(boolean)* –
  A boolean that indicates whether the snapshot data is encrypted using the HSM keys of the source cluster. `true` indicates that the data is encrypted using HSM keys.

* **AccountsWithRestoreAccess** *(list)* –
  A list of the AWS customer accounts authorized to restore the snapshot. Returns `null` if no accounts are authorized. Visible only to the snapshot owner.
    
    · **(dict)** –
      
      Describes an AWS customer account authorized to restore a snapshot.
      
      · **AccountId** *(string)* –
        
        The identifier of an AWS customer account authorized to restore a snapshot.

* **OwnerAccount** *(string)* –
  For manual snapshots, the AWS customer account used to create or copy the snapshot. For automatic snapshots, the owner of the cluster. The owner can perform all snapshot actions, such as sharing a manual snapshot.

* **TotalBackupSizeInMegaBytes** *(float)* –
  The size of the complete set of backup data that would be used to restore the cluster.

* **ActualIncrementalBackupSizeInMegaBytes** *(float)* –
  The size of the incremental backup.

* **BackupProgressInMegaBytes** *(float)* –
  The number of megabytes that have been transferred to the snapshot backup.

* **CurrentBackupRateInMegaBytesPerSecond** *(float)* –
  The number of megabytes per second being transferred to the snapshot backup. Returns `0` for a completed backup.

* **EstimatedSecondsToCompletion** *(integer)* –
  The estimate of the time remaining before the snapshot backup will complete. Returns `0` for a completed backup.
* **ElapsedTimeInSeconds** *(integer)* –
  The amount of time an in-progress snapshot backup has been running, or the amount of time it took a completed backup to finish.

* **SourceRegion** *(string)* –
  The source region from which the snapshot was copied.

* **Tags** *(list)* –
  The list of tags for the cluster snapshot.
  - *(dict)* –
    A tag consisting of a name/value pair for a resource.
    - **Key** *(string)* –
      The key, or name, for the resource tag.
    - **Value** *(string)* –
      The value for the resource tag.

* **RestorableNodeTypes** *(list)* –
  The list of node types that this cluster snapshot is able to restore into.
  - *(string)* –

**delete_cluster_subnet_group(****kwargs**)**
Deletes the specified cluster subnet group.

**Request Syntax**

```python
response = client.delete_cluster_subnet_group(
    ClusterSubnetGroupName='string'
)
```

**Parameters**  
ClusterSubnetGroupName *(string)* – [REQUIRED]
  The name of the cluster subnet group name to be deleted.

**Returns**  
None

**delete_event_subscription(****kwargs**)**
Deletes an Amazon Redshift event notification subscription.

**Request Syntax**

```python
response = client.delete_event_subscription(
    SubscriptionName='string'
)
```

**Parameters**  
SubscriptionName *(string)* – [REQUIRED]
  The name of the Amazon Redshift event notification subscription to be deleted.

**Returns**  
None

**delete_hsm_client_certificate(****kwargs**)**
Deletes the specified HSM client certificate.

**Request Syntax**

```python
response = client.delete_hsm_client_certificate(
    HsmClientCertificateIdentifier='string'
)
```
Parameters `HsmClientCertificateIdentifier (string)` – [REQUIRED]
The identifier of the HSM client certificate to be deleted.

Returns None

`delete_hsm_configuration(**kwargs)`
Deletes the specified Amazon Redshift HSM configuration.

Request Syntax

```python
response = client.delete_hsm_configuration(
    HsmConfigurationIdentifier='string'
)
```

Parameters `HsmConfigurationIdentifier (string)` – [REQUIRED]
The identifier of the Amazon Redshift HSM configuration to be deleted.

Returns None

`delete_snapshot_copy_grant(**kwargs)`
Deletes the specified snapshot copy grant.

Request Syntax

```python
response = client.delete_snapshot_copy_grant(
    SnapshotCopyGrantName='string'
)
```

Parameters `SnapshotCopyGrantName (string)` – [REQUIRED]
The name of the snapshot copy grant to delete.

Returns None

`delete_tags(**kwargs)`
Deletes a tag or tags from a resource. You must provide the ARN of the resource from which you want to delete the tag or tags.

Request Syntax

```python
response = client.delete_tags(
    ResourceName='string',
    TagKeys=[
        'string',
    ]
)
```

Parameters

- `ResourceName (string)` – [REQUIRED]
The Amazon Resource Name (ARN) from which you want to remove the tag or tags. For example, arn:aws:redshift:us-east-1:123456789:cluster:t1.
- `TagKeys (list)` – [REQUIRED]
The tag key that you want to delete.

Returns None

`describe_cluster_parameter_groups(**kwargs)`
Returns a list of Amazon Redshift parameter groups, including parameter groups you created and the
default parameter group. For each parameter group, the response includes the parameter group name, description, and parameter group family name. You can optionally specify a name to retrieve the description of a specific parameter group.

For more information about parameters and parameter groups, go to Amazon Redshift Parameter Groups in the Amazon Redshift Cluster Management Guide.

If you specify both tag keys and tag values in the same request, Amazon Redshift returns all parameter groups that match any combination of the specified keys and values. For example, if you have owner and environment for tag keys, and admin and test for tag values, all parameter groups that have any combination of those values are returned.

If both tag keys and values are omitted from the request, parameter groups are returned regardless of whether they have tag keys or values associated with them.

Request Syntax

```python
response = client.describe_cluster_parameter_groups(
    ParameterGroupName='string',
    MaxRecords=123,
    Marker='string',
    TagKeys=[
        'string',
    ],
    TagValues=[
        'string',
    ]
)
```

### Parameters

- **ParameterGroupName** (*string*) – The name of a specific parameter group for which to return details. By default, details about all parameter groups and the default parameter group are returned.

- **MaxRecords** (*integer*) – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified `MaxRecords` value, a value is returned in the `Marker` field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.
  
  Default: 100

  Constraints: minimum 20, maximum 100.

- **Marker** (*string*) – An optional parameter that specifies the starting point to return a set of response records. When the results of a DescribeClusterParameterGroups request exceed the value specified in `MaxRecords`, AWS returns a value in the `Marker` field of the response. You can retrieve the next set of response records by providing the returned marker value in the `Marker` parameter and retrying the request.

- **TagKeys** (*list*) – A tag key or keys for which you want to return all matching cluster parameter groups that are associated with the specified key or keys. For example, suppose that you have parameter groups that are tagged with keys called owner and environment. If you specify both of these tag keys in the request, Amazon Redshift returns a response with the parameter groups that have either or both of these tag keys associated with them.

- **TagValues** (*list*) – A tag value or values for which you want to return all matching cluster parameter groups that are associated with the specified tag value or values. For example, suppose that you have parameter groups that are tagged
with values called admin and test. If you specify both of these tag values in
the request, Amazon Redshift returns a response with the parameter groups that
have either or both of these tag values associated with them.

- (string) –

Return type dict

Returns

Response Syntax

```
{
    'Marker': 'string',
    'ParameterGroups': [  
        {
            'ParameterGroupName': 'string',
            'ParameterGroupFamily': 'string',
            'Description': 'string',
            'Tags': [  
                {
                    'Key': 'string',
                    'Value': 'string'
                },
            ],
        },
    ],
}
```

Response Structure

- (dict) –

Contains the output from the DescribeClusterParameterGroups action.

- Marker (string) –

A value that indicates the starting point for the next set of response records
in a subsequent request. If a value is returned in a response, you can
retrieve the next set of records by providing this returned marker value in
the Marker parameter and retrying the command. If the Marker field is
empty, all response records have been retrieved for the request.

- ParameterGroups (list) –

A list of ClusterParameterGroup instances. Each instance describes one
cluster parameter group.

- (dict) –

Describes a parameter group.

  - ParameterGroupName (string) –

    The name of the cluster parameter group.

  - ParameterGroupFamily (string) –

    The name of the cluster parameter group family that this cluster
    parameter group is compatible with.

  - Description (string) –

    The description of the parameter group.

  - Tags (list) –

    The list of tags for the cluster parameter group.

  - (dict) –

    A tag consisting of a name/value pair for a resource.
**Key (string)** –
The key, or name, for the resource tag.

**Value (string)** –
The value for the resource tag.

describe_cluster_parameters(**kwargs)

Returns a detailed list of parameters contained within the specified Amazon Redshift parameter group. For each parameter the response includes information such as parameter name, description, data type, value, whether the parameter value is modifiable, and so on.

You can specify `source` filter to retrieve parameters of only specific type. For example, to retrieve parameters that were modified by a user action such as from `ModifyClusterParameterGroup`, you can specify `source` equal to `user`.

For more information about parameters and parameter groups, go to Amazon Redshift Parameter Groups in the Amazon Redshift Cluster Management Guide.

**Request Syntax**

```python
response = client.describe_cluster_parameters(
    ParameterGroupName='string',
    Source='string',
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**

- **ParameterGroupName (string)** – [REQUIRED]
  The name of a cluster parameter group for which to return details.

- **Source (string)** – The parameter types to return. Specify `user` to show parameters that are different from the default. Similarly, specify `engine-default` to show parameters that are the same as the default parameter group.
  
  Default: All parameter types returned.

  Valid Values: `user` | `engine-default`

- **MaxRecords (integer)** – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified `MaxRecords` value, a value is returned in a `marker` field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.
  
  Default: 100

  Constraints: minimum 20, maximum 100.

- **Marker (string)** – An optional parameter that specifies the starting point to return a set of response records. When the results of a `DescribeClusterParameters` request exceed the value specified in `MaxRecords`, AWS returns a value in the `Marker` field of the response. You can retrieve the next set of response records by providing the returned marker value in the `Marker` parameter and retrying the request.

**Return type** `dict`

**Returns**

**Response Syntax**

3.1. Services
```json
{
  'Parameters': [
    {
      'ParameterName': 'string',
      'ParameterValue': 'string',
      'Description': 'string',
      'Source': 'string',
      'DataType': 'string',
      'AllowedValues': 'string',
      'ApplyType': 'static'|'dynamic',
      'IsModifiable': True|False,
      'MinimumEngineVersion': 'string'
    }
  ],
  'Marker': 'string'
}
```

**Response Structure**

- *(dict)*

  Contains the output from the DescribeClusterParameters action.

  - **Parameters (list)**

    A list of Parameter instances. Each instance lists the parameters of one cluster parameter group.
    
    - *(dict)*

      Describes a parameter in a cluster parameter group.
      
      - **ParameterName (string)**
      
        The name of the parameter.
      
      - **ParameterValue (string)**
      
        The value of the parameter.
      
      - **Description (string)**
      
        A description of the parameter.
      
      - **Source (string)**
      
        The source of the parameter value, such as “engine-default” or “user”.
      
      - **DataType (string)**
      
        The data type of the parameter.
      
      - **AllowedValues (string)**
      
        The valid range of values for the parameter.
      
      - **ApplyType (string)**
      
        Specifies how to apply the parameter. Supported value: static.
      
      - **IsModifiable (boolean)**
      
        If true, the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.
      
      - **MinimumEngineVersion (string)**
      
        The earliest engine version to which the parameter can apply.

  - **Marker (string)**
A value that indicates the starting point for the next set of response records in a subsequent request. If a value is returned in a response, you can retrieve the next set of records by providing this returned marker value in the Marker parameter and retrying the command. If the Marker field is empty, all response records have been retrieved for the request.

**describe_cluster_security_groups(**kwargs)

Returns information about Amazon Redshift security groups. If the name of a security group is specified, the response will contain only information about only that security group.

For information about managing security groups, go to Amazon Redshift Cluster Security Groups in the Amazon Redshift Cluster Management Guide.

If you specify both tag keys and tag values in the same request, Amazon Redshift returns all security groups that match any combination of the specified keys and values. For example, if you have owner and environment for tag keys, and admin and test for tag values, all security groups that have any combination of those values are returned.

If both tag keys and values are omitted from the request, security groups are returned regardless of whether they have tag keys or values associated with them.

**Request Syntax**

```python
response = client.describe_cluster_security_groups(
    ClusterSecurityGroupName='string',
    MaxRecords=123,
    Marker='string',
    TagKeys=[
        'string',
    ],
    TagValues=[
        'string',
    ]
)
```

**Parameters**

- **ClusterSecurityGroupName** *(string)* – The name of a cluster security group for which you are requesting details. You can specify either the Marker parameter or a ClusterSecurityGroupName parameter, but not both.

  Example: securitygroup1

- **MaxRecords** *(integer)* – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified MaxRecords value, a value is returned in a marker field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.

  Default: 100

  Constraints: minimum 20, maximum 100.

- **Marker** *(string)* – An optional parameter that specifies the starting point to return a set of response records. When the results of a DescribeClusterSecurityGroups request exceed the value specified in MaxRecords, AWS returns a value in the Marker field of the response. You can retrieve the next set of response records by providing the returned marker value in the Marker parameter and retrying the request.

  Constraints: You can specify either the ClusterSecurityGroupName parameter or the Marker parameter, but not both.
TagKeys (list) – A tag key or keys for which you want to return all matching cluster security groups that are associated with the specified key or keys. For example, suppose that you have security groups that are tagged with keys called owner and environment. If you specify both of these tag keys in the request, Amazon Redshift returns a response with the security groups that have either or both of these tag keys associated with them.

TagValues (list) – A tag value or values for which you want to return all matching cluster security groups that are associated with the specified tag value or values. For example, suppose that you have security groups that are tagged with values called admin and test. If you specify both of these tag values in the request, Amazon Redshift returns a response with the security groups that have either or both of these tag values associated with them.

Return type dict

Response Syntax

```
{
    'Marker': 'string',
    'ClusterSecurityGroups': [
        {
            'ClusterSecurityGroupName': 'string',
            'Description': 'string',
            'EC2SecurityGroups': [
                {
                    'Status': 'string',
                    'EC2SecurityGroupName': 'string',
                    'EC2SecurityGroupOwnerId': 'string',
                    'Tags': [
                        {
                            'Key': 'string',
                            'Value': 'string'
                        }
                    ]
                }
            ],
            'IPRanges': [
                {
                    'Status': 'string',
                    'CIDRIP': 'string',
                    'Tags': [
                        {
                            'Key': 'string',
                            'Value': 'string'
                        }
                    ]
                }
            ],
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                }
            ]
        }
    ]
}
```
Response Structure

- **(dict)** –
  Contains the output from the DescribeClusterSecurityGroups action.

  - **Marker (string)** –
    A value that indicates the starting point for the next set of response records in a subsequent request. If a value is returned in a response, you can retrieve the next set of records by providing this returned marker value in the Marker parameter and retrying the command. If the Marker field is empty, all response records have been retrieved for the request.

  - **ClusterSecurityGroups (list)** –
    A list of ClusterSecurityGroup instances.

    - **(dict)** –
      Describes a security group.

        - **ClusterSecurityGroupName (string)** –
          The name of the cluster security group to which the operation was applied.

        - **Description (string)** –
          A description of the security group.

        - **EC2SecurityGroups (list)** –
          A list of EC2 security groups that are permitted to access clusters associated with this cluster security group.

          - **(dict)** –
            Describes an Amazon EC2 security group.

            - **Status (string)** –
              The status of the EC2 security group.

            - **EC2SecurityGroupName (string)** –
              The name of the EC2 Security Group.

            - **EC2SecurityGroupOwnerId (string)** –
              The AWS ID of the owner of the EC2 security group specified in the EC2SecurityGroupName field.

            - **Tags (list)** –
              The list of tags for the EC2 security group.

              - **(dict)** –
                A tag consisting of a name/value pair for a resource.

                - **Key (string)** –
                  The key, or name, for the resource tag.

                - **Value (string)** –
                  The value for the resource tag.

            - **IPRanges (list)** –
              A list of IP ranges (CIDR blocks) that are permitted to access clusters associated with this cluster security group.
(dict) –
Describes an IP range used in a security group.
- **Status** (string) –
The status of the IP range, for example, “authorized”.
- **CIDRIP** (string) –
The IP range in Classless Inter-Domain Routing (CIDR) notation.
- **Tags** (list) –
The list of tags for the IP range.
  (dict) –
  A tag consisting of a name/value pair for a resource.
  - **Key** (string) –
The key, or name, for the resource tag.
  - **Value** (string) –
The value for the resource tag.
  - **Tags** (list) –
The list of tags for the cluster security group.
  (dict) –
  A tag consisting of a name/value pair for a resource.
  - **Key** (string) –
The key, or name, for the resource tag.
  - **Value** (string) –
The value for the resource tag.

**describe_cluster_snapshots** (**kwargs)**
Returns one or more snapshot objects, which contain metadata about your cluster snapshots. By default, this operation returns information about all snapshots of all clusters that are owned by your AWS customer account. No information is returned for snapshots owned by inactive AWS customer accounts.

If you specify both tag keys and tag values in the same request, Amazon Redshift returns all snapshots that match any combination of the specified keys and values. For example, if you have `owner` and `environment` for tag keys, and `admin` and `test` for tag values, all snapshots that have any combination of those values are returned. Only snapshots that you own are returned in the response; shared snapshots are not returned with the tag key and tag value request parameters.

If both tag keys and values are omitted from the request, snapshots are returned regardless of whether they have tag keys or values associated with them.

**Request Syntax**

```python
response = client.describe_cluster_snapshots(
    ClusterIdentifier='string',
    SnapshotIdentifier='string',
    SnapshotType='string',
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    MaxRecords=123,
    Marker='string',
    OwnerAccount='string',
    TagKeys=[
        'string',
```
Parameters

- **ClusterIdentifier** *(string)* – The identifier of the cluster for which information about snapshots is requested.
- **SnapshotIdentifier** *(string)* – The snapshot identifier of the snapshot about which to return information.
- **SnapshotType** *(string)* – The type of snapshots for which you are requesting information. By default, snapshots of all types are returned. Valid Values: `automated` | `manual`
- **StartTime** *(datetime)* – A value that requests only snapshots created at or after the specified time. The time value is specified in ISO 8601 format. For more information about ISO 8601, go to the ISO8601 Wikipedia page.
  
  Example: `2012-07-16T18:00:00Z`
- **EndTime** *(datetime)* – A time value that requests only snapshots created at or before the specified time. The time value is specified in ISO 8601 format. For more information about ISO 8601, go to the ISO8601 Wikipedia page.
  
  Example: `2012-07-16T18:00:00Z`
- **MaxRecords** *(integer)* – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified `MaxRecords` value, a value is returned in the `Marker` field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.
  
  Default: 100
  
  Constraints: minimum 20, maximum 100.
- **Marker** *(string)* – An optional parameter that specifies the starting point to return a set of response records. When the results of a `DescribeClusterSnapshots` request exceed the value specified in `MaxRecords`, AWS returns a value in the `Marker` field of the response. You can retrieve the next set of response records by providing the returned marker value in the `Marker` parameter and retrying the request.
- **OwnerAccount** *(string)* – The AWS customer account used to create or copy the snapshot. Use this field to filter the results to snapshots owned by a particular account. To describe snapshots you own, either specify your AWS customer account, or do not specify the parameter.
- **TagKeys** *(list)* – A tag key or keys for which you want to return all matching cluster snapshots that are associated with the specified key or keys. For example, suppose that you have snapshots that are tagged with keys called `owner` and `environment`. If you specify both of these tag keys in the request, Amazon Redshift returns a response with the snapshots that have either or both of these tag keys associated with them.
  
  – *(string)* –
- **TagValues** *(list)* – A tag value or values for which you want to return all matching cluster snapshots that are associated with the specified tag value or values. For example, suppose that you have snapshots that are tagged with values called `admin` and `test`. If you specify both of these tag values in the request, Amazon Redshift returns a response with the snapshots that have either or both of these tag values associated with them.
Return type  dict

Returns

Response Syntax

```python
{
    'Marker': 'string',
    'Snapshots': [
        {
            'SnapshotIdentifier': 'string',
            'ClusterIdentifier': 'string',
            'SnapshotCreateTime': datetime(2015, 1, 1),
            'Status': 'string',
            'Port': 123,
            'AvailabilityZone': 'string',
            'ClusterCreateTime': datetime(2015, 1, 1),
            'MasterUsername': 'string',
            'ClusterVersion': 'string',
            'SnapshotType': 'string',
            'NodeType': 'string',
            'NumberOfNodes': 123,
            'DBName': 'string',
            'VpcId': 'string',
            'Encrypted': True|False,
            'KmsKeyId': 'string',
            'EncryptedWithHSM': True|False,
            'AccountsWithRestoreAccess': [
                {
                    'AccountId': 'string'
                }]
            ,
            'OwnerAccount': 'string',
            'TotalBackupSizeInMegaBytes': 123.0,
            'ActualIncrementalBackupSizeInMegaBytes': 123.0,
            'BackupProgressInMegaBytes': 123.0,
            'CurrentBackupRateInMegaBytesPerSecond': 123.0,
            'EstimatedSecondsToCompletion': 123,
            'ElapsedTimeInSeconds': 123,
            'SourceRegion': 'string',
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                }],
            'RestorableNodeTypes': [
                'string'
            ]
        },
    ],
    'OwnerAccount': 'string',
}"
```

Response Structure

- (dict) –

Contains the output from the DescribeClusterSnapshots action.

- Marker (string) –
A value that indicates the starting point for the next set of response records in a subsequent request. If a value is returned in a response, you can retrieve the next set of records by providing this returned marker value in the Marker parameter and retrying the command. If the Marker field is empty, all response records have been retrieved for the request.

- **Snapshots** *(list)*

A list of Snapshot instances.

* *(dict)*

  Describes a snapshot.

  - **SnapshotIdentifier** *(string)*
    
    The snapshot identifier that is provided in the request.

  - **ClusterIdentifier** *(string)*
    
    The identifier of the cluster for which the snapshot was taken.

  - **SnapshotCreateTime** *(datetime)*
    
    The time (UTC) when Amazon Redshift began the snapshot. A snapshot contains a copy of the cluster data as of this exact time.

  - **Status** *(string)*
    
    The snapshot status. The value of the status depends on the API operation used.

    - CreateClusterSnapshot and CopyClusterSnapshot returns status as “creating”.
    - DescribeClusterSnapshots returns status as “creating”, “available”, “final snapshot”, or “failed”.
    - DeleteClusterSnapshot returns status as “deleted”.

  - **Port** *(integer)*
    
    The port that the cluster is listening on.

  - **AvailabilityZone** *(string)*
    
    The Availability Zone in which the cluster was created.

  - **ClusterCreateTime** *(datetime)*
    
    The time (UTC) when the cluster was originally created.

  - **MasterUsername** *(string)*
    
    The master user name for the cluster.

  - **ClusterVersion** *(string)*
    
    The version ID of the Amazon Redshift engine that is running on the cluster.

  - **SnapshotType** *(string)*
    
    The snapshot type. Snapshots created using CreateClusterSnapshot and CopyClusterSnapshot will be of type “manual”.

  - **NodeType** *(string)*
    
    The node type of the nodes in the cluster.

  - **NumberOfNodes** *(integer)*
    
    The number of nodes in the cluster.

  - **DBName** *(string)*
    
    The name of the database that was created when the cluster was created.
- **VpcId (string)** –
  The VPC identifier of the cluster if the snapshot is from a cluster in a VPC. Otherwise, this field is not in the output.
- **Encrypted (boolean)** –
  If true, the data in the snapshot is encrypted at rest.
- **KmsKeyId (string)** –
  The AWS Key Management Service (KMS) key ID of the encryption key that was used to encrypt data in the cluster from which the snapshot was taken.
- **EncryptedWithHSM (boolean)** –
  A boolean that indicates whether the snapshot data is encrypted using the HSM keys of the source cluster. true indicates that the data is encrypted using HSM keys.
- **AccountsWithRestoreAccess (list)** –
  A list of the AWS customer accounts authorized to restore the snapshot. Returns null if no accounts are authorized. Visible only to the snapshot owner.
- **(dict)** –
  Describes an AWS customer account authorized to restore a snapshot.
- **AccountId (string)** –
  The identifier of an AWS customer account authorized to restore a snapshot.
- **OwnerAccount (string)** –
  For manual snapshots, the AWS customer account used to create or copy the snapshot. For automatic snapshots, the owner of the cluster. The owner can perform all snapshot actions, such as sharing a manual snapshot.
- **TotalBackupSizeInMegaBytes (float)** –
  The size of the complete set of backup data that would be used to restore the cluster.
- **ActualIncrementalBackupSizeInMegaBytes (float)** –
  The size of the incremental backup.
- **BackupProgressInMegaBytes (float)** –
  The number of megabytes that have been transferred to the snapshot backup.
- **CurrentBackupRateInMegaBytesPerSecond (float)** –
  The number of megabytes per second being transferred to the snapshot backup. Returns 0 for a completed backup.
- **EstimatedSecondsToCompletion (integer)** –
  The estimate of the time remaining before the snapshot backup will complete. Returns 0 for a completed backup.
- **ElapsedTimeInSeconds (integer)** –
  The amount of time an in-progress snapshot backup has been running, or the amount of time it took a completed backup to finish.
· **SourceRegion (string)** –
  The source region from which the snapshot was copied.

· **Tags (list)** –
  The list of tags for the cluster snapshot.

· **Key (string)** –
  The key, or name, for the resource tag.

· **Value (string)** –
  The value for the resource tag.

· **RestorableNodeTypes (list)** –
  The list of node types that this cluster snapshot is able to restore into.

**describe_cluster_subnet_groups (**)kwargs**

Returns one or more cluster subnet group objects, which contain metadata about your cluster subnet groups. By default, this operation returns information about all cluster subnet groups that are defined in your AWS account.

If you specify both tag keys and tag values in the same request, Amazon Redshift returns all subnet groups that match any combination of the specified keys and values. For example, if you have `owner` and `environment` for tag keys, and `admin` and `test` for tag values, all subnet groups that have any combination of those values are returned.

If both tag keys and values are omitted from the request, subnet groups are returned regardless of whether they have tag keys or values associated with them.

**Request Syntax**

```python
response = client.describe_cluster_subnet_groups(
    ClusterSubnetGroupName='string',
    MaxRecords=123,
    Marker='string',
    TagKeys=[
        'string',
    ],
    TagValues=[
        'string',
    ]
)
```

**Parameters**

- **ClusterSubnetGroupName (string)** – The name of the cluster subnet group for which information is requested.
- **MaxRecords (integer)** – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified **MaxRecords** value, a value is returned in a marker field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.

  Default: 100

Constraints: minimum 20, maximum 100.
• **Marker** *(string)* – An optional parameter that specifies the starting point to return a set of response records. When the results of a DescribeClusterSubnetGroups request exceed the value specified in MaxRecords, AWS returns a value in the Marker field of the response. You can retrieve the next set of response records by providing the returned marker value in the Marker parameter and retrying the request.

• **TagKeys** *(list)* – A tag key or keys for which you want to return all matching cluster subnet groups that are associated with the specified key or keys. For example, suppose that you have subnet groups that are tagged with keys called owner and environment. If you specify both of these tag keys in the request, Amazon Redshift returns a response with the subnet groups that have either or both of these tag keys associated with them.

  – *(string)* –

• **TagValues** *(list)* – A tag value or values for which you want to return all matching cluster subnet groups that are associated with the specified tag value or values. For example, suppose that you have subnet groups that are tagged with values called admin and test. If you specify both of these tag values in the request, Amazon Redshift returns a response with the subnet groups that have either or both of these tag values associated with them.

  – *(string)* –

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Marker': 'string',
    'ClusterSubnetGroups': [  
        {
            'ClusterSubnetGroupName': 'string',
            'Description': 'string',
            'VpcId': 'string',
            'SubnetGroupStatus': 'string',
            'Subnets': [  
                {
                    'SubnetIdentifier': 'string',
                    'SubnetAvailabilityZone': {  
                        'Name': 'string'  
                    },
                    'SubnetStatus': 'string'
                },
                ...
            ],
            'Tags': [  
                {
                    'Key': 'string',
                    'Value': 'string'
                },
                ...
            ]
        },
        ...
    ],
}
```

**Response Structure**

• *(dict)* –

Contains the output from the DescribeClusterSubnetGroups action.

  – **Marker** *(string)* –
A value that indicates the starting point for the next set of response records in a subsequent request. If a value is returned in a response, you can retrieve the next set of records by providing this returned marker value in the **Marker** parameter and retrying the command. If the **Marker** field is empty, all response records have been retrieved for the request.

- **ClusterSubnetGroups** *(list)*
  
  A list of **ClusterSubnetGroup** instances.

  *(dict)*

  Describes a subnet group.

  - **ClusterSubnetGroupName** *(string)*
    
    The name of the cluster subnet group.

  - **Description** *(string)*
    
    The description of the cluster subnet group.

  - **VpcId** *(string)*
    
    The VPC ID of the cluster subnet group.

  - **SubnetGroupStatus** *(string)*
    
    The status of the cluster subnet group. Possible values are **Complete**, **Incomplete** and **Invalid**.

  - **Subnets** *(list)*
    
    A list of the VPC Subnet elements.

  *(dict)*

  Describes a subnet.

  - **SubnetIdentifier** *(string)*
    
    The identifier of the subnet.

  - **SubnetAvailabilityZone** *(dict)*
    
    Describes an availability zone.

  - **Name** *(string)*
    
    The name of the availability zone.

  - **SubnetStatus** *(string)*
    
    The status of the subnet.

  - **Tags** *(list)*
    
    The list of tags for the cluster subnet group.

  *(dict)*

  A tag consisting of a name/value pair for a resource.

  - **Key** *(string)*
    
    The key, or name, for the resource tag.

  - **Value** *(string)*
    
    The value for the resource tag.

**describe_cluster_versions** (**kwargs**)

Returns descriptions of the available Amazon Redshift cluster versions. You can call this operation even before creating any clusters to learn more about the Amazon Redshift versions. For more information about managing clusters, go to Amazon Redshift Clusters in the Amazon Redshift Cluster Management Guide

**Request Syntax**
response = client.describe_cluster_versions(
    ClusterVersion='string',
    ClusterParameterGroupFamily='string',
    MaxRecords=123,
    Marker='string'
)

Parameters

- **ClusterVersion** *(string)* – The specific cluster version to return.
  
  Example: 1.0

- **ClusterParameterGroupFamily** *(string)* – The name of a specific cluster parameter group family to return details for.

  Constraints:
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **MaxRecords** *(integer)* – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified MaxRecords value, a value is returned in a marker field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.

  Default: 100

  Constraints: minimum 20, maximum 100.

- **Marker** *(string)* – An optional parameter that specifies the starting point to return a set of response records. When the results of a DescribeClusterVersions request exceed the value specified in MaxRecords, AWS returns a value in the Marker field of the response. You can retrieve the next set of response records by providing the returned marker value in the Marker parameter and retrying the request.

Return type **dict**

Returns

**Response Syntax**

```python
{
    'Marker': 'string',
    'ClusterVersions': [
        {
            'ClusterVersion': 'string',
            'ClusterParameterGroupFamily': 'string',
            'Description': 'string'
        },
    ]
}
```

**Response Structure**

- *(dict)* –

  Contains the output from the DescribeClusterVersions action.

  - **Marker** *(string)* –

    A value that indicates the starting point for the next set of response records in a subsequent request. If a value is returned in a response, you can retrieve the next set of records by providing this returned marker value in
the Marker parameter and retrying the command. If the Marker field is empty, all response records have been retrieved for the request.

- **ClusterVersions (list)** –

  A list of Version elements.

  * **(dict)** –

    Describes a cluster version, including the parameter group family and description of the version.

    - **ClusterVersion (string)** –
      The version number used by the cluster.

    - **ClusterParameterGroupFamily (string)** –
      The name of the cluster parameter group family for the cluster.

    - **Description (string)** –
      The description of the cluster version.

**describe_clusters (**kwargs**)**

Returns properties of provisioned clusters including general cluster properties, cluster database properties, maintenance and backup properties, and security and access properties. This operation supports pagination. For more information about managing clusters, go to Amazon Redshift Clusters in the Amazon Redshift Cluster Management Guide.

If you specify both tag keys and tag values in the same request, Amazon Redshift returns all clusters that match any combination of the specified keys and values. For example, if you have owner and environment for tag keys, and admin and test for tag values, all clusters that have any combination of those values are returned.

If both tag keys and values are omitted from the request, clusters are returned regardless of whether they have tag keys or values associated with them.

**Request Syntax**

```python
response = client.describe_clusters(
    ClusterIdentifier='string',
    MaxRecords=123,
    Marker='string',
    TagKeys=[
        'string',
    ],
    TagValues=[
        'string',
    ]
)
```

**Parameters**

- **ClusterIdentifier (string)** – The unique identifier of a cluster whose properties you are requesting. This parameter is case sensitive.

  The default is that all clusters defined for an account are returned.

- **MaxRecords (integer)** – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified MaxRecords value, a value is returned in a marker field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.

  Default: 100
Constraints: minimum 20, maximum 100.

- **Marker** *(string)* – An optional parameter that specifies the starting point to return a set of response records. When the results of a DescribeClusters request exceed the value specified in `MaxRecords`, AWS returns a value in the `Marker` field of the response. You can retrieve the next set of response records by providing the returned marker value in the `Marker` parameter and retrying the request.

  Constraints: You can specify either the `ClusterIdentifier` parameter or the `Marker` parameter, but not both.

- **TagKeys** *(list)* – A tag key or keys for which you want to return all matching clusters that are associated with the specified key or keys. For example, suppose that you have clusters that are tagged with keys called `owner` and `environment`. If you specify both of these tag keys in the request, Amazon Redshift returns a response with the clusters that have either or both of these tag keys associated with them.
  
  - *(string)*

- **TagValues** *(list)* – A tag value or values for which you want to return all matching clusters that are associated with the specified tag value or values. For example, suppose that you have clusters that are tagged with values called `admin` and `test`. If you specify both of these tag values in the request, Amazon Redshift returns a response with the clusters that have either or both of these tag values associated with them.
  
  - *(string)*

**Returns** 

**Response Syntax**

```python
{
    'Marker': 'string',
    'Clusters': [
        {
            'ClusterIdentifier': 'string',
            'NodeType': 'string',
            'ClusterStatus': 'string',
            'ModifyStatus': 'string',
            'MasterUsername': 'string',
            'DBName': 'string',
            'Endpoint': {
                'Address': 'string',
                'Port': 123
            },
            'ClusterCreateTime': datetime(2015, 1, 1),
            'AutomatedSnapshotRetentionPeriod': 123,
            'ClusterSecurityGroups': [
                {
                    'ClusterSecurityGroupName': 'string',
                    'Status': 'string'
                }
            ],
            'VpcSecurityGroups': [
                {
                    'VpcSecurityGroupId': 'string',
                    'Status': 'string'
                }
            ],
            'ClusterParameterGroups': [
            
        }
    ]
}
```

**Return type** `dict`

**Returns**
\[
\{
    'ParameterGroupName': 'string',
    'ParameterApplyStatus': 'string',
    'ClusterParameterStatusList': [
        {

\]
Response Structure

- **(dict)** –

Contains the output from the DescribeClusters action.

- **Marker (string)** –

A value that indicates the starting point for the next set of response records in a subsequent request. If a value is returned in a response, you can retrieve the next set of records by providing this returned marker value in the `Marker` parameter and retrying the command. If the `Marker` field is empty, all response records have been retrieved for the request.

- **Clusters (list)** –

A list of Cluster objects, where each object describes one cluster.

- **(dict)** –

Describes a cluster.

  - **ClusterIdentifier (string)** –

    The unique identifier of the cluster.

  - **NodeType (string)** –

    The node type for the nodes in the cluster.

  - **ClusterStatus (string)** –

    The current state of this cluster. Possible values include `available`, `creating`, `deleting`, `rebooting`, `renaming`, and `resizing`.

  - **ModifyStatus (string)** –

    The status of a modify operation, if any, initiated for the cluster.

  - **MasterUsername (string)** –

    The master user name for the cluster. This name is used to connect to the database that is specified in `DBName`.

  - **DBName (string)** –

    The name of the initial database that was created when the cluster was created. This same name is returned for the life of the cluster. If an initial database was not specified, a database named “dev” was created by default.

  - **Endpoint (dict)** –

    The connection endpoint.

  - **Address (string)** –
The DNS address of the Cluster.

- **Port** *(integer)* — The port that the database engine is listening on.

- **ClusterCreateTime** *(datetime)* — The date and time that the cluster was created.

- **AutomatedSnapshotRetentionPeriod** *(integer)* — The number of days that automatic cluster snapshots are retained.

- **ClusterSecurityGroups** *(list)* — A list of cluster security group that are associated with the cluster. Each security group is represented by an element that contains `ClusterSecurityGroup.Name` and `ClusterSecurityGroup.Status` subelements.

  Cluster security groups are used when the cluster is not created in a VPC. Clusters that are created in a VPC use VPC security groups, which are listed by the `VpcSecurityGroups` parameter.

  - *(dict)* — Describes a security group.

    - **ClusterSecurityGroupName** *(string)* — The name of the cluster security group.

    - **Status** *(string)* — The status of the cluster security group.

- **VpcSecurityGroups** *(list)* — A list of Virtual Private Cloud (VPC) security groups that are associated with the cluster. This parameter is returned only if the cluster is in a VPC.

  - *(dict)* — Describes the members of a VPC security group.

    - **VpcSecurityGroupId** *(string)* —

    - **Status** *(string)* —

    - **ClusterParameterGroups** *(list)* — The list of cluster parameter groups that are associated with this cluster. Each parameter group in the list is returned with its status.

      - *(dict)* — Describes the status of a parameter group.

        - **ParameterGroupName** *(string)* — The name of the cluster parameter group.

        - **ParameterApplyStatus** *(string)* — The status of parameter updates.

        - **ClusterParameterStatusList** *(list)* — The list of parameter statuses.

For more information about parameters and parameter groups, go to [Amazon Redshift Parameter Groups](https://docs.aws.amazon.com/redshift/latest克拉/cluster.html) in the [Amazon Redshift Cluster Management Guide](https://docs.aws.amazon.com/redshift/latest克拉/cluster.html).
· (dict) –
  Describes the status of a parameter group.
  · ParameterName (string) –
    The name of the parameter.
  · ParameterApplyStatus (string) –
    The status of the parameter that indicates whether the parameter is in sync with the database, waiting for a cluster reboot, or encountered an error when being applied.

The following are possible statuses and descriptions.
  · in-sync: The parameter value is in sync with the database.
  · pending-reboot: The parameter value will be applied after the cluster reboots.
  · applying: The parameter value is being applied to the database.
  · invalid-parameter: Cannot apply the parameter value because it has an invalid value or syntax.
  · apply-deferred: The parameter contains static property changes. The changes are deferred until the cluster reboots.
  · apply-error: Cannot connect to the cluster. The parameter change will be applied after the cluster reboots.
  · unknown-error: Cannot apply the parameter change right now. The change will be applied after the cluster reboots.

  · ParameterApplyErrorDescription (string) –
    The error that prevented the parameter from being applied to the database.
  · ClusterSubnetGroupName (string) –
    The name of the subnet group that is associated with the cluster. This parameter is valid only when the cluster is in a VPC.
  · VpcId (string) –
    The identifier of the VPC the cluster is in, if the cluster is in a VPC.
  · AvailabilityZone (string) –
    The name of the Availability Zone in which the cluster is located.
  · PreferredMaintenanceWindow (string) –
    The weekly time range (in UTC) during which system maintenance can occur.
  · PendingModifiedValues (dict) –
    If present, changes to the cluster are pending. Specific pending changes are identified by subelements.
  · MasterUserPassword (string) –
    The pending or in-progress change of the master user password for the cluster.
  · NodeType (string) –
    The pending or in-progress change of the cluster’s node type.
  · NumberOfNodes (integer) –
The pending or in-progress change of the number of nodes in the cluster.

- **ClusterType** *(string)* – The pending or in-progress change of the cluster type.

- **ClusterVersion** *(string)* – The pending or in-progress change of the service version.

- **AutomatedSnapshotRetentionPeriod** *(integer)* – The pending or in-progress change of the automated snapshot retention period.

- **ClusterIdentifier** *(string)* – The pending or in-progress change of the new identifier for the cluster.

- **ClusterVersion** *(string)* – The version ID of the Amazon Redshift engine that is running on the cluster.

- **AllowVersionUpgrade** *(boolean)* – If true, major version upgrades will be applied automatically to the cluster during the maintenance window.

- **NumberOfNodes** *(integer)* – The number of compute nodes in the cluster.

- **PubliclyAccessible** *(boolean)* – If true, the cluster can be accessed from a public network.

- **Encrypted** *(boolean)* – If true, data in the cluster is encrypted at rest.

- **RestoreStatus** *(dict)* – Describes the status of a cluster restore action. Returns null if the cluster was not created by restoring a snapshot.

- **Status** *(string)* – The status of the restore action. Returns starting, restoring, completed, or failed.

- **CurrentRestoreRateInMegaBytesPerSecond** *(float)* – The number of megabytes per second being transferred from the backup storage. Returns the average rate for a completed backup.

- **SnapshotSizeInMegaBytes** *(integer)* – The size of the set of snapshot data used to restore the cluster.

- **ProgressInMegaBytes** *(integer)* – The number of megabytes that have been transferred from snapshot storage.

- **ElapsedTimeInSeconds** *(integer)* – The amount of time an in-progress restore has been running, or the amount of time it took a completed restore to finish.

- **EstimatedTimeToCompletionInSeconds** *(integer)* – The estimate of the time remaining before the restore will complete. Returns 0 for a completed restore.
- **HsmStatus (dict)** –
  Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.
  
  Values: active, applying

- **HsmClientCertificateIdentifier (string)** –
  Specifies the name of the HSM client certificate the Amazon Redshift cluster uses to retrieve the data encryption keys stored in an HSM.

- **HsmConfigurationIdentifier (string)** –
  Specifies the name of the HSM configuration that contains the information the Amazon Redshift cluster can use to retrieve and store keys in an HSM.

- **Status (string)** –
  Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.
  
  Values: active, applying

- **ClusterSnapshotCopyStatus (dict)** –
  Returns the destination region and retention period that are configured for cross-region snapshot copy.

  - **DestinationRegion (string)** –
    The destination region that snapshots are automatically copied to when cross-region snapshot copy is enabled.

  - **RetentionPeriod (integer)** –
    The number of days that automated snapshots are retained in the destination region after they are copied from a source region.

  - **SnapshotCopyGrantName (string)** –
    The name of the snapshot copy grant.

- **ClusterPublicKey (string)** –
  The public key for the cluster.

- **ClusterNodes (list)** –
  The nodes in a cluster.

  - **(dict)** –
    The identifier of a node in a cluster.

  - **NodeRole (string)** –
    Whether the node is a leader node or a compute node.

  - **PrivateIPAddress (string)** –
    The private IP address of a node within a cluster.

  - **PublicIPAddress (string)** –
    The public IP address of a node within a cluster.

  - **ElasticIpStatus (dict)** –
    Describes the status of the elastic IP (EIP) address.
Boto3 Documentation, Release 1.1.4

- **ElasticIp** *(string)* –
  The elastic IP (EIP) address for the cluster.

- **Status** *(string)* –
  Describes the status of the elastic IP (EIP) address.

- **ClusterRevisionNumber** *(string)* –
  The specific revision number of the database in the cluster.

- **Tags** *(list)* –
  The list of tags for the cluster.

- **Key** *(string)* –
  The key, or name, for the resource tag.

- **Value** *(string)* –
  The value for the resource tag.

- **KmsKeyId** *(string)* –
  The AWS Key Management Service (KMS) key ID of the encryption key used to encrypt data in the cluster.

**describe_default_cluster_parameters** (**kwargs**)

Returns a list of parameter settings for the specified parameter group family.

For more information about parameters and parameter groups, go to Amazon Redshift Parameter Groups in the Amazon Redshift Cluster Management Guide.

**Request Syntax**

```python
response = client.describe_default_cluster_parameters(
    ParameterGroupFamily='string',
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**

- **ParameterGroupFamily** *(string)* – [REQUIRED]
  The name of the cluster parameter group family.

- **MaxRecords** *(integer)* – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified MaxRecords value, a value is returned in a **marker** field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.

  Default: 100

  Constraints: minimum 20, maximum 100.

- **Marker** *(string)* – An optional parameter that specifies the starting point to return a set of response records. When the results of a DescribeDefaultClusterParameters request exceed the value specified in MaxRecords, AWS returns a value in the Marker field of the response. You can retrieve the next set of response records by providing the returned marker value in the Marker parameter and retrying the request.

**Return type** `dict`
Returns

Response Syntax

```
{
    'DefaultClusterParameters': {
        'ParameterGroupFamily': 'string',
        'Marker': 'string',
        'Parameters': [
            {
                'ParameterName': 'string',
                'ParameterValue': 'string',
                'Description': 'string',
                'Source': 'string',
                'DataType': 'string',
                'AllowedValues': 'string',
                'ApplyType': 'static'|'dynamic',
                'IsModifiable': True|False,
                'MinimumEngineVersion': 'string'
            }
        ]
    }
}
```

Response Structure

- (dict) – Describes the default cluster parameters for a parameter group family.
  - DefaultClusterParameters (dict) – Describes the default cluster parameters for a parameter group family.
    - ParameterGroupFamily (string) – The name of the cluster parameter group family to which the engine default parameters apply.
    - Marker (string) – A value that indicates the starting point for the next set of response records in a subsequent request. If a value is returned in a response, you can retrieve the next set of records by providing this returned marker value in the Marker parameter and retrying the command. If the Marker field is empty, all response records have been retrieved for the request.
    - Parameters (list) – The list of cluster default parameters.
      - (dict) – Describes a parameter in a cluster parameter group.
        - ParameterName (string) – The name of the parameter.
        - ParameterValue (string) – The value of the parameter.
        - Description (string) – A description of the parameter.
        - Source (string) –
The source of the parameter value, such as “engine-default” or “user”.

- **DataType (string)** –
  
The data type of the parameter.

- **AllowedValues (string)** –
  
The valid range of values for the parameter.

- **ApplyType (string)** –
  
  Specifies how to apply the parameter. Supported value: static.

- **IsModifiable (boolean)** –
  
  If true, the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.

- **MinimumEngineVersion (string)** –
  
  The earliest engine version to which the parameter can apply.

### describe_event_categories(**kwargs)

Displays a list of event categories for all event source types, or for a specified source type. For a list of the event categories and source types, go to Amazon Redshift Event Notifications.

**Request Syntax**

```python
response = client.describe_event_categories(
    SourceType='string'
)
```

**Parameters SourceType (string)** – The source type, such as cluster or parameter group, to which the described event categories apply.

Valid values: cluster, snapshot, parameter group, and security group.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'EventCategoriesMapList': [
        {
            'SourceType': 'string',
            'Events': [
                {
                    'EventId': 'string',
                    'EventCategories': [
                        'string',
                    ],
                    'EventDescription': 'string',
                    'Severity': 'string'
                }
            ]
        }
    ]
}
```

**Response Structure**

- (dict) –
– **EventCategoriesMapList** *(list)* –

A list of event categories descriptions.

* *(dict)* –

  * **SourceType** *(string)* –

  The Amazon Redshift source type, such as cluster or cluster-snapshot, that the returned categories belong to.

  * **Events** *(list)* –

  The events in the event category.

    * *(dict)* –

    * **EventId** *(string)* –

      The identifier of an Amazon Redshift event.

    * **EventCategories** *(list)* –

      The category of an Amazon Redshift event.

    * *(string)* –

    * **EventDescription** *(string)* –

      The description of an Amazon Redshift event.

    * **Severity** *(string)* –

      The severity of the event.

    Values: ERROR, INFO

**describe_event_subscriptions** *(**kwargs)*

Lists descriptions of all the Amazon Redshift event notifications subscription for a customer account. If you specify a subscription name, lists the description for that subscription.

**Request Syntax**

```python
response = client.describe_event_subscriptions(
    SubscriptionName='string',
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**

- **SubscriptionName** *(string)* – The name of the Amazon Redshift event notification subscription to be described.

- **MaxRecords** *(integer)* – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified `MaxRecords` value, a value is returned in the `Marker` field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.

  Default: 100

  Constraints: minimum 20, maximum 100.

- **Marker** *(string)* – An optional parameter that specifies the starting point to return a set of response records. When the results of a DescribeEventSubscriptions request exceed the value specified in `MaxRecords`, AWS returns a value in the `Marker` field of the response. You can retrieve the next set of response records by providing the returned marker value in the `Marker` parameter and retrying the request.

**Return type** `dict`
Returns

Response Syntax

```
{
    'Marker': 'string',
    'EventSubscriptionsList': [
        {
            'CustomerAwsId': 'string',
            'CustSubscriptionId': 'string',
            'SnsTopicArn': 'string',
            'Status': 'string',
            'SubscriptionCreationTime': datetime(2015, 1, 1),
            'SourceType': 'string',
            'SourceIdsList': [
                'string',
            ],
            'EventCategoriesList': [
                'string',
            ],
            'Severity': 'string',
            'Enabled': True|False,
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                },
            ],
        },
    ],
}
```

Response Structure

- *(dict)* –
  - **Marker** *(string)* –
    A value that indicates the starting point for the next set of response records in a subsequent request. If a value is returned in a response, you can retrieve the next set of records by providing this returned marker value in the Marker parameter and retrying the command. If the Marker field is empty, all response records have been retrieved for the request.

- **EventSubscriptionsList** *(list)* –
  A list of event subscriptions.
  - *(dict)* –
    - **CustomerAwsId** *(string)* –
      The AWS customer account associated with the Amazon Redshift event notification subscription.
    - **CustSubscriptionId** *(string)* –
      The name of the Amazon Redshift event notification subscription.
    - **SnsTopicArn** *(string)* –
      The Amazon Resource Name (ARN) of the Amazon SNS topic used by the event notification subscription.
    - **Status** *(string)* –
The status of the Amazon Redshift event notification subscription.

Constraints:
- Can be one of the following: active | no-permission | topic-not-exist
- The status “no-permission” indicates that Amazon Redshift no longer has permission to post to the Amazon SNS topic. The status “topic-not-exist” indicates that the topic was deleted after the subscription was created.
- **SubscriptionCreationTime** (datetime) – The date and time the Amazon Redshift event notification subscription was created.
- **SourceType** (string) – The source type of the events returned the Amazon Redshift event notification, such as cluster, or cluster-snapshot.
- **SourceIdsList** (list) – A list of the sources that publish events to the Amazon Redshift event notification subscription.
- **EventCategoriesList** (list) – The list of Amazon Redshift event categories specified in the event notification subscription.
  - Values: Configuration, Management, Monitoring, Security
- **Severity** (string) – The event severity specified in the Amazon Redshift event notification subscription.
  - Values: ERROR, INFO
- **Enabled** (boolean) – A Boolean value indicating whether the subscription is enabled. `true` indicates the subscription is enabled.
- **Tags** (list) – The list of tags for the event subscription.
  - A tag consisting of a name/value pair for a resource.
  - **Key** (string) – The key, or name, for the resource tag.
  - **Value** (string) – The value for the resource tag.

**describe_events** (**kwargs**)

Returns events related to clusters, security groups, snapshots, and parameter groups for the past 14 days. Events specific to a particular cluster, security group, snapshot or parameter group can be obtained by providing the name as a parameter. By default, the past hour of events are returned.

**Request Syntax**
response = client.describe_events(
    SourceIdentifier='string',
    SourceType='cluster'|'cluster-parameter-group'|'cluster-security-group'|'cluster-snapshot',
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    Duration=123,
    MaxRecords=123,
    Marker='string'
)

Parameters

• **SourceIdentifier** *(string)* – The identifier of the event source for which events will be returned. If this parameter is not specified, then all sources are included in the response.

  Constraints:

  If **SourceIdentifier** is supplied, **SourceType** must also be provided.
  – Specify a cluster identifier when **SourceType** is *cluster*.
  – Specify a cluster security group name when **SourceType** is *cluster-security-group*.
  – Specify a cluster parameter group name when **SourceType** is *cluster-parameter-group*.
  – Specify a cluster snapshot identifier when **SourceType** is *cluster-snapshot*.

• **SourceType** *(string)* – The event source to retrieve events for. If no value is specified, all events are returned.

  Constraints:

  If **SourceType** is supplied, **SourceIdentifier** must also be provided.
  – Specify *cluster* when **SourceIdentifier** is a cluster identifier.
  – Specify *cluster-security-group* when **SourceIdentifier** is a cluster security group name.
  – Specify *cluster-parameter-group* when **SourceIdentifier** is a cluster parameter group name.
  – Specify *cluster-snapshot* when **SourceIdentifier** is a cluster snapshot identifier.

• **StartTime** *(datetime)* – The beginning of the time interval to retrieve events for, specified in ISO 8601 format. For more information about ISO 8601, go to the ISO8601 Wikipedia page.

  Example: 2009-07-08T18:00Z

• **EndTime** *(datetime)* – The end of the time interval for which to retrieve events, specified in ISO 8601 format. For more information about ISO 8601, go to the ISO8601 Wikipedia page.

  Example: 2009-07-08T18:00Z

• **Duration** *(integer)* – The number of minutes prior to the time of the request for which to retrieve events. For example, if the request is sent at 18:00 and you specify a duration of 60, then only events which have occurred after 17:00 will be returned.

  Default: 60

• **MaxRecords** *(integer)* – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified **MaxRecords** value, a value is returned in a *marker* field of the response. You
can retrieve the next set of records by retrying the command with the returned marker value.

Default: 100

Constraints: minimum 20, maximum 100.

• **Marker (string)** – An optional parameter that specifies the starting point to return a set of response records. When the results of a DescribeEvents request exceed the value specified in `MaxRecords`, AWS returns a value in the `Marker` field of the response. You can retrieve the next set of response records by providing the returned marker value in the `Marker` parameter and retrying the request.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{ 'Marker': 'string',
  'Events': [
    {
      'SourceIdentifier': 'string',
      'SourceType': 'cluster'|'cluster-parameter-group'|'cluster-security-group'
      'Message': 'string',
      'EventCategories': [
        'string',
      ],
      'Severity': 'string',
      'Date': datetime(2015, 1, 1),
      'EventId': 'string'
    },
  ]
}
```

**Response Structure**

- `(dict)` – Contains the output from the DescribeEvents action.
  
  - **Marker (string)** – A value that indicates the starting point for the next set of response records in a subsequent request. If a value is returned in a response, you can retrieve the next set of records by providing this returned marker value in the `Marker` parameter and retrying the command. If the `Marker` field is empty, all response records have been retrieved for the request.

  - **Events (list)** – A list of Event instances.
    
    - `(dict)` – Describes an event.
      
      - **SourceIdentifier (string)** – The identifier for the source of the event.
      
      - **SourceType (string)** – The source type for this event.
      
      - **Message (string)** – The text of this event.
- **EventCategories** *(list)* –
  A list of the event categories.
  Values: Configuration, Management, Monitoring, Security
- **Severity** *(string)* –
  The severity of the event.
  Values: ERROR, INFO
- **Date** *(datetime)* –
  The date and time of the event.
- **EventId** *(string)* –
  The identifier of the event.

**describe_hsm_client_certificates** (**kwargs**)
Returns information about the specified HSM client certificate. If no certificate ID is specified, returns information about all the HSM certificates owned by your AWS customer account.

If you specify both tag keys and tag values in the same request, Amazon Redshift returns all HSM client certificates that match any combination of the specified keys and values. For example, if you have `owner` and `environment` for tag keys, and `admin` and `test` for tag values, all HSM client certificates that have any combination of those values are returned.

If both tag keys and values are omitted from the request, HSM client certificates are returned regardless of whether they have tag keys or values associated with them.

**Request Syntax**

```python
response = client.describe_hsm_client_certificates(
    HsmClientCertificateIdentifier='string',
    MaxRecords=123,
    Marker='string',
    TagKeys=[
        'string',
    ],
    TagValues=[
        'string',
    ]
)
```

**Parameters**

- **HsmClientCertificateIdentifier** *(string)* – The identifier of a specific HSM client certificate for which you want information. If no identifier is specified, information is returned for all HSM client certificates owned by your AWS customer account.
- **MaxRecords** *(integer)* – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified `MaxRecords` value, a value is returned in a `marker` field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.
  Default: 100
  Constraints: minimum 20, maximum 100.
- **Marker** *(string)* – An optional parameter that specifies the starting point to return a set of response records. When the results of a `DescribeHsmClientCertificates` request exceed the value specified in `MaxRecords`, AWS returns a value
in the Marker field of the response. You can retrieve the next set of response records by providing the returned marker value in the Marker parameter and retrying the request.

- **TagKeys (list)** – A tag key or keys for which you want to return all matching HSM client certificates that are associated with the specified key or keys. For example, suppose that you have HSM client certificates that are tagged with keys called owner and environment. If you specify both of these tag keys in the request, Amazon Redshift returns a response with the HSM client certificates that have either or both of these tag keys associated with them.

  - (string)

- **TagValues (list)** – A tag value or values for which you want to return all matching HSM client certificates that are associated with the specified tag value or values. For example, suppose that you have HSM client certificates that are tagged with values called admin and test. If you specify both of these tag values in the request, Amazon Redshift returns a response with the HSM client certificates that have either or both of these tag values associated with them.

  - (string)

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Marker': 'string',
    'HsmClientCertificates': [
        {
            'HsmClientCertificateIdentifier': 'string',
            'HsmClientCertificatePublicKey': 'string',
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                }]
        }
    ]
}
```

**Response Structure**

- **(dict)** – 
  - **Marker (string)** – 
    
    A value that indicates the starting point for the next set of response records in a subsequent request. If a value is returned in a response, you can retrieve the next set of records by providing this returned marker value in the Marker parameter and retrying the command. If the Marker field is empty, all response records have been retrieved for the request.
  
  - **HsmClientCertificates (list)** – 
    
    A list of the identifiers for one or more HSM client certificates used by Amazon Redshift clusters to store and retrieve database encryption keys in an HSM.

    - **(dict)** – 
      
      Returns information about an HSM client certificate. The certificate is stored in a secure Hardware Storage Module (HSM), and used by the Amazon Redshift cluster to encrypt data files.
**HsmClientCertificateIdentifier** *(string)* – The identifier of the HSM client certificate.

**HsmClientCertificatePublicKey** *(string)* – The public key that the Amazon Redshift cluster will use to connect to the HSM. You must register the public key in the HSM.

**Tags** *(list)* – The list of tags for the HSM client certificate.

**Key** *(string)* – The key, or name, for the resource tag.

**Value** *(string)* – The value for the resource tag.

### `describe_hsm_configurations(**kwargs)`

Returns information about the specified Amazon Redshift HSM configuration. If no configuration ID is specified, returns information about all the HSM configurations owned by your AWS customer account.

If you specify both tag keys and tag values in the same request, Amazon Redshift returns all HSM connections that match any combination of the specified keys and values. For example, if you have `owner` and `environment` for tag keys, and `admin` and `test` for tag values, all HSM connections that have any combination of those values are returned.

If both tag keys and values are omitted from the request, HSM connections are returned regardless of whether they have tag keys or values associated with them.

#### Request Syntax

```python
response = client.describe_hsm_configurations(
    HsmConfigurationIdentifier='string',
    MaxRecords=123,
    Marker='string',
    TagKeys=[
        'string',
    ],
    TagValues=[
        'string',
    ]
)
```

#### Parameters

- **HsmConfigurationIdentifier** *(string)* – The identifier of a specific Amazon Redshift HSM configuration to be described. If no identifier is specified, information is returned for all HSM configurations owned by your AWS customer account.

- **MaxRecords** *(integer)* – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified `MaxRecords` value, a value is returned in a `marker` field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.

  Default: 100

  Constraints: minimum 20, maximum 100.
- **Marker (string)** – An optional parameter that specifies the starting point to return a set of response records. When the results of a DescribeHsmConfigurations request exceed the value specified in `MaxRecords`, AWS returns a value in the `Marker` field of the response. You can retrieve the next set of response records by providing the returned marker value in the `Marker` parameter and retrying the request.

- **TagKeys (list)** – A tag key or keys for which you want to return all matching HSM configurations that are associated with the specified key or keys. For example, suppose that you have HSM configurations that are tagged with keys called `owner` and `environment`. If you specify both of these tag keys in the request, Amazon Redshift returns a response with the HSM configurations that have either or both of these tag keys associated with them.

- **TagValues (list)** – A tag value or values for which you want to return all matching HSM configurations that are associated with the specified tag value or values. For example, suppose that you have HSM configurations that are tagged with values called `admin` and `test`. If you specify both of these tag values in the request, Amazon Redshift returns a response with the HSM configurations that have either or both of these tag values associated with them.

Return type: dict

Returns

Response Syntax

```python
{
    'Marker': 'string',
    'HsmConfigurations': [
        {
            'HsmConfigurationIdentifier': 'string',
            'Description': 'string',
            'HsmIpAddress': 'string',
            'HsmPartitionName': 'string',
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                }
            ]
        }
    ]
}
```

Response Structure

- **(dict)** –
  - **Marker (string)** –
    A value that indicates the starting point for the next set of response records in a subsequent request. If a value is returned in a response, you can retrieve the next set of records by providing this returned marker value in the `Marker` parameter and retrying the command. If the `Marker` field is empty, all response records have been retrieved for the request.

- **HsmConfigurations (list)** –
  A list of Amazon Redshift HSM configurations.
  ```
  # (dict)
  ```
Returns information about an HSM configuration, which is an object that describes to Amazon Redshift clusters the information they require to connect to an HSM where they can store database encryption keys.

- **HsmConfigurationIdentifier** *(string)* – The name of the Amazon Redshift HSM configuration.
- **Description** *(string)* – A text description of the HSM configuration.
- **HsmIpAddress** *(string)* – The IP address that the Amazon Redshift cluster must use to access the HSM.
- **HsmPartitionName** *(string)* – The name of the partition in the HSM where the Amazon Redshift clusters will store their database encryption keys.
- **Tags** *(list)* – The list of tags for the HSM configuration.
  - *(dict)* – A tag consisting of a name/value pair for a resource.
  - **Key** *(string)* – The key, or name, for the resource tag.
  - **Value** *(string)* – The value for the resource tag.

**describe_logging_status**(**kwargs**)  
Describes whether information, such as queries and connection attempts, is being logged for the specified Amazon Redshift cluster.

**Request Syntax**

```python
response = client.describe_logging_status(
    ClusterIdentifier='string'
)
```

**Parameters**  
**ClusterIdentifier** *(string)* – [REQUIRED]  
The identifier of the cluster to get the logging status from.

**Example:** examplecluster

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'LoggingEnabled': True|False,
    'BucketName': 'string',
    'S3KeyPrefix': 'string',
    'LastSuccessfulDeliveryTime': datetime(2015, 1, 1),
    'LastFailureTime': datetime(2015, 1, 1),
    'LastFailureMessage': 'string'
}
```

**Response Structure**

3.1. Services
• (dict) –
  Describes the status of logging for a cluster.
  - LoggingEnabled (boolean) –
    true if logging is on, false if logging is off.
  - BucketName (string) –
    The name of the S3 bucket where the log files are stored.
  - S3KeyPrefix (string) –
    The prefix applied to the log file names.
  - LastSuccessfulDeliveryTime (datetime) –
    The last time when logs were delivered.
  - LastFailureTime (datetime) –
    The last time when logs failed to be delivered.
  - LastFailureMessage (string) –
    The message indicating that logs failed to be delivered.

describe_orderable_cluster_options(**kwargs)
Returns a list of orderable cluster options. Before you create a new cluster you can use this operation to
find what options are available, such as the EC2 Availability Zones (AZ) in the specific AWS region that
you can specify, and the node types you can request. The node types differ by available storage, memory,
CPU and price. With the cost involved you might want to obtain a list of cluster options in the specific
region and specify values when creating a cluster. For more information about managing clusters, go to
Amazon Redshift Clusters in the Amazon Redshift Cluster Management Guide

Request Syntax

response = client.describe_orderable_cluster_options(
    ClusterVersion='string',
    NodeType='string',
    MaxRecords=123,
    Marker='string'
)

Parameters

• ClusterVersion (string) – The version filter value. Specify this parameter to show only the available offerings matching the specified version.
  Default: All versions.
  Constraints: Must be one of the version returned from DescribeClusterVersions.

• NodeType (string) – The node type filter value. Specify this parameter to show only the available offerings matching the specified node type.

• MaxRecords (integer) – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified MaxRecords value, a value is returned in a marker field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.
  Default: 100
  Constraints: minimum 20, maximum 100.

• Marker (string) – An optional parameter that specifies the starting point to return a set of response records. When the results of a DescribeOrderableClusterOptions request exceed the value specified in MaxRecords, AWS returns a
value in the Marker field of the response. You can retrieve the next set of response records by providing the returned marker value in the Marker parameter and retrying the request.

**Return type**  dict

**Returns**

**Response Syntax**

```json
{
    'OrderableClusterOptions': [
        {
            'ClusterVersion': 'string',
            'ClusterType': 'string',
            'NodeType': 'string',
            'AvailabilityZones': [
                {
                    'Name': 'string'
                },
            ],
        },
    ],
    'Marker': 'string'
}
```

**Response Structure**

- `(dict)` — Contains the output from the DescribeOrderableClusterOptions action.
  - `OrderableClusterOptions (list)` —
    - An OrderableClusterOption structure containing information about orderable options for the Cluster.
      - `(dict)` —
        - Describes an orderable cluster option.
          - `ClusterVersion (string)` —
            - The version of the orderable cluster.
          - `ClusterType (string)` —
            - The cluster type, for example multi-node.
          - `NodeType (string)` —
            - The node type for the orderable cluster.
          - `AvailabilityZones (list)` —
            - A list of availability zones for the orderable cluster.
              - `(dict)` —
                - Describes an availability zone.
                  - `Name (string)` —
                    - The name of the availability zone.
          - `Marker (string)` —
            - A value that indicates the starting point for the next set of response records in a subsequent request. If a value is returned in response, you can retrieve the next set of records by providing this returned marker value in the Marker parameter and retrying the command. If the Marker field is empty, all response records have been retrieved for the request.
describe_reserved_node_offerings(**kwargs)

Returns a list of the available reserved node offerings by Amazon Redshift with their descriptions including the node type, the fixed and recurring costs of reserving the node and duration the node will be reserved for you. These descriptions help you determine which reserve node offering you want to purchase. You then use the unique offering ID in you call to PurchaseReservedNodeOffering to reserve one or more nodes for your Amazon Redshift cluster.

For more information about reserved node offerings, go to Purchasing Reserved Nodes in the Amazon Redshift Cluster Management Guide.

Request Syntax

response = client.describe_reserved_node_offerings(
    ReservedNodeOfferingId='string',
    MaxRecords=123,
    Marker='string'
)

Parameters

- **ReservedNodeOfferingId** (string) – The unique identifier for the offering.
- **MaxRecords** (integer) – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified MaxRecords value, a value is returned in a marker field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.
  
  Default: 100

  Constraints: minimum 20, maximum 100.
- **Marker** (string) – An optional parameter that specifies the starting point to return a set of response records. When the results of a DescribeReservedNodeOfferings request exceed the value specified in MaxRecords, AWS returns a value in the Marker field of the response. You can retrieve the next set of response records by providing the returned marker value in the Marker parameter and retrying the request.

Return type  dict

Returns

Response Syntax

```
{
    'Marker': 'string',
    'ReservedNodeOfferings': [
        {
            'ReservedNodeOfferingId': 'string',
            'NodeType': 'string',
            'Duration': 123,
            'FixedPrice': 123.0,
            'UsagePrice': 123.0,
            'CurrencyCode': 'string',
            'OfferingType': 'string',
            'RecurringCharges': [
                {
                    'RecurringChargeAmount': 123.0,
                    'RecurringChargeFrequency': 'string'
                },
            ],
        },
    ],
}
```
Response Structure

- **(dict)** –

Contains the output from the DescribeReservedNodeOfferings action.

- **Marker (string)** –

A value that indicates the starting point for the next set of response records in a subsequent request. If a value is returned in a response, you can retrieve the next set of records by providing this returned marker value in the `Marker` parameter and retrying the command. If the `Marker` field is empty, all response records have been retrieved for the request.

- **ReservedNodeOfferings (list)** –

A list of reserved node offerings.

- **(dict)** –

Describes a reserved node offering.

  - **ReservedNodeOfferingId (string)** –

    The offering identifier.

  - **NodeType (string)** –

    The node type offered by the reserved node offering.

  - **Duration (integer)** –

    The duration, in seconds, for which the offering will reserve the node.

  - **FixedPrice (float)** –

    The upfront fixed charge you will pay to purchase the specific reserved node offering.

  - **UsagePrice (float)** –

    The rate you are charged for each hour the cluster that is using the offering is running.

  - **CurrencyCode (string)** –

    The currency code for the compute nodes offering.

  - **OfferingType (string)** –

    The anticipated utilization of the reserved node, as defined in the reserved node offering.

- **RecurringCharges (list)** –

The charge to your account regardless of whether you are creating any clusters using the node offering. Recurring charges are only in effect for heavy-utilization reserved nodes.

- **(dict)** –

Describes a recurring charge.

  - **RecurringChargeAmount (float)** –

    The amount charged per the period of time specified by the recurring charge frequency.

  - **RecurringChargeFrequency (string)** –

    The frequency at which the recurring charge amount is applied.
describe_reserved_nodes(**kwargs)

Returns the descriptions of the reserved nodes.

Request Syntax

```python
response = client.describe_reserved_nodes(
    ReservedNodeId='string',
    MaxRecords=123,
    Marker='string'
)
```

Parameters

- **ReservedNodeId (string)** – Identifier for the node reservation.
- **MaxRecords (integer)** – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified MaxRecords value, a value is returned in a marker field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.
  
  Default: 100
  
  Constraints: minimum 20, maximum 100.
- **Marker (string)** – An optional parameter that specifies the starting point to return a set of response records. When the results of a DescribeReservedNodes request exceed the value specified in MaxRecords, AWS returns a value in the Marker field of the response. You can retrieve the next set of response records by providing the returned marker value in the Marker parameter and retrying the request.

Return type: dict

Response Syntax

```python
{
    'Marker': 'string',
    'ReservedNodes': [
        {
            'ReservedNodeId': 'string',
            'ReservedNodeOfferingId': 'string',
            'NodeType': 'string',
            'StartTime': datetime(2015, 1, 1),
            'Duration': 123,
            'FixedPrice': 123.0,
            'UsagePrice': 123.0,
            'CurrencyCode': 'string',
            'NodeCount': 123,
            'State': 'string',
            'OfferingType': 'string',
            'RecurringCharges': [
                {
                    'RecurringChargeAmount': 123.0,
                    'RecurringChargeFrequency': 'string'
                }
            ]
        }
    ]
}
```
Response Structure

- *(dict)* –
  Contains the output from the DescribeReservedNodes action.

  - **Marker** *(string)* –
    A value that indicates the starting point for the next set of response records in a subsequent request. If a value is returned in a response, you can retrieve the next set of records by providing this returned marker value in the `Marker` parameter and retrying the command. If the `Marker` field is empty, all response records have been retrieved for the request.

  - **ReservedNodes** *(list)* –
    The list of reserved nodes.
    *
    *(dict)* –
    Describes a reserved node. You can call the DescribeReservedNodeOfferings API to obtain the available reserved node offerings.
    
    - **ReservedNodeOfferingId** *(string)* –
      The unique identifier for the reservation.
    
    - **ReservedNodeOfferingId** *(string)* –
      The identifier for the reserved node offering.
    
    - **NodeType** *(string)* –
      The node type of the reserved node.
    
    - **StartTime** *(datetime)* –
      The time the reservation started. You purchase a reserved node offering for a duration. This is the start time of that duration.
    
    - **Duration** *(integer)* –
      The duration of the node reservation in seconds.
    
    - **FixedPrice** *(float)* –
      The fixed cost Amazon Redshift charges you for this reserved node.
    
    - **UsagePrice** *(float)* –
      The hourly rate Amazon Redshift charges you for this reserved node.
    
    - **CurrencyCode** *(string)* –
      The currency code for the reserved cluster.
    
    - **NodeCount** *(integer)* –
      The number of reserved compute nodes.
    
    - **State** *(string)* –
      The state of the reserved compute node.

    Possible Values:
    - pending-payment-This reserved node has recently been purchased, and the sale has been approved, but payment has not yet been confirmed.
    - active-This reserved node is owned by the caller and is available for use.
    - payment-failed-Payment failed for the purchase attempt.
- **OfferingType** *(string)* –
  The anticipated utilization of the reserved node, as defined in the reserved node offering.

- **RecurringCharges** *(list)* –
  The recurring charges for the reserved node.
  - *(dict)* –
    Describes a recurring charge.

- **RecurringChargeAmount** *(float)* –
  The amount charged per the period of time specified by the recurring charge frequency.

- **RecurringChargeFrequency** *(string)* –
  The frequency at which the recurring charge amount is applied.

```python
describe_resize(**kwargs)
```

Returns information about the last resize operation for the specified cluster. If no resize operation has ever been initiated for the specified cluster, a HTTP 404 error is returned. If a resize operation was initiated and completed, the status of the resize remains as **SUCCEEDED** until the next resize.

A resize operation can be requested using ModifyCluster and specifying a different number or type of nodes for the cluster.

**Request Syntax**

```python
response = client.describe_resize(
    ClusterIdentifier='string'
)
```

**Parameters**  
**ClusterIdentifier** *(string)* – [REQUIRED]
  The unique identifier of a cluster whose resize progress you are requesting. This parameter is case-sensitive.

By default, resize operations for all clusters defined for an AWS account are returned.

**Return type**  
**dict**

**Response Syntax**

```python
{
    'TargetNodeType': 'string',
    'TargetNumberOfNodes': 123,
    'TargetClusterType': 'string',
    'Status': 'string',
    'ImportTablesCompleted': [  
        'string',
    ],
    'ImportTablesInProgress': [  
        'string',
    ],
    'ImportTablesNotStarted': [  
        'string',
    ],
    'AvgResizeRateInMegaBytesPerSecond': 123.0,
    'TotalResizeDataInMegaBytes': 123,
    'ProgressInMegaBytes': 123,
}
```
Response Structure

- *(dict)* –

Describes the result of a cluster resize operation.

- **TargetNodeType** *(string)* –
  The node type that the cluster will have after the resize operation is complete.

- **TargetNumberOfNodes** *(integer)* –
  The number of nodes that the cluster will have after the resize operation is complete.

- **TargetClusterType** *(string)* –
  The cluster type after the resize operation is complete.
  Valid Values: *multi-node|single-node*

- **Status** *(string)* –
  The status of the resize operation.
  Valid Values: *NONE|IN_PROGRESS|FAILED|SUCCEEDED*

- **ImportTablesCompleted** *(list)* –
  The names of tables that have been completely imported.
  Valid Values: List of table names.
  *

- **ImportTablesInProgress** *(list)* –
  The names of tables that are being currently imported.
  Valid Values: List of table names.
  *

- **ImportTablesNotStarted** *(list)* –
  The names of tables that have not been yet imported.
  Valid Values: List of table names.
  *

- **AvgResizeRateInMegaBytesPerSecond** *(float)* –
  The average rate of the resize operation over the last few minutes, measured in megabytes per second. After the resize operation completes, this value shows the average rate of the entire resize operation.

- **TotalResizeDataInMegaBytes** *(integer)* –
  The estimated total amount of data, in megabytes, on the cluster before the resize operation began.

- **ProgressInMegaBytes** *(integer)* –
  While the resize operation is in progress, this value shows the current amount of data, in megabytes, that has been processed so far. When the resize operation is complete, this value shows the total amount of data, in megabytes, on the cluster, which may be more or less than TotalResizeDataInMegaBytes (the estimated total amount of data before resize).
– **ElapsedTimeInSeconds** (*integer*) –

The amount of seconds that have elapsed since the resize operation began. After the resize operation completes, this value shows the total actual time, in seconds, for the resize operation.

– **EstimatedTimeToCompletionInSeconds** (*integer*) –

The estimated time remaining, in seconds, until the resize operation is complete. This value is calculated based on the average resize rate and the estimated amount of data remaining to be processed. Once the resize operation is complete, this value will be 0.

describe_snapshot_copy_grants(**kwargs)**

Returns a list of snapshot copy grants owned by the AWS account in the destination region.

For more information about managing snapshot copy grants, go to Amazon Redshift Database Encryption in the *Amazon Redshift Cluster Management Guide*.

**Request Syntax**

```python
response = client.describe_snapshot_copy_grants(
    SnapshotCopyGrantName='string',
    MaxRecords=123,
    Marker='string',
    TagKeys=[
        'string',
    ],
    TagValues=[
        'string',
    ]
)
```

**Parameters**

- **SnapshotCopyGrantName** (*string*) – The name of the snapshot copy grant.
- **MaxRecords** (*integer*) – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified **MaxRecords** value, a value is returned in a **Marker** field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.

  Default: 100

  Constraints: minimum 20, maximum 100.
- **Marker** (*string*) – An optional parameter that specifies the starting point to return a set of response records. When the results of a **DescribeSnapshotCopyGrant** request exceed the value specified in **MaxRecords**, AWS returns a value in the **Marker** field of the response. You can retrieve the next set of response records by providing the returned marker value in the **Marker** parameter and retrying the request.

  Constraints: You can specify either the **SnapshotCopyGrantName** parameter or the **Marker** parameter, but not both.
- **TagKeys** (*list*) – A tag key or keys for which you want to return all matching resources that are associated with the specified key or keys. For example, suppose that you have resources tagged with keys called **owner** and **environment**. If you specify both of these tag keys in the request, Amazon Redshift returns a response with all resources that have either or both of these tag keys associated with them.
  - **(string)** –
• **TagValues** (*list*) – A tag value or values for which you want to return all matching resources that are associated with the specified value or values. For example, suppose that you have resources tagged with values called `admin` and `test`. If you specify both of these tag values in the request, Amazon Redshift returns a response with all resources that have either or both of these tag values associated with them.

  - (string) –

**Return type**  
dict

**Returns**

**Response Syntax**

```json
{
    'Marker': 'string',
    'SnapshotCopyGrants': [
        {
            'SnapshotCopyGrantName': 'string',
            'KmsKeyId': 'string',
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                }
            ],
            'KmsKeyId': 'string'
        }
    ]
}
```

**Response Structure**

- (dict) –

  The result of the snapshot copy grant.

  - **Marker** (*string*) –

    An optional parameter that specifies the starting point to return a set of response records. When the results of a `DescribeSnapshotCopyGrant` request exceed the value specified in `MaxRecords`, AWS returns a value in the `Marker` field of the response. You can retrieve the next set of response records by providing the returned marker value in the `Marker` parameter and retrying the request.

    Constraints: You can specify either the `SnapshotCopyGrantName` parameter or the `Marker` parameter, but not both.

  - **SnapshotCopyGrants** (*list*) –

    The list of snapshot copy grants.

    - (dict) –

      The snapshot copy grant that grants Amazon Redshift permission to encrypt copied snapshots with the specified customer master key (CMK) from AWS KMS in the destination region.

      For more information about managing snapshot copy grants, go to [Amazon Redshift Database Encryption](https://docs.aws.amazon.com/redshift/latest/gsg-rse.html) in the *Amazon Redshift Cluster Management Guide*.

      - **SnapshotCopyGrantName** (*string*) –

        The name of the snapshot copy grant.
describe_tags(**kwargs)

Returns a list of tags. You can return tags from a specific resource by specifying an ARN, or you can return all tags for a given type of resource, such as clusters, snapshots, and so on.

The following are limitations for DescribeTags:

- You cannot specify an ARN and a resource-type value together in the same request.
- You cannot use the MaxRecords and Marker parameters together with the ARN parameter.
- The MaxRecords parameter can be a range from 10 to 50 results to return in a request.

If you specify both tag keys and tag values in the same request, Amazon Redshift returns all resources that match any combination of the specified keys and values. For example, if you have owner and environment for tag keys, and admin and test for tag values, all resources that have any combination of those values are returned.

If both tag keys and values are omitted from the request, resources are returned regardless of whether they have tag keys or values associated with them.

Request Syntax

```python
response = client.describe_tags(
    ResourceName='string',
    ResourceType='string',
    MaxRecords=123,
    Marker='string',
    TagKeys=[
        'string',
    ],
    TagValues=[
        'string',
    ]
)
```

Parameters

- **ResourceName** *(string)* – The Amazon Resource Name (ARN) for which you want to describe the tag or tags. For example, arn:aws:redshift:us-east-1:123456789:cluster:t1.
- **ResourceType** *(string)* – The type of resource with which you want to view tags. Valid resource types are:
  - Cluster
  - CIDR/IP
  - EC2 security group
  - Snapshot
  - Cluster security group
For more information about Amazon Redshift resource types and constructing ARNs, go to Constructing an Amazon Redshift Amazon Resource Name (ARN) in the Amazon Redshift Cluster Management Guide.

- **MaxRecords (integer)** – The maximum number or response records to return in each call. If the number of remaining response records exceeds the specified MaxRecords value, a value is returned in a marker field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.

- **Marker (string)** – A value that indicates the starting point for the next set of response records in a subsequent request. If a value is returned in a response, you can retrieve the next set of records by providing this returned marker value in the marker parameter and retrying the command. If the marker field is empty, all response records have been retrieved for the request.

- **TagKeys (list)** – A tag key or keys for which you want to return all matching resources that are associated with the specified key or keys. For example, suppose that you have resources tagged with keys called owner and environment. If you specify both of these tag keys in the request, Amazon Redshift returns a response with all resources that have either or both of these tag keys associated with them.

- **TagValues (list)** – A tag value or values for which you want to return all matching resources that are associated with the specified value or values. For example, suppose that you have resources tagged with values called admin and test. If you specify both of these tag values in the request, Amazon Redshift returns a response with all resources that have either or both of these tag values associated with them.

Return type  dict

Returns

Response Syntax

```
{
    'TaggedResources': [
        {
            'Tag': {
                'Key': 'string',
                'Value': 'string'
            },
            'ResourceName': 'string',
            'ResourceType': 'string'
        },
        {
            'Marker': 'string'
        }
    ]
}
```

Response Structure

- **(dict)** –

  Contains the output from the DescribeTags action.

- **TaggedResources (list)** –
A list of tags with their associated resources.
  * (dict) –
    A tag and its associated resource.
      · Tag (dict) –
        The tag for the resource.
          · Key (string) –
            The key, or name, for the resource tag.
          · Value (string) –
            The value for the resource tag.
      · ResourceName (string) –
        The Amazon Resource Name (ARN) with which the tag is associated. For example, arn:aws:redshift:us-east-1:123456789:cluster:t1.
      · ResourceType (string) –
        The type of resource with which the tag is associated. Valid resource types are:
          · Cluster
          · CIDR/IP
          · EC2 security group
          · Snapshot
          · Cluster security group
          · Subnet group
          · HSM connection
          · HSM certificate
          · Parameter group
        For more information about Amazon Redshift resource types and constructing ARNs, go to Constructing an Amazon Redshift Amazon Resource Name (ARN) in the Amazon Redshift Cluster Management Guide.
  · Marker (string) –
    A value that indicates the starting point for the next set of response records in a subsequent request. If a value is returned in a response, you can retrieve the next set of records by providing this returned marker value in the Marker parameter and retrying the command. If the Marker field is empty, all response records have been retrieved for the request.

disable_logging(**kwargs)
Stops logging information, such as queries and connection attempts, for the specified Amazon Redshift cluster.

Request Syntax

```
response = client.disable_logging(
    ClusterIdentifier='string'
)
```

Parameters  
ClusterIdentifier (string) – [REQUIRED]
  The identifier of the cluster on which logging is to be stopped.

Example: examplecluster

Return type  dict
Returns

Response Syntax

```python
{
    'LoggingEnabled': True|False,
    'BucketName': 'string',
    'S3KeyPrefix': 'string',
    'LastSuccessfulDeliveryTime': datetime(2015, 1, 1),
    'LastFailureTime': datetime(2015, 1, 1),
    'LastFailureMessage': 'string'
}
```

Response Structure

- **(dict)** – Describes the status of logging for a cluster.
  - **LoggingEnabled** *(boolean)* – 
    true if logging is on, false if logging is off.
  - **BucketName** *(string)* – The name of the S3 bucket where the log files are stored.
  - **S3KeyPrefix** *(string)* – The prefix applied to the log file names.
  - **LastSuccessfulDeliveryTime** *(datetime)* – The last time when logs were delivered.
  - **LastFailureTime** *(datetime)* – The last time when logs failed to be delivered.
  - **LastFailureMessage** *(string)* – The message indicating that logs failed to be delivered.

`disable_snapshot_copy(**kwargs)`
Disables the automatic copying of snapshots from one region to another region for a specified cluster.

If your cluster and its snapshots are encrypted using a customer master key (CMK) from AWS KMS, use DeleteSnapshotCopyGrant to delete the grant that grants Amazon Redshift permission to the CMK in the destination region.

Request Syntax

```python
response = client.disable_snapshot_copy(
    ClusterIdentifier='string'
)
```

**Parameters** `ClusterIdentifier (string) – [REQUIRED]`

- The unique identifier of the source cluster that you want to disable copying of snapshots to a destination region.

  Constraints: Must be the valid name of an existing cluster that has cross-region snapshot copy enabled.

**Return type** `dict`

**Returns**

Boto3 Documentation, Release 1.1.4

Response Structure

- **(dict)** –
  
  Describes a cluster.

  - **Cluster (dict)** –
    
    Describes a cluster.

    - **ClusterIdentifier (string)** –
      
      The unique identifier of the cluster.

    - **NodeType (string)** –
      
      The node type for the nodes in the cluster.

    - **ClusterStatus (string)** –
      
      The current state of this cluster. Possible values include available, creating, deleting, rebooting, renaming, and resizing.

    - **ModifyStatus (string)** –

---

3.1. Services 3697
The status of a modify operation, if any, initiated for the cluster.

* MasterUsername (string) –

The master user name for the cluster. This name is used to connect to the database that is specified in DBName.

* DBName (string) –

The name of the initial database that was created when the cluster was created. This same name is returned for the life of the cluster. If an initial database was not specified, a database named “dev” was created by default.

* Endpoint (dict) –

The connection endpoint.

  · Address (string) –
    
    The DNS address of the Cluster.
  
  · Port (integer) –
    
    The port that the database engine is listening on.

* ClusterCreateTime (datetime) –

The date and time that the cluster was created.

* AutomatedSnapshotRetentionPeriod (integer) –

The number of days that automatic cluster snapshots are retained.

* ClusterSecurityGroups (list) –

A list of cluster security group that are associated with the cluster. Each security group is represented by an element that contains ClusterSecurityGroup.Name and ClusterSecurityGroup.Status subelements.

Cluster security groups are used when the cluster is not created in a VPC. Clusters that are created in a VPC use VPC security groups, which are listed by the VpcSecurityGroups parameter.

  · (dict) –
    
    Describes a security group.
  
  · ClusterSecurityGroupName (string) –
    
    The name of the cluster security group.
  
  · Status (string) –
    
    The status of the cluster security group.

* VpcSecurityGroups (list) –

A list of Virtual Private Cloud (VPC) security groups that are associated with the cluster. This parameter is returned only if the cluster is in a VPC.

  · (dict) –
    
    Describes the members of a VPC security group.
  
  · VpcSecurityGroupId (string) –
    
    · Status (string) –
      
      The status of the VPC security group.

* ClusterParameterGroups (list) –

The list of cluster parameter groups that are associated with this cluster. Each parameter group in the list is returned with its status.

  · (dict) –
    
    Describes the status of a parameter group.
· **ParameterGroupName** *(string)* –
  
The name of the cluster parameter group.

· **ParameterApplyStatus** *(string)* –
  
The status of parameter updates.

· **ClusterParameterStatusList** *(list)* –
  
The list of parameter statuses.

For more information about parameters and parameter groups, go to Amazon Redshift Parameter Groups in the Amazon Redshift Cluster Management Guide.

· *(dict)* –
  
  Describes the status of a parameter group.

· **ParameterName** *(string)* –
  
The name of the parameter.

· **ParameterApplyStatus** *(string)* –
  
The status of the parameter that indicates whether the parameter is in sync with the database, waiting for a cluster reboot, or encountered an error when being applied.

The following are possible statuses and descriptions.

· **in-sync**: The parameter value is in sync with the database.
· **pending-reboot**: The parameter value will be applied after the cluster reboots.
· **applying**: The parameter value is being applied to the database.
· **invalid-parameter**: Cannot apply the parameter value because it has an invalid value or syntax.
· **apply-deferred**: The parameter contains static property changes. The changes are deferred until the cluster reboots.
· **apply-error**: Cannot connect to the cluster. The parameter change will be applied after the cluster reboots.
· **unknown-error**: Cannot apply the parameter change right now. The change will be applied after the cluster reboots.

· **ParameterApplyErrorDescription** *(string)* –
  
The error that prevented the parameter from being applied to the database.

· **ClusterSubnetGroupName** *(string)* –
  
The name of the subnet group that is associated with the cluster. This parameter is valid only when the cluster is in a VPC.

· **VpcId** *(string)* –
  
The identifier of the VPC the cluster is in, if the cluster is in a VPC.

· **AvailabilityZone** *(string)* –
  
The name of the Availability Zone in which the cluster is located.

· **PreferredMaintenanceWindow** *(string)* –
  
The weekly time range (in UTC) during which system maintenance can occur.

· **PendingModifiedValues** *(dict)* –
If present, changes to the cluster are pending. Specific pending changes are identified by subelements.

- **MasterUserPassword (string)** –
  The pending or in-progress change of the master user password for the cluster.

- **NodeType (string)** –
  The pending or in-progress change of the cluster’s node type.

- **NumberOfNodes (integer)** –
  The pending or in-progress change of the number of nodes in the cluster.

- **ClusterType (string)** –
  The pending or in-progress change of the cluster type.

- **ClusterVersion (string)** –
  The version ID of the Amazon Redshift engine that is running on the cluster.

- **AllowVersionUpgrade (boolean)** –
  If true, major version upgrades will be applied automatically to the cluster during the maintenance window.

- **NumberOfNodes (integer)** –
  The number of compute nodes in the cluster.

- **PubliclyAccessible (boolean)** –
  If true, the cluster can be accessed from a public network.

- **Encrypted (boolean)** –
  If true, data in the cluster is encrypted at rest.

- **RestoreStatus (dict)** –
  Describes the status of a cluster restore action. Returns null if the cluster was not created by restoring a snapshot.
   
   - **Status (string)** –
     The status of the restore action. Returns starting, restoring, completed, or failed.

   - **CurrentRestoreRateInMegaBytesPerSecond (float)** –
     The number of megabytes per second being transferred from the backup storage. Returns the average rate for a completed backup.

   - **SnapshotSizeInMegaBytes (integer)** –
     The size of the set of snapshot data used to restore the cluster.

   - **ProgressInMegaBytes (integer)** –
The number of megabytes that have been transferred from snapshot storage.

- **ElapsedTimeInSeconds (integer)** –
  
The amount of time an in-progress restore has been running, or the amount of time it took a completed restore to finish.

- **EstimatedTimeToCompletionInSeconds (integer)** –
  
The estimate of the time remaining before the restore will complete. Returns 0 for a completed restore.

* **HsmStatus (dict)** –
  
Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.

Values: active, applying

- **HsmClientCertificateIdentifier (string)** –
  
Specifies the name of the HSM client certificate the Amazon Redshift cluster uses to retrieve the data encryption keys stored in an HSM.

- **HsmConfigurationIdentifier (string)** –
  
Specifies the name of the HSM configuration that contains the information the Amazon Redshift cluster can use to retrieve and store keys in an HSM.

- **Status (string)** –
  
Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.

Values: active, applying

* **ClusterSnapshotCopyStatus (dict)** –
  
Returns the destination region and retention period that are configured for cross-region snapshot copy.

- **DestinationRegion (string)** –
  
The destination region that snapshots are automatically copied to when cross-region snapshot copy is enabled.

- **RetentionPeriod (integer)** –
  
The number of days that automated snapshots are retained in the destination region after they are copied from a source region.

- **SnapshotCopyGrantName (string)** –
  
The name of the snapshot copy grant.

* **ClusterPublicKey (string)** –
  
The public key for the cluster.

* **ClusterNodes (list)** –
  
The nodes in a cluster.

- **(dict)** –
  
The identifier of a node in a cluster.

- **NodeRole (string)** –
  
Whether the node is a leader node or a compute node.
- **PrivateIPAddress** *(string)* –
The private IP address of a node within a cluster.

- **PublicIPAddress** *(string)* –
The public IP address of a node within a cluster.

* **ElasticIpStatus** *(dict)* –
Describes the status of the elastic IP (EIP) address.

  - **ElasticIp** *(string)* –
The elastic IP (EIP) address for the cluster.
  
  - **Status** *(string)* –
  Describes the status of the elastic IP (EIP) address.

* **ClusterRevisionNumber** *(string)* –
The specific revision number of the database in the cluster.

* **Tags** *(list)* –
The list of tags for the cluster.

  - *(dict)* –
    A tag consisting of a name/value pair for a resource.

    - **Key** *(string)* –
      The key, or name, for the resource tag.

    - **Value** *(string)* –
      The value for the resource tag.

* **KmsKeyId** *(string)* –
The AWS Key Management Service (KMS) key ID of the encryption key used to encrypt data in the cluster.

**enable_logging(**kwargs**)

Starts logging information, such as queries and connection attempts, for the specified Amazon Redshift cluster.

**Request Syntax**

```python
response = client.enable_logging(
    ClusterIdentifier='string',
    BucketName='string',
    S3KeyPrefix='string'
)
```

**Parameters**

- **ClusterIdentifier** *(string)* – [REQUIRED]
The identifier of the cluster on which logging is to be started.

  Example: examplecluster

- **BucketName** *(string)* – [REQUIRED]
The name of an existing S3 bucket where the log files are to be stored.

  Constraints:
  
  - Must be in the same region as the cluster
  
  - The cluster must have read bucket and put object permissions

- **S3KeyPrefix** *(string)* – The prefix applied to the log file names.

  Constraints:
– Cannot exceed 512 characters
– Cannot contain spaces(), double quotes ("), single quotes (‘), a backslash (\), or control characters. The hexadecimal codes for invalid characters are:
  * x00 to x20
  – x22
  – x27
  – x5c
  – x7f or larger

Return type  dict
Returns

Response Syntax

```
{
    'LoggingEnabled': True|False,
    'BucketName': 'string',
    'S3KeyPrefix': 'string',
    'LastSuccessfulDeliveryTime': datetime(2015, 1, 1),
    'LastFailureTime': datetime(2015, 1, 1),
    'LastFailureMessage': 'string'
}
```

Response Structure

• (dict) –
  Describes the status of logging for a cluster.
  – LoggingEnabled (boolean) –
    true if logging is on, false if logging is off.
  – BucketName (string) –
    The name of the S3 bucket where the log files are stored.
  – S3KeyPrefix (string) –
    The prefix applied to the log file names.
  – LastSuccessfulDeliveryTime (datetime) –
    The last time when logs were delivered.
  – LastFailureTime (datetime) –
    The last time when logs failed to be delivered.
  – LastFailureMessage (string) –
    The message indicating that logs failed to be delivered.

**enable_snapshot_copy(****kwargs**)**

Enables the automatic copy of snapshots from one region to another region for a specified cluster.

Request Syntax

```
response = client.enable_snapshot_copy(
    ClusterIdentifier='string',
    DestinationRegion='string',
    RetentionPeriod=123,
    SnapshotCopyGrantName='string'
)
```

Parameters

• ClusterIdentifier (string) – [REQUIRED]

    The unique identifier of the source cluster to copy snapshots from.
Constraints: Must be the valid name of an existing cluster that does not already have cross-region snapshot copy enabled.

- **DestinationRegion** *(string)* – [REQUIRED]

  The destination region that you want to copy snapshots to.

  Constraints: Must be the name of a valid region. For more information, see Regions and Endpoints in the Amazon Web Services General Reference.

- **RetentionPeriod** *(integer)* – The number of days to retain automated snapshots in the destination region after they are copied from the source region.

  Default: 7.

  Constraints: Must be at least 1 and no more than 35.

- **SnapshotCopyGrantName** *(string)* – The name of the snapshot copy grant to use when snapshots of an AWS KMS-encrypted cluster are copied to the destination region.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Cluster': {
        'ClusterIdentifier': 'string',
        'NodeType': 'string',
        'ClusterStatus': 'string',

Response Structure

- **(dict)** –
  
  Describes a cluster.
  
  - **Cluster (dict)** –
    
    Describes a cluster.
    
    - **ClusterIdentifier (string)** –
      
      The unique identifier of the cluster.
    
    - **NodeType (string)** –
      
      The node type for the nodes in the cluster.
    
    - **ClusterStatus (string)** –
      
      The current state of this cluster. Possible values include `available`, `creating`, `deleting`, `rebooting`, `renaming`, and `resizing`.
    
    - **ModifyStatus (string)** –
      
      The status of a modify operation, if any, initiated for the cluster.
    
    - **MasterUsername (string)** –
      
      The master user name for the cluster. This name is used to connect to the database that is specified in `DBName`.
    
    - **DBName (string)** –
      
      The name of the initial database that was created when the cluster was created. This same name is returned for the life of the cluster. If an initial database was not specified, a database named “dev” was created by default.
    
    - **Endpoint (dict)** –
      
      The connection endpoint.
      
      - **Address (string)** –
        
        The DNS address of the Cluster.
      
      - **Port (integer)** –
        
        The port that the database engine is listening on.
    
    - **ClusterCreateTime (datetime)** –
      
      The date and time that the cluster was created.
    
    - **AutomatedSnapshotRetentionPeriod (integer)** –
      
      The number of days that automatic cluster snapshots are retained.
    
    - **ClusterSecurityGroups (list)** –
      
      A list of cluster security group that are associated with the cluster. Each security group is represented by an element that contains `ClusterSecurityGroup.Name` and `ClusterSecurityGroup.Status` subelements.
      
      Cluster security groups are used when the cluster is not created in a VPC. Clusters that are created in a VPC use VPC security groups, which are listed by the `VpcSecurityGroups` parameter.
      
      - **VpcSecurityGroups (list)** –
        
        Describes a security group.
· **ClusterSecurityGroupName** *(string)* –
  The name of the cluster security group.

· **Status** *(string)* –
  The status of the cluster security group.

* **VpcSecurityGroups** *(list)* –
A list of Virtual Private Cloud (VPC) security groups that are associated with the cluster. This parameter is returned only if the cluster is in a VPC.
  · *(dict)* –
    Describes the members of a VPC security group.

· **VpcSecurityGroupId** *(string)* –

· **Status** *(string)* –

* **ClusterParameterGroups** *(list)* –
The list of cluster parameter groups that are associated with this cluster. Each parameter group in the list is returned with its status.
  · *(dict)* –
    Describes the status of a parameter group.

· **ParameterGroupName** *(string)* –
  The name of the cluster parameter group.

· **ParameterApplyStatus** *(string)* –
  The status of parameter updates.

· **ClusterParameterStatusList** *(list)* –
The list of parameter statuses.

For more information about parameters and parameter groups, go to [Amazon Redshift Parameter Groups](https://docs.aws.amazon.com/redshift/latest/guides/parameter-groups.html) in the Amazon Redshift Cluster Management Guide.

· *(dict)* –
  Describes the status of a parameter group.

· **ParameterName** *(string)* –
  The name of the parameter.

· **ParameterApplyStatus** *(string)* –
  The status of the parameter that indicates whether the parameter is in sync with the database, waiting for a cluster reboot, or encountered an error when being applied.

The following are possible statuses and descriptions.

- **in-sync**: The parameter value is in sync with the database.
- **pending-reboot**: The parameter value will be applied after the cluster reboots.
- **applying**: The parameter value is being applied to the database.
- **invalid-parameter**: Cannot apply the parameter value because it has an invalid value or syntax.
- **apply-deferred**: The parameter contains static property changes. The changes are deferred until the cluster reboots.
- **apply-error**: Cannot connect to the cluster. The parameter change will be applied after the cluster reboots.
· **unknown-error**: Cannot apply the parameter change right now. The change will be applied after the cluster reboots.
  
  · **ParameterApplyErrorDescription** *(string)* –

  The error that prevented the parameter from being applied to the database.

  · **ClusterSubnetGroupName** *(string)* –

  The name of the subnet group that is associated with the cluster. This parameter is valid only when the cluster is in a VPC.

  · **VpcId** *(string)* –

  The identifier of the VPC the cluster is in, if the cluster is in a VPC.

  · **AvailabilityZone** *(string)* –

  The name of the Availability Zone in which the cluster is located.

  · **PreferredMaintenanceWindow** *(string)* –

  The weekly time range (in UTC) during which system maintenance can occur.

  · **PendingModifiedValues** *(dict)* –

  If present, changes to the cluster are pending. Specific pending changes are identified by subelements.
  
  · **MasterUserPassword** *(string)* –

  The pending or in-progress change of the master user password for the cluster.

  · **NodeType** *(string)* –

  The pending or in-progress change of the cluster’s node type.

  · **NumberOfNodes** *(integer)* –

  The pending or in-progress change of the number of nodes in the cluster.

  · **ClusterType** *(string)* –

  The pending or in-progress change of the cluster type.

  · **ClusterVersion** *(string)* –

  The pending or in-progress change of the service version.

  · **AutomatedSnapshotRetentionPeriod** *(integer)* –

  The pending or in-progress change of the automated snapshot retention period.

  · **ClusterIdentifier** *(string)* –

  The pending or in-progress change of the new identifier for the cluster.

  · **ClusterVersion** *(string)* –

  The version ID of the Amazon Redshift engine that is running on the cluster.

  · **AllowVersionUpgrade** *(boolean)* –

  If true, major version upgrades will be applied automatically to the cluster during the maintenance window.

  · **NumberOfNodes** *(integer)* –

  The number of compute nodes in the cluster.
* **PubliclyAccessible** *(boolean)* —
  
  If `true`, the cluster can be accessed from a public network.

* **Encrypted** *(boolean)* —
  
  If `true`, data in the cluster is encrypted at rest.

* **RestoreStatus** *(dict)* —
  
  Describes the status of a cluster restore action. Returns null if the cluster was not created by restoring a snapshot.
  
  - **Status** *(string)* —
    
    The status of the restore action. Returns starting, restoring, completed, or failed.
  
  - **CurrentRestoreRateInMegaBytesPerSecond** *(float)* —
    
    The number of megabytes per second being transferred from the backup storage. Returns the average rate for a completed backup.
  
  - **SnapshotSizeInMegaBytes** *(integer)* —
    
    The size of the set of snapshot data used to restore the cluster.
  
  - **ProgressInMegaBytes** *(integer)* —
    
    The number of megabytes that have been transferred from snapshot storage.
  
  - **ElapsedTimeInSeconds** *(integer)* —
    
    The amount of time an in-progress restore has been running, or the amount of time it took a completed restore to finish.
  
  - **EstimatedTimeToCompletionInSeconds** *(integer)* —
    
    The estimate of the time remaining before the restore will complete. Returns 0 for a completed restore.

* **HsmStatus** *(dict)* —
  
  Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.

  Values: active, applying
  
  - **HsmClientCertificateIdentifier** *(string)* —
    
    Specifies the name of the HSM client certificate the Amazon Redshift cluster uses to retrieve the data encryption keys stored in an HSM.
  
  - **HsmConfigurationIdentifier** *(string)* —
    
    Specifies the name of the HSM configuration that contains the information the Amazon Redshift cluster can use to retrieve and store keys in an HSM.
  
  - **Status** *(string)* —
    
    Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.

    Values: active, applying

* **ClusterSnapshotCopyStatus** *(dict)* —
  
  Returns the destination region and retention period that are configured for cross-region snapshot copy.
· **DestinationRegion** (*string*) –
  The destination region that snapshots are automatically copied to when cross-region snapshot copy is enabled.

· **RetentionPeriod** (*integer*) –
  The number of days that automated snapshots are retained in the destination region after they are copied from a source region.

· **SnapshotCopyGrantName** (*string*) –
  The name of the snapshot copy grant.

* **ClusterPublicKey** (*string*) –
  The public key for the cluster.

* **ClusterNodes** (*list*) –
  The nodes in a cluster.
  · (*dict*) –
    The identifier of a node in a cluster.
  · **NodeRole** (*string*) –
    Whether the node is a leader node or a compute node.

· **PrivateIPAddress** (*string*) –
  The private IP address of a node within a cluster.

· **PublicIPAddress** (*string*) –
  The public IP address of a node within a cluster.

* **ElasticIpStatus** (*dict*) –
  Describes the status of the elastic IP (EIP) address.
  · **ElasticIp** (*string*) –
    The elastic IP (EIP) address for the cluster.
  · **Status** (*string*) –
    Describes the status of the elastic IP (EIP) address.

* **ClusterRevisionNumber** (*string*) –
  The specific revision number of the database in the cluster.

* **Tags** (*list*) –
  The list of tags for the cluster.
  · (*dict*) –
    A tag consisting of a name/value pair for a resource.
  · **Key** (*string*) –
    The key, or name, for the resource tag.
  · **Value** (*string*) –
    The value for the resource tag.

* **KmsKeyId** (*string*) –
  The AWS Key Management Service (KMS) key ID of the encryption key used to encrypt data in the cluster.

**generate_presigned_url**(*ClientMethod*, *Params=None*, *ExpiresIn=3600*, *HttpMethod=None*)

Generate a presigned url given a client, its method, and arguments

**Parameters**

· **ClientMethod** (*string*) – The client method to presign for
• **Params** (*dict*) – The parameters normally passed to `ClientMethod`.

• **ExpiresIn** (*int*) – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)

• **HttpMethod** (*string*) – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns** The presigned url

```python
get Paginator (operation_name)
```

Create a paginator for an operation.

**Parameters** operation_name (*string*) – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get Paginator("create_foo")`.

**Raises** **OperationNotPageableError** Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

**Return type** L{botocore.paginate.Paginator} Returns A paginator object.

```python
get Waiter (waiter_name)
```

**modify_cluster**(**kwargs)**

Modifies the settings for a cluster. For example, you can add another security or parameter group, update the preferred maintenance window, or change the master user password. Resetting a cluster password or modifying the security groups associated with a cluster do not need a reboot. However, modifying a parameter group requires a reboot for parameters to take effect. For more information about managing clusters, go to Amazon Redshift Clusters in the Amazon Redshift Cluster Management Guide.

You can also change node type and the number of nodes to scale up or down the cluster. When resizing a cluster, you must specify both the number of nodes and the node type even if one of the parameters does not change.

**Request Syntax**

```python
response = client.modify_cluster(
    ClusterIdentifier='string',
    ClusterType='string',
    NodeType='string',
    NumberOfNodes=123,
    ClusterSecurityGroups=[
        'string',
    ],
    VpcSecurityGroupIds=[
        'string',
    ],
    MasterUserPassword='string',
    ClusterParameterGroupName='string',
    AutomatedSnapshotRetentionPeriod=123,
    PreferredMaintenanceWindow='string',
    ClusterVersion='string',
    AllowVersionUpgrade=True|False,
    HsmClientCertificateIdentifier='string',
    HsmConfigurationIdentifier='string',
    NewClusterIdentifier='string'
)
```

**Parameters**

• **ClusterIdentifier** (*string*) – [REQUIRED]
The unique identifier of the cluster to be modified.

Example: `examplecluster`

- **ClusterType (string)** – The new cluster type.

  When you submit your cluster resize request, your existing cluster goes into a read-only mode. After Amazon Redshift provisions a new cluster based on your resize requirements, there will be outage for a period while the old cluster is deleted and your connection is switched to the new cluster. You can use DescribeResize to track the progress of the resize request.

  Valid Values: `multi-node | single-node`

- **NodeType (string)** – The new node type of the cluster. If you specify a new node type, you must also specify the number of nodes parameter.

  When you submit your request to resize a cluster, Amazon Redshift sets access permissions for the cluster to read-only. After Amazon Redshift provisions a new cluster according to your resize requirements, there will be a temporary outage while the old cluster is deleted and your connection is switched to the new cluster. When the new connection is complete, the original access permissions for the cluster are restored. You can use DescribeResize to track the progress of the resize request.

  Valid Values: `ds1.xlarge | ds1.8xlarge | ds2.xlarge | ds2.8xlarge | dc1.large | dc1.8xlarge`.

- **NumberOfNodes (integer)** – The new number of nodes of the cluster. If you specify a new number of nodes, you must also specify the node type parameter.

  When you submit your request to resize a cluster, Amazon Redshift sets access permissions for the cluster to read-only. After Amazon Redshift provisions a new cluster according to your resize requirements, there will be a temporary outage while the old cluster is deleted and your connection is switched to the new cluster. When the new connection is complete, the original access permissions for the cluster are restored. You can use DescribeResize to track the progress of the resize request.

  Valid Values: Integer greater than 0.

- **ClusterSecurityGroups (list)** – A list of cluster security groups to be authorized on this cluster. This change is asynchronously applied as soon as possible.

  Security groups currently associated with the cluster, and not in the list of groups to apply, will be revoked from the cluster.

  Constraints:
  - Must be 1 to 255 alphanumeric characters or hyphens
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **VpcSecurityGroupIds (list)** – A list of virtual private cloud (VPC) security groups to be associated with the cluster.

- **MasterUserPassword (string)** – The new password for the cluster master user. This change is asynchronously applied as soon as possible. Between the time of the request and the completion of the request, the MasterUserPassword element exists in the PendingModifiedValues element of the operation response.

  Note: Operations never return the password, so this operation provides a way
to regain access to the master user account for a cluster if the password is lost.

Default: Uses existing setting.

Constraints:
- Must be between 8 and 64 characters in length.
- Must contain at least one uppercase letter.
- Must contain at least one lowercase letter.
- Must contain one number.
- Can be any printable ASCII character (ASCII code 33 to 126) except ' (single quote), " (double quote), /, @, or space.

• **ClusterParameterGroupName** *(string)* – The name of the cluster parameter group to apply to this cluster. This change is applied only after the cluster is rebooted. To reboot a cluster use RebootCluster.

Default: Uses existing setting.

Constraints: The cluster parameter group must be in the same parameter group family that matches the cluster version.

• **AutomatedSnapshotRetentionPeriod** *(integer)* – The number of days that automated snapshots are retained. If the value is 0, automated snapshots are disabled. Even if automated snapshots are disabled, you can still create manual snapshots when you want with CreateClusterSnapshot.

If you decrease the automated snapshot retention period from its current value, existing automated snapshots that fall outside of the new retention period will be immediately deleted.

Default: Uses existing setting.

Constraints: Must be a value from 0 to 35.

• **PreferredMaintenanceWindow** *(string)* – The weekly time range (in UTC) during which system maintenance can occur, if necessary. If system maintenance is necessary during the window, it may result in an outage.

This maintenance window change is made immediately. If the new maintenance window indicates the current time, there must be at least 120 minutes between the current time and end of the window in order to ensure that pending changes are applied.

Default: Uses existing setting.

Format: ddd:hh24:mi-ddd:hh24:mi, for example wed:07:30-wed:08:00.

Valid Days: Mon | Tue | Wed | Thu | Fri | Sat | Sun

Constraints: Must be at least 30 minutes.

• **ClusterVersion** *(string)* – The new version number of the Amazon Redshift engine to upgrade to.

For major version upgrades, if a non-default cluster parameter group is currently in use, a new cluster parameter group in the cluster parameter group family for the new version must be specified. The new cluster parameter group can be the default for that cluster parameter group family. For more information about parameters and parameter groups, go to Amazon Redshift Parameter Groups in the Amazon Redshift Cluster Management Guide.

Example: 1.0

• **AllowVersionUpgrade** *(boolean)* – If true, major version upgrades will be applied automatically to the cluster during the maintenance window.
Default: false

- **HsmClientCertificateIdentifier** (string) – Specifies the name of the HSM client certificate the Amazon Redshift cluster uses to retrieve the data encryption keys stored in an HSM.

- **HsmConfigurationIdentifier** (string) – Specifies the name of the HSM configuration that contains the information the Amazon Redshift cluster can use to retrieve and store keys in an HSM.

- **NewClusterIdentifier** (string) – The new identifier for the cluster.

  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens.
  - Alphaabetic characters must be lowercase.
  - First character must be a letter.
  - Cannot end with a hyphen or contain two consecutive hyphens.
  - Must be unique for all clusters within an AWS account.

  Example: `examplecluster`

Return type  dict

Returns

Response Syntax

3714 Chapter 3. API Reference
Response Structure

- (dict) –
  Describes a cluster.
  - Cluster (dict) –
    Describes a cluster.
    * ClusterIdentifier (string) –
      The unique identifier of the cluster.
    * NodeType (string) –
      The node type for the nodes in the cluster.
    * ClusterStatus (string) –
      The current state of this cluster. Possible values include available, creating, deleting, rebooting, renaming, and resizing.
    * ModifyStatus (string) –
      The status of a modify operation, if any, initiated for the cluster.
    * MasterUsername (string) –
      The master user name for the cluster. This name is used to connect to the database that is specified in DBName.
    * DBName (string) –
      The name of the initial database that was created when the cluster was created. This same name is returned for the life of the cluster. If an initial database was not specified, a database named “dev” was created by default.
    * Endpoint (dict) –
      The connection endpoint.
      · Address (string) –
        The DNS address of the Cluster.
      · Port (integer) –
        The port that the database engine is listening on.
    * ClusterCreateTime (datetime) –
      The date and time that the cluster was created.
    * AutomatedSnapshotRetentionPeriod (integer) –
      The number of days that automatic cluster snapshots are retained.
    * ClusterSecurityGroups (list) –
      A list of cluster security group that are associated with the cluster. Each security group is represented by an element that contains ClusterSecurityGroup.Name and ClusterSecurityGroup.Status subelements.
      Cluster security groups are used when the cluster is not created in a VPC. Clusters that are created in a VPC use VPC security groups, which are listed by the VpcSecurityGroups parameter.
      · (dict) –
        Describes a security group.
- **ClusterSecurityGroupName** *(string)* –
  The name of the cluster security group.
- **Status** *(string)* –
  The status of the cluster security group.

* **VpcSecurityGroups** *(list)* –
  A list of Virtual Private Cloud (VPC) security groups that are associated with the cluster. This parameter is returned only if the cluster is in a VPC.
  - *(dict)* –
    Describes the members of a VPC security group.
    - **VpcSecurityGroupId** *(string)* –
    - **Status** *(string)* –

* **ClusterParameterGroups** *(list)* –
  The list of cluster parameter groups that are associated with this cluster. Each parameter group in the list is returned with its status.
  - *(dict)* –
    Describes the status of a parameter group.
    - **ParameterGroupName** *(string)* –
      The name of the cluster parameter group.
    - **ParameterApplyStatus** *(string)* –
      The status of parameter updates.
  - **ClusterParameterStatusList** *(list)* –
    The list of parameter statuses.
    
    For more information about parameters and parameter groups, go to Amazon Redshift Parameter Groups in the Amazon Redshift Cluster Management Guide.
    - *(dict)* –
      Describes the status of a parameter group.
    - **ParameterName** *(string)* –
      The name of the parameter.
    - **ParameterApplyStatus** *(string)* –
      The status of the parameter that indicates whether the parameter is in sync with the database, waiting for a cluster reboot, or encountered an error when being applied.

    The following are possible statuses and descriptions.
    - **in-sync**: The parameter value is in sync with the database.
    - **pending-reboot**: The parameter value will be applied after the cluster reboots.
    - **applying**: The parameter value is being applied to the database.
    - **invalid-parameter**: Cannot apply the parameter value because it has an invalid value or syntax.
    - **apply-deferred**: The parameter contains static property changes. The changes are deferred until the cluster reboots.
    - **apply-error**: Cannot connect to the cluster. The parameter change will be applied after the cluster reboots.
unknown-error: Cannot apply the parameter change right now. The change will be applied after the cluster reboots.

ParameterApplyErrorDescription (string) –

The error that prevented the parameter from being applied to the database.

* ClusterSubnetGroupName (string) –

The name of the subnet group that is associated with the cluster. This parameter is valid only when the cluster is in a VPC.

* VpcId (string) –

The identifier of the VPC the cluster is in, if the cluster is in a VPC.

* AvailabilityZone (string) –

The name of the Availability Zone in which the cluster is located.

* PreferredMaintenanceWindow (string) –

The weekly time range (in UTC) during which system maintenance can occur.

* PendingModifiedValues (dict) –

If present, changes to the cluster are pending. Specific pending changes are identified by subelements.

  · MasterUserPassword (string) –

The pending or in-progress change of the master user password for the cluster.

  · NodeType (string) –

The pending or in-progress change of the cluster’s node type.

  · NumberOfNodes (integer) –

The pending or in-progress change of the number of nodes in the cluster.

  · ClusterType (string) –

The pending or in-progress change of the cluster type.

  · ClusterVersion (string) –

The pending or in-progress change of the service version.

  · AutomatedSnapshotRetentionPeriod (integer) –

The pending or in-progress change of the automated snapshot retention period.

  · ClusterIdentifier (string) –

The pending or in-progress change of the new identifier for the cluster.

* ClusterVersion (string) –

The version ID of the Amazon Redshift engine that is running on the cluster.

* AllowVersionUpgrade (boolean) –

If true, major version upgrades will be applied automatically to the cluster during the maintenance window.

* NumberOfNodes (integer) –

The number of compute nodes in the cluster.
* **PubliclyAccessible** *(boolean)* –
  If `true`, the cluster can be accessed from a public network.

* **Encrypted** *(boolean)* –
  If `true`, data in the cluster is encrypted at rest.

* **RestoreStatus** *(dict)* –
  Describes the status of a cluster restore action. Returns null if the cluster was not created by restoring a snapshot.
  - **Status** *(string)* –
    The status of the restore action. Returns starting, restoring, completed, or failed.
  - **CurrentRestoreRateInMegaBytesPerSecond** *(float)* –
    The number of megabytes per second being transferred from the backup storage. Returns the average rate for a completed backup.
  - **SnapshotSizeInMegaBytes** *(integer)* –
    The size of the set of snapshot data used to restore the cluster.
  - **ProgressInMegaBytes** *(integer)* –
    The number of megabytes that have been transferred from snapshot storage.
  - **ElapsedTimeInSeconds** *(integer)* –
    The amount of time an in-progress restore has been running, or the amount of time it took a completed restore to finish.
  - **EstimatedTimeToCompletionInSeconds** *(integer)* –
    The estimate of the time remaining before the restore will complete. Returns 0 for a completed restore.

* **HsmStatus** *(dict)* –
  Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.
  Values: active, applying
  - **HsmClientCertificateIdentifier** *(string)* –
    Specifies the name of the HSM client certificate the Amazon Redshift cluster uses to retrieve the data encryption keys stored in an HSM.
  - **HsmConfigurationIdentifier** *(string)* –
    Specifies the name of the HSM configuration that contains the information the Amazon Redshift cluster can use to retrieve and store keys in an HSM.
  - **Status** *(string)* –
    Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.
    Values: active, applying

* **ClusterSnapshotCopyStatus** *(dict)* –
  Returns the destination region and retention period that are configured for cross-region snapshot copy.
- **DestinationRegion** (string) –
  The destination region that snapshots are automatically copied to when cross-region snapshot copy is enabled.
- **RetentionPeriod** (integer) –
  The number of days that automated snapshots are retained in the destination region after they are copied from a source region.
- **SnapshotCopyGrantName** (string) –
  The name of the snapshot copy grant.
  
  * **ClusterPublicKey** (string) –
    The public key for the cluster.
- **ClusterNodes** (list) –
  The nodes in a cluster.
  - (dict) –
    The identifier of a node in a cluster.
  - **NodeRole** (string) –
    Whether the node is a leader node or a compute node.
  - **PrivateIPAddress** (string) –
    The private IP address of a node within a cluster.
  - **PublicIPAddress** (string) –
    The public IP address of a node within a cluster.
  - **ElasticIpStatus** (dict) –
    Describes the status of the elastic IP (EIP) address.
    - **ElasticIp** (string) –
      The elastic IP (EIP) address for the cluster.
    - **Status** (string) –
      Describes the status of the elastic IP (EIP) address.
- **ClusterRevisionNumber** (string) –
  The specific revision number of the database in the cluster.
- **Tags** (list) –
  The list of tags for the cluster.
  - (dict) –
    A tag consisting of a name/value pair for a resource.
    - **Key** (string) –
      The key, or name, for the resource tag.
    - **Value** (string) –
      The value for the resource tag.
  - **KmsKeyId** (string) –
    The AWS Key Management Service (KMS) key ID of the encryption key used to encrypt data in the cluster.

**modify_cluster_parameter_group** (**kwargs**)
Modifies the parameters of a parameter group.

For more information about parameters and parameter groups, go to Amazon Redshift Parameter Groups in the Amazon Redshift Cluster Management Guide.
Request Syntax

```python
response = client.modify_cluster_parameter_group(
    ParameterGroupName='string',
    Parameters=[
        {
            'ParameterName': 'string',
            'ParameterValue': 'string',
            'Description': 'string',
            'Source': 'string',
            'DataType': 'string',
            'AllowedValues': 'string',
            'ApplyType': 'static'|'dynamic',
            'IsModifiable': True|False,
            'MinimumEngineVersion': 'string'
        },
    ],
)
```

Parameters

- **ParameterGroupName** *(string)* – [REQUIRED]
  
The name of the parameter group to be modified.

- **Parameters** *(list)* – [REQUIRED]
  
  An array of parameters to be modified. A maximum of 20 parameters can be modified in a single request.

  For each parameter to be modified, you must supply at least the parameter name and parameter value; other name-value pairs of the parameter are optional.

  For the workload management (WLM) configuration, you must supply all the name-value pairs in the `wlm_json_configuration` parameter.

  - *(dict)* –
    
    Describes a parameter in a cluster parameter group.
    
    ```
    * **ParameterName** *(string)* –
      
      The name of the parameter.
    
    * **ParameterValue** *(string)* –
      
      The value of the parameter.
    
    * **Description** *(string)* –
      
      A description of the parameter.
    
    * **Source** *(string)* –
      
      The source of the parameter value, such as “engine-default” or “user”.
    
    * **DataType** *(string)* –
      
      The data type of the parameter.
    
    * **AllowedValues** *(string)* –
      
      The valid range of values for the parameter.
    
    * **ApplyType** *(string)* –
      
      Specifies how to apply the parameter. Supported value: static.
    
    * **IsModifiable** *(boolean)* –
    ```
If true, the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.

* MinimumEngineVersion (string) –
  The earliest engine version to which the parameter can apply.

**modify_cluster_subnet_group(**kwargs)**
Modifies a cluster subnet group to include the specified list of VPC subnets. The operation replaces the existing list of subnets with the new list of subnets.

**Request Syntax**

```python
response = client.modify_cluster_subnet_group(
    ClusterSubnetGroupName='string',
    Description='string',
    SubnetIds=[
        'string',
    ]
)
```

**Parameters**

- **ClusterSubnetGroupName (string)** – [REQUIRED]
  The name of the subnet group to be modified.
- **Description (string)** – A text description of the subnet group to be modified.
- **SubnetIds (list)** – [REQUIRED]
  An array of VPC subnet IDs. A maximum of 20 subnets can be modified in a single request.
  - (string) –
.Response Structure

- (dict) –

  - ClusterSubnetGroup (dict) –

    Describes a subnet group.

    - ClusterSubnetGroupName (string) –

      The name of the cluster subnet group.

    - Description (string) –

      The description of the cluster subnet group.

    - VpcId (string) –

      The VPC ID of the cluster subnet group.

    - SubnetGroupStatus (string) –

      The status of the cluster subnet group. Possible values are Complete, Incomplete and Invalid.

    - Subnets (list) –

      A list of the VPC Subnet elements.

        - (dict) –

          Describes a subnet.

          - SubnetIdentifier (string) –

            The identifier of the subnet.

          - SubnetAvailabilityZone (dict) –

            Describes an availability zone.

            - Name (string) –

              The name of the availability zone.

            - SubnetStatus (string) –
The status of the subnet.

* Tags (list) –

The list of tags for the cluster subnet group.

  * (dict) –
    
    A tag consisting of a name/value pair for a resource.

  * Key (string) –

    The key, or name, for the resource tag.

  * Value (string) –

    The value for the resource tag.

modify_event_subscription(**kwargs)

Modifies an existing Amazon Redshift event notification subscription.

Request Syntax

```python
response = client.modify_event_subscription(
    SubscriptionName='string',
    SnsTopicArn='string',
    SourceType='string',
    SourceIds=['string'],
    EventCategories=['string'],
    Severity='string',
    Enabled=True|False
)
```

Parameters

* SubscriptionName (string) – [REQUIRED]

  The name of the modified Amazon Redshift event notification subscription.

* SnsTopicArn (string) – The Amazon Resource Name (ARN) of the SNS topic to be used by the event notification subscription.

* SourceType (string) – The type of source that will be generating the events. For example, if you want to be notified of events generated by a cluster, you would set this parameter to cluster. If this value is not specified, events are returned for all Amazon Redshift objects in your AWS account. You must specify a source type in order to specify source IDs.

  Valid values: cluster, cluster-parameter-group, cluster-security-group, and cluster-snapshot.

* SourceIds (list) – A list of one or more identifiers of Amazon Redshift source objects. All of the objects must be of the same type as was specified in the source type parameter. The event subscription will return only events generated by the specified objects. If not specified, then events are returned for all objects within the source type specified.

  Example: my-cluster-1, my-cluster-2

  Example: my-snapshot-20131010

* EventCategories (list) – Specifies the Amazon Redshift event categories to be published by the event notification subscription.

  Values: Configuration, Management, Monitoring, Security
- **Severity** *(string)* – Specifies the Amazon Redshift event severity to be published by the event notification subscription.

  Values: ERROR, INFO

- **Enabled** *(boolean)* – A Boolean value indicating if the subscription is enabled. `true` indicates the subscription is enabled

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'EventSubscription': {
        'CustomerAwsId': 'string',
        'CustSubscriptionId': 'string',
        'SnsTopicArn': 'string',
        'Status': 'string',
        'SubscriptionCreationTime': datetime(2015, 1, 1),
        'SourceType': 'string',
        'SourceIdsList': [
            'string',
        ],
        'EventCategoriesList': [
            'string',
        ],
        'Severity': 'string',
        'Enabled': True|False,
        'Tags': [
            {
                'Key': 'string',
                'Value': 'string'
            },
        ]
    }
}
```

**Response Structure**

- *(dict)*
  - **EventSubscription** *(dict)*
    - **CustomerAwsId** *(string)* – The AWS customer account associated with the Amazon Redshift event notification subscription.
    - **CustSubscriptionId** *(string)* – The name of the Amazon Redshift event notification subscription.
    - **SnsTopicArn** *(string)* – The Amazon Resource Name (ARN) of the Amazon SNS topic used by the event notification subscription.
    - **Status** *(string)* – The status of the Amazon Redshift event notification subscription.
      Constraints:
      - Can be one of the following: active | no-permission | topic-not-exist
The status “no-permission” indicates that Amazon Redshift no longer has permission to post to the Amazon SNS topic. The status “topic-not-exist” indicates that the topic was deleted after the subscription was created.

* **SubscriptionCreationTime** *(datetime)* –
  The date and time the Amazon Redshift event notification subscription was created.

* **SourceType** *(string)* –
  The source type of the events returned the Amazon Redshift event notification, such as cluster, or cluster-snapshot.

* **SourceIdsList** *(list)* –
  A list of the sources that publish events to the Amazon Redshift event notification subscription.

* **EventCategoriesList** *(list)* –
  The list of Amazon Redshift event categories specified in the event notification subscription.
  Values: Configuration, Management, Monitoring, Security

* **Severity** *(string)* –
  The event severity specified in the Amazon Redshift event notification subscription.
  Values: ERROR, INFO

* **Enabled** *(boolean)* –
  A Boolean value indicating whether the subscription is enabled.
  true indicates the subscription is enabled.

* **Tags** *(list)* –
  The list of tags for the event subscription.

  * **Key** *(string)* –
    The key, or name, for the resource tag.
  
  * **Value** *(string)* –
    The value for the resource tag.

**modify_snapshot_copy_retention_period** (**kwargs**)
Modifies the number of days to retain automated snapshots in the destination region after they are copied from the source region.

**Request Syntax**

```python
response = client.modify_snapshot_copy_retention_period(
    ClusterIdentifier='string',
    RetentionPeriod=123
)
```

**Parameters**

* **ClusterIdentifier** *(string)* – [REQUIRED]
The unique identifier of the cluster for which you want to change the retention period for automated snapshots that are copied to a destination region.

Constraints: Must be the valid name of an existing cluster that has cross-region snapshot copy enabled.

- **RetentionPeriod** *(integer) – [REQUIRED]*

The number of days to retain automated snapshots in the destination region after they are copied from the source region.

If you decrease the retention period for automated snapshots that are copied to a destination region, Amazon Redshift will delete any existing automated snapshots that were copied to the destination region and that fall outside of the new retention period.

Constraints: Must be at least 1 and no more than 35.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Cluster': {
        'ClusterIdentifier': 'string',
        'NodeType': 'string',
        'ClusterStatus': 'string',
        'ModifyStatus': 'string',
        'MasterUsername': 'string',

Response Structure

- (dict) –
  Describes a cluster.
  - Cluster (dict) –
    Describes a cluster.
    * ClusterIdentifier (string) –
      The unique identifier of the cluster.
    * NodeType (string) –
      The node type for the nodes in the cluster.
    * ClusterStatus (string) –
      The current state of this cluster. Possible values include available, creating, deleting, rebooting, renaming, and resizing.
    * ModifyStatus (string) –
      The status of a modify operation, if any, initiated for the cluster.
    * MasterUsername (string) –
      The master user name for the cluster. This name is used to connect to the database that is specified in DBName.
    * DBName (string) –
      The name of the initial database that was created when the cluster was created. This same name is returned for the life of the cluster. If an initial database was not specified, a database named “dev” was created by default.
    * Endpoint (dict) –
      The connection endpoint.
      - Address (string) –
        The DNS address of the Cluster.
      - Port (integer) –
        The port that the database engine is listening on.
    * ClusterCreateTime (datetime) –
      The date and time that the cluster was created.
    * AutomatedSnapshotRetentionPeriod (integer) –
      The number of days that automatic cluster snapshots are retained.
    * ClusterSecurityGroups (list) –
      A list of cluster security group that are associated with the cluster. Each security group is represented by an element that contains ClusterSecurityGroup.Name and ClusterSecurityGroup.Status subelements.
      Cluster security groups are used when the cluster is not created in a VPC. Clusters that are created in a VPC use VPC security groups, which are listed by the VpcSecurityGroups parameter.
      - (dict) –
        Describes a security group.
- **ClusterSecurityGroupName** *(string)* –
  The name of the cluster security group.
- **Status** *(string)* –
  The status of the cluster security group.

* **VpcSecurityGroups** *(list)* –
  A list of Virtual Private Cloud (VPC) security groups that are associated with the cluster. This parameter is returned only if the cluster is in a VPC.
  - *(dict)* –
    Describes the members of a VPC security group.
    - **VpcSecurityGroupId** *(string)* –
    - **Status** *(string)* –

* **ClusterParameterGroups** *(list)* –
  The list of cluster parameter groups that are associated with this cluster. Each parameter group in the list is returned with its status.
  - *(dict)* –
    Describes the status of a parameter group.
    - **ParameterGroupName** *(string)* –
    - **ParameterApplyStatus** *(string)* –
      The status of parameter updates.
    - **ClusterParameterStatusList** *(list)* –
      The list of parameter statuses.
      - *(dict)* –
        Describes the status of a parameter group.
        - **ParameterName** *(string)* –
        - **ParameterApplyStatus** *(string)* –
          The status of the parameter that indicates whether the parameter is in sync with the database, waiting for a cluster reboot, or encountered an error when being applied.

  The following are possible statuses and descriptions.
  - **in-sync** : The parameter value is in sync with the database.
  - **pending-reboot** : The parameter value will be applied after the cluster reboots.
  - **applying** : The parameter value is being applied to the database.
  - **invalid-parameter** : Cannot apply the parameter value because it has an invalid value or syntax.
  - **apply-deferred** : The parameter contains static property changes. The changes are deferred until the cluster reboots.
  - **apply-error** : Cannot connect to the cluster. The parameter change will be applied after the cluster reboots.
unknown-error: Cannot apply the parameter change right now. The change will be applied after the cluster reboots.

ParameterApplyErrorDescription (string) –

The error that prevented the parameter from being applied to the database.

* ClusterSubnetGroupName (string) –

The name of the subnet group that is associated with the cluster. This parameter is valid only when the cluster is in a VPC.

* VpcId (string) –

The identifier of the VPC the cluster is in, if the cluster is in a VPC.

* AvailabilityZone (string) –

The name of the Availability Zone in which the cluster is located.

* PreferredMaintenanceWindow (string) –

The weekly time range (in UTC) during which system maintenance can occur.

* PendingModifiedValues (dict) –

If present, changes to the cluster are pending. Specific pending changes are identified by subelements.

  * MasterUserPassword (string) –

    The pending or in-progress change of the master user password for the cluster.

  * NodeType (string) –

    The pending or in-progress change of the cluster’s node type.

  * NumberOfNodes (integer) –

    The pending or in-progress change of the number of nodes in the cluster.

  * ClusterType (string) –

    The pending or in-progress change of the cluster type.

  * ClusterVersion (string) –

    The pending or in-progress change of the service version.

  * AutomatedSnapshotRetentionPeriod (integer) –

    The pending or in-progress change of the automated snapshot retention period.

  * ClusterIdentifier (string) –

    The pending or in-progress change of the new identifier for the cluster.

* ClusterVersion (string) –

The version ID of the Amazon Redshift engine that is running on the cluster.

* AllowVersionUpgrade (boolean) –

If true, major version upgrades will be applied automatically to the cluster during the maintenance window.

* NumberOfNodes (integer) –

The number of compute nodes in the cluster.
* **PubliclyAccessible** *(boolean)*
  
  If `true`, the cluster can be accessed from a public network.

* **Encrypted** *(boolean)*
  
  If `true`, data in the cluster is encrypted at rest.

* **RestoreStatus** *(dict)*
  
  Describes the status of a cluster restore action. Returns null if the cluster was not created by restoring a snapshot.
  
  - **Status** *(string)*
    
    The status of the restore action. Returns starting, restoring, completed, or failed.
  
  - **CurrentRestoreRateInMegaBytesPerSecond** *(float)*
    
    The number of megabytes per second being transferred from the backup storage. Returns the average rate for a completed backup.
  
  - **SnapshotSizeInMegaBytes** *(integer)*
    
    The size of the set of snapshot data used to restore the cluster.
  
  - **ProgressInMegaBytes** *(integer)*
    
    The number of megabytes that have been transferred from snapshot storage.
  
  - **ElapsedTimeInSeconds** *(integer)*
    
    The amount of time an in-progress restore has been running, or the amount of time it took a completed restore to finish.
  
  - **EstimatedTimeToCompletionInSeconds** *(integer)*
    
    The estimate of the time remaining before the restore will complete. Returns 0 for a completed restore.

* **HsmStatus** *(dict)*
  
  Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.

  Values: active, applying
  
  - **HsmClientCertificateIdentifier** *(string)*
    
    Specifies the name of the HSM client certificate the Amazon Redshift cluster uses to retrieve the data encryption keys stored in an HSM.
  
  - **HsmConfigurationIdentifier** *(string)*
    
    Specifies the name of the HSM configuration that contains the information the Amazon Redshift cluster can use to retrieve and store keys in an HSM.
  
  - **Status** *(string)*
    
    Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.

  Values: active, applying

* **ClusterSnapshotCopyStatus** *(dict)*
  
  Returns the destination region and retention period that are configured for cross-region snapshot copy.
· **DestinationRegion** *(string)* –
  The destination region that snapshots are automatically copied to when cross-region snapshot copy is enabled.

· **RetentionPeriod** *(integer)* –
  The number of days that automated snapshots are retained in the destination region after they are copied from a source region.

· **SnapshotCopyGrantName** *(string)* –
  The name of the snapshot copy grant.

* **ClusterPublicKey** *(string)* –
  The public key for the cluster.

* **ClusterNodes** *(list)* –
  The nodes in a cluster.
  · *(dict)* –
    · **NodeRole** *(string)* –
      Whether the node is a leader node or a compute node.

· **PrivateIPAddress** *(string)* –
  The private IP address of a node within a cluster.

· **PublicIPAddress** *(string)* –
  The public IP address of a node within a cluster.

* **ElasticIpStatus** *(dict)* –
  Describes the status of the elastic IP (EIP) address.
  · **ElasticIp** *(string)* –
    The elastic IP (EIP) address for the cluster.
  · **Status** *(string)* –
    Describes the status of the elastic IP (EIP) address.

* **ClusterRevisionNumber** *(string)* –
  The specific revision number of the database in the cluster.

* **Tags** *(list)* –
  The list of tags for the cluster.
  · *(dict)* –
    · **Key** *(string)* –
      The key, or name, for the resource tag.
    · **Value** *(string)* –
      The value for the resource tag.

* **KmsKeyId** *(string)* –
  The AWS Key Management Service (KMS) key ID of the encryption key used to encrypt data in the cluster.

**purchase_reserved_node_offering** *(**kwargs*)

Allows you to purchase reserved nodes. Amazon Redshift offers a predefined set of reserved node offerings. You can purchase one or more of the offerings. You can call the DescribeReservedNodeOfferings
API to obtain the available reserved node offerings. You can call this API by providing a specific reserved node offering and the number of nodes you want to reserve.

For more information about reserved node offerings, go to Purchasing Reserved Nodes in the Amazon Redshift Cluster Management Guide.

Request Syntax

```python
response = client.purchase_reserved_node_offering(
    ReservedNodeOfferingId='string',
    NodeCount=123
)
```

Parameters

- **ReservedNodeOfferingId (string)** – [REQUIRED]
  
The unique identifier of the reserved node offering you want to purchase.

- **NodeCount (integer)** – The number of reserved nodes you want to purchase.
  
  Default: 1

Returns

- **Response Syntax**

```json
{
    'ReservedNode': {
        'ReservedNodeId': 'string',
        'ReservedNodeOfferingId': 'string',
        'NodeType': 'string',
        'StartTime': datetime(2015, 1, 1),
        'Duration': 123,
        'FixedPrice': 123.0,
        'UsagePrice': 123.0,
        'CurrencyCode': 'string',
        'NodeCount': 123,
        'State': 'string',
        'OfferingType': 'string',
        'RecurringCharges': [
            {
                'RecurringChargeAmount': 123.0,
                'RecurringChargeFrequency': 'string'
            }
        ]
    }
}
```

Response Structure

- **(dict)** –
  
  Describes a reserved node. You can call the DescribeReservedNodeOfferings API to obtain the available reserved node offerings.

  - **ReservedNode (dict)** –

    Describes a reserved node. You can call the DescribeReservedNodeOfferings API to obtain the available reserved node offerings.

    - **ReservedNodeId (string)** –

      The unique identifier for the reservation.
* **ReservedNodeOfferingId** *(string)* –
  The identifier for the reserved node offering.
* **NodeType** *(string)* –
  The node type of the reserved node.
* **StartTime** *(datetime)* –
  The time the reservation started. You purchase a reserved node offering for a duration. This is the start time of that duration.
* **Duration** *(integer)* –
  The duration of the node reservation in seconds.
* **FixedPrice** *(float)* –
  The fixed cost Amazon Redshift charges you for this reserved node.
* **UsagePrice** *(float)* –
  The hourly rate Amazon Redshift charges you for this reserved node.
* **CurrencyCode** *(string)* –
  The currency code for the reserved cluster.
* **NodeCount** *(integer)* –
  The number of reserved compute nodes.
* **State** *(string)* –
  The state of the reserved compute node.
  Possible Values:
  - pending-payment-This reserved node has recently been purchased, and the sale has been approved, but payment has not yet been confirmed.
  - active-This reserved node is owned by the caller and is available for use.
  - payment-failed-Payment failed for the purchase attempt.
* **OfferingType** *(string)* –
  The anticipated utilization of the reserved node, as defined in the reserved node offering.
* **RecurringCharges** *(list)* –
  The recurring charges for the reserved node.
  · *(dict)* –
    Describes a recurring charge.
  · **RecurringChargeAmount** *(float)* –
    The amount charged per the period of time specified by the recurring charge frequency.
  · **RecurringChargeFrequency** *(string)* –
    The frequency at which the recurring charge amount is applied.

**reboot_cluster(** **kwargs**
Reboots a cluster. This action is taken as soon as possible. It results in a momentary outage to the cluster, during which the cluster status is set to rebooting. A cluster event is created when the reboot is completed. Any pending cluster modifications (see ModifyCluster) are applied at this reboot. For more information about managing clusters, go to Amazon Redshift Clusters in the Amazon Redshift Cluster Management Guide.
Request Syntax

```python
response = client.reboot_cluster(
    ClusterIdentifier='string'
)
```

Parameters

**ClusterIdentifier** *(string)* – [REQUIRED]

The cluster identifier.

Return type: dict

Returns

Response Syntax

```json
{
    'Cluster': {
        'ClusterIdentifier': 'string',
        'NodeType': 'string',
        'ClusterStatus': 'string',

```
Describes a cluster.

* **ClusterIdentifier** *(string)* –
  The unique identifier of the cluster.

* **NodeType** *(string)* –
  The node type for the nodes in the cluster.

* **ClusterStatus** *(string)* –
  The current state of this cluster. Possible values include `available`, `creating`, `deleting`, `rebooting`, `renaming`, and `resizing`.

* **ModifyStatus** *(string)* –
  The status of a modify operation, if any, initiated for the cluster.

* **MasterUsername** *(string)* –
  The master user name for the cluster. This name is used to connect to the database that is specified in **DBName**.

* **DBName** *(string)* –
  The name of the initial database that was created when the cluster was created. This same name is returned for the life of the cluster. If an initial database was not specified, a database named “dev” was created by default.

* **Endpoint** *(dict)* –
  The connection endpoint.
  · **Address** *(string)* –
    The DNS address of the Cluster.
  · **Port** *(integer)* –
    The port that the database engine is listening on.

* **ClusterCreateTime** *(datetime)* –
  The date and time that the cluster was created.

* **AutomatedSnapshotRetentionPeriod** *(integer)* –
  The number of days that automatic cluster snapshots are retained.

* **ClusterSecurityGroups** *(list)* –
  A list of cluster security group that are associated with the cluster. Each security group is represented by an element that contains **ClusterSecurityGroupName** and **Status** subelements.

Cluster security groups are used when the cluster is not created in a VPC. Clusters that are created in a VPC use VPC security groups, which are listed by the **VpcSecurityGroups** parameter.

* **VpcSecurityGroups** *(list)* –
A list of Virtual Private Cloud (VPC) security groups that are associated with the cluster. This parameter is returned only if the cluster is in a VPC.

- (dict) –
  Describes the members of a VPC security group.
  - `VpcSecurityGroupId` (string) –
  - `Status` (string) –

* `ClusterParameterGroups` (list) –

The list of cluster parameter groups that are associated with this cluster. Each parameter group in the list is returned with its status.

- (dict) –
  Describes the status of a parameter group.
  - `ParameterGroupName` (string) –
  - `ParameterApplyStatus` (string) –
    - The status of parameter updates.
  - `ClusterParameterStatusList` (list) –
    - The list of parameter statuses.

For more information about parameters and parameter groups, go to Amazon Redshift Parameter Groups in the Amazon Redshift Cluster Management Guide.

- (dict) –
  Describes the status of a parameter group.
  - `ParameterName` (string) –
    - The name of the parameter.
  - `ParameterApplyStatus` (string) –
    - The status of the parameter that indicates whether the parameter is in sync with the database, waiting for a cluster reboot, or encountered an error when being applied.

The following are possible statuses and descriptions.

- `in-sync`: The parameter value is in sync with the database.
- `pending-reboot`: The parameter value will be applied after the cluster reboots.
- `applying`: The parameter value is being applied to the database.
- `invalid-parameter`: Cannot apply the parameter value because it has an invalid value or syntax.
- `apply-deferred`: The parameter contains static property changes. The changes are deferred until the cluster reboots.
- `apply-error`: Cannot connect to the cluster. The parameter change will be applied after the cluster reboots.
- `unknown-error`: Cannot apply the parameter change right now. The change will be applied after the cluster reboots.

- `ParameterApplyErrorDescription` (string) –
  - The error that prevented the parameter from being applied to the database.
ClusterSubnetGroupName (string) –  
The name of the subnet group that is associated with the cluster.  
This parameter is valid only when the cluster is in a VPC.

VpcId (string) –  
The identifier of the VPC the cluster is in, if the cluster is in a VPC.

AvailabilityZone (string) –  
The name of the Availability Zone in which the cluster is located.

PreferredMaintenanceWindow (string) –  
The weekly time range (in UTC) during which system maintenance 
can occur.

PendingModifiedValues (dict) –  
If present, changes to the cluster are pending. Specific pending 
changes are identified by subelements.
  · MasterUserPassword (string) –  
    The pending or in-progress change of the master user pass-
    word for the cluster.
  · NodeType (string) –  
    The pending or in-progress change of the cluster’s node type.
  · NumberOfNodes (integer) –  
    The pending or in-progress change of the number of nodes in 
    the cluster.
  · ClusterType (string) –  
    The pending or in-progress change of the cluster type.
  · ClusterVersion (string) –  
    The pending or in-progress change of the service version.
  · AutomatedSnapshotRetentionPeriod (integer) –  
    The pending or in-progress change of the automated snapshot 
    retention period.
  · ClusterIdentifier (string) –  
    The pending or in-progress change of the new identifier for 
    the cluster.

ClusterVersion (string) –  
The version ID of the Amazon Redshift engine that is running on 
the cluster.

AllowVersionUpgrade (boolean) –  
If true, major version upgrades will be applied automatically to 
the cluster during the maintenance window.

NumberOfNodes (integer) –  
The number of compute nodes in the cluster.

PubliclyAccessible (boolean) –  
If true, the cluster can be accessed from a public network.

Encrypted (boolean) –  
If true, data in the cluster is encrypted at rest.

RestoreStatus (dict) –
Describes the status of a cluster restore action. Returns null if the cluster was not created by restoring a snapshot.

- **Status (string)** –

  The status of the restore action. Returns starting, restoring, completed, or failed.

- **CurrentRestoreRateInMegabytesPerSecond (float)** –

  The number of megabytes per second being transferred from the backup storage. Returns the average rate for a completed backup.

- **SnapshotSizeInMegabytes (integer)** –

  The size of the set of snapshot data used to restore the cluster.

- **ProgressInMegabytes (integer)** –

  The number of megabytes that have been transferred from snapshot storage.

- **ElapsedTimeInSeconds (integer)** –

  The amount of time an in-progress restore has been running, or the amount of time it took a completed restore to finish.

- **EstimatedTimeToCompletionInSeconds (integer)** –

  The estimate of the time remaining before the restore will complete. Returns 0 for a completed restore.

* **HsmStatus (dict)** –

  Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.

  Values: active, applying

  - **HsmClientCertificateIdentifier (string)** –

    Specifies the name of the HSM client certificate the Amazon Redshift cluster uses to retrieve the data encryption keys stored in an HSM.

  - **HsmConfigurationIdentifier (string)** –

    Specifies the name of the HSM configuration that contains the information the Amazon Redshift cluster can use to retrieve and store keys in an HSM.

  - **Status (string)** –

    Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.

    Values: active, applying

* **ClusterSnapshotCopyStatus (dict)** –

  Returns the destination region and retention period that are configured for cross-region snapshot copy.

  - **DestinationRegion (string)** –

    The destination region that snapshots are automatically copied to when cross-region snapshot copy is enabled.

  - **RetentionPeriod (integer)** –

    The number of days that automated snapshots are retained in the destination region after they are copied from a source region.
region.

- **SnapshotCopyGrantName (string)** –
  The name of the snapshot copy grant.

- **ClusterPublicKey (string)** –
  The public key for the cluster.

- **ClusterNodes (list)** –
  The nodes in a cluster.
  - **(dict)** –
    The identifier of a node in a cluster.
  - **NodeRole (string)** –
    Whether the node is a leader node or a compute node.
  - **PrivateIPAddress (string)** –
    The private IP address of a node within a cluster.
  - **PublicIPAddress (string)** –
    The public IP address of a node within a cluster.

- **ElasticIpStatus (dict)** –
  Describes the status of the elastic IP (EIP) address.
  - **ElasticIp (string)** –
    The elastic IP (EIP) address for the cluster.
  - **Status (string)** –
    Describes the status of the elastic IP (EIP) address.

- **ClusterRevisionNumber (string)** –
  The specific revision number of the database in the cluster.

- **Tags (list)** –
  The list of tags for the cluster.
  - **(dict)** –
    A tag consisting of a name/value pair for a resource.
  - **Key (string)** –
    The key, or name, for the resource tag.
  - **Value (string)** –
    The value for the resource tag.

- **KmsKeyId (string)** –
  The AWS Key Management Service (KMS) key ID of the encryption key used to encrypt data in the cluster.

**reset_cluster_parameter_group(**kwargs)**

Sets one or more parameters of the specified parameter group to their default values and sets the source values of the parameters to “engine-default”. To reset the entire parameter group specify the `ResetAllParameters` parameter. For parameter changes to take effect you must reboot any associated clusters.

**Request Syntax**

```python
response = client.reset_cluster_parameter_group(
    ParameterGroupName='string',
    ResetAllParameters=True|False,
    Parameters=[
        {
```
Parameters

- **ParameterGroupName** *(string)* – [REQUIRED]
  The name of the cluster parameter group to be reset.

- **ResetAllParameters** *(boolean)* – If `true`, all parameters in the specified parameter group will be reset to their default values.
  
  Default: `true`

- **Parameters** *(list)* – An array of names of parameters to be reset. If `ResetAllParameters` option is not used, then at least one parameter name must be supplied.
  
  Constraints: A maximum of 20 parameters can be reset in a single request.

  - *(dict)* –
    
    Describes a parameter in a cluster parameter group.
    
    - **ParameterName** *(string)* –
      The name of the parameter.
    
    - **ParameterValue** *(string)* –
      The value of the parameter.
    
    - **Description** *(string)* –
      A description of the parameter.
    
    - **Source** *(string)* –
      The source of the parameter value, such as “engine-default” or “user”.
    
    - **DataType** *(string)* –
      The data type of the parameter.
    
    - **AllowedValues** *(string)* –
      The valid range of values for the parameter.
    
    - **ApplyType** *(string)* –
      Specifies how to apply the parameter. Supported value: `static`.
    
    - **IsModifiable** *(boolean)* –
      If `true`, the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.
    
    - **MinimumEngineVersion** *(string)* –
      The earliest engine version to which the parameter can apply.

Return type  `dict`

Returns

Response Syntax
Response Structure

- (dict) –
  Contains the output from the ModifyClusterParameterGroup and ResetClusterParameterGroup actions and indicate the parameter group involved and the status of the operation on the parameter group.

  - ParameterGroupName (string) –
    The name of the cluster parameter group.

  - ParameterGroupStatus (string) –
    The status of the parameter group. For example, if you made a change to a parameter group name-value pair, then the change could be pending a reboot of an associated cluster.

restore_from_cluster_snapshot(**kwargs)

Creates a new cluster from a snapshot. By default, Amazon Redshift creates the resulting cluster with the same configuration as the original cluster from which the snapshot was created, except that the new cluster is created with the default cluster security and parameter groups. After Amazon Redshift creates the cluster, you can use the ModifyCluster API to associate a different security group and different parameter group with the restored cluster. If you are using a DS node type, you can also choose to change to another DS node type of the same size during restore.

If you restore a cluster into a VPC, you must provide a cluster subnet group where you want the cluster restored.

For more information about working with snapshots, go to Amazon Redshift Snapshots in the Amazon Redshift Cluster Management Guide.

Request Syntax

```python
response = client.restore_from_cluster_snapshot(
    ClusterIdentifier='string',
    SnapshotIdentifier='string',
    SnapshotClusterIdentifier='string',
    Port=123,
    AvailabilityZone='string',
    AllowVersionUpgrade=True|False,
    ClusterSubnetGroupName='string',
    PubliclyAccessible=True|False,
    OwnerAccount='string',
    HsmClientCertificateIdentifier='string',
    HsmConfigurationIdentifier='string',
    ElasticIp='string',
    ClusterParameterGroupName='string',
    ClusterSecurityGroups=[
        'string',
    ],
    VpcSecurityGroupIds=[
        'string',
    ],
    PreferredMaintenanceWindow='string',
    AutomatedSnapshotRetentionPeriod=123,
    KmsKeyId='string',
)```
Parameters

- **ClusterIdentifier** *(string)* – [REQUIRED]
  
  The identifier of the cluster that will be created from restoring the snapshot.
  
  Constraints:
  - Must contain from 1 to 63 alphanumeric characters or hyphens.
  - Alphabetic characters must be lowercase.
  - First character must be a letter.
  - Cannot end with a hyphen or contain two consecutive hyphens.
  - Must be unique for all clusters within an AWS account.

- **SnapshotIdentifier** *(string)* – [REQUIRED]
  
  The name of the snapshot from which to create the new cluster. This parameter isn’t case sensitive.
  
  Example: `my-snapshot-id`

- **SnapshotClusterIdentifier** *(string)* – The name of the cluster the source snapshot was created from. This parameter is required if your IAM user has a policy containing a snapshot resource element that specifies anything other than * for the cluster name.

- **Port** *(integer)* – The port number on which the cluster accepts connections.
  
  Default: The same port as the original cluster.
  
  Constraints: Must be between 1115 and 65535.

- **AvailabilityZone** *(string)* – The Amazon EC2 Availability Zone in which to restore the cluster.
  
  Default: A random, system-chosen Availability Zone.
  
  Example: `us-east-1a`

- **AllowVersionUpgrade** *(boolean)* – If `true`, major version upgrades can be applied during the maintenance window to the Amazon Redshift engine that is running on the cluster.
  
  Default: `true`

- **ClusterSubnetGroupName** *(string)* – The name of the subnet group where you want to cluster restored.
  
  A snapshot of cluster in VPC can be restored only in VPC. Therefore, you must provide subnet group name where you want the cluster restored.

- **PubliclyAccessible** *(boolean)* – If `true`, the cluster can be accessed from a public network.

- **OwnerAccount** *(string)* – The AWS customer account used to create or copy the snapshot. Required if you are restoring a snapshot you do not own, optional if you own the snapshot.

- **HsmClientCertificateIdentifier** *(string)* – Specifies the name of the HSM client certificate the Amazon Redshift cluster uses to retrieve the data encryption keys stored in an HSM.

- **HsmConfigurationIdentifier** *(string)* – Specifies the name of the HSM configuration that contains the information the Amazon Redshift cluster can use to retrieve and store keys in an HSM.

- **ElasticIp** *(string)* – The elastic IP (EIP) address for the cluster.

- **ClusterParameterGroupName** *(string)* – The name of the parameter group to be associated with this cluster.
Default: The default Amazon Redshift cluster parameter group. For information about the default parameter group, go to Working with Amazon Redshift Parameter Groups.

Constraints:
- Must be 1 to 255 alphanumeric characters or hyphens.
- First character must be a letter.
- Cannot end with a hyphen or contain two consecutive hyphens.

• **ClusterSecurityGroups** *(list)* – A list of security groups to be associated with this cluster.

Default: The default cluster security group for Amazon Redshift.

Cluster security groups only apply to clusters outside of VPCs.

  – *(string)*

• **VpcSecurityGroupIds** *(list)* – A list of Virtual Private Cloud (VPC) security groups to be associated with the cluster.

Default: The default VPC security group is associated with the cluster.

VPC security groups only apply to clusters in VPCs.

  – *(string)*

• **PreferredMaintenanceWindow** *(string)* – The weekly time range (in UTC) during which automated cluster maintenance can occur.

Default: The value selected for the cluster from which the snapshot was taken. For more information about the time blocks for each region, see Maintenance Windows in Amazon Redshift Cluster Management Guide.

Valid Days: Mon | Tue | Wed | Thu | Fri | Sat | Sun

Constraints: Minimum 30-minute window.

• **AutomatedSnapshotRetentionPeriod** *(integer)* – The number of days that automated snapshots are retained. If the value is 0, automated snapshots are disabled. Even if automated snapshots are disabled, you can still create manual snapshots when you want with CreateClusterSnapshot.

Default: The value selected for the cluster from which the snapshot was taken.

Constraints: Must be a value from 0 to 35.

• **KmsKeyId** *(string)* – The AWS Key Management Service (KMS) key ID of the encryption key that you want to use to encrypt data in the cluster that you restore from a shared snapshot.

• **NodeType** *(string)* – The node type that the restored cluster will be provisioned with.

Default: The node type of the cluster from which the snapshot was taken. You can modify this if you are using any DS node type. In that case, you can choose to restore into another DS node type of the same size. For example, you can restore `ds1.8xlarge` into `ds2.8xlarge`, or `ds2.xlarge` into `ds1.xlarge`. If you have a DC instance type, you must restore into that same instance type and size. In other words, you can only restore a `dc1.large` instance type into another `dc1.large` instance type. For more information about node types, see About Clusters and Nodes in the Amazon Redshift Cluster Management Guide.

Return type: **dict**

Response Structure

- (dict) – Describes a cluster.
  - Cluster (dict) – Describes a cluster.
    - ClusterIdentifier (string) – The unique identifier of the cluster.
    - NodeType (string) – The node type for the nodes in the cluster.
    - ClusterStatus (string) – The current state of this cluster. Possible values include available, creating, deleting, rebooting, renaming, and resizing.
    - ModifyStatus (string) –
The status of a modify operation, if any, initiated for the cluster.

* **MasterUsername** *(string)* –
  The master user name for the cluster. This name is used to connect to the database that is specified in **DBName**.

* **DBName** *(string)* –
  The name of the initial database that was created when the cluster was created. This same name is returned for the life of the cluster. If an initial database was not specified, a database named “dev” was created by default.

* **Endpoint** *(dict)* –
  The connection endpoint.
  - **Address** *(string)* –
    The DNS address of the Cluster.
  - **Port** *(integer)* –
    The port that the database engine is listening on.

* **ClusterCreateTime** *(datetime)* –
  The date and time that the cluster was created.

* **AutomatedSnapshotRetentionPeriod** *(integer)* –
  The number of days that automatic cluster snapshots are retained.

* **ClusterSecurityGroups** *(list)* –
  A list of cluster security group that are associated with the cluster. Each security group is represented by an element that contains **ClusterSecurityGroupName** and **ClusterSecurityGroup.Status** subelements.

Cluster security groups are used when the cluster is not created in a VPC. Clusters that are created in a VPC use VPC security groups, which are listed by the **VpcSecurityGroups** parameter.

- *(dict)* –
  Describes a security group.
  - **ClusterSecurityGroupName** *(string)* –
    The name of the cluster security group.
  - **Status** *(string)* –
    The status of the cluster security group.

* **VpcSecurityGroups** *(list)* –
  A list of Virtual Private Cloud (VPC) security groups that are associated with the cluster. This parameter is returned only if the cluster is in a VPC.

- *(dict)* –
  Describes the members of a VPC security group.
  - **VpcSecurityGroupId** *(string)* –
  - **Status** *(string)* –

* **ClusterParameterGroups** *(list)* –
  The list of cluster parameter groups that are associated with this cluster. Each parameter group in the list is returned with its status.

- *(dict)* –
  Describes the status of a parameter group.
ParameterGroupName (string) –

The name of the cluster parameter group.

ParameterApplyStatus (string) –

The status of parameter updates.

ClusterParameterStatusList (list) –

The list of parameter statuses.

For more information about parameters and parameter groups, go to Amazon Redshift Parameter Groups in the Amazon Redshift Cluster Management Guide.

(dict) –

Describes the status of a parameter group.

ParameterName (string) –

The name of the parameter.

ParameterApplyStatus (string) –

The status of the parameter that indicates whether the parameter is in sync with the database, waiting for a cluster reboot, or encountered an error when being applied.

The following are possible statuses and descriptions.

- in-sync: The parameter value is in sync with the database.
- pending-reboot: The parameter value will be applied after the cluster reboots.
- applying: The parameter value is being applied to the database.
- invalid-parameter: Cannot apply the parameter value because it has an invalid value or syntax.
- apply-deferred: The parameter contains static property changes. The changes are deferred until the cluster reboots.
- apply-error: Cannot connect to the cluster. The parameter change will be applied after the cluster reboots.
- unknown-error: Cannot apply the parameter change right now. The change will be applied after the cluster reboots.

ParameterApplyErrorDescription (string) –

The error that prevented the parameter from being applied to the database.

* ClusterSubnetGroupName (string) –

The name of the subnet group that is associated with the cluster. This parameter is valid only when the cluster is in a VPC.

* VpcId (string) –

The identifier of the VPC the cluster is in, if the cluster is in a VPC.

* AvailabilityZone (string) –

The name of the Availability Zone in which the cluster is located.

* PreferredMaintenanceWindow (string) –

The weekly time range (in UTC) during which system maintenance can occur.

* PendingModifiedValues (dict) –
If present, changes to the cluster are pending. Specific pending changes are identified by subelements.

- **MasterUserPassword** *(string)* –
  The pending or in-progress change of the master user password for the cluster.

- **NodeType** *(string)* –
  The pending or in-progress change of the cluster’s node type.

- **NumberOfNodes** *(integer)* –
  The pending or in-progress change of the number of nodes in the cluster.

- **ClusterType** *(string)* –
  The pending or in-progress change of the cluster type.

- **ClusterVersion** *(string)* –
  The pending or in-progress change of the service version.

- **AutomatedSnapshotRetentionPeriod** *(integer)* –
  The pending or in-progress change of the automated snapshot retention period.

- **ClusterIdentifier** *(string)* –
  The pending or in-progress change of the new identifier for the cluster.

- **ClusterVersion** *(string)* –
  The version ID of the Amazon Redshift engine that is running on the cluster.

- **AllowVersionUpgrade** *(boolean)* –
  If true, major version upgrades will be applied automatically to the cluster during the maintenance window.

- **NumberOfNodes** *(integer)* –
  The number of compute nodes in the cluster.

- **PubliclyAccessible** *(boolean)* –
  If true, the cluster can be accessed from a public network.

- **Encrypted** *(boolean)* –
  If true, data in the cluster is encrypted at rest.

- **RestoreStatus** *(dict)* –
  Describes the status of a cluster restore action. Returns null if the cluster was not created by restoring a snapshot.

  - **Status** *(string)* –
    The status of the restore action. Returns starting, restoring, completed, or failed.

  - **CurrentRestoreRateInMegaBytesPerSecond** *(float)* –
    The number of megabytes per second being transferred from the backup storage. Returns the average rate for a completed backup.

  - **SnapshotSizeInMegaBytes** *(integer)* –
    The size of the set of snapshot data used to restore the cluster.

  - **ProgressInMegaBytes** *(integer)* –
The number of megabytes that have been transferred from snapshot storage.

- **ElapsedTimeInSeconds (integer)** –
  
  The amount of time an in-progress restore has been running, or the amount of time it took a completed restore to finish.

- **EstimatedTimeToCompletionInSeconds (integer)** –
  
  The estimate of the time remaining before the restore will complete. Returns 0 for a completed restore.

* **HsmStatus (dict)** –

  Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.

  Values: active, applying

  - **HsmClientCertificateIdentifier (string)** –
    
    Specifies the name of the HSM client certificate the Amazon Redshift cluster uses to retrieve the data encryption keys stored in an HSM.

  - **HsmConfigurationIdentifier (string)** –
    
    Specifies the name of the HSM configuration that contains the information the Amazon Redshift cluster can use to retrieve and store keys in an HSM.

  - **Status (string)** –
    
    Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.

    Values: active, applying

* **ClusterSnapshotCopyStatus (dict)** –

  Returns the destination region and retention period that are configured for cross-region snapshot copy.

  - **DestinationRegion (string)** –
    
    The destination region that snapshots are automatically copied to when cross-region snapshot copy is enabled.

  - **RetentionPeriod (integer)** –
    
    The number of days that automated snapshots are retained in the destination region after they are copied from a source region.

  - **SnapshotCopyGrantName (string)** –
    
    The name of the snapshot copy grant.

* **ClusterPublicKey (string)** –

  The public key for the cluster.

* **ClusterNodes (list)** –

  The nodes in a cluster.

  - **(dict)** –
    
    The identifier of a node in a cluster.

  - **NodeRole (string)** –
    
    Whether the node is a leader node or a compute node.
- **PrivateIPAddress** *(string)* –
  The private IP address of a node within a cluster.

- **PublicIPAddress** *(string)* –
  The public IP address of a node within a cluster.

- **ElasticIpStatus** *(dict)* –
  Describes the status of the elastic IP (EIP) address.
  - **ElasticIp** *(string)* –
    The elastic IP (EIP) address for the cluster.
  - **Status** *(string)* –
    Describes the status of the elastic IP (EIP) address.

- **ClusterRevisionNumber** *(string)* –
  The specific revision number of the database in the cluster.

- **Tags** *(list)* –
  The list of tags for the cluster.
  - **(dict)** –
    A tag consisting of a name/value pair for a resource.
  - **Key** *(string)* –
    The key, or name, for the resource tag.
  - **Value** *(string)* –
    The value for the resource tag.

- **KmsKeyId** *(string)* –
  The AWS Key Management Service (KMS) key ID of the encryption key used to encrypt data in the cluster.

```python
revoke_cluster_security_group_ingress(**kwargs)
```

Revoke an ingress rule in an Amazon Redshift security group for a previously authorized IP range or Amazon EC2 security group. To add an ingress rule, see `AuthorizeClusterSecurityGroupIngress`. For information about managing security groups, go to Amazon Redshift Cluster Security Groups in the Amazon Redshift Cluster Management Guide.

**Request Syntax**

```python
response = client.revoke_cluster_security_group_ingress(
    ClusterSecurityGroupName='string',
    CIDRIP='string',
    EC2SecurityGroupName='string',
    EC2SecurityGroupOwnerId='string'
)
```

**Parameters**

- **ClusterSecurityGroupName** *(string)* – [REQUIRED]
  The name of the security Group from which to revoke the ingress rule.

- **CIDRIP** *(string)* – The IP range for which to revoke access. This range must be a valid Classless Inter-Domain Routing (CIDR) block of IP addresses. If CIDRIP is specified, EC2SecurityGroupName and EC2SecurityGroupOwnerId cannot be provided.

- **EC2SecurityGroupName** *(string)* – The name of the EC2 Security Group whose access is to be revoked. If EC2SecurityGroupName is specified,
EC2SecurityGroupOwnerId must also be provided and CIDRIP cannot be provided.

- **EC2SecurityGroupOwnerId** *(string)* – The AWS account number of the owner of the security group specified in the EC2SecurityGroupName parameter. The AWS access key ID is not an acceptable value. If EC2SecurityGroupOwnerId is specified, EC2SecurityGroupName must also be provided, and CIDRIP cannot be provided.

Example: 111122223333

**Return type**  *dict*

**Returns**

**Response Syntax**

```python
{
    'ClusterSecurityGroup': {
        'ClusterSecurityGroupName': 'string',
        'Description': 'string',
        'EC2SecurityGroups': [
            {
                'Status': 'string',
                'EC2SecurityGroupName': 'string',
                'EC2SecurityGroupOwnerId': 'string',
                'Tags': [
                    {
                        'Key': 'string',
                        'Value': 'string'
                    }
                ]
            }
        ],
        'IPRanges': [
            {
                'Status': 'string',
                'CIDRIP': 'string',
                'Tags': [
                    {
                        'Key': 'string',
                        'Value': 'string'
                    }
                ]
            }
        ],
        'Tags': [
            {
                'Key': 'string',
                'Value': 'string'
            }
        ]
    }
}
```

**Response Structure**

- *(dict)* – Describes a security group.
  - **ClusterSecurityGroup** *(dict)* – Describes a security group.
* **ClusterSecurityGroupName** *(string)* —
  The name of the cluster security group to which the operation was applied.

* **Description** *(string)* —
  A description of the security group.

* **EC2SecurityGroups** *(list)* —
  A list of EC2 security groups that are permitted to access clusters associated with this cluster security group.
  
  · *(dict)* —
    * **Status** *(string)* —
      The status of the EC2 security group.
    
    · **EC2SecurityGroupName** *(string)* —
      The name of the EC2 Security Group.
    
    · **EC2SecurityGroupOwnerId** *(string)* —
      The AWS ID of the owner of the EC2 security group specified in the **EC2SecurityGroupName** field.
    
    · **Tags** *(list)* —
      The list of tags for the EC2 security group.
      
      · *(dict)* —
        * **Key** *(string)* —
          The key, or name, for the resource tag.
        
        · **Value** *(string)* —
          The value for the resource tag.

* **IPRanges** *(list)* —
  A list of IP ranges (CIDR blocks) that are permitted to access clusters associated with this cluster security group.
  
  · *(dict)* —
    * **Status** *(string)* —
      The status of the IP range, for example, “authorized”.
    
    · **CIDRIP** *(string)* —
      The IP range in Classless Inter-Domain Routing (CIDR) notation.
    
    · **Tags** *(list)* —
      The list of tags for the IP range.
      
      · *(dict)* —
        * **Key** *(string)* —
          The key, or name, for the resource tag.
        
        · **Value** *(string)* —
          The value for the resource tag.
* Tags (list) –
  The list of tags for the cluster security group.
  
  * (dict) –
    A tag consisting of a name/value pair for a resource.
    
    * Key (string) –
      The key, or name, for the resource tag.
    
    * Value (string) –
      The value for the resource tag.

revoke_snapshot_access (**kwargs)
Removes the ability of the specified AWS customer account to restore the specified snapshot. If the
to Amazon Redshift Snapshots in the Amazon
account is currently restoring the snapshot, the restore will run to completion.

For more information about working with snapshots, go to Amazon Redshift Snapshots in the Amazon
Redshift Cluster Management Guide .

Request Syntax

```python
response = client.revoke_snapshot_access(
    SnapshotIdentifier='string',
    SnapshotClusterIdentifier='string',
    AccountWithRestoreAccess='string'
)
```

Parameters

- **SnapshotIdentifier (string)** – [REQUIRED]
  The identifier of the snapshot that the account can no longer access.

- **SnapshotClusterIdentifier (string)** – The identifier of the cluster the snapshot
  was created from. This parameter is required if your IAM user has a policy
  containing a snapshot resource element that specifies anything other than * for
  the cluster name.

- **AccountWithRestoreAccess (string)** – [REQUIRED]
  The identifier of the AWS customer account that can no longer restore the spec-
  ified snapshot.

Return type  dict

Returns

Response Syntax

```json
{
    'Snapshot': {
        'SnapshotIdentifier': 'string',
        'ClusterIdentifier': 'string',
        'SnapshotCreateTime': datetime(2015, 1, 1),
        'Status': 'string',
        'Port': 123,
        'AvailabilityZone': 'string',
        'ClusterCreateTime': datetime(2015, 1, 1),
        'MasterUsername': 'string',
        'ClusterVersion': 'string',
        'SnapshotType': 'string',
        'NodeType': 'string',
        'NumberOfNodes': 123,
        'DBName': 'string',
```
'VpcId': 'string',
'Encrypted': True|False,
'KmsKeyId': 'string',
'EncryptedWithHSM': True|False,
'AccountsWithRestoreAccess': [
    {'AccountId': 'string'},
],
'OwnerAccount': 'string',
'TotalBackupSizeInMegaBytes': 123.0,
'ActualIncrementalBackupSizeInMegaBytes': 123.0,
'BackupProgressInMegaBytes': 123.0,
'CurrentBackupRateInMegaBytesPerSecond': 123.0,
'EstimatedSecondsToCompletion': 123,
'ElapsedTimeInSeconds': 123,
'SourceRegion': 'string',
'Tags': [
    {'Key': 'string',
     'Value': 'string'
    },
],
'RestorablesNodeTypes': [
    'string'
]
}

Response Structure

- (dict) –
  
  Describes a snapshot.

  - **Snapshot (dict)** –
    
    Describes a snapshot.

    1. **SnapshotIdentifier (string)** –
      
      The snapshot identifier that is provided in the request.

    2. **ClusterIdentifier (string)** –
      
      The identifier of the cluster for which the snapshot was taken.

    3. **SnapshotCreateTime (datatime)** –
      
      The time (UTC) when Amazon Redshift began the snapshot. A snapshot contains a copy of the cluster data as of this exact time.

    4. **Status (string)** –
      
      The snapshot status. The value of the status depends on the API operation used.
      
      - CreateClusterSnapshot and CopyClusterSnapshot returns status as “creating”.
      - DescribeClusterSnapshots returns status as “creating”, “available”, “final snapshot”, or “failed”.
      - DeleteClusterSnapshot returns status as “deleted”.

    5. **Port (integer)** –
      
      The port that the cluster is listening on.

    6. **AvailabilityZone (string)** –
* **ClusterCreateTime** *(datetime)* –
  The time (UTC) when the cluster was originally created.

* **MasterUsername** *(string)* –
  The master user name for the cluster.

* **ClusterVersion** *(string)* –
  The version ID of the Amazon Redshift engine that is running on the cluster.

* **SnapshotType** *(string)* –
  The snapshot type. Snapshots created using `CreateClusterSnapshot` and `CopyClusterSnapshot` will be of type “manual”.

* **NodeType** *(string)* –
  The node type of the nodes in the cluster.

* **NumberOfNodes** *(integer)* –
  The number of nodes in the cluster.

* **DBName** *(string)* –
  The name of the database that was created when the cluster was created.

* **VpcId** *(string)* –
  The VPC identifier of the cluster if the snapshot is from a cluster in a VPC. Otherwise, this field is not in the output.

* **Encrypted** *(boolean)* –
  If `true`, the data in the snapshot is encrypted at rest.

* **KmsKeyId** *(string)* –
  The AWS Key Management Service (KMS) key ID of the encryption key that was used to encrypt data in the cluster from which the snapshot was taken.

* **EncryptedWithHSM** *(boolean)* –
  A boolean that indicates whether the snapshot data is encrypted using the HSM keys of the source cluster. `true` indicates that the data is encrypted using HSM keys.

* **AccountsWithRestoreAccess** *(list)* –
  A list of the AWS customer accounts authorized to restore the snapshot. Returns `null` if no accounts are authorized. Visible only to the snapshot owner.

  · **(dict)** –
    Describes an AWS customer account authorized to restore a snapshot.

    · **AccountId** *(string)* –
      The identifier of an AWS customer account authorized to restore a snapshot.

* **OwnerAccount** *(string)* –
  For manual snapshots, the AWS customer account used to create or copy the snapshot. For automatic snapshots, the owner of the cluster. The owner can perform all snapshot actions, such as sharing a manual snapshot.
* **TotalBackupSizeInMegaBytes** *(float)* –
  The size of the complete set of backup data that would be used to restore the cluster.

* **ActualIncrementalBackupSizeInMegaBytes** *(float)* –
  The size of the incremental backup.

* **BackupProgressInMegaBytes** *(float)* –
  The number of megabytes that have been transferred to the snapshot backup.

* **CurrentBackupRateInMegaBytesPerSecond** *(float)* –
  The number of megabytes per second being transferred to the snapshot backup. Returns 0 for a completed backup.

* **EstimatedSecondsToCompletion** *(integer)* –
  The estimate of the time remaining before the snapshot backup will complete. Returns 0 for a completed backup.

* **ElapsedTimeInSeconds** *(integer)* –
  The amount of time an in-progress snapshot backup has been running, or the amount of time it took a completed backup to finish.

* **SourceRegion** *(string)* –
  The source region from which the snapshot was copied.

* **Tags** *(list)* –
  The list of tags for the cluster snapshot.
  · *(dict)* –
    A tag consisting of a name/value pair for a resource.
    · **Key** *(string)* –
      The key, or name, for the resource tag.
    · **Value** *(string)* –
      The value for the resource tag.

* **RestorableNodeTypes** *(list)* –
  The list of node types that this cluster snapshot is able to restore into.
  · *(string)* –

rotate_encryption_key(**kwargs)**
Rotates the encryption keys for a cluster.

**Request Syntax**

```python
response = client.rotate_encryption_key(
    ClusterIdentifier='string'
)
```

**Parameters**

**ClusterIdentifier** *(string)* – [REQUIRED]
The unique identifier of the cluster that you want to rotate the encryption keys for.

Constraints: Must be the name of valid cluster that has encryption enabled.

**Return type** `dict`

**Returns**

**Response Syntax**
Response Structure

- (dict) –
  Describes a cluster.
  - Cluster (dict) –
    Describes a cluster.
    * ClusterIdentifier (string) –
      The unique identifier of the cluster.
    * NodeType (string) –
      The node type for the nodes in the cluster.
    * ClusterStatus (string) –
      The current state of this cluster. Possible values include available, creating, deleting, rebooting, renaming, and resizing.
    * ModifyStatus (string) –
The status of a modify operation, if any, initiated for the cluster.

* **MasterUsername** *(string)* –

The master user name for the cluster. This name is used to connect to the database that is specified in **DBName**.

* **DBName** *(string)* –

The name of the initial database that was created when the cluster was created. This same name is returned for the life of the cluster. If an initial database was not specified, a database named “dev” was created by default.

* **Endpoint** *(dict)* –

The connection endpoint.

  - **Address** *(string)* –

    The DNS address of the Cluster.

  - **Port** *(integer)* –

    The port that the database engine is listening on.

* **ClusterCreateTime** *(datetime)* –

The date and time that the cluster was created.

* **AutomatedSnapshotRetentionPeriod** *(integer)* –

The number of days that automatic cluster snapshots are retained.

* **ClusterSecurityGroups** *(list)* –

A list of cluster security group that are associated with the cluster. Each security group is represented by an element that contains `ClusterSecurityGroup.Name` and `ClusterSecurityGroup.Status` subelements.

Cluster security groups are used when the cluster is not created in a VPC. Clusters that are created in a VPC use VPC security groups, which are listed by the **VpcSecurityGroups** parameter.

  - *(dict)* –

    Describes a security group.

    - **ClusterSecurityGroupName** *(string)* –

      The name of the cluster security group.

    - **Status** *(string)* –

      The status of the cluster security group.

* **VpcSecurityGroups** *(list)* –

A list of Virtual Private Cloud (VPC) security groups that are associated with the cluster. This parameter is returned only if the cluster is in a VPC.

  - *(dict)* –

    Describes the members of a VPC security group.

    - **VpcSecurityGroupId** *(string)* –

    - **Status** *(string)* –

* **ClusterParameterGroups** *(list)* –

The list of cluster parameter groups that are associated with this cluster. Each parameter group in the list is returned with its status.

  - *(dict)* –

    Describes the status of a parameter group.
· **ParameterGroupName** *(string)* –
  The name of the cluster parameter group.
· **ParameterApplyStatus** *(string)* –
  The status of parameter updates.
· **ClusterParameterStatusList** *(list)* –
  The list of parameter statuses.

For more information about parameters and parameter groups, go to Amazon Redshift Parameter Groups in the Amazon Redshift Cluster Management Guide.
· *(dict)* –
  Describes the status of a parameter group.
· **ParameterName** *(string)* –
  The name of the parameter.
· **ParameterApplyStatus** *(string)* –
  The status of the parameter that indicates whether the parameter is in sync with the database, waiting for a cluster reboot, or encountered an error when being applied.

The following are possible statuses and descriptions.
· **in-sync**: The parameter value is in sync with the database.
· **pending-reboot**: The parameter value will be applied after the cluster reboots.
· **applying**: The parameter value is being applied to the database.
· **invalid-parameter**: Cannot apply the parameter value because it has an invalid value or syntax.
· **apply-deferred**: The parameter contains static property changes. The changes are deferred until the cluster reboots.
· **apply-error**: Cannot connect to the cluster. The parameter change will be applied after the cluster reboots.
· **unknown-error**: Cannot apply the parameter change right now. The change will be applied after the cluster reboots.
· **ParameterApplyErrorDescription** *(string)* –
  The error that prevented the parameter from being applied to the database.

* **ClusterSubnetGroupName** *(string)* –
  The name of the subnet group that is associated with the cluster. This parameter is valid only when the cluster is in a VPC.
* **VpcId** *(string)* –
  The identifier of the VPC the cluster is in, if the cluster is in a VPC.
* **AvailabilityZone** *(string)* –
  The name of the Availability Zone in which the cluster is located.
* **PreferredMaintenanceWindow** *(string)* –
  The weekly time range (in UTC) during which system maintenance can occur.
* **PendingModifiedValues** *(dict)* –
If present, changes to the cluster are pending. Specific pending changes are identified by subelements.

- **MasterUserPassword (string)** –
  The pending or in-progress change of the master user password for the cluster.

- **NodeType (string)** –
  The pending or in-progress change of the cluster's node type.

- **NumberOfNodes (integer)** –
  The pending or in-progress change of the number of nodes in the cluster.

- **ClusterType (string)** –
  The pending or in-progress change of the cluster type.

- **ClusterVersion (string)** –
  The pending or in-progress change of the service version.

- **AutomatedSnapshotRetentionPeriod (integer)** –
  The pending or in-progress change of the automated snapshot retention period.

- **ClusterIdentifier (string)** –
  The pending or in-progress change of the new identifier for the cluster.

- **ClusterVersion (string)** –
  The version ID of the Amazon Redshift engine that is running on the cluster.

- **AllowVersionUpgrade (boolean)** –
  If `true`, major version upgrades will be applied automatically to the cluster during the maintenance window.

- **NumberOfNodes (integer)** –
  The number of compute nodes in the cluster.

- **PubliclyAccessible (boolean)** –
  If `true`, the cluster can be accessed from a public network.

- **Encrypted (boolean)** –
  If `true`, data in the cluster is encrypted at rest.

- **RestoreStatus (dict)** –
  Describes the status of a cluster restore action. Returns null if the cluster was not created by restoring a snapshot.
  - **Status (string)** –
    The status of the restore action. Returns starting, restoring, completed, or failed.
  - **CurrentRestoreRateInMegabytesPerSecond (float)** –
    The number of megabytes per second being transferred from the backup storage. Returns the average rate for a completed backup.
  - **SnapshotSizeInMegabytes (integer)** –
    The size of the set of snapshot data used to restore the cluster.
  - **ProgressInMegabytes (integer)** –
The number of megabytes that have been transferred from snapshot storage.

- **ElapsedTimeInSeconds (integer)** –

  The amount of time an in-progress restore has been running, or the amount of time it took a completed restore to finish.

- **EstimatedTimeToCompletionInSeconds (integer)** –

  The estimate of the time remaining before the restore will complete. Returns 0 for a completed restore.

* **HsmStatus (dict)** –

  Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.

  Values: active, applying

  - **HsmClientCertificateIdentifier (string)** –

    Specifies the name of the HSM client certificate the Amazon Redshift cluster uses to retrieve the data encryption keys stored in an HSM.

  - **HsmConfigurationIdentifier (string)** –

    Specifies the name of the HSM configuration that contains the information the Amazon Redshift cluster can use to retrieve and store keys in an HSM.

  - **Status (string)** –

    Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.

    Values: active, applying

* **ClusterSnapshotCopyStatus (dict)** –

  Returns the destination region and retention period that are configured for cross-region snapshot copy.

  - **DestinationRegion (string)** –

    The destination region that snapshots are automatically copied to when cross-region snapshot copy is enabled.

  - **RetentionPeriod (integer)** –

    The number of days that automated snapshots are retained in the destination region after they are copied from a source region.

  - **SnapshotCopyGrantName (string)** –

    The name of the snapshot copy grant.

* **ClusterPublicKey (string)** –

  The public key for the cluster.

* **ClusterNodes (list)** –

  The nodes in a cluster.

  - **(dict)** –

    The identifier of a node in a cluster.

  - **NodeRole (string)** –

    Whether the node is a leader node or a compute node.
- **PrivateIPAddress** *(string)* – The private IP address of a node within a cluster.
- **PublicIPAddress** *(string)* – The public IP address of a node within a cluster.

* **ElasticIpStatus** *(dict)* – Describes the status of the elastic IP (EIP) address.
  - **ElasticIp** *(string)* – The elastic IP (EIP) address for the cluster.
  - **Status** *(string)* – Describes the status of the elastic IP (EIP) address.

* **ClusterRevisionNumber** *(string)* – The specific revision number of the database in the cluster.

* **Tags** *(list)* – The list of tags for the cluster.
  - *(dict)* – A tag consisting of a name/value pair for a resource.
    - **Key** *(string)* – The key, or name, for the resource tag.
    - **Value** *(string)* – The value for the resource tag.

* **KmsKeyId** *(string)* – The AWS Key Management Service (KMS) key ID of the encryption key used to encrypt data in the cluster.

**Paginators**

The available paginators are:

- `Redshift.Paginator.DescribeClusterParameterGroups`
- `Redshift.Paginator.DescribeClusterParameters`
- `Redshift.Paginator.DescribeClusterSecurityGroups`
- `Redshift.Paginator.DescribeClusterSnapshots`
- `Redshift.Paginator.DescribeClusterSubnetGroups`
- `Redshift.Paginator.DescribeClusterVersions`
- `Redshift.Paginator.DescribeClusters`
- `Redshift.Paginator.DescribeDefaultClusterParameters`
- `Redshift.Paginator.DescribeEventSubscriptions`
- `Redshift.Paginator.DescribeEvents`
- `Redshift.Paginator.DescribeHsmClientCertificates`
- `Redshift.Paginator.DescribeHsmConfigurations`
- `Redshift.Paginator.DescribeOrderableClusterOptions`
class Redshift.Paginator.DescribeClusterParameterGroups

paginator = client.get_paginator('describe_cluster_parameter_groups')

paginate(**kwargs)

Creates an iterator that will paginate through responses from
Redshift.Client.describe_cluster_parameter_groups().

Request Syntax

response_iterator = paginator.paginate(
    ParameterGroupName='string',
    TagKeys=[
        'string',
    ],
    TagValues=[
        'string',
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **ParameterGroupName** (string) – The name of a specific parameter group for which to return details. By default, details about all parameter groups and the default parameter group are returned.

- **TagKeys** (list) – A tag key or keys for which you want to return all matching cluster parameter groups that are associated with the specified key or keys. For example, suppose that you have parameter groups that are tagged with keys called owner and environment. If you specify both of these tag keys in the request, Amazon Redshift returns a response with the parameter groups that have either or both of these tag keys associated with them.

  - (string)

- **TagValues** (list) – A tag value or values for which you want to return all matching cluster parameter groups that are associated with the specified tag value or values. For example, suppose that you have parameter groups that are tagged with values called admin and test. If you specify both of these tag values in the request, Amazon Redshift returns a response with the parameter groups that have either or both of these tag values associated with them.

  - (string)

- **PaginationConfig** (dict) – A dictionary that provides parameters to control pagination.

  - **MaxItems** (integer) –

    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

  - **PageSize** (integer) –

    The size of each page.
– **StartingToken** (*string*) –

A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'ParameterGroups': [
        {
            'ParameterGroupName': 'string',
            'ParameterGroupFamily': 'string',
            'Description': 'string',
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                }
            ],
        },
    ],
    'NextToken': 'string'
}
```

**Response Structure**

* (dict) –

Contains the output from the `DescribeClusterParameterGroups` action.

– **ParameterGroups** (*list*) –

A list of `ClusterParameterGroup` instances. Each instance describes one cluster parameter group.

* (dict) –

Describes a parameter group.

  * **ParameterGroupName** (*string*) –

    The name of the cluster parameter group.

  * **ParameterGroupFamily** (*string*) –

    The name of the cluster parameter group family that this cluster parameter group is compatible with.

  * **Description** (*string*) –

    The description of the parameter group.

  * **Tags** (*list*) –

    The list of tags for the cluster parameter group.

  (dict) –

    A tag consisting of a name/value pair for a resource.

    * **Key** (*string*) –

      The key, or name, for the resource tag.

    * **Value** (*string*) –

      The value for the resource tag.

– **NextToken** (*string*) –

A token to resume pagination.
class Redshift.Paginator.DescribeClusterParameters

paginator = client.get_paginator('describe_cluster_parameters')

paginate(**kwargs)

Creates an iterator that will paginate through responses from Redshift.Client.describe_cluster_parameters().

Request Syntax

response_iterator = paginator.paginate(
    ParameterGroupName='string',
    Source='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

• **ParameterGroupName** *(string) – [REQUIRED]*
  The name of a cluster parameter group for which to return details.

• **Source** *(string) –* The parameter types to return. Specify *user* to show parameters that are different from the default. Similarly, specify *engine-default* to show parameters that are the same as the default parameter group.
  Default: All parameter types returned.
  Valid Values: *user* | *engine-default*

• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  – **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a *NextToken* will be provided in the output that you can use to resume pagination.

  – **PageSize** *(integer)* –
    The size of each page.

  – **StartingToken** *(string)* –
    A token to specify where to start pagination. This is the *NextToken* from a previous response.

Return type  dict

Returns

Response Syntax

```json
{
    'Parameters': [
        {
            'ParameterName': 'string',
            'ParameterValue': 'string',
            'Description': 'string',
            'Source': 'string',
            'DataType': 'string',
        }
    ]
}
```
'AllowedValues': 'string',
'ApplyType': 'static'|'dynamic',
'IsModifiable': True|False,
'MinimumEngineVersion': 'string'
},
],
'NextToken': 'string'
}

Response Structure

- **(dict)** –

  Contains the output from the DescribeClusterParameters action.

  - **Parameters**(list) –

    A list of Parameter instances. Each instance lists the parameters of one
    cluster parameter group.

    - *(dict)* –

      Describes a parameter in a cluster parameter group.

      - **ParameterName**(string) –

        The name of the parameter.

      - **ParameterValue**(string) –

        The value of the parameter.

      - **Description**(string) –

        A description of the parameter.

      - **Source**(string) –

        The source of the parameter value, such as “engine-default”
        or “user”.

      - **DataType**(string) –

        The data type of the parameter.

      - **AllowedValues**(string) –

        The valid range of values for the parameter.

      - **ApplyType**(string) –

        Specifies how to apply the parameter. Supported value: static.

      - **IsModifiable**(boolean) –

        If true, the parameter can be modified. Some parameters
        have security or operational implications that prevent them
        from being changed.

      - **MinimumEngineVersion**(string) –

        The earliest engine version to which the parameter can apply.

  - **NextToken**(string) –

    A token to resume pagination.

class Redshift.Paginator.DescribeClusterSecurityGroups

    paginator = client.get_paginator('describe_cluster_security_groups')
paginate(**kwargs)

Creates an iterator that will paginate through responses from
Redshift.Client.describe_cluster_security_groups().

Request Syntax

```python
response_iterator = paginator.paginate(
    ClusterSecurityGroupName='string',
    TagKeys=[
        'string',
    ],
    TagValues=[
        'string',
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **ClusterSecurityGroupName** *(string)* — The name of a cluster security group for
  which you are requesting details. You can specify either the `Marker`
  parameter or a `ClusterSecurityGroupName` parameter, but not both.
  Example: `securitygroup1`

- **TagKeys** *(list)* — A tag key or keys for which you want to return all matching
  cluster security groups that are associated with the specified key or keys. For
  example, suppose that you have security groups that are tagged with keys called
  `owner` and `environment`. If you specify both of these tag keys in the request,
  Amazon Redshift returns a response with the security groups that have either or
  both of these tag keys associated with them.

  - *(string)*

- **TagValues** *(list)* — A tag value or values for which you want to return all match-
  ing cluster security groups that are associated with the specified tag value or
  values. For example, suppose that you have security groups that are tagged with
  values called `admin` and `test`. If you specify both of these tag values in the
  request, Amazon Redshift returns a response with the security groups that have
  either or both of these tag values associated with them.

  - *(string)*

- **PaginationConfig** *(dict)* — A dictionary that provides parameters to control pag-
  ination.

  - **MaxItems** *(integer)* — The total number of items to return. If the total number of
    items available is more than the value specified in max-items then a `NextToken`
    will be provided in the output that you can use to resume pagination.

  - **PageSize** *(integer)* — The size of each page.

  - **StartingToken** *(string)* — A token to specify where to start paginating. This is the `NextToken`
    from a previous response.

Return type `dict`

Returns
Response Syntax

{  
  'ClusterSecurityGroups': [  
    {  
      'ClusterSecurityGroupName': 'string',  
      'Description': 'string',  
      'EC2SecurityGroups': [  
        {  
          'Status': 'string',  
          'EC2SecurityGroupName': 'string',  
          'EC2SecurityGroupOwnerId': 'string',  
          'Tags': [  
            {  
              'Key': 'string',  
              'Value': 'string'  
            }  
          ]  
        }  
      ]  
    },  
    'IPRanges': [  
      {

        'CIDRIP': 'string',  
        'Tags': [  
          {  
            'Key': 'string',  
            'Value': 'string'  
          }  
        ]  
      }  
    ],  
    'Tags': [  
      {  
        'Key': 'string',  
        'Value': 'string'  
      }  
    ],  
    'NextToken': 'string'  
  ]

Response Structure

• (dict) –  
Contains the output from the DescribeClusterSecurityGroups action.
  
  – ClusterSecurityGroups (list) –  
  A list of ClusterSecurityGroup instances.
    
    * (dict) –  
    Describes a security group.
      
      • ClusterSecurityGroupName (string) –  
      The name of the cluster security group to which the operation was applied.
      
      • Description (string) –  
      A description of the security group.
- **EC2SecurityGroups** *(list)* –
  A list of EC2 security groups that are permitted to access clusters associated with this cluster security group.
  - *(dict)* –
    Describes an Amazon EC2 security group.
    - **Status** *(string)* –
      The status of the EC2 security group.
    - **EC2SecurityGroupName** *(string)* –
      The name of the EC2 Security Group.
    - **EC2SecurityGroupOwnerId** *(string)* –
      The AWS ID of the owner of the EC2 security group specified in the **EC2SecurityGroupName** field.
  - **Tags** *(list)* –
    The list of tags for the EC2 security group.
    - *(dict)* –
      A tag consisting of a name/value pair for a resource.
      - **Key** *(string)* –
        The key, or name, for the resource tag.
      - **Value** *(string)* –
        The value for the resource tag.
  - **IPRanges** *(list)* –
    A list of IP ranges (CIDR blocks) that are permitted to access clusters associated with this cluster security group.
    - *(dict)* –
      Describes an IP range used in a security group.
      - **Status** *(string)* –
        The status of the IP range, for example, “authorized”.
      - **CIDRIP** *(string)* –
        The IP range in Classless Inter-Domain Routing (CIDR) notation.
      - **Tags** *(list)* –
        The list of tags for the IP range.
        - *(dict)* –
          A tag consisting of a name/value pair for a resource.
          - **Key** *(string)* –
            The key, or name, for the resource tag.
          - **Value** *(string)* –
            The value for the resource tag.
      - **Tags** *(list)* –
        The list of tags for the cluster security group.
        - *(dict)* –
          A tag consisting of a name/value pair for a resource.
          - **Key** *(string)* –
            The key, or name, for the resource tag.
· **Value** (string) –
  The value for the resource tag.

· **NextToken** (string) –
  A token to resume pagination.

```python
class Redshift.Paginator.DescribeClusterSnapshots
```

```python
paginator = client.get_paginator('describe_cluster_snapshots')
paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `Redshift.Client.describe_cluster_snapshots()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    ClusterIdentifier='string',
    SnapshotIdentifier='string',
    SnapshotType='string',
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    OwnerAccount='string',
    TagKeys=['string'],
    TagValues=['string'],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **ClusterIdentifier** (string) – The identifier of the cluster for which information about snapshots is requested.
- **SnapshotIdentifier** (string) – The snapshot identifier of the snapshot about which to return information.
- **SnapshotType** (string) – The type of snapshots for which you are requesting information. By default, snapshots of all types are returned.
  Valid Values: `automated` | `manual`
- **StartTime** (datetime) – A value that requests only snapshots created at or after the specified time. The time value is specified in ISO 8601 format. For more information about ISO 8601, go to the ISO8601 Wikipedia page.
  Example: `2012-07-16T18:00:00Z`
- **EndTime** (datetime) – A time value that requests only snapshots created at or before the specified time. The time value is specified in ISO 8601 format. For more information about ISO 8601, go to the ISO8601 Wikipedia page.
  Example: `2012-07-16T18:00:00Z`
- **OwnerAccount** (string) – The AWS customer account used to create or copy the snapshot. Use this field to filter the results to snapshots owned by a particular
account. To describe snapshots you own, either specify your AWS customer account, or do not specify the parameter.

- **TagKeys** *(list)* – A tag key or keys for which you want to return all matching cluster snapshots that are associated with the specified key or keys. For example, suppose that you have snapshots that are tagged with keys called owner and environment. If you specify both of these tag keys in the request, Amazon Redshift returns a response with the snapshots that have either or both of these tag keys associated with them.
  
  - *(string)* –

- **TagValues** *(list)* – A tag value or values for which you want to return all matching cluster snapshots that are associated with the specified tag value or values. For example, suppose that you have snapshots that are tagged with values called admin and test. If you specify both of these tag values in the request, Amazon Redshift returns a response with the snapshots that have either or both of these tag values associated with them.
  
  - *(string)* –

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  - **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  
  - **PageSize** *(integer)* –
    
    The size of each page.
  
  - **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** *dict*

**Returns**

**Response Syntax**

```json

Response Structure

- (dict) –
  Contains the output from the DescribeClusterSnapshots action.
    - Snapshots (list) –
      A list of Snapshot instances.
        * (dict) –
          Describes a snapshot.
            - SnapshotIdentifier (string) –
              The snapshot identifier that is provided in the request.
            - ClusterIdentifier (string) –
              The identifier of the cluster for which the snapshot was taken.
            - SnapshotCreateTime (datetime) –
              The time (UTC) when Amazon Redshift began the snapshot.
              A snapshot contains a copy of the cluster data as of this exact time.
            - Status (string) –
              The snapshot status. The value of the status depends on the API operation used.
              - CreateClusterSnapshot and CopyClusterSnapshot returns status as “creating”.
              - DescribeClusterSnapshots returns status as “creating”, “available”, “final snapshot”, or “failed”.
              - DeleteClusterSnapshot returns status as “deleted”.
            - Port (integer) –
              The port that the cluster is listening on.
            - AvailabilityZone (string) –
The Availability Zone in which the cluster was created.

- **ClusterCreateTime** *(datetime)* –
  The time (UTC) when the cluster was originally created.

- **MasterUsername** *(string)* –
  The master user name for the cluster.

- **ClusterVersion** *(string)* –
  The version ID of the Amazon Redshift engine that is running on the cluster.

- **SnapshotType** *(string)* –
  The snapshot type. Snapshots created using CreateClusterSnapshot and CopyClusterSnapshot will be of type “manual”.

- **NodeType** *(string)* –
  The node type of the nodes in the cluster.

- **NumberOfNodes** *(integer)* –
  The number of nodes in the cluster.

- **DBName** *(string)* –
  The name of the database that was created when the cluster was created.

- **VpcId** *(string)* –
  The VPC identifier of the cluster if the snapshot is from a cluster in a VPC. Otherwise, this field is not in the output.

- **Encrypted** *(boolean)* –
  If `true`, the data in the snapshot is encrypted at rest.

- **KmsKeyId** *(string)* –
  The AWS Key Management Service (KMS) key ID of the encryption key that was used to encrypt data in the cluster from which the snapshot was taken.

- **EncryptedWithHSM** *(boolean)* –
  A boolean that indicates whether the snapshot data is encrypted using the HSM keys of the source cluster. `true` indicates that the data is encrypted using HSM keys.

- **AccountsWithRestoreAccess** *(list)* –
  A list of the AWS customer accounts authorized to restore the snapshot. Returns `null` if no accounts are authorized. Visible only to the snapshot owner.

  - *(dict)* –
    Describes an AWS customer account authorized to restore a snapshot.

    - **AccountId** *(string)* –
      The identifier of an AWS customer account authorized to restore a snapshot.

    - **OwnerAccount** *(string)* –
      For manual snapshots, the AWS customer account used to create or copy the snapshot. For automatic snapshots, the owner of the cluster. The owner can perform all snapshot actions, such as sharing a manual snapshot.
· **TotalBackupSizeInMegaBytes** *(float)* –
  The size of the complete set of backup data that would be used to restore the cluster.

· **ActualIncrementalBackupSizeInMegaBytes** *(float)* –
  The size of the incremental backup.

· **BackupProgressInMegaBytes** *(float)* –
  The number of megabytes that have been transferred to the snapshot backup.

· **CurrentBackupRateInMegaBytesPerSecond** *(float)* –
  The number of megabytes per second being transferred to the snapshot backup. Returns 0 for a completed backup.

· **EstimatedSecondsToCompletion** *(integer)* –
  The estimate of the time remaining before the snapshot backup will complete. Returns 0 for a completed backup.

· **ElapsedTimeInSeconds** *(integer)* –
  The amount of time an in-progress snapshot backup has been running, or the amount of time it took a completed backup to finish.

· **SourceRegion** *(string)* –
  The source region from which the snapshot was copied.

· **Tags** *(list)* –
  The list of tags for the cluster snapshot.

  · **(dict)** –
    A tag consisting of a name/value pair for a resource.

  · **Key** *(string)* –
    The key, or name, for the resource tag.

  · **Value** *(string)* –
    The value for the resource tag.

· **RestorableNodeTypes** *(list)* –
  The list of node types that this cluster snapshot is able to restore into.

  · **(string)** –
    A token to resume pagination.

```python
class Redshift.Paginator.DescribeClusterSubnetGroups

paginator = client.get_paginator('describe_cluster_subnet_groups')

paginate(**kwargs)

Creates an iterator that will paginate through responses from
Redshift.Client.describe_cluster_subnet_groups().

Request Syntax

response_iterator = paginator.paginate(
    ClusterSubnetGroupName='string',
)```
TagKeys=[
    'string',
],
TagValues=[
    'string',
],
PaginationConfig={
    'MaxItems': 123,
    'PageSize': 123,
    'StartingToken': 'string'
}

Parameters

- **ClusterSubnetGroupName (string)** – The name of the cluster subnet group for which information is requested.
- **TagKeys (list)** – A tag key or keys for which you want to return all matching cluster subnet groups that are associated with the specified key or keys. For example, suppose that you have subnet groups that are tagged with keys called `owner` and `environment`. If you specify both of these tag keys in the request, Amazon Redshift returns a response with the subnet groups that have either or both of these tag keys associated with them.
  - (string)
- **TagValues (list)** – A tag value or values for which you want to return all matching cluster subnet groups that are associated with the specified tag value or values. For example, suppose that you have subnet groups that are tagged with values called `admin` and `test`. If you specify both of these tag values in the request, Amazon Redshift returns a response with the subnet groups that have either or both of these tag values associated with them.
  - (string)
- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize (integer)** –
    The size of each page.
  - **StartingToken (string)** –
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

Return type  dict

Returns

Response Syntax

```json
{
    'ClusterSubnetGroups': [
        {
            'ClusterSubnetGroupName': 'string',
            'Description': 'string',
            'VpcId': 'string',
            'SubnetGroupStatus': 'string',
            'Subnets': [
```

```json
{
    'SubnetIdentifier': 'string',
    'SubnetAvailabilityZone': {
        'Name': 'string'
    },
    'SubnetStatus': 'string'
},
'Tags': [
    {
        'Key': 'string',
        'Value': 'string'
    }
],
'NextToken': 'string'
}

Response Structure

- (dict) –
  Contains the output from the DescribeClusterSubnetGroups action.

  - ClusterSubnetGroups (list) –
    A list of ClusterSubnetGroup instances.
      * (dict) –
        Describes a subnet group.
          - ClusterSubnetGroupName (string) –
            The name of the cluster subnet group.
          - Description (string) –
            The description of the cluster subnet group.
          - VpcId (string) –
            The VPC ID of the cluster subnet group.
          - SubnetGroupStatus (string) –
            The status of the cluster subnet group. Possible values are Complete, Incomplete and Invalid.
          - Subnets (list) –
            A list of the VPC Subnet elements.
              * (dict) –
                Describes a subnet.
                  - SubnetIdentifier (string) –
                    The identifier of the subnet.
                  - SubnetAvailabilityZone (dict) –
                    Describes an availability zone.
                    - Name (string) –
                      The name of the availability zone.
                  - SubnetStatus (string) –
                    The status of the subnet.
                  - Tags (list) –
```
The list of tags for the cluster subnet group.

- (dict) –
  A tag consisting of a name/value pair for a resource.
  - Key (string) –
    The key, or name, for the resource tag.
  - Value (string) –
    The value for the resource tag.

- NextToken (string) –
  A token to resume pagination.

class Redshift.Paginator.DescribeClusterVersions

    paginator = client.get_paginator('describe_cluster_versions')

    paginate (**kwargs)
        Creates an iterator that will paginate through responses from
        Redshift.Client.describe_cluster_versions().

    Parameters

        - ClusterVersion (string) – The specific cluster version to return.
          Example: 1.0

        - ClusterParameterGroupFamily (string) – The name of a specific cluster pa-
          rameter group family to return details for.

        - PaginationConfig (dict) – A dictionary that provides parameters to control pag-
          ination.

          - MaxItems (integer) –
            The total number of items to return. If the total number of items available
            is more than the value specified in max-items then a NextToken will be
            provided in the output that you can use to resume pagination.

          - PageSize (integer) –
            The size of each page.

          - StartingToken (string) –
            A token to specify where to start paginating. This is the NextToken
            from a previous response.
Return type  

dict

Returns

Response Syntax

```python
{
    'ClusterVersions': [
        {
            'ClusterVersion': 'string',
            'ClusterParameterGroupFamily': 'string',
            'Description': 'string'
        },
    ],
    'NextToken': 'string'
}
```

Response Structure

• *(dict)* –

  Contains the output from the DescribeClusterVersions action.

  – **ClusterVersions** *(list)* –

    A list of **Version** elements.

    • *(dict)* –

      Describes a cluster version, including the parameter group family and description of the version.

      • **ClusterVersion** *(string)* –

        The version number used by the cluster.

      • **ClusterParameterGroupFamily** *(string)* –

        The name of the cluster parameter group family for the cluster.

      • **Description** *(string)* –

        The description of the cluster version.

  – **NextToken** *(string)* –

    A token to resume pagination.

```python
class Redshift.Paginator.DescribeClusters

paginator = client.get_paginator('describe_clusters')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `Redshift.Client.describe_clusters()`.

Request Syntax

```python
response_iterator = paginator.paginate(
    ClusterIdentifier='string',
    TagKeys=[
        'string',
    ],
    TagValues=[
        'string',
    ],
```
PaginationConfig={
    'MaxItems': 123,
    'PageSize': 123,
    'StartingToken': 'string'
}

Parameters

- **ClusterIdentifier** *(string)* – The unique identifier of a cluster whose properties you are requesting. This parameter is case sensitive.

The default is that all clusters defined for an account are returned.

- **TagKeys** *(list)* – A tag key or keys for which you want to return all matching clusters that are associated with the specified key or keys. For example, suppose that you have clusters that are tagged with keys called *owner* and *environment*. If you specify both of these tag keys in the request, Amazon Redshift returns a response with the clusters that have either or both of these tag keys associated with them.

  - *(string)*

- **TagValues** *(list)* – A tag value or values for which you want to return all matching clusters that are associated with the specified tag value or values. For example, suppose that you have clusters that are tagged with values called *admin* and *test*. If you specify both of these tag values in the request, Amazon Redshift returns a response with the clusters that have either or both of these tag values associated with them.

  - *(string)*

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

  - **MaxItems** *(integer)* – The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

  - **PageSize** *(integer)* – The size of each page.

  - **StartingToken** *(string)* – A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict

Returns

Response Syntax

```
{
    'Clusters': [
        {
            'ClusterIdentifier': 'string',
            'NodeType': 'string',
            'ClusterStatus': 'string',
            'ModifyStatus': 'string',
            'MasterUsername': 'string',
            'DBName': 'string',
            'Endpoint': {
                'Address': 'string',
                'Port': 123
            }
```

3.1. Services
'ClusterSnapshotCopyStatus': {  'DestinationRegion': 'string',  'RetentionPeriod': 123,  'SnapshotCopyGrantName': 'string'
},
'ClusterPublicKey': 'string',
'ClusterNodes': [  {  'NodeRole': 'string',  'PrivateIPAddress': 'string',  'PublicIPAddress': 'string'
  },
],
'ElasticIpStatus': {  'ElasticIp': 'string',  'Status': 'string'
},
'ClusterRevisionNumber': 'string',
'Tags': [  {  'Key': 'string',  'Value': 'string'
  },
],
'KmsKeyId': 'string'
},
'NextToken': 'string'
}

Response Structure
* (dict) –
  Contains the output from the DescribeClusters action.
  – Clusters (list) –
    A list of Cluster objects, where each object describes one cluster.
    * (dict) –
      Describes a cluster.
      - ClusterIdentifier (string) –
        The unique identifier of the cluster.
      - NodeType (string) –
        The node type for the nodes in the cluster.
      - ClusterStatus (string) –
        The current state of this cluster. Possible values include available, creating, deleting, rebooting, renaming, and resizing.
      - ModifyStatus (string) –
        The status of a modify operation, if any, initiated for the cluster.
      - MasterUsername (string) –
        The master user name for the cluster. This name is used to connect to the database that is specified in DBName.
- **DBName** *(string)* –
  The name of the initial database that was created when the cluster was created. This same name is returned for the life of the cluster. If an initial database was not specified, a database named “dev” was created by default.

- **Endpoint** *(dict)* –
  The connection endpoint.
  - **Address** *(string)* –
  The DNS address of the Cluster.
  - **Port** *(integer)* –
  The port that the database engine is listening on.

- **ClusterCreateTime** *(datetime)* –
  The date and time that the cluster was created.

- **AutomatedSnapshotRetentionPeriod** *(integer)* –
  The number of days that automatic cluster snapshots are retained.

- **ClusterSecurityGroups** *(list)* –
  A list of cluster security group that are associated with the cluster. Each security group is represented by an element that contains `ClusterSecurityGroup.Name` and `ClusterSecurityGroup.Status` subelements.

  Cluster security groups are used when the cluster is not created in a VPC. Clusters that are created in a VPC use VPC security groups, which are listed by the `VpcSecurityGroups` parameter.

- **VpcSecurityGroups** *(list)* –
  A list of Virtual Private Cloud (VPC) security groups that are associated with the cluster. This parameter is returned only if the cluster is in a VPC.

- **ClusterParameterGroups** *(list)* –
  The list of cluster parameter groups that are associated with this cluster. Each parameter group in the list is returned with its status.
· **ParameterGroupName** *(string)* –
  The name of the cluster parameter group.

· **ParameterApplyStatus** *(string)* –
  The status of parameter updates.

· **ClusterParameterStatusList** *(list)* –
  The list of parameter statuses.

For more information about parameters and parameter groups, go to Amazon Redshift Parameter Groups in the Amazon Redshift Cluster Management Guide.

· **(dict)** –
  Describes the status of a parameter group.

· **ParameterName** *(string)* –
  The name of the parameter.

· **ParameterApplyStatus** *(string)* –
  The status of the parameter that indicates whether the parameter is in sync with the database, waiting for a cluster reboot, or encountered an error when being applied.

The following are possible statuses and descriptions.

· **in-sync**: The parameter value is in sync with the database.
· **pending-reboot**: The parameter value will be applied after the cluster reboots.
· **applying**: The parameter value is being applied to the database.
· **invalid-parameter**: Cannot apply the parameter value because it has an invalid value or syntax.
· **apply-deferred**: The parameter contains static property changes. The changes are deferred until the cluster reboots.
· **apply-error**: Cannot connect to the cluster. The parameter change will be applied after the cluster reboots.
· **unknown-error**: Cannot apply the parameter change right now. The change will be applied after the cluster reboots.

· **ParameterApplyErrorDescription** *(string)* –
  The error that prevented the parameter from being applied to the database.

· **ClusterSubnetGroupName** *(string)* –
  The name of the subnet group that is associated with the cluster. This parameter is valid only when the cluster is in a VPC.

· **VpcId** *(string)* –
  The identifier of the VPC the cluster is in, if the cluster is in a VPC.

· **AvailabilityZone** *(string)* –
  The name of the Availability Zone in which the cluster is located.

· **PreferredMaintenanceWindow** *(string)* –
  The weekly time range (in UTC) during which system maintenance can occur.
· **PendingModifiedValues** *(dict)* –
  If present, changes to the cluster are pending. Specific pending changes are identified by subelements.

· **MasterUserPassword** *(string)* –
  The pending or in-progress change of the master user password for the cluster.

· **NodeType** *(string)* –
  The pending or in-progress change of the cluster’s node type.

· **NumberOfNodes** *(integer)* –
  The pending or in-progress change of the number of nodes in the cluster.

· **ClusterType** *(string)* –
  The pending or in-progress change of the cluster type.

· **ClusterVersion** *(string)* –
  The version ID of the Amazon Redshift engine that is running on the cluster.

· **AutomatedSnapshotRetentionPeriod** *(integer)* –
  The pending or in-progress change of the automated snapshot retention period.

· **ClusterIdentifier** *(string)* –
  The pending or in-progress change of the new identifier for the cluster.

· **CurrentRestoreRateInMegaBytesPerSecond** *(float)* –
  The number of megabytes per second being transferred from the backup storage. Returns the average rate for a completed backup.

· **SnapshotSizeInMegaBytes** *(integer)* –
  The size of the set of snapshot data used to restore the cluster.
- **ProgressInMegaBytes** *(integer)* –
  The number of megabytes that have been transferred from snapshot storage.
- **ElapsedTimeInSeconds** *(integer)* –
  The amount of time an in-progress restore has been running, or the amount of time it took a completed restore to finish.
- **EstimatedTimeToCompletionInSeconds** *(integer)* –
  The estimate of the time remaining before the restore will complete. Returns 0 for a completed restore.
- **HsmStatus** *(dict)* –
  Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.
  Values: active, applying
- **HsmClientCertificateIdentifier** *(string)* –
  Specifies the name of the HSM client certificate the Amazon Redshift cluster uses to retrieve the data encryption keys stored in an HSM.
- **HsmConfigurationIdentifier** *(string)* –
  Specifies the name of the HSM configuration that contains the information the Amazon Redshift cluster can use to retrieve and store keys in an HSM.
- **Status** *(string)* –
  Reports whether the Amazon Redshift cluster has finished applying any HSM settings changes specified in a modify cluster command.
  Values: active, applying
- **ClusterSnapshotCopyStatus** *(dict)* –
  Returns the destination region and retention period that are configured for cross-region snapshot copy.
  - **DestinationRegion** *(string)* –
    The destination region that snapshots are automatically copied to when cross-region snapshot copy is enabled.
  - **RetentionPeriod** *(integer)* –
    The number of days that automated snapshots are retained in the destination region after they are copied from a source region.
- **SnapshotCopyGrantName** *(string)* –
  The name of the snapshot copy grant.
- **ClusterPublicKey** *(string)* –
  The public key for the cluster.
- **ClusterNodes** *(list)* –
  The nodes in a cluster.
  *(dict)* –
  The identifier of a node in a cluster.
- **NodeRole** *(string)* –
  Whether the node is a leader node or a compute node.
- **PrivateIPAddress** *(string)* –
  The private IP address of a node within a cluster.
- **PublicIPAddress** *(string)* –
  The public IP address of a node within a cluster.
- **ElasticIpStatus** *(dict)* –
  Describes the status of the elastic IP (EIP) address.
- **ElasticIp** *(string)* –
  The elastic IP (EIP) address for the cluster.
- **Status** *(string)* –
  Describes the status of the elastic IP (EIP) address.
- **ClusterRevisionNumber** *(string)* –
  The specific revision number of the database in the cluster.
- **Tags** *(list)* –
  The list of tags for the cluster.
  *(dict)* –
  A tag consisting of a name/value pair for a resource.
  - **Key** *(string)* –
    The key, or name, for the resource tag.
  - **Value** *(string)* –
    The value for the resource tag.
- **KmsKeyId** *(string)* –
  The AWS Key Management Service (KMS) key ID of the encryption key used to encrypt data in the cluster.
- **NextToken** *(string)* –
  A token to resume pagination.

```python
class Redshift.Paginator.DescribeDefaultClusterParameters

paginator = client.get_paginator('describe_default_cluster_parameters')

paginate(**kwargs)
    Creates an iterator that will paginate through responses from
    Redshift.Client.describe_default_cluster_parameters().

    Request Syntax

    response_iterator = paginator.paginate(
        ParameterGroupFamily='string',
        PaginationConfig={
            'MaxItems': 123,
            'PageSize': 123,
            'StartingToken': 'string'
        }
    )
```

**Parameters**
**ParameterGroupFamily** *(string)* – [REQUIRED]

The name of the cluster parameter group family.

**PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

  - **MaxItems** *(integer)* –

    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

  - **PageSize** *(integer)* –

    The size of each page.

  - **StartingToken** *(string)* –

    A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** *dict*

**Returns**

**Response Syntax**

```json
{
  'DefaultClusterParameters': {
    'ParameterGroupFamily': 'string',
    'Marker': 'string',
    'Parameters': [
      {
        'ParameterName': 'string',
        'ParameterValue': 'string',
        'Description': 'string',
        'Source': 'string',
        'DataType': 'string',
        'AllowedValues': 'string',
        'ApplyType': 'static'|'dynamic',
        'IsModifiable': True|False,
        'MinimumEngineVersion': 'string'
      }
    ],
    'NextToken': 'string'
  }
}
```

**Response Structure**

- *(dict)* –

  Describes the default cluster parameters for a parameter group family.

- **DefaultClusterParameters** *(dict)* –

  Describes the default cluster parameters for a parameter group family.

  - **ParameterGroupFamily** *(string)* –

    The name of the cluster parameter group family to which the engine default parameters apply.

  - **Marker** *(string)* –

    A value that indicates the starting point for the next set of response records in a subsequent request. If a value is returned in a response, you can retrieve the next set of records by providing this returned marker value in the Marker parameter and retrying the command.
If the `Marker` field is empty, all response records have been retrieved for the request.

* **Parameters** *(list)* –

The list of cluster default parameters.

  · *(dict)* –

    Describes a parameter in a cluster parameter group.

    · **ParameterName** *(string)* –

      The name of the parameter.

    · **ParameterValue** *(string)* –

      The value of the parameter.

    · **Description** *(string)* –

      A description of the parameter.

    · **Source** *(string)* –

      The source of the parameter value, such as “engine-default” or “user”.

    · **DataType** *(string)* –

      The data type of the parameter.

    · **AllowedValues** *(string)* –

      The valid range of values for the parameter.

    · **ApplyType** *(string)* –

      Specifies how to apply the parameter. Supported value: `static`.

    · **IsModifiable** *(boolean)* –

      If `true`, the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.

    · **MinimumEngineVersion** *(string)* –

      The earliest engine version to which the parameter can apply.

  · **NextToken** *(string)* –

    A token to resume pagination.

class Redshift.Paginator.DescribeEventSubscriptions

    paginator = client.get_paginator('describe_event_subscriptions')

    paginate(**kwargs)

    Creates an iterator that will paginate through responses from `Redshift.Client.describe_event_subscriptions()`.

    Request Syntax

        response_iterator = paginator.paginate(
            SubscriptionName='string',
            PaginationConfig={
                'MaxItems': 123,
                'PageSize': 123,
                'StartingToken': 'string'
Parameters

- **SubscriptionName** (string) – The name of the Amazon Redshift event notification subscription to be described.
- **PaginationConfig** (dict) – A dictionary that provides parameters to control pagination.
  - **MaxItems** (integer) – The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize** (integer) – The size of each page.
  - **StartingToken** (string) – A token to specify where to start paginating. This is the `NextToken` from a previous response.

Return type  dict

Returns

Response Syntax

```python
{
    'EventSubscriptionsList': [
        {
            'CustomerAwsId': 'string',
            'CustSubscriptionId': 'string',
            'SnsTopicArn': 'string',
            'Status': 'string',
            'SubscriptionCreationTime': datetime(2015, 1, 1),
            'SourceType': 'string',
            'SourceIdsList': [
                'string',
            ],
            'EventCategoriesList': [
                'string',
            ],
            'Severity': 'string',
            'Enabled': True|False,
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                },
            ],
            'NextToken': 'string'
        }
    ]
}
```

Response Structure

- *(dict)* –
  - **EventSubscriptionsList** *(list)* – A list of event subscriptions.
- **CustomerAwsId**: (string) –
  The AWS customer account associated with the Amazon Redshift event notification subscription.

- **CustSubscriptionId**: (string) –
  The name of the Amazon Redshift event notification subscription.

- **SnsTopicArn**: (string) –
  The Amazon Resource Name (ARN) of the Amazon SNS topic used by the event notification subscription.

- **Status**: (string) –
  The status of the Amazon Redshift event notification subscription.

  Constraints:
  - Can be one of the following: active | no-permission | topic-not-exist
  - The status “no-permission” indicates that Amazon Redshift no longer has permission to post to the Amazon SNS topic. The status “topic-not-exist” indicates that the topic was deleted after the subscription was created.

- **SubscriptionCreationTime**: (datetime) –
  The date and time the Amazon Redshift event notification subscription was created.

- **SourceType**: (string) –
  The source type of the events returned the Amazon Redshift event notification, such as cluster, or cluster-snapshot.

- **SourceIdsList**: (list) –
  A list of the sources that publish events to the Amazon Redshift event notification subscription.

- **EventCategoriesList**: (list) –
  The list of Amazon Redshift event categories specified in the event notification subscription.

  Values: Configuration, Management, Monitoring, Security

- **Severity**: (string) –
  The event severity specified in the Amazon Redshift event notification subscription.

  Values: ERROR, INFO

- **Enabled**: (boolean) –
  A Boolean value indicating whether the subscription is enabled. `true` indicates the subscription is enabled.

- **Tags**: (list) –
  The list of tags for the event subscription.

  A tag consisting of a name/value pair for a resource.
· **Key** *(string)* –
  The key, or name, for the resource tag.

· **Value** *(string)* –
  The value for the resource tag.

  · **NextToken** *(string)* –
    A token to resume pagination.

class Redshift.Paginator.DescribeEvents

```
paginator = client.get_paginator('describe_events')

paginate(**kwargs)

Creates an iterator that will paginate through responses from
Redshift.Client.describe_events().
```

Request Syntax

```
response_iterator = paginator.paginate(
    SourceIdentifier='string',
    SourceType='cluster'|'cluster-parameter-group'|'cluster-security-group'|'cluster-snapshot',
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    Duration=123,
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **SourceIdentifier** *(string)* – The identifier of the event source for which events will be returned. If this parameter is not specified, then all sources are included in the response.

  Constraints:

  If **SourceIdentifier** is supplied, **SourceType** must also be provided.

    · Specify a cluster identifier when **SourceType** is cluster.
    · Specify a cluster security group name when **SourceType** is cluster-security-group.
    · Specify a cluster parameter group name when **SourceType** is cluster-parameter-group.
    · Specify a cluster snapshot identifier when **SourceType** is cluster-snapshot.

- **SourceType** *(string)* – The event source to retrieve events for. If no value is specified, all events are returned.

  Constraints:

  If **SourceType** is supplied, **SourceIdentifier** must also be provided.

    · Specify cluster when **SourceIdentifier** is a cluster identifier.
    · Specify cluster-security-group when **SourceIdentifier** is a cluster security group name.
    · Specify cluster-parameter-group when **SourceIdentifier** is a cluster parameter group name.
- Specify `cluster-snapshot` when `SourceIdentifier` is a cluster snapshot identifier.

- **StartTime** *(datetime)* – The beginning of the time interval to retrieve events for, specified in ISO 8601 format. For more information about ISO 8601, go to the ISO8601 Wikipedia page.

  Example: 2009-07-08T18:00Z

- **EndTime** *(datetime)* – The end of the time interval for which to retrieve events, specified in ISO 8601 format. For more information about ISO 8601, go to the ISO8601 Wikipedia page.

  Example: 2009-07-08T18:00Z

- **Duration** *(integer)* – The number of minutes prior to the time of the request for which to retrieve events. For example, if the request is sent at 18:00 and you specify a duration of 60, then only events which have occurred after 17:00 will be returned.

  Default: 60

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

  - **MaxItems** *(integer)* –

    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.

  - **PageSize** *(integer)* –

    The size of each page.

  - **StartingToken** *(string)* –

    A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'Events': [
        {
            'SourceIdentifier': 'string',
            'SourceType': 'cluster'|'cluster-parameter-group'|'cluster-security-group'|'cluster-snapshot',
            'Message': 'string',
            'EventCategories': [
                'string',
            ],
            'Severity': 'string',
            'Date': datetime(2015, 1, 1),
            'EventId': 'string'
        },
        {
            'NextToken': 'string'
        }
    ]
}
```

**Response Structure**

- **(dict)** –

  Contains the output from the DescribeEvents action.

  - **Events** *(list)* –
A list of Event instances.

* (dict) –

Describes an event.

  - **SourceIdentifier** (string) –
    The identifier for the source of the event.
  
  - **SourceType** (string) –
    The source type for this event.
  
  - **Message** (string) –
    The text of this event.
  
  - **EventCategories** (list) –
    A list of the event categories.
    Values: Configuration, Management, Monitoring, Security
  
  - **Severity** (string) –
    The severity of the event.
    Values: ERROR, INFO
  
  - **Date** (datetime) –
    The date and time of the event.
  
  - **EventId** (string) –
    The identifier of the event.

  - **NextToken** (string) –
    A token to resume pagination.

```python
class Redshift.Paginator.DescribeHsmClientCertificates

paginator = client.get_paginator('describe_hsm_client_certificates')

paginate(**kwargs)

Creates an iterator that will paginate through responses from
Redshift.Client.describe_hsm_client_certificates().
```

**Request Syntax**

```python
response_iterator = paginator.paginate(
    HsmClientCertificateIdentifier='string',
    TagKeys=[
        'string',
    ],
    TagValues=[
        'string',
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**
• **HsmClientCertificateIdentifier** *(string)* – The identifier of a specific HSM client certificate for which you want information. If no identifier is specified, information is returned for all HSM client certificates owned by your AWS customer account.

• **TagKeys** *(list)* – A tag key or keys for which you want to return all matching HSM client certificates that are associated with the specified key or keys. For example, suppose that you have HSM client certificates that are tagged with keys called `owner` and `environment`. If you specify both of these tag keys in the request, Amazon Redshift returns a response with the HSM client certificates that have either or both of these tag keys associated with them.
  – *(string)*

• **TagValues** *(list)* – A tag value or values for which you want to return all matching HSM client certificates that are associated with the specified tag value or values. For example, suppose that you have HSM client certificates that are tagged with values called `admin` and `test`. If you specify both of these tag values in the request, Amazon Redshift returns a response with the HSM client certificates that have either or both of these tag values associated with them.
  – *(string)*

• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  – **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  – **PageSize** *(integer)* –
    The size of each page.
  – **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
  'HsmClientCertificates': [
    {
      'HsmClientCertificateIdentifier': 'string',
      'HsmClientCertificatePublicKey': 'string',
      'Tags': [
        {
          'Key': 'string',
          'Value': 'string'
        }
      ],
    },
    ...
  ],
  'NextToken': 'string'
}
```

**Response Structure**

• *(dict)* –
  – **HsmClientCertificates** *(list)* –

A list of the identifiers for one or more HSM client certificates used by
Amazon Redshift clusters to store and retrieve database encryption keys in an HSM.

*(dict)* –

Returns information about an HSM client certificate. The certificate is stored in a secure Hardware Storage Module (HSM), and used by the Amazon Redshift cluster to encrypt data files.

- **HsmClientCertificateIdentifier** *(string)* –
  
The identifier of the HSM client certificate.

- **HsmClientCertificatePublicKey** *(string)* –
  
The public key that the Amazon Redshift cluster will use to connect to the HSM. You must register the public key in the HSM.

- **Tags** *(list)* –
  
The list of tags for the HSM client certificate.

  *(dict)* –

  A tag consisting of a name/value pair for a resource.

  - **Key** *(string)* –
    
The key, or name, for the resource tag.

  - **Value** *(string)* –
    
The value for the resource tag.

- **NextToken** *(string)* –
  
A token to resume pagination.

class Redshift.Paginator.DescribeHsmConfigurations

```
paginator = client.get_paginator('describe_hsm_configurations')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `Redshift.Client.describe_hsm_configurations()`.

**Request Syntax**

```
response_iterator = paginator.paginate(
    HsmConfigurationIdentifier='string',
    TagKeys=[
        'string',
    ],
    TagValues=[
        'string',
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**
• **HsmConfigurationIdentifier** *(string)* – The identifier of a specific Amazon Redshift HSM configuration to be described. If no identifier is specified, information is returned for all HSM configurations owned by your AWS customer account.

• **TagKeys** *(list)* – A tag key or keys for which you want to return all matching HSM configurations that are associated with the specified key or keys. For example, suppose that you have HSM configurations that are tagged with keys called `owner` and `environment`. If you specify both of these tag keys in the request, Amazon Redshift returns a response with the HSM configurations that have either or both of these tag keys associated with them.

  – *(string)* –

• **TagValues** *(list)* – A tag value or values for which you want to return all matching HSM configurations that are associated with the specified tag value or values. For example, suppose that you have HSM configurations that are tagged with values called `admin` and `test`. If you specify both of these tag values in the request, Amazon Redshift returns a response with the HSM configurations that have either or both of these tag values associated with them.

  – *(string)* –

• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

  – **MaxItems** *(integer)* – The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.

  – **PageSize** *(integer)* – The size of each page.

  – **StartingToken** *(string)* – A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** *dict*

**Returns**

**Response Syntax**

```json
{
    'HsmConfigurations': [
        {
            'HsmConfigurationIdentifier': 'string',
            'Description': 'string',
            'HsmIpAddress': 'string',
            'HsmPartitionName': 'string',
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                }
            ],
        },
        'NextToken': 'string'
    }
}
```

**Response Structure**

• *(dict)* –
- **HsmConfigurations** *(list)*

  A list of Amazon Redshift HSM configurations.

  * *(dict)*

  Returns information about an HSM configuration, which is an object that describes to Amazon Redshift clusters the information they require to connect to an HSM where they can store database encryption keys.

  - **HsmConfigurationIdentifier** *(string)*

    The name of the Amazon Redshift HSM configuration.

  - **Description** *(string)*

    A text description of the HSM configuration.

  - **HsmIpAddress** *(string)*

    The IP address that the Amazon Redshift cluster must use to access the HSM.

  - **HsmPartitionName** *(string)*

    The name of the partition in the HSM where the Amazon Redshift clusters will store their database encryption keys.

  - **Tags** *(list)*

    The list of tags for the HSM configuration.

    * *(dict)*

    A tag consisting of a name/value pair for a resource.

    - **Key** *(string)*

      The key, or name, for the resource tag.

    - **Value** *(string)*

      The value for the resource tag.

- **NextToken** *(string)*

  A token to resume pagination.

```python
class Redshift.Paginator.DescribeOrderableClusterOptions

paginator = client.get_paginator('describe_orderable_cluster_options')

paginate(**kwargs)

    Creates an iterator that will paginate through responses from Redshift.Client.describe_orderable_cluster_options().

    Request Syntax

    response_iterator = paginator.paginate(
        ClusterVersion='string',
        NodeType='string',
        PaginationConfig={
            'MaxItems': 123,
            'PageSize': 123,
            'StartingToken': 'string'
        }
    )

    Parameters
```
• **ClusterVersion** *(string)* – The version filter value. Specify this parameter to show only the available offerings matching the specified version.

  Default: All versions.

  Constraints: Must be one of the version returned from DescribeClusterVersions.

• **NodeType** *(string)* – The node type filter value. Specify this parameter to show only the available offerings matching the specified node type.

• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  – **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a *NextToken* will be provided in the output that you can use to resume pagination.

  – **PageSize** *(integer)* –
    
    The size of each page.

  – **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the *NextToken* from a previous response.

**Return type**: dict

**Returns**

**Response Syntax**

```python
{
    'OrderableClusterOptions': [ 
        {
            'ClusterVersion': 'string',
            'ClusterType': 'string',
            'NodeType': 'string',
            'AvailabilityZones': [ 
                {
                    'Name': 'string'
                },
            ],
        },
    ],
    'NextToken': 'string'
}
```

**Response Structure**

• *(dict)* –

  Contains the output from the DescribeOrderableClusterOptions action.

  – **OrderableClusterOptions** *(list)* –

    An OrderableClusterOption structure containing information about orderable options for the Cluster.

    * *(dict)* –

      Describes an orderable cluster option.

      • **ClusterVersion** *(string)* –

        The version of the orderable cluster.

      • **ClusterType** *(string)* –

        The cluster type, for example *multi-node*. 
- **NodeType** *(string)* –
  The node type for the orderable cluster.
- **AvailabilityZones** *(list)* –
  A list of availability zones for the orderable cluster.
- **Name** *(string)* –
  The name of the availability zone.
- **NextToken** *(string)* –
  A token to resume pagination.

```python
class Redshift.Paginator.DescribeReservedNodeOfferings

paginator = client.get_paginator('describe_reserved_node_offerings')
paginate(**kwargs)
```

Creates an iterator that will paginate through responses from
Redshift.Client.describe_reserved_node_offerings().

### Request Syntax

```python
response_iterator = paginator.paginate(
    ReservedNodeOfferingId='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

### Parameters

- **ReservedNodeOfferingId** *(string)* – The unique identifier for the offering.
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available
    is more than the value specified in max-items then a NextToken will be
    provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –
    The size of each page.
  - **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the NextToken
    from a previous response.

### Return type  `dict`

### Response Syntax

```python
{
    'ReservedNodeOfferings': [
    ]
}
```
'ReservedNodeOfferingId': 'string',
'NodeType': 'string',
'Duration': 123,
'FixedPrice': 123.0,
'UsagePrice': 123.0,
'CurrencyCode': 'string',
'OfferingType': 'string',
'RecurringCharges': [{
    'RecurringChargeAmount': 123.0,
    'RecurringChargeFrequency': 'string'
  }],
'NextToken': 'string'
}

Response Structure

• (dict) –

Contains the output from the DescribeReservedNodeOfferings action.

  - ReservedNodeOfferings (list) –

    A list of reserved node offerings.

  • (dict) –

    Describes a reserved node offering.

      • ReservedNodeOfferingId (string) –

        The offering identifier.

      • NodeType (string) –

        The node type offered by the reserved node offering.

      • Duration (integer) –

        The duration, in seconds, for which the offering will reserve the node.

      • FixedPrice (float) –

        The upfront fixed charge you will pay to purchase the specific reserved node offering.

      • UsagePrice (float) –

        The rate you are charged for each hour the cluster that is using the offering is running.

      • CurrencyCode (string) –

        The currency code for the compute nodes offering.

      • OfferingType (string) –

        The anticipated utilization of the reserved node, as defined in the reserved node offering.

      • RecurringCharges (list) –

        The charge to your account regardless of whether you are creating any clusters using the node offering. Recurring charges are only in effect for heavy-utilization reserved nodes.

      • (dict) –

        Describes a recurring charge.
- **RecurringChargeAmount** (*float*) —
  The amount charged per the period of time specified by the recurring charge frequency.
- **RecurringChargeFrequency** (*string*) —
  The frequency at which the recurring charge amount is applied.

- **NextToken** (*string*) —
  A token to resume pagination.

```python
class Redshift.Paginator.DescribeReservedNodes

paginator = client.get_paginator('describe_reserved_nodes')

paginate(**kwargs)

Creates an iterator that will paginate through responses from Redshift.Client.describe_reserved_nodes().

**Request Syntax**

```python
response_iterator = paginator.paginate(
    ReservedNodeId='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **ReservedNodeId** (*string*) — Identifier for the node reservation.
- **PaginationConfig** (*dict*) — A dictionary that provides parameters to control pagination.
  - **MaxItems** (*integer*) —
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize** (*integer*) —
    The size of each page.
  - **StartingToken** (*string*) —
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'ReservedNodes': [
        
        'ReservedNodeId': 'string',
        'ReservedNodeOfferingId': 'string',
        'NodeType': 'string',
    ]
}
```
'StartTime': datetime(2015, 1, 1),
'Duration': 123,
'FixedPrice': 123.0,
'UsagePrice': 123.0,
'CurrencyCode': 'string',
'NodeCount': 123,
'State': 'string',
'OfferingType': 'string',
'RecurringCharges': [
  {
    'RecurringChargeAmount': 123.0,
    'RecurringChargeFrequency': 'string'
  },
  
},
],
'NextToken': 'string'

Response Structure

• (dict) –
  Contains the output from the DescribeReservedNodes action.
  
  – **ReservedNodes** (list) –
  
  The list of reserved nodes.
  * (dict) –
  
  Describes a reserved node. You can call the DescribeReservedNodeOfferings API to obtain the available reserved node offerings.
  
  • **ReservedNodeId** (string) –
  
  The unique identifier for the reservation.
  
  • **ReservedNodeOfferingId** (string) –
  
  The identifier for the reserved node offering.
  
  • **NodeType** (string) –
  
  The node type of the reserved node.
  
  • **StartTime** (datetime) –
  
  The time the reservation started. You purchase a reserved node offering for a duration. This is the start time of that duration.
  
  • **Duration** (integer) –
  
  The duration of the node reservation in seconds.
  
  • **FixedPrice** (float) –
  
  The fixed cost Amazon Redshift charges you for this reserved node.
  
  • **UsagePrice** (float) –
  
  The hourly rate Amazon Redshift charges you for this reserved node.
  
  • **CurrencyCode** (string) –
  
  The currency code for the reserved cluster.
  
  • **NodeCount** (integer) –
The number of reserved compute nodes.

- **State (string)** –

  The state of the reserved compute node.

  Possible Values:
  - pending-payment-This reserved node has recently been purchased, and the sale has been approved, but payment has not yet been confirmed.
  - active-This reserved node is owned by the caller and is available for use.
  - payment-failed-Payment failed for the purchase attempt.

- **OfferingType (string)** –

  The anticipated utilization of the reserved node, as defined in the reserved node offering.

- **RecurringCharges (list)** –

  The recurring charges for the reserved node.

  - (dict) –

    Describes a recurring charge.

    - **RecurringChargeAmount (float)** –

      The amount charged per the period of time specified by the recurring charge frequency.

    - **RecurringChargeFrequency (string)** –

      The frequency at which the recurring charge amount is applied.

- **NextToken (string)** –

  A token to resume pagination.

**Waiters**

The available waiters are:

- `Redshift.Waiter.ClusterAvailable`
- `Redshift.Waiter.ClusterDeleted`
- `Redshift.Waiter.SnapshotAvailable`

```python
class Redshift.Waiter.ClusterAvailable

waiter = client.get_waiter('cluster_available')

wait(**kwargs)

polls Redshift.Client.describe_clusters() every 60 seconds until a successful state is reached. An error is returned after 30 failed checks.

**Request Syntax**

```python
waiter.wait(
    ClusterIdentifier='string',
    MaxRecords=123,
    Marker='string',
    TagKeys=[
```
Parameters

- **ClusterIdentifier** *(string)* – The unique identifier of a cluster whose properties you are requesting. This parameter is case sensitive.

  The default is that all clusters defined for an account are returned.

- **MaxRecords** *(integer)* – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified MaxRecords value, a value is returned in the marker field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.

  Default: 100

  Constraints: minimum 20, maximum 100.

- **Marker** *(string)* – An optional parameter that specifies the starting point to return a set of response records. When the results of a DescribeClusters request exceed the value specified in MaxRecords, AWS returns a value in the Marker field of the response. You can retrieve the next set of response records by providing the returned marker value in the Marker parameter and retrying the request.

  Constraints: You can specify either the ClusterIdentifier parameter or the Marker parameter, but not both.

- **TagKeys** *(list)* – A tag key or keys for which you want to return all matching clusters that are associated with the specified key or keys. For example, suppose that you have clusters that are tagged with keys called owner and environment. If you specify both of these tag keys in the request, Amazon Redshift returns a response with the clusters that have either or both of these tag keys associated with them.

  - *(string)* –

- **TagValues** *(list)* – A tag value or values for which you want to return all matching clusters that are associated with the specified tag value or values. For example, suppose that you have clusters that are tagged with values called admin and test. If you specify both of these tag values in the request, Amazon Redshift returns a response with the clusters that have either or both of these tag values associated with them.

  - *(string)* –

Returns

None

```python
class Redshift.Waiter.ClusterDeleted

waiter = client.get_waiter('cluster_deleted')

wait(**kwargs)
```

Polls `Redshift.Client.describe_clusters()` every 60 seconds until a successful state is reached. An error is returned after 30 failed checks.

Request Syntax
waiter.wait(
    ClusterIdentifier='string',
    MaxRecords=123,
    Marker='string',
    TagKeys=[
        'string',
    ],
    TagValues=[
        'string',
    ]
)

Parameters

- **ClusterIdentifier** *(string)* – The unique identifier of a cluster whose properties you are requesting. This parameter is case sensitive.
  
The default is that all clusters defined for an account are returned.

- **MaxRecords** *(integer)* – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified `MaxRecords` value, a value is returned in a `marker` field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.
  
  Default: 100

  Constraints: minimum 20, maximum 100.

- **Marker** *(string)* – An optional parameter that specifies the starting point to return a set of response records. When the results of a DescribeClusters request exceed the value specified in `MaxRecords`, AWS returns a value in the `Marker` field of the response. You can retrieve the next set of response records by providing the returned marker value in the `Marker` parameter and retrying the request.

  Constraints: You can specify either the `ClusterIdentifier` parameter or the `Marker` parameter, but not both.

- **TagKeys** *(list)* – A tag key or keys for which you want to return all matching clusters that are associated with the specified key or keys. For example, suppose that you have clusters that are tagged with keys called `owner` and `environment`. If you specify both of these tag keys in the request, Amazon Redshift returns a response with the clusters that have either or both of these tag keys associated with them.
  
  - *(string)* –

- **TagValues** *(list)* – A tag value or values for which you want to return all matching clusters that are associated with the specified tag value or values. For example, suppose that you have clusters that are tagged with values called `admin` and `test`. If you specify both of these tag values in the request, Amazon Redshift returns a response with the clusters that have either or both of these tag values associated with them.
  
  - *(string)* –

Returns None

class Redshift.Waiter.SnapshotAvailable

```python
waiter = client.get_waiter('snapshot_available')

wait(**kwargs)
```
Polls `Redshift.Client.describe_cluster_snapshots()` every 15 seconds until a successful state is reached. An error is returned after 20 failed checks.

**Request Syntax**

```python
waiter.wait(
    ClusterIdentifier='string',
    SnapshotIdentifier='string',
    SnapshotType='string',
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    MaxRecords=123,
    Marker='string',
    OwnerAccount='string',
    TagKeys=[
        'string',
    ],
    TagValues=[
        'string',
    ]
)
```

**Parameters**

- **ClusterIdentifier** *(string)* – The identifier of the cluster for which information about snapshots is requested.
- **SnapshotIdentifier** *(string)* – The snapshot identifier of the snapshot about which to return information.
- **SnapshotType** *(string)* – The type of snapshots for which you are requesting information. By default, snapshots of all types are returned. Valid Values: `automated` | `manual`
- **StartTime** *(datetime)* – A value that requests only snapshots created at or after the specified time. The time value is specified in ISO 8601 format. For more information about ISO 8601, go to the ISO8601 Wikipedia page.
  
  Example: `2012-07-16T18:00:00Z`
- **EndTime** *(datetime)* – A time value that requests only snapshots created at or before the specified time. The time value is specified in ISO 8601 format. For more information about ISO 8601, go to the ISO8601 Wikipedia page.
  
  Example: `2012-07-16T18:00:00Z`
- **MaxRecords** *(integer)* – The maximum number of response records to return in each call. If the number of remaining response records exceeds the specified `MaxRecords` value, a value is returned in a `marker` field of the response. You can retrieve the next set of records by retrying the command with the returned marker value.
  
  Default: 100
  
  Constraints: minimum 20, maximum 100.
- **Marker** *(string)* – An optional parameter that specifies the starting point to return a set of response records. When the results of a `DescribeClusterSnapshots` request exceed the value specified in `MaxRecords`, AWS returns a value in the `Marker` field of the response. You can retrieve the next set of response records by providing the returned marker value in the `Marker` parameter and retrying the request.
- **OwnerAccount** *(string)* – The AWS customer account used to create or copy the snapshot. Use this field to filter the results to snapshots owned by a particular
account. To describe snapshots you own, either specify your AWS customer account, or do not specify the parameter.

- **TagKeys** *(list)* – A tag key or keys for which you want to return all matching cluster snapshots that are associated with the specified key or keys. For example, suppose that you have snapshots that are tagged with keys called *owner* and *environment*. If you specify both of these tag keys in the request, Amazon Redshift returns a response with the snapshots that have either or both of these tag keys associated with them.
  
  ```python
  - (string) –
  ```

- **TagValues** *(list)* – A tag value or values for which you want to return all matching cluster snapshots that are associated with the specified tag value or values. For example, suppose that you have snapshots that are tagged with values called *admin* and *test*. If you specify both of these tag values in the request, Amazon Redshift returns a response with the snapshots that have either or both of these tag values associated with them.
  
  ```python
  - (string) –
  ```

**Returns** None

## Route53

### Table of Contents
- Route53
  - Client
  - Paginators
  - Waiters

### Client

**class** `Route53.Client`  
A low-level client representing Amazon Route 53:

```python
import boto3

client = boto3.client('route53')
```

These are the available methods:

- `associate_vpc_with_hosted_zone()`  
- `can_paginate()`  
- `change_resource_record_sets()`  
- `change_tags_for_resource()`  
- `create_health_check()`  
- `create_hosted_zone()`  
- `create_reusable_delegation_set()`  
- `delete_health_check()`  
- `delete_hosted_zone()`  
- `delete_reusable_delegation_set()`  
- `disassociate_vpc_from_hosted_zone()`  
- `generate_presigned_url()`  
- `get_change()`  
- `get_checker_ip_ranges()`
associate_vpc_with_hosted_zone(**kwargs)
This action associates a VPC with an hosted zone.

To associate a VPC with an hosted zone, send a POST request to the 2013-04-01/hostedzone/*hosted zone ID*/associatevpc resource. The request body must include an XML document with an AssociateVPCWithHostedZoneRequest element. The response returns the AssociateVPCWithHostedZoneResponse element that contains ChangeInfo for you to track the progress of the AssociateVPCWithHostedZoneRequest you made. See GetChange operation for how to track the progress of your change.

Request Syntax

```python
response = client.associate_vpc_with_hosted_zone(
    HostedZoneId='string',
    VPC={
        'VPCRegion': 'us-east-1'|'us-west-1'|'us-west-2'|'eu-west-1'|'eu-central-1'|'ap-southeast-1'|'ap-southeast-2'|'ap-northeast-1'|'sa-east-1'|'cn-north-1',
        'VPCId': 'string'
    },
    Comment='string'
)
```

Parameters

- **HostedZoneId (string)** – [REQUIRED]
  
  The ID of the hosted zone you want to associate your VPC with.

  Note that you cannot associate a VPC with a hosted zone that doesn’t have an existing VPC association.

- **VPC (dict)** – [REQUIRED]
  
  The VPC that you want your hosted zone to be associated with.
  
  - **VPCRegion (string)** –
  
  - **VPCId (string)** –

  A VPC ID

- **Comment (string)** – Optional: Any comments you want to include about a AssociateVPCWithHostedZoneRequest.

Return type **dict**
Returns

Response Syntax

```python
{
    'ChangeInfo': {
        'Id': 'string',
        'Status': 'PENDING'|'INSYNC',
        'SubmittedAt': datetime(2015, 1, 1),
        'Comment': 'string'
    }
}
```

Response Structure

- (dict) –
  A complex type containing the response information for the request.
    - ChangeInfo (dict) –
      A complex type that contains the ID, the status, and the date and time of your AssociateVPCWithHostedZoneRequest.
        - Id (string) –
          The ID of the request. Use this ID to track when the change has completed across all Amazon Route 53 DNS servers.
        - Status (string) –
          The current state of the request. PENDING indicates that this request has not yet been applied to all Amazon Route 53 DNS servers.
          Valid Values: PENDING | INSYNC
        - SubmittedAt (datetime) –
          The date and time the change was submitted, in the format YYYY-MM-DDThh:mm:ssZ, as specified in the ISO 8601 standard (for example, 2009-11-19T19:37:58Z). The Z after the time indicates that the time is listed in Coordinated Universal Time (UTC), which is synonymous with Greenwich Mean Time in this context.
        - Comment (string) –
          A complex type that describes change information about changes made to your hosted zone.
          This element contains an ID that you use when performing a GetChange action to get detailed information about the change.

can_paginate (operation_name)

Check if an operation can be paginated.

Parameters operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you'd normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

Returns True if the operation can be paginated, False otherwise.

change_resource_record_sets (**kwargs)

Use this action to create or change your authoritative DNS information. To use this action, send a POST request to the 2013-04-01/hostedzone/*hosted Zone ID*/rrset resource. The request body must include an XML document with a ChangeResourceRecordSetsRequest element.
Changes are a list of change items and are considered transactional. For more information on transactional changes, also known as change batches, see Creating, Changing, and Deleting Resource Record Sets Using the Route 53 API in the Amazon Route 53 Developer Guide.

**Warning:** Due to the nature of transactional changes, you cannot delete the same resource record set more than once in a single change batch. If you attempt to delete the same change batch more than once, Route 53 returns an **InvalidChangeBatch** error.

In response to a `ChangeResourceRecordSets` request, your DNS data is changed on all Route 53 DNS servers. Initially, the status of a change is **PENDING**. This means the change has not yet propagated to all the authoritative Route 53 DNS servers. When the change is propagated to all hosts, the change returns a status of **INSYNC**.

Note the following limitations on a `ChangeResourceRecordSets` request:

- A request cannot contain more than 100 Change elements.
- A request cannot contain more than 1000 ResourceRecord elements.

The sum of the number of characters (including spaces) in all `Value` elements in a request cannot exceed 32,000 characters.

**Request Syntax**

```python
response = client.change_resource_record_sets(
    HostedZoneId='string',
    ChangeBatch={
        'Comment': 'string',
        'Changes': [
            {'Action': 'CREATE'|'DELETE'|'UPSERT',
             'ResourceRecordSet': {
                 'Name': 'string',
                 'Type': 'SOA'|'A'|'TXT'|'NS'|'CNAME'|'MX'|'PTR'|'SRV'|'SPF'|'AAAA',
                 'SetIdentifier': 'string',
                 'Weight': 123,
                 'Region': 'us-east-1'|'us-west-1'|'us-west-2'|'eu-west-1'|'eu-central-1',
                 'GeoLocation': {
                     'ContinentCode': 'string',
                     'CountryCode': 'string',
                     'SubdivisionCode': 'string'
                 },
                 'Failover': 'PRIMARY'|'SECONDARY',
                 'TTL': 123,
                 'ResourceRecords': [
                     {'Value': 'string'},
                 ],
             },
             'AliasTarget': {
                 'HostedZoneId': 'string',
                 'DNSName': 'string',
                 'EvaluateTargetHealth': True|False
             },
             'HealthCheckId': 'string'
         }
     }
)
```
Parameters

- **HostedZoneId (string)** – [REQUIRED]
  
  The ID of the hosted zone that contains the resource record sets that you want to change.

- **ChangeBatch (dict)** – [REQUIRED]
  
  A complex type that contains an optional comment and the Changes element.
  
  - **Comment (string)** –
    
    *Optional: Any comments you want to include about a change batch request.*

  - **Changes (list)** – [REQUIRED]
    
    A complex type that contains one Change element for each resource record set that you want to create or delete.
    
    * (dict) –

    A complex type that contains the information for each change in a change batch request.
    
    - **Action (string)** – [REQUIRED]
      
      The action to perform.
      
      Valid values: CREATE | DELETE | UPSERT
    
    - **ResourceRecordSet (dict)** – [REQUIRED]
      
      Information about the resource record set to create or delete.
      
      - **Name (string)** – [REQUIRED]
        
        The domain name of the current resource record set.
      
      - **Type (string)** – [REQUIRED]
        
        The type of the current resource record set.
      
      - **SetIdentifier (string)** –
        
        Weighted, Latency, Geo, and Failover resource record sets only: An identifier that differentiates among multiple resource record sets that have the same combination of DNS name and type.
      
      - **Weight (integer)** –
        
        Weighted resource record sets only: Among resource record sets that have the same combination of DNS name and type, a value that determines what portion of traffic for the current resource record set is routed to the associated location.
      
      - **Region (string)** –
        
        Latency-based resource record sets only: Among resource record sets that have the same combination of DNS name and type, a value that specifies the AWS region for the current resource record set.
      
      - **GeoLocation (dict)** –
        
        Geo location resource record sets only: Among resource record sets that have the same combination of DNS name and type, a value that specifies the geo location for the current resource record set.
      
      - **ContinentCode (string)** –
The code for a continent geo location. Note: only continent locations have a continent code.

Valid values: AF | AN | AS | EU | OC | SA

- **CountryCode (string)** –

  The code for a country geo location. The default location uses ‘*’ for the country code and will match all locations that are not matched by a geo location.

  The default geo location uses an * for the country code. All other country codes follow the ISO 3166 two-character code.

- **SubdivisionCode (string)** –

  The code for a country’s subdivision (e.g., a province of Canada). A subdivision code is only valid with the appropriate country code.

- **Failover (string)** –

  *Failover resource record sets only:* Among resource record sets that have the same combination of DNS name and type, a value that indicates whether the current resource record set is a primary or secondary resource record set. A failover set may contain at most one resource record set marked as primary and one resource record set marked as secondary. A resource record set marked as primary will be returned if any of the following are true: (1) an associated health check is passing, (2) if the resource record set is an alias with the evaluate target health and at least one target resource record set is healthy, (3) both the primary and secondary resource record set are failing health checks or (4) there is no secondary resource record set.

  A secondary resource record set will be returned if: (1) the primary is failing a health check and either the secondary is passing a health check or has no associated health check, or (2) there is no primary resource record set.

Valid values: PRIMARY | SECONDARY

- **TTL (integer)** –

  The cache time to live for the current resource record set.

- **ResourceRecords (list)** –

  A complex type that contains the resource records for the current resource record set.

- **(dict)** –

  A complex type that contains the value of the Value element for the current resource record set.

- **Value (string)** – [REQUIRED]

  The value of the Value element for the current resource record set.
- **AliasTarget** *(dict)* –
  
  *Alias resource record sets only:* Information about the AWS resource to which you are redirecting traffic.

- **HostedZoneId** *(string)* – *[REQUIRED]*

  *Alias resource record sets only:* The value of the hosted zone ID for the AWS resource.

  For more information and an example, see Creating Alias Resource Record Sets in the Amazon Route 53 Developer Guide.

- **DNSName** *(string)* – *[REQUIRED]*

  *Alias resource record sets only:* The external DNS name associated with the AWS Resource.

  For more information and an example, see Creating Alias Resource Record Sets in the Amazon Route 53 Developer Guide.

- **EvaluateTargetHealth** *(boolean)* – *[REQUIRED]*

  *Alias resource record sets only:* A boolean value that indicates whether this Resource Record Set should respect the health status of any health checks associated with the ALIAS target record which it is linked to.

  For more information and an example, see Creating Alias Resource Record Sets in the Amazon Route 53 Developer Guide.

- **HealthCheckId** *(string)* –

  *Health Check resource record sets only, not required for alias resource record sets:* An identifier that is used to identify health check associated with the resource record set.

Return type  dict

Returns

Response Syntax

```json
{
  'ChangeInfo': {
    'Id': 'string',
    'Status': 'PENDING'|'INSYNC',
    'SubmittedAt': datetime(2015, 1, 1),
    'Comment': 'string'
  }
}
```

Response Structure

- *(dict)* –

  A complex type containing the response for the request.

  - **ChangeInfo** *(dict)* –

    A complex type that contains information about changes made to your hosted zone.
This element contains an ID that you use when performing a GetChange action to get detailed information about the change.

* **Id (string)** –
  
The ID of the request. Use this ID to track when the change has completed across all Amazon Route 53 DNS servers.

* **Status (string)** –
  
The current state of the request. **PENDING** indicates that this request has not yet been applied to all Amazon Route 53 DNS servers.

  **Valid Values:** **PENDING** | **INSYNC**

* **SubmittedAt (datetime)** –
  
The date and time the change was submitted, in the format **YYYY-MM-DDThh:mm:ssZ**, as specified in the ISO 8601 standard (for example, 2009-11-19T19:37:58Z). The **Z** after the time indicates that the time is listed in Coordinated Universal Time (UTC), which is synonymous with Greenwich Mean Time in this context.

* **Comment (string)** –
  
  A complex type that describes change information about changes made to your hosted zone.

  This element contains an ID that you use when performing a GetChange action to get detailed information about the change.

**change_tags_for_resource (**kwargs**)**

**Request Syntax**

```python
response = client.change_tags_for_resource(
    ResourceType='healthcheck'|'hostedzone',
    ResourceId='string',
    AddTags=[
        {'Key': 'string', 'Value': 'string'},
    ],
    RemoveTagKeys=['string'],
)
```

**Parameters**

- **ResourceType (string) – [REQUIRED]**
  
  The type of the resource.
  
  - The resource type for health checks is **healthcheck**.
  
  - The resource type for hosted zones is **hostedzone**.

- **ResourceId (string) – [REQUIRED]**
  
  The ID of the resource for which you want to add, change, or delete tags.

- **AddTags (list)** – A complex type that contains a list of Tag elements. Each Tag element identifies a tag that you want to add or update for the specified resource.
  
  - (dict) –
  
    A single tag containing a key and value.
  
    - **Key (string)** –
  
      The key for a Tag.
* Value (string) –

  The value for a Tag.

• RemoveTagKeys (list) – A list of Tag keys that you want to remove from the specified resource.
  – (string) –

Return type: dict

Returns:

Response Syntax

{}  

Response Structure

• (dict) –

Empty response for the request.

create_health_check (**kwargs)

This action creates a new health check.

To create a new health check, send a POST request to the 2013-04-01/healthcheck resource. The request body must include an XML document with a CreateHealthCheckRequest element. The response returns the CreateHealthCheckResponse element that contains metadata about the health check.

Request Syntax

```python
response = client.create_health_check(
    CallerReference='string',
    HealthCheckConfig={
        'IPAddress': 'string',
        'Port': 123,
        'Type': 'HTTP'|'HTTPS'|'HTTP_STR_MATCH'|'HTTPS_STR_MATCH'|'TCP'|'CALCULATED',
        'ResourcePath': 'string',
        'FullyQualifiedDomainName': 'string',
        'SearchString': 'string',
        'RequestInterval': 123,
        'FailureThreshold': 123,
        'MeasureLatency': True|False,
        'Inverted': True|False,
        'HealthThreshold': 123,
        'ChildHealthChecks': [
            'string',
        ]
    }
)
```

Parameters:

• CallerReference (string) – [REQUIRED]

  A unique string that identifies the request and that allows failed CreateHealthCheck requests to be retried without the risk of executing the operation twice. You must use a unique CallerReference string every time you create a health check. CallerReference can be any unique string; you might choose to use a string that identifies your project.

  Valid characters are any Unicode code points that are legal in an XML 1.0 document. The UTF-8 encoding of the value must be less than 128 bytes.
• **HealthCheckConfig** *(dict)* – [REQUIRED]

A complex type that contains health check configuration.

  - **IPAddress** *(string)* –

    IP Address of the instance being checked.

  - **Port** *(integer)* –

    Port on which connection will be opened to the instance to health check. For HTTP and HTTP_STR_MATCH this defaults to 80 if the port is not specified. For HTTPS and HTTPS_STR_MATCH this defaults to 443 if the port is not specified.

  - **Type** *(string)* – [REQUIRED]

    The type of health check to be performed. Currently supported types are TCP, HTTP, HTTPS, HTTP_STR_MATCH, and HTTPS_STR_MATCH.

  - **ResourcePath** *(string)* –

    Path to ping on the instance to check the health. Required for HTTP, HTTPS, HTTP_STR_MATCH, and HTTPS_STR_MATCH health checks, HTTP request is issued to the instance on the given port and path.

  - **FullyQualifiedDomainName** *(string)* –

    Fully qualified domain name of the instance to be health checked.

  - **SearchString** *(string)* –

    A string to search for in the body of a health check response. Required for HTTP_STR_MATCH and HTTPS_STR_MATCH health checks.

  - **RequestInterval** *(integer)* –

    The number of seconds between the time that Route 53 gets a response from your endpoint and the time that it sends the next health-check request. Each Route 53 health checker makes requests at this interval. Valid values are 10 and 30. The default value is 30.

  - **FailureThreshold** *(integer)* –

    The number of consecutive health checks that an endpoint must pass or fail for Route 53 to change the current status of the endpoint from unhealthy to healthy or vice versa. Valid values are integers between 1 and 10. For more information, see “How Amazon Route 53 Determines Whether an Endpoint Is Healthy” in the Amazon Route 53 Developer Guide.

  - **MeasureLatency** *(boolean)* –

    A Boolean value that indicates whether you want Route 53 to measure the latency between health checkers in multiple AWS regions and your endpoint and to display CloudWatch latency graphs in the Route 53 console.

  - **Inverted** *(boolean)* –

    A boolean value that indicates whether the status of health check should be inverted. For example, if a health check is healthy but Inverted is `True`, then Route 53 considers the health check to be unhealthy.

  - **HealthThreshold** *(integer)* –

    The minimum number of child health checks that must be healthy for Route 53 to consider the parent health check to be healthy. Valid values are integers between 0 and 256, inclusive.

  - **ChildHealthChecks** *(list)* –
For a specified parent health check, a list of HealthCheckId values for
the associated child health checks.

* (string) –

Returns

**Response Syntax**

```json
{
    'HealthCheck': {
        'Id': 'string',
        'CallerReference': 'string',
        'HealthCheckConfig': {
            'IPAddress': 'string',
            'Port': 123,
            'Type': 'HTTP'|'HTTPS'|'HTTP_STR_MATCH'|'HTTPS_STR_MATCH'|'TCP'|'CALCULATED',
            'ResourcePath': 'string',
            'FullyQualifiedDomainName': 'string',
            'SearchString': 'string',
            'RequestInterval': 123,
            'FailureThreshold': 123,
            'MeasureLatency': True|False,
            'Inverted': True|False,
            'HealthThreshold': 123,
            'ChildHealthChecks': [
                'string',
            ],
        },
        'HealthCheckVersion': 123
    },
    'Location': 'string'
}
```

**Response Structure**

- (dict) –

  A complex type containing the response information for the new health check.

  - **HealthCheck** (dict) –

    A complex type that contains identifying information about the health check.

    - Id (string) –

      The ID of the specified health check.

    - CallerReference (string) –

      A unique string that identifies the request to create the health check.

    - HealthCheckConfig (dict) –

      A complex type that contains the health check configuration.

      · IPAddress (string) –

        IP Address of the instance being checked.

      · Port (integer) –

        Port on which connection will be opened to the instance to health check. For HTTP and HTTP_STR_MATCH this defaults to 80 if the port is not specified. For HTTPS and HTTPS_STR_MATCH this defaults to 443 if the port is not specified.
· **Type** *(string)* –
  
The type of health check to be performed. Currently supported types are TCP, HTTP, HTTPS, HTTP_STR_MATCH, and HTTPS_STR_MATCH.

· **ResourcePath** *(string)* –
  
  Path to ping on the instance to check the health. Required for HTTP, HTTPS, HTTP_STR_MATCH, and HTTPS_STR_MATCH health checks. HTTP request is issued to the instance on the given port and path.

· **FullyQualifiedDomainName** *(string)* –
  
  Fully qualified domain name of the instance to be health checked.

· **SearchString** *(string)* –
  
  A string to search for in the body of a health check response. Required for HTTP_STR_MATCH and HTTPS_STR_MATCH health checks.

· **RequestInterval** *(integer)* –
  
  The number of seconds between the time that Route 53 gets a response from your endpoint and the time that it sends the next health-check request.

  Each Route 53 health checker makes requests at this interval. Valid values are 10 and 30. The default value is 30.

· **FailureThreshold** *(integer)* –
  
  The number of consecutive health checks that an endpoint must pass or fail for Route 53 to change the current status of the endpoint from unhealthy to healthy or vice versa.

  Valid values are integers between 1 and 10. For more information, see “How Amazon Route 53 Determines Whether an Endpoint Is Healthy” in the Amazon Route 53 Developer Guide.

· **MeasureLatency** *(boolean)* –
  
  A Boolean value that indicates whether you want Route 53 to measure the latency between health checkers in multiple AWS regions and your endpoint and to display CloudWatch latency graphs in the Route 53 console.

· **Inverted** *(boolean)* –
  
  A boolean value that indicates whether the status of health check should be inverted. For example, if a health check is healthy but **Inverted** is **True**, then Route 53 considers the health check to be unhealthy.

· **HealthThreshold** *(integer)* –
  
  The minimum number of child health checks that must be healthy for Route 53 to consider the parent health check to be healthy. Valid values are integers between 0 and 256, inclusive.

· **ChildHealthChecks** *(list)* –
  
  For a specified parent health check, a list of HealthCheckId values for the associated child health checks.
checks.

- (string) –
  * HealthCheckVersion (integer) –
    The version of the health check. You can optionally pass this value in a call to UpdateHealthCheck to prevent overwriting another change to the health check.

- Location (string) –
  The unique URL representing the new health check.

create_hosted_zone(**kwargs)

This action creates a new hosted zone.

To create a new hosted zone, send a POST request to the 2013-04-01/hostedzone resource. The request body must include an XML document with a CreateHostedZoneRequest element. The response returns the CreateHostedZoneResponse element that contains metadata about the hosted zone.

Route 53 automatically creates a default SOA record and four NS records for the zone. The NS records in the hosted zone are the name servers you give your registrar to delegate your domain to. For more information about SOA and NS records, see NS and SOA Records that Route 53 Creates for a Hosted Zone in the Amazon Route 53 Developer Guide.

When you create a zone, its initial status is PENDING. This means that it is not yet available on all DNS servers. The status of the zone changes to INSYNC when the NS and SOA records are available on all Route 53 DNS servers.

When trying to create a hosted zone using a reusable delegation set, you could specify an optional DelegationSetId, and Route53 would assign those 4 NS records for the zone, instead of allotting a new one.

Request Syntax

response = client.create_hosted_zone(
    Name='string',
    VPC={
        'VPCRegion': 'us-east-1'|'us-west-1'|'us-west-2'|'eu-west-1'|'eu-central-1'|'ap-southeast-1'|'ap-southeast-2'|'ap-northeast-1'|'sa-east-1'|'cn-north-1',
        'VPCId': 'string'
    },
    CallerReference='string',
    HostedZoneConfig={
        'Comment': 'string',
        'PrivateZone': True|False
    },
    DelegationSetId='string'
)

Parameters

- Name (string) – [REQUIRED]
  The name of the domain. This must be a fully-specified domain, for example, www.example.com. The trailing dot is optional; Route 53 assumes that the domain name is fully qualified. This means that Route 53 treats www.example.com (without a trailing dot) and www.example.com. (with a trailing dot) as identical.

  This is the name you have registered with your DNS registrar. You should ask your registrar to change the authoritative name servers for your domain to the set of NameServers elements returned in DelegationSet.
• **VPC** *(dict)* – The VPC that you want your hosted zone to be associated with. By providing this parameter, your newly created hosted cannot be resolved anywhere other than the given VPC.
  
  – **VPCRegion** *(string)* –
  
  – **VPCId** *(string)* –
    
    A VPC ID
  
• **CallerReference** *(string)* – [REQUIRED]
  
  A unique string that identifies the request and that allows failed CreateHostedZone requests to be retried without the risk of executing the operation twice. You must use a unique CallerReference string every time you create a hosted zone. CallerReference can be any unique string; you might choose to use a string that identifies your project, such as DNSMigration_01.

  Valid characters are any Unicode code points that are legal in an XML 1.0 document. The UTF-8 encoding of the value must be less than 128 bytes.

• **HostedZoneConfig** *(dict)* – A complex type that contains an optional comment about your hosted zone.
  
  – **Comment** *(string)* –
    
    An optional comment about your hosted zone. If you don’t want to specify a comment, you can omit the HostedZoneConfig and Comment elements from the XML document.
  
  – **PrivateZone** *(boolean)* –
    
    A value that indicates whether this is a private hosted zone. The value is returned in the response; do not specify it in the request.

• **DelegationSetId** *(string)* – The delegation set id of the reusable delgation set whose NS records you want to assign to the new hosted zone.

**Return type**  
`dict`

**Returns**

**Response Syntax**

```
{
  'HostedZone': {
    'Id': 'string',
    'Name': 'string',
    'CallerReference': 'string',
    'Config': {
      'Comment': 'string',
      'PrivateZone': True|False
    },
    'ResourceRecordSetCount': 123
  },
  'ChangeInfo': {
    'Id': 'string',
    'Status': 'PENDING'|'INSYNC',
    'SubmittedAt': datetime(2015, 1, 1),
    'Comment': 'string'
  },
  'DelegationSet': {
    'Id': 'string',
    'CallerReference': 'string',
    'NameServers': ['string', ...
  }
}```
Response Structure

- (dict) –
  A complex type containing the response information for the new hosted zone.
    - HostedZone (dict) –
      A complex type that contains identifying information about the hosted zone.
        * Id (string) –
          The ID of the specified hosted zone.
        * Name (string) –
          The name of the domain. This must be a fully-specified domain, for example, www.example.com. The trailing dot is optional; Route 53 assumes that the domain name is fully qualified. This means that Route 53 treats www.example.com (without a trailing dot) and www.example.com. (with a trailing dot) as identical.
          This is the name you have registered with your DNS registrar. You should ask your registrar to change the authoritative name servers for your domain to the set of NameServers elements returned in DelegationSet.
        * CallerReference (string) –
          A unique string that identifies the request to create the hosted zone.
        * Config (dict) –
          A complex type that contains the Comment element.
            - Comment (string) –
              An optional comment about your hosted zone. If you don’t want to specify a comment, you can omit the HostedZoneConfig and Comment elements from the XML document.
            - PrivateZone (boolean) –
              A value that indicates whether this is a private hosted zone. The value is returned in the response; do not specify it in the request.
          * ResourceRecordSetCount (integer) –
            Total number of resource record sets in the hosted zone.
        - ChangeInfo (dict) –
          A complex type that contains information about the request to create a hosted zone. This includes an ID that you use when you call the GetChange action to get the current status of the change request.
            * Id (string) –
The ID of the request. Use this ID to track when the change has completed across all Amazon Route 53 DNS servers.

* **Status (string)** –
  The current state of the request. **PENDING** indicates that this request has not yet been applied to all Amazon Route 53 DNS servers.

Valid Values: **PENDING|INSYNC**

* **SubmittedAt (datetime)** –
  The date and time the change was submitted, in the format **YYYY-MM-DDThh:mm:ssZ**, as specified in the ISO 8601 standard (for example, 2009-11-19T19:37:58Z). The Z after the time indicates that the time is listed in Coordinated Universal Time (UTC), which is synonymous with Greenwich Mean Time in this context.

* **Comment (string)** –
  A complex type that describes change information about changes made to your hosted zone.

This element contains an ID that you use when performing a GetChange action to get detailed information about the change.

- **DelegationSet (dict)** –
  A complex type that contains name server information.

  * **Id (string)** –
  * **CallerReference (string)** –
  * **NameServers (list)** –

  A complex type that contains the authoritative name servers for the hosted zone. Use the method provided by your domain registrar to add an NS record to your domain for each **NameServer** that is assigned to your hosted zone.

    * (string) –

- **VPC (dict)** –
  * **VPCRegion (string)** –
  * **VPCId (string)** –

  A VPC ID

- **Location (string)** –

  The unique URL representing the new hosted zone.

create_reusable_delegation_set (**kwargs)**

This action creates a reusable delegationSet.

To create a new reusable delegationSet, send a POST request to the **2013-04-01/delegationset** resource. The request body must include an XML document with a **CreateReusableDelegationSetRequest** element. The response returns the **CreateReusableDelegationSetResponse** element that contains metadata about the delegationSet.

If the optional parameter HostedZoneId is specified, it marks the delegationSet associated with that particular hosted zone as reusable.

**Request Syntax**

```python
response = client.create_reusable_delegation_set(  
    CallerReference='string',
```
HostedZoneId='string'

Parameters

- **CallerReference (string)** – [REQUIRED]
  A unique string that identifies the request and that allows failed CreateReusableDelegationSet requests to be retried without the risk of executing the operation twice. You must use a unique CallerReference string every time you create a reusable delegation set. CallerReference can be any unique string; you might choose to use a string that identifies your project, such as DNSMigration_01.

  Valid characters are any Unicode code points that are legal in an XML 1.0 document. The UTF-8 encoding of the value must be less than 128 bytes.

- **HostedZoneId (string)** – The ID of the hosted zone whose delegation set you want to mark as reusable. It is an optional parameter.

Return type  dict

Returns

Response Syntax

```python
{
    'DelegationSet': {
        'Id': 'string',
        'CallerReference': 'string',
        'NameServers': [
            'string',
        ],
    },
    'Location': 'string'
}
```

Response Structure

- (dict) –
  - **DelegationSet (dict)** –
    A complex type that contains name server information.
    - **Id (string)** –
    - **CallerReference (string)** –
    - **NameServers (list)** –
      A complex type that contains the authoritative name servers for the hosted zone. Use the method provided by your domain registrar to add an NS record to your domain for each NameServer that is assigned to your hosted zone.
    - (string) –
  - **Location (string)** –
    The unique URL representing the new reusuable delegation set.

**delete_health_check (**kwargs**)

This action deletes a health check. To delete a health check, send a DELETE request to the 2013-04-01/healthcheck/*health check ID* resource.
Warning: You can delete a health check only if there are no resource record sets associated with this health check. If resource record sets are associated with this health check, you must disassociate them before you can delete your health check. If you try to delete a health check that is associated with resource record sets, Route 53 will deny your request with a HealthCheckInUse error. For information about disassociating the records from your health check, see ChangeResourceRecordSets.

Request Syntax

```python
response = client.delete_health_check(
    HealthCheckId='string'
)
```

Parameters

HealthCheckId (string) – [REQUIRED]

The ID of the health check to delete.

Return type: dict

Returns

Response Syntax

```
{}
```

Response Structure

- (dict) –

Empty response for the request.

delete_hosted_zone(**kwargs)

This action deletes a hosted zone. To delete a hosted zone, send a DELETE request to the 2013-04-01/hostedzone/*hosted zone ID*/resource.

For more information about deleting a hosted zone, see Deleting a Hosted Zone in the Amazon Route 53 Developer Guide.

Warning: You can delete a hosted zone only if there are no resource record sets other than the default SOA record and NS resource record sets. If your hosted zone contains other resource record sets, you must delete them before you can delete your hosted zone. If you try to delete a hosted zone that contains other resource record sets, Route 53 will deny your request with a HostedZoneNotEmpty error. For information about deleting records from your hosted zone, see ChangeResourceRecordSets.

Request Syntax

```python
response = client.delete_hosted_zone(
    Id='string'
)
```

Parameters

Id (string) – [REQUIRED]

The ID of the hosted zone you want to delete.

Return type: dict

Returns

Response Syntax

Response Structure

- (dict) –
  A complex type containing the response information for the request.
  - ChangeInfo (dict) –
    A complex type that contains the ID, the status, and the date and time of your delete request.
    * Id (string) –
      The ID of the request. Use this ID to track when the change has completed across all Amazon Route 53 DNS servers.
    * Status (string) –
      The current state of the request. PENDING indicates that this request has not yet been applied to all Amazon Route 53 DNS servers.
      Valid Values: PENDING | INSYNC
    * SubmittedAt (datetime) –
      The date and time the change was submitted, in the format YYYY-MM-DDThh:mm:ssZ, as specified in the ISO 8601 standard (for example, 2009-11-19T19:37:58Z). The Z after the time indicates that the time is listed in Coordinated Universal Time (UTC), which is synonymous with Greenwich Mean Time in this context.
    * Comment (string) –
      A complex type that describes change information about changes made to your hosted zone.
      This element contains an ID that you use when performing a GetChange action to get detailed information about the change.

delete_reusable_delegation_set (**kwargs)

This action deletes a reusable delegation set. To delete a reusable delegation set, send a DELETE request to the 2013-04-01/delegationset/*delegation set ID* resource.

Warning: You can delete a reusable delegation set only if there are no associated hosted zones. If your reusable delegation set contains associated hosted zones, you must delete them before you can delete your reusable delegation set. If you try to delete a reusable delegation set that contains associated hosted zones, Route 53 will deny your request with a DelegationSetInUse error.

Request Syntax

```python
response = client.delete_reusable_delegation_set(
    Id='string'
)
```

Parameters Id (string) – [REQUIRED]
The ID of the reusable delegation set you want to delete.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{}
```

**Response Structure**

- `(dict)`

   Empty response for the request.

**disassociate_vpc_from_hosted_zone(**kwargs)**

This action disassociates a VPC from a hosted zone.

To disassociate a VPC to a hosted zone, send a POST request to the `2013-04-01/hostedzone/*hosted zone ID*/disassociatevpc` resource. The request body must include an XML document with a `DisassociateVPCFromHostedZoneRequest` element. The response returns the `DisassociateVPCFromHostedZoneResponse` element that contains `ChangeInfo` for you to track the progress of the `DisassociateVPCFromHostedZoneRequest` you made. See `GetChange` operation for how to track the progress of your change.

**Request Syntax**

```python
response = client.disassociate_vpc_from_hosted_zone(
    HostedZoneId='string',
    VPC={
        'VPCRegion': 'us-east-1'|'us-west-1'|'us-west-2'|'eu-west-1'|'eu-central-1'|'ap-southeast-1'|'ap-southeast-2'|'ap-northeast-1'|'sa-east-1'|'cn-north-1',
        'VPCId': 'string'
    },
    Comment='string'
)
```

**Parameters**

- **HostedZoneId** *(string)* – [REQUIRED]

  The ID of the hosted zone you want to disassociate your VPC from.

  Note that you cannot disassociate the last VPC from a hosted zone.

- **VPC** *(dict)* – [REQUIRED]

  The VPC that you want your hosted zone to be disassociated from.

  - **VPCRegion** *(string)* –

  - **VPCId** *(string)* –

    A VPC ID

- **Comment** *(string)* – Optional: Any comments you want to include about a `DisassociateVPCFromHostedZoneRequest`.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'ChangeInfo': {
        'Id': 'string',
        'Status': 'PENDING'|'INSYNC',
        'SubmittedAt': datetime(2015, 1, 1),
    }
}
```
Response Structure

- **(dict)** –
  A complex type containing the response information for the request.

  - **ChangeInfo (dict)** –
    A complex type that contains the ID, the status, and the date and time of your **DisassociateVPCFromHostedZoneRequest**.
    
    - **Id (string)** –
      The ID of the request. Use this ID to track when the change has completed across all Amazon Route 53 DNS servers.
    
    - **Status (string)** –
      The current state of the request. **PENDING** indicates that this request has not yet been applied to all Amazon Route 53 DNS servers.

    Valid Values: **PENDING|INSYNC**

    - **SubmittedAt (datetime)** –
      The date and time the change was submitted, in the format **YYYY-MM-DDTh:mm:ssZ**, as specified in the ISO 8601 standard (for example, **2009-11-19T19:37:58Z**). The **Z** after the time indicates that the time is listed in Coordinated Universal Time (UTC), which is synonymous with Greenwich Mean Time in this context.

    - **Comment (string)** –
      A complex type that describes change information about changes made to your hosted zone.

      This element contains an ID that you use when performing a **GetChange** action to get detailed information about the change.

---

**generate_presigned_url** *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

**Parameters**

- **ClientMethod (string)** – The client method to presign for
- **Params (dict)** – The parameters normally passed to **ClientMethod**.
- **ExpiresIn (int)** – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod (string)** – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns** The presigned url

**get_change(****kwargs**)*

This action returns the current status of a change batch request. The status is one of the following values:

- **PENDING** indicates that the changes in this request have not replicated to all Route 53 DNS servers. This is the initial status of all change batch requests.
- **INSYNC** indicates that the changes have replicated to all Amazon Route 53 DNS servers.

**Request Syntax**

```python
response = client.get_change(
    Id='string'
)
```
Parameters  **Id (string)** – [REQUIRED]

The ID of the change batch request. The value that you specify here is the value that `ChangeResourceRecordSets` returned in the Id element when you submitted the request.

**Return type**  dict

**Returns**

**Response Syntax**

```json
{
    'ChangeInfo': {
        'Id': 'string',
        'Status': 'PENDING'|'INSYNC',
        'SubmittedAt': datetime(2015, 1, 1),
        'Comment': 'string'
    }
}
```

**Response Structure**

- (dict) – A complex type that contains the `ChangeInfo` element.
  - **ChangeInfo (dict)** – A complex type that contains information about the specified change batch, including the change batch ID, the status of the change, and the date and time of the request.
    - **Id (string)** – The ID of the request. Use this ID to track when the change has completed across all Amazon Route 53 DNS servers.
    - **Status (string)** – The current state of the request. `PENDING` indicates that this request has not yet been applied to all Amazon Route 53 DNS servers.
      - **Valid Values:** `PENDING` | `INSYNC`
    - **SubmittedAt (datetime)** – The date and time the change was submitted, in the format `YYYY-MM-DDThh:mm:ssZ`, as specified in the ISO 8601 standard (for example, `2009-11-19T19:37:58Z`). The `Z` after the time indicates that the time is listed in Coordinated Universal Time (UTC), which is synonymous with Greenwich Mean Time in this context.
      - **Comment (string)** – A complex type that describes change information about changes made to your hosted zone.
        - This element contains an ID that you use when performing a `GetChange` action to get detailed information about the change.

**get_checker_ip_ranges ()**

To retrieve a list of the IP ranges used by Amazon Route 53 health checkers to check the health of your resources, send a GET request to the `2013-04-01/checkeripranges` resource. You can use these IP addresses to configure router and firewall rules to allow health checkers to check the health of your resources.

**Request Syntax**
response = client.get_checker_ip_ranges()

    Return type  dict
    Returns

    Response Syntax

    
    
    'CheckerIpRanges': [
        'string',
    ]

    )

    Response Structure

    •  (dict) –
        A complex type that contains the CheckerIpRanges element.
        –  CheckerIpRanges (list) –
            A complex type that contains sorted list of IP ranges in CIDR format for
            Amazon Route 53 health checkers.

get_geo_location(**kwargs)

To retrieve a single geo location, send a GET request to the 2013-04-01/geolocation resource
with one of these options: continentcode | countrycode | countrycode and subdivisioncode.

Request Syntax

response = client.get_geo_location(
    ContinentCode='string',
    CountryCode='string',
    SubdivisionCode='string'
)

Parameters

•  ContinentCode (string) – The code for a continent geo location. Note: only
    continent locations have a continent code.

    Valid values: AF | AN | AS | EU | OC | NA | SA

    Constraint: Specifying ContinentCode with either CountryCode or
    SubdivisionCode returns an InvalidInput error.

•  CountryCode (string) – The code for a country geo location. The default lo-
    cation uses ‘*’ for the country code and will match all locations that are not
    matched by a geo location.

    The default geo location uses a * for the country code. All other country codes
    follow the ISO 3166 two-character code.

•  SubdivisionCode (string) – The code for a country’s subdivision (e.g., a
    province of Canada). A subdivision code is only valid with the appropriate coun-
    try code.

    Constraint: Specifying SubdivisionCode without CountryCode returns
    an InvalidInput error.

    Return type  dict
    Returns

    Response Syntax
{  
'GeoLocationDetails': {  
'ContinentCode': 'string',  
'ContinentName': 'string',  
'CountryCode': 'string',  
'CountryName': 'string',  
'SubdivisionCode': 'string',  
'SubdivisionName': 'string'  
}  
}

Response Structure
• (dict) –
A complex type containing information about the specified geo location.
  – GeoLocationDetails (dict) –
A complex type that contains the information about the specified geo location.
  * ContinentCode (string) –
The code for a continent geo location. Note: only continent locations have a continent code.
  * ContinentName (string) –
The name of the continent. This element is only present if ContinentCode is also present.
  * CountryCode (string) –
The code for a country geo location. The default location uses ‘*’ for the country code and will match all locations that are not matched by a geo location.
  The default geo location uses a * for the country code. All other country codes follow the ISO 3166 two-character code.
  * CountryName (string) –
The name of the country. This element is only present if CountryCode is also present.
  * SubdivisionCode (string) –
The code for a country’s subdivision (e.g., a province of Canada). A subdivision code is only valid with the appropriate country code.
  * SubdivisionName (string) –
The name of the subdivision. This element is only present if SubdivisionCode is also present.

get_health_check(**kwargs)
To retrieve the health check, send a GET request to the 2013-04-01/healthcheck/*health check ID* resource.

Request Syntax

response = client.get_health_check(  
  HealthCheckId='string'  
)

Parameters HealthCheckId (string) – [REQUIRED]
The ID of the health check to retrieve.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'HealthCheck': {
        'Id': 'string',
        'CallerReference': 'string',
        'HealthCheckConfig': {
            'IPAddress': 'string',
            'Port': 123,
            'Type': 'HTTP'|'HTTPS'|'HTTP_STR_MATCH'|'HTTPS_STR_MATCH'|'TCP'|'CALCULATED',
            'ResourcePath': 'string',
            'FullyQualifiedDomainName': 'string',
            'SearchString': 'string',
            'RequestInterval': 123,
            'FailureThreshold': 123,
            'MeasureLatency': True|False,
            'Inverted': True|False,
            'HealthThreshold': 123,
            'ChildHealthChecks': [
                'string',
            ],
        },
        'HealthCheckVersion': 123
    }
}
```

**Response Structure**

- `(dict)` – A complex type containing information about the specified health check.
  - **HealthCheck** (dict) – A complex type that contains the information about the specified health check.
    - **Id** (string) – The ID of the specified health check.
    - **CallerReference** (string) – A unique string that identifies the request to create the health check.
    - **HealthCheckConfig** (dict) – A complex type that contains the health check configuration.
      - **IPAddress** (string) – IP Address of the instance being checked.
      - **Port** (integer) – Port on which connection will be opened to the instance to health check. For HTTP and HTTP_STR_MATCH this defaults to 80 if the port is not specified. For HTTPS and HTTPS_STR_MATCH this defaults to 443 if the port is not specified.
      - **Type** (string) –
The type of health check to be performed. Currently supported types are TCP, HTTP, HTTPS, HTTP_STR_MATCH, and HTTPS_STR_MATCH.

- **ResourcePath** *(string)* –
  Path to ping on the instance to check the health. Required for HTTP, HTTPS, HTTP_STR_MATCH, and HTTPS_STR_MATCH health checks. HTTP request is issued to the instance on the given port and path.

- **FullyQualifiedDomainName** *(string)* –
  Fully qualified domain name of the instance to be health checked.

- **SearchString** *(string)* –
  A string to search for in the body of a health check response. Required for HTTP_STR_MATCH and HTTPS_STR_MATCH health checks.

- **RequestInterval** *(integer)* –
  The number of seconds between the time that Route 53 gets a response from your endpoint and the time that it sends the next health-check request.

  Each Route 53 health checker makes requests at this interval. Valid values are 10 and 30. The default value is 30.

- **FailureThreshold** *(integer)* –
  The number of consecutive health checks that an endpoint must pass or fail for Route 53 to change the current status of the endpoint from unhealthy to healthy or vice versa.

  Valid values are integers between 1 and 10. For more information, see “How Amazon Route 53 Determines Whether an Endpoint Is Healthy” in the Amazon Route 53 Developer Guide.

- **MeasureLatency** *(boolean)* –
  A Boolean value that indicates whether you want Route 53 to measure the latency between health checkers in multiple AWS regions and your endpoint and to display CloudWatch latency graphs in the Route 53 console.

- **Inverted** *(boolean)* –
  A boolean value that indicates whether the status of health check should be inverted. For example, if a health check is healthy but Inverted is True, then Route 53 considers the health check to be unhealthy.

- **HealthThreshold** *(integer)* –
  The minimum number of child health checks that must be healthy for Route 53 to consider the parent health check to be healthy. Valid values are integers between 0 and 256, inclusive.

- **ChildHealthChecks** *(list)* –
  For a specified parent health check, a list of HealthCheckId values for the associated child health checks.
* HealthCheckVersion (integer) –

The version of the health check. You can optionally pass this value in a call to UpdateHealthCheck to prevent overwriting another change to the health check.

**get_health_check_count()**

To retrieve a count of all your health checks, send a GET request to the 2013-04-01/healthcheckcount resource.

**Request Syntax**

```python
response = client.get_health_check_count()
```

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'HealthCheckCount': 123
}
```

**Response Structure**

- (dict) –

A complex type that contains the count of health checks associated with the current AWS account.

- HealthCheckCount (integer) –

The number of health checks associated with the current AWS account.

**get_health_check_last_failure_reason(**kwargs**)**

If you want to learn why a health check is currently failing or why it failed most recently (if at all), you can get the failure reason for the most recent failure. Send a GET request to the 2013-04-01/healthcheck/*health check ID*/lastfailurereason resource.

**Request Syntax**

```python
response = client.get_health_check_last_failure_reason(

    HealthCheckId='string'
)
```

**Parameters** HealthCheckId (string) – [REQUIRED]

The ID of the health check for which you want to retrieve the reason for the most recent failure.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'HealthCheckObservations': [

        {
            'IPAddress': 'string',
            'StatusReport': {

                'Status': 'string',
                'CheckedTime': datetime(2015, 1, 1)
            }
        }
    }
}
```
Response Structure

- (dict) – A complex type that contains information about the most recent failure for the specified health check.
  - HealthCheckObservations (list) – A list that contains one HealthCheckObservation element for each Route 53 health checker.
    - (dict) – A complex type that contains the IP address of a Route 53 health checker and the reason for the health check status.
      - IPAddress (string) – The IP address of the Route 53 health checker that performed the health check.
      - StatusReport (dict) – A complex type that contains information about the health check status for the current observation.
        - Status (string) – The observed health check status.
        - CheckedTime (datetime) – The date and time the health check status was observed, in the format YYYY-MM-DDThh:mm:ssZ, as specified in the ISO 8601 standard (for example, 2009-11-19T19:37:58Z). The Z after the time indicates that the time is listed in Coordinated Universal Time (UTC), which is synonymous with Greenwich Mean Time in this context.

get_health_check_status(**kwargs)

To retrieve the health check status, send a GET request to the 2013-04-01/healthcheck/*health check ID* /status resource. You can use this call to get a health check’s current status.

Request Syntax

```python
response = client.get_health_check_status(
    HealthCheckId='string'
)
```

Parameters HealthCheckId (string) – [REQUIRED]

The ID of the health check for which you want to retrieve the most recent status.

Return type dict

Returns

Response Syntax

```python
{
    'HealthCheckObservations': [
        {
            'IPAddress': 'string',
            'StatusReport': {
                'Status': 'string',
                'CheckedTime': '2009-11-19T19:37:58Z'
            }
        }
    ]
}
```
'StatusReport': {
    'Status': 'string',
    'CheckedTime': datetime(2015, 1, 1)
},
},
]

Response Structure

- (dict) –
  A complex type that contains information about the status of the specified health check.

- HealthCheckObservations (list) –
  A list that contains one HealthCheckObservation element for each Route 53 health checker.

  - (dict) –
    A complex type that contains the IP address of a Route 53 health checker and the reason for the health check status.
    - IPAddress (string) –
      The IP address of the Route 53 health checker that performed the health check.
    - StatusReport (dict) –
      A complex type that contains information about the health check status for the current observation.
      - Status (string) –
        The observed health check status.
      - CheckedTime (datetime) –
        The date and time the health check status was observed, in the format YYYY-MM-DDThh:mm:ssZ, as specified in the ISO 8601 standard (for example, 2009-11-19T19:37:58Z). The Z after the time indicates that the time is listed in Coordinated Universal Time (UTC), which is synonymous with Greenwich Mean Time in this context.

get_hosted_zone(**kwargs)

To retrieve the delegation set for a hosted zone, send a GET request to the 2013-04-01/hostedzone/*hosted zone ID* resource. The delegation set is the four Route 53 name servers that were assigned to the hosted zone when you created it.

Request Syntax

response = client.get_hosted_zone(
    Id='string'
)

Parameters

- Id (string) – [REQUIRED]
  The ID of the hosted zone for which you want to get a list of the name servers in the delegation set.

Return type dict
Returns

Response Syntax

3.1. Services
```json
{
    'HostedZone': {
        'Id': 'string',
        'Name': 'string',
        'CallerReference': 'string',
        'Config': {
            'Comment': 'string',
            'PrivateZone': True|False
        },
        'ResourceRecordSetCount': 123
    },
    'DelegationSet': {
        'Id': 'string',
        'CallerReference': 'string',
        'NameServers': [
            'string',
        ],
    },
    'VPCs': [
        {
            'VPCRegion': 'us-east-1'|'us-west-1'|'us-west-2'|'eu-west-1'|'eu-central-1'|'ap-southeast-1'|'ap-southeast-2'|'ap-northeast-1'|'sa-east-1'|'cn-north-1',
            'VPCId': 'string'
        },
    ]
}
```

**Response Structure**

- *(dict)* – A complex type containing information about the specified hosted zone.
  - **HostedZone** *(dict)* – A complex type that contains the information about the specified hosted zone.
    - **Id** *(string)* – The ID of the specified hosted zone.
    - **Name** *(string)* – The name of the domain. This must be a fully-specified domain, for example, www.example.com. The trailing dot is optional; Route 53 assumes that the domain name is fully qualified. This means that Route 53 treats www.example.com (without a trailing dot) and www.example.com (with a trailing dot) as identical. This is the name you have registered with your DNS registrar. You should ask your registrar to change the authoritative name servers for your domain to the set of NameServers elements returned in DelegationSet.
    - **CallerReference** *(string)* – A unique string that identifies the request to create the hosted zone.
    - **Config** *(dict)* – A complex type that contains the Comment element.
      - **Comment** *(string)* – An optional comment about your hosted zone. If you don’t want to specify a comment, you can omit the
HostedZoneConfig and Comment elements from the XML document.
  · **PrivateZone** *(boolean)* –
    A value that indicates whether this is a private hosted zone. The value is returned in the response; do not specify it in the request.
  · **ResourceRecordSetCount** *(integer)* –
    Total number of resource record sets in the hosted zone.
  · **DelegationSet** *(dict)* –
    A complex type that contains information about the name servers for the specified hosted zone.
    · **Id** *(string)* –
    · **CallerReference** *(string)* –
    · **NameServers** *(list)* –
      A complex type that contains the authoritative name servers for the hosted zone. Use the method provided by your domain registrar to add an NS record to your domain for each NameServer that is assigned to your hosted zone.
    · *(string)* –
  · **VPCs** *(list)* –
    A complex type that contains information about VPCs associated with the specified hosted zone.
    · *(dict)* –
      · **VPCRegion** *(string)* –
      · **VPCId** *(string)* –
        A VPC ID

**get_hosted_zone_count** ()
To retrieve a count of all your hosted zones, send a GET request to the `2013-04-01/hostedzonecount` resource.

**Request Syntax**

```python
response = client.get_hosted_zone_count()
```

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'HostedZoneCount': 123
}
```

**Response Structure**

  · *(dict)* –
    A complex type that contains the count of hosted zones associated with the current AWS account.
    · **HostedZoneCount** *(integer)* –
      The number of hosted zones associated with the current AWS account.
get_paginator(operation_name)
Create a paginator for an operation.

Parameters operation_name (string) – The operation name. This is the same name as
the method name on the client. For example, if the method name is create_foo,
and you'd normally invoke the operation as client.create_foo(**kwargs),
if the create_foo operation can be paginated, you can use the call
client.get_paginator("create_foo").

Raises OperationNotPageableError Raised if the operation is not pageable. You can use
the client.can_paginate method to check if an operation is pageable.

Return type L{botocore.paginate.Paginator}
Returns A paginator object.

getReusableDelegationSet(**kwargs)
To retrieve the reusable delegation set, send a GET request to the
2013-04-01/delegationset/*delegation set ID* resource.

Request Syntax

response = client.get_reusable_delegation_set(
    Id='string'
)

Parameters Id (string) – [REQUIRED]
The ID of the reusable delegation set for which you want to get a list of the name server.

Return type  dict
Returns

Response Syntax

{
    'DelegationSet': {
        'Id': 'string',
        'CallerReference': 'string',
        'NameServers': [
            'string',
        ]
    }
}

Response Structure

• (dict) –
  A complex type containing information about the specified reusable delegation
  set.

  – DelegationSet (dict) –
    A complex type that contains the information about the nameservers for
    the specified delegation set ID.
    • Id (string) –
    • CallerReference (string) –
    • NameServers (list) –
      A complex type that contains the authoritative name servers for the
      hosted zone. Use the method provided by your domain registrar to
      add an NS record to your domain for each NameServer that is
      assigned to your hosted zone.
    • (string) –
**get_waiter**(*waiter_name*)

**list_geo_locations**( **kwargs)

To retrieve a list of supported geo locations, send a GET request to the 2013-04-01/geolocations resource. The response to this request includes a GeoLocationDetailsList element with zero, one, or multiple GeoLocationDetails child elements. The list is sorted by country code, and then subdivision code, followed by continents at the end of the list.

By default, the list of geo locations is displayed on a single page. You can control the length of the page that is displayed by using the MaxItems parameter. If the list is truncated, IsTruncated will be set to true and a combination of NextContinentCode, NextCountryCode, NextSubdivisionCode will be populated. You can pass these as parameters to StartContinentCode, StartCountryCode, StartSubdivisionCode to control the geo location that the list begins with.

**Request Syntax**

```python
response = client.list_geo_locations(
    StartContinentCode='string',
    StartCountryCode='string',
    StartSubdivisionCode='string',
    MaxItems='string'
)
```

**Parameters**

- **StartContinentCode** *(string)* – The first continent code in the lexicographic ordering of geo locations that you want the ListGeoLocations request to list. For non-continent geo locations, this should be null.
  
  Valid values: **AF** | **AN** | **AS** | **EU** | **OC** | **NA** | **SA**

- **StartCountryCode** *(string)* – The first country code in the lexicographic ordering of geo locations that you want the ListGeoLocations request to list.

  The default geo location uses a * for the country code. All other country codes follow the ISO 3166 two-character code.

- **StartSubdivisionCode** *(string)* – The first subdivision code in the lexicographic ordering of geo locations that you want the ListGeoLocations request to list.

- **MaxItems** *(string)* – The maximum number of geo locations you want in the response body.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
   'GeoLocationDetailsList': [
   {
       'ContinentCode': 'string',
       'ContinentName': 'string',
       'CountryCode': 'string',
       'CountryName': 'string',
       'SubdivisionCode': 'string',
   },
   
   
}
Response Structure

- **(dict)** –
  A complex type that contains information about the geo locations that are returned by the request and information about the response.

  - **GeoLocationDetailsList (list)** –
    A complex type that contains information about the geo locations that are returned by the request.

    - **(dict)** –
      A complex type that contains information about a `GeoLocation`

      - **ContinentCode (string)** –
        The code for a continent geo location. Note: only continent locations have a continent code.

      - **ContinentName (string)** –
        The name of the continent. This element is only present if ContinentCode is also present.

      - **CountryCode (string)** –
        The code for a country geo location. The default location uses ‘*’ for the country code and will match all locations that are not matched by a geo location.

        The default geo location uses a * for the country code. All other country codes follow the ISO 3166 two-character code.

      - **CountryName (string)** –
        The name of the country. This element is only present if CountryCode is also present.

      - **SubdivisionCode (string)** –
        The code for a country’s subdivision (e.g., a province of Canada). A subdivision code is only valid with the appropriate country code.

      - **SubdivisionName (string)** –
        The name of the subdivision. This element is only present if SubdivisionCode is also present.

  - **IsTruncated (boolean)** –
    A flag that indicates whether there are more geo locations to be listed. If your results were truncated, you can make a follow-up request for the next page of results by using the values included in the ListGeoLocationsResponse$NextContinentCode, ListGeoLocationsResponse$NextCountryCode and ListGeoLocationsResponse$NextSubdivisionCode elements.
Valid Values: true | false

- **NextContinentCode** *(string)* –
  If the results were truncated, the continent code of the next geo location in the list. This element is present only if ListGeoLocationsResponse$IsTruncated is true and the next geo location to list is a continent location.

- **NextCountryCode** *(string)* –
  If the results were truncated, the country code of the next geo location in the list. This element is present only if ListGeoLocationsResponse$IsTruncated is true and the next geo location to list is not a continent location.

- **NextSubdivisionCode** *(string)* –
  If the results were truncated, the subdivision code of the next geo location in the list. This element is present only if ListGeoLocationsResponse$IsTruncated is true and the next geo location has a subdivision.

- **MaxItems** *(string)* –
  The maximum number of records you requested. The maximum value of MaxItems is 100.

```python
list_health_checks(**kwargs)
```

To retrieve a list of your health checks, send a GET request to the 2013-04-01/healthcheck resource. The response to this request includes a HealthChecks element with zero, one, or multiple HealthCheck child elements. By default, the list of health checks is displayed on a single page. You can control the length of the page that is displayed by using the MaxItems parameter. You can use the Marker parameter to control the health check that the list begins with.

**Note:** Amazon Route 53 returns a maximum of 100 items. If you set MaxItems to a value greater than 100, Amazon Route 53 returns only the first 100.

**Request Syntax**

```python
response = client.list_health_checks(
    Marker='string',
    MaxItems='string'
)
```

**Parameters**

- **Marker** *(string)* – If the request returned more than one page of results, submit another request and specify the value of NextMarker from the last response in the marker parameter to get the next page of results.

- **MaxItems** *(string)* – Specify the maximum number of health checks to return per page of results.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'HealthChecks': [
        {
            'Id': 'string',
            'CallerReference': 'string',
            'HealthCheckConfig': {
```
Response Structure

- **(dict)** – A complex type that contains the response for the request.
  - **HealthChecks (list)** –
    - A complex type that contains information about the health checks associated with the current AWS account.
      - **(dict)** – A complex type that contains identifying information about the health check.
        - **Id (string)** – The ID of the specified health check.
        - **CallerReference (string)** – A unique string that identifies the request to create the health check.
        - **HealthCheckConfig (dict)** – A complex type that contains the health check configuration.
          - **IPAddress (string)** – IP Address of the instance being checked.
          - **Port (integer)** – Port on which connection will be opened to the instance to health check. For HTTP and HTTP_STR_MATCH this defaults to 80 if the port is not specified. For HTTPS and HTTPS_STR_MATCH this defaults to 443 if the port is not specified.
          - **Type (string)** – The type of health check to be performed. Currently supported types are TCP, HTTP, HTTPS, HTTP_STR_MATCH, HTTPS_STR_MATCH.
and HTTPS_STR_MATCH.

- **ResourcePath** *(string)*
  
  Path to ping on the instance to check the health. Required for HTTP, HTTPS, HTTP_STR_MATCH, and HTTPS_STR_MATCH health checks. HTTP request is issued to the instance on the given port and path.

- **FullyQualifiedDomainName** *(string)*
  
  Fully qualified domain name of the instance to be health checked.

- **SearchString** *(string)*
  
  A string to search for in the body of a health check response. Required for HTTP_STR_MATCH and HTTPS_STR_MATCH health checks.

- **RequestInterval** *(integer)*
  
  The number of seconds between the time that Route 53 gets a response from your endpoint and the time that it sends the next health-check request.

  Each Route 53 health checker makes requests at this interval. Valid values are 10 and 30. The default value is 30.

- **FailureThreshold** *(integer)*
  
  The number of consecutive health checks that an endpoint must pass or fail for Route 53 to change the current status of the endpoint from unhealthy to healthy or vice versa.

  Valid values are integers between 1 and 10. For more information, see “How Amazon Route 53 Determines Whether an Endpoint Is Healthy” in the Amazon Route 53 Developer Guide.

- **MeasureLatency** *(boolean)*
  
  A Boolean value that indicates whether you want Route 53 to measure the latency between health checkers in multiple AWS regions and your endpoint and to display CloudWatch latency graphs in the Route 53 console.

- **Inverted** *(boolean)*
  
  A boolean value that indicates whether the status of health check should be inverted. For example, if a health check is healthy but Inverted is True, then Route 53 considers the health check to be unhealthy.

- **HealthThreshold** *(integer)*
  
  The minimum number of child health checks that must be healthy for Route 53 to consider the parent health check to be healthy. Valid values are integers between 0 and 256, inclusive.

- **ChildHealthChecks** *(list)*
  
  For a specified parent health check, a list of HealthCheckId values for the associated child health checks.

- **HealthCheckVersion** *(integer)*
  
  3.1. Services 3847
The version of the health check. You can optionally pass this value in a call to UpdateHealthCheck to prevent overwriting another change to the health check.

- **Marker (string)** –
  If the request returned more than one page of results, submit another request and specify the value of `NextMarker` from the last response in the marker parameter to get the next page of results.

- **IsTruncated (boolean)** –
  A flag indicating whether there are more health checks to be listed. If your results were truncated, you can make a follow-up request for the next page of results by using the `Marker` element.

  **Valid Values:** `true` | `false`

- **NextMarker (string)** –
  Indicates where to continue listing health checks. If `ListHealthChecksResponse$IsTruncated` is `true`, make another request to `ListHealthChecks` and include the value of the `NextMarker` element in the `Marker` element to get the next page of results.

- **MaxItems (string)** –
  The maximum number of health checks to be included in the response body. If the number of health checks associated with this AWS account exceeds `MaxItems`, the value of `ListHealthChecksResponse$IsTruncated` in the response is `true`. Call `ListHealthChecks` again and specify the value of `ListHealthChecksResponse$NextMarker` in the `ListHostedZonesRequest$Marker` element to get the next page of results.

### list_hosted_zones(**kwargs)

To retrieve a list of your hosted zones, send a GET request to the `2013-04-01/hostedzone` resource. The response to this request includes a `HostedZones` element with zero, one, or multiple `HostedZone` child elements. By default, the list of hosted zones is displayed on a single page. You can control the length of the page that is displayed by using the `MaxItems` parameter. You can use the `Marker` parameter to control the hosted zone that the list begins with.

**Note:** Amazon Route 53 returns a maximum of 100 items. If you set `MaxItems` to a value greater than 100, Amazon Route 53 returns only the first 100.

### Request Syntax

```python
response = client.list_hosted_zones(
    Marker='string',
    MaxItems='string',
    DelegationSetId='string'
)
```

**Parameters**

- **Marker (string)** – If the request returned more than one page of results, submit another request and specify the value of `NextMarker` from the last response in the marker parameter to get the next page of results.

- **MaxItems (string)** – Specify the maximum number of hosted zones to return per page of results.

- **DelegationSetId (string)** –

**Return type** dict

**Returns**
Response Syntax

```json
{
   'HostedZones': [
      {
         'Id': 'string',
         'Name': 'string',
         'CallerReference': 'string',
         'Config': {
            'Comment': 'string',
            'PrivateZone': True|False
         },
         'ResourceRecordSetCount': 123
      },
      'Marker': 'string',
      'IsTruncated': True|False,
      'NextMarker': 'string',
      'MaxItems': 'string'
   }
}
```

Response Structure

- (dict) – A complex type that contains the response for the request.
  - HostedZones (list) – A complex type that contains information about the hosted zones associated with the current AWS account.
    * (dict) – A complex type that contain information about the specified hosted zone.
      - Id (string) – The ID of the specified hosted zone.
      - Name (string) – The name of the domain. This must be a fully-specified domain, for example, www.example.com. The trailing dot is optional; Route 53 assumes that the domain name is fully qualified. This means that Route 53 treats www.example.com (without a trailing dot) and www.example.com. (with a trailing dot) as identical.
        This is the name you have registered with your DNS registrar. You should ask your registrar to change the authoritative name servers for your domain to the set of NameServers elements returned in DelegationSet.
      - CallerReference (string) – A unique string that identifies the request to create the hosted zone.
      - Config (dict) – A complex type that contains the Comment element.
        - Comment (string) – An optional comment about your hosted zone. If you don’t want to specify a comment, you can omit the
HostedZoneConfig and Comment elements from the XML document.

- **PrivateZone (boolean)** –
  A value that indicates whether this is a private hosted zone. The value is returned in the response; do not specify it in the request.

- **ResourceRecordSetCount (integer)** –
  Total number of resource record sets in the hosted zone.

- **Marker (string)** –
  If the request returned more than one page of results, submit another request and specify the value of NextMarker from the last response in the marker parameter to get the next page of results.

- **IsTruncated (boolean)** –
  A flag indicating whether there are more hosted zones to be listed. If your results were truncated, you can make a follow-up request for the next page of results by using the Marker element.

  Valid Values: true | false

- **NextMarker (string)** –
  Indicates where to continue listing hosted zones. If ListHostedZonesResponse$IsTruncated is true, make another request to ListHostedZones and include the value of the NextMarker element in the Marker element to get the next page of results.

- **MaxItems (string)** –
  The maximum number of hosted zones to be included in the response body. If the number of hosted zones associated with this AWS account exceeds MaxItems, the value of ListHostedZonesResponse$IsTruncated in the response is true. Call ListHostedZones again and specify the value of ListHostedZonesResponse$NextMarker in the ListHostedZonesRequest$Marker element to get the next page of results.

### list_hosted_zones_by_name(**kwargs)**

To retrieve a list of your hosted zones in lexicographic order, send a GET request to the 2013-04-01/hostedzonesbyname resource. The response to this request includes a HostedZones element with zero or more HostedZone child elements lexicographically ordered by DNS name. By default, the list of hosted zones is displayed on a single page. You can control the length of the page that is displayed by using the MaxItems parameter. You can use the DNSName and HostedZoneId parameters to control the hosted zone that the list begins with.

**Note:** Amazon Route 53 returns a maximum of 100 items. If you set MaxItems to a value greater than 100, Amazon Route 53 returns only the first 100.

### Request Syntax

```python
response = client.list_hosted_zones_by_name(
    DNSName='string',
    HostedZoneId='string',
    MaxItems='string'
)
```

### Parameters
• **DNSName** (*string*) – The first name in the lexicographic ordering of domain names that you want the `ListHostedZonesByNameRequest` request to list.

If the request returned more than one page of results, submit another request and specify the value of `NextDNSName` and `NextHostedZoneId` from the last response in the `DNSName` and `HostedZoneId` parameters to get the next page of results.

• **HostedZoneId** (*string*) – If the request returned more than one page of results, submit another request and specify the value of `NextDNSName` and `NextHostedZoneId` from the last response in the `DNSName` and `HostedZoneId` parameters to get the next page of results.

• **MaxItems** (*string*) – Specify the maximum number of hosted zones to return per page of results.

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'HostedZones': [
        {
            'Id': 'string',
            'Name': 'string',
            'CallerReference': 'string',
            'Config': {
                'Comment': 'string',
                'PrivateZone': True|False
            },
            'ResourceRecordSetCount': 123
        },
        {
            'DNSName': 'string',
            'HostedZoneId': 'string',
            'IsTruncated': True|False,
            'NextDNSName': 'string',
            'NextHostedZoneId': 'string',
            'MaxItems': 'string'
        }
    ],
    'DNSName': 'string',
    'HostedZoneId': 'string',
    'IsTruncated': True|False,
    'NextDNSName': 'string',
    'NextHostedZoneId': 'string',
    'MaxItems': 'string'
}
```

**Response Structure**

• *(dict)* –  
  
  A complex type that contains the response for the request.

  • **HostedZones** (*list*) –  
    
    A complex type that contains information about the hosted zones associated with the current AWS account.

    • *(dict)* –  
      
      A complex type that contains information about the specified hosted zone.

      • **Id** (*string*) –  
        
        The ID of the specified hosted zone.

      • **Name** (*string*) –  
        
        The name of the domain. This must be a fully-specified domain, for example, www.example.com. The trailing dot is
optional; Route 53 assumes that the domain name is fully qualified. This means that Route 53 treats www.example.com (without a trailing dot) and www.example.com. (with a trailing dot) as identical.

This is the name you have registered with your DNS registrar. You should ask your registrar to change the authoritative name servers for your domain to the set of NameServers elements returned in DelegationSet.

- **CallerReference (string)** –
  A unique string that identifies the request to create the hosted zone.

- **Config (dict)** –
  A complex type that contains the Comment element.

  - **Comment (string)** –
    An optional comment about your hosted zone. If you don’t want to specify a comment, you can omit the HostedZoneConfig and Comment elements from the XML document.

- **PrivateZone (boolean)** –
  A value that indicates whether this is a private hosted zone. The value is returned in the response; do not specify it in the request.

- **ResourceRecordSetCount (integer)** –
  Total number of resource record sets in the hosted zone.

- **DNSName (string)** –
  The DNSName value sent in the request.

- **HostedZoneId (string)** –
  The HostedZoneId value sent in the request.

- **IsTruncated (boolean)** –
  A flag indicating whether there are more hosted zones to be listed. If your results were truncated, you can make a follow-up request for the next page of results by using the NextDNSName and NextHostedZoneId elements.

  Valid Values: true | false

- **NextDNSName (string)** –
  If ListHostedZonesByNameResponse$IsTruncated is true, there are more hosted zones associated with the current AWS account. To get the next page of results, make another request to ListHostedZonesByName. Specify the value of ListHostedZonesByNameResponse$NextDNSName in the ListHostedZonesByNameRequest$DNSName element and ListHostedZonesByNameRequest$NextHostedZoneId in the ListHostedZonesByNameRequest$HostedZoneId element.

- **NextHostedZoneId (string)** –
  If ListHostedZonesByNameResponse$IsTruncated is true, there are more hosted zones associated with the current AWS account. To get the next page of results, make another request to
ListHostedZonesByName. Specify the value of ListHostedZonesByNameResponse$NextDNSName in the ListHostedZonesByNameRequest$DNSName element and ListHostedZonesByNameResponse$NextHostedZoneId in the ListHostedZonesByNameRequest$HostedZoneId element.

- **MaxItems (string)**

  The maximum number of hosted zones to be included in the response body. If the number of hosted zones associated with this AWS account exceeds `MaxItems`, the value of ListHostedZonesByNameResponse$IsTruncated in the response is `true`. Call `ListHostedZonesByName` again and specify the value of ListHostedZonesByNameResponse$NextDNSName and ListHostedZonesByNameResponse$NextHostedZoneId elements respectively to get the next page of results.

`list_resource_record_sets(**kwargs)`

Imagine all the resource record sets in a zone listed out in front of you. Imagine them sorted lexicographically first by DNS name (with the labels reversed, like “com.amazon.www” for example), and secondarily, lexicographically by record type. This operation retrieves at most `MaxItems` resource record sets from this list, in order, starting at a position specified by the Name and Type arguments:

- If both Name and Type are omitted, this means start the results at the first RRSET in the Hosted-Zone.
- If Name is specified but Type is omitted, this means start the results at the first RRSET in the list whose name is greater than or equal to Name.
- If both Name and Type are specified, this means start the results at the first RRSET in the list whose name is greater than or equal to Name and whose type is greater than or equal to Type.
- It is an error to specify the Type but not the Name.

Use `ListResourceRecordSets` to retrieve a single known record set by specifying the record set’s name and type, and setting `MaxItems = 1`.

To retrieve all the records in a HostedZone, first pause any processes making calls to ChangeResourceRecordSets. Initially call `ListResourceRecordSets` without a Name and Type to get the first page of record sets. For subsequent calls, set Name and Type to the NextName and NextType values returned by the previous response.

In the presence of concurrent `ChangeResourceRecordSets` calls, there is no consistency of results across calls to `ListResourceRecordSets`. The only way to get a consistent multi-page snapshot of all RRSETs in a zone is to stop making changes while pagination is in progress.

However, the results from `ListResourceRecordSets` are consistent within a page. If `MakeChange` calls are taking place concurrently, the result of each one will either be completely visible in your results or not at all. You will not see partial changes, or changes that do not ultimately succeed. (This follows from the fact that `MakeChange` is atomic)

The results from `ListResourceRecordSets` are strongly consistent with `ChangeResourceRecordSets`. To be precise, if a single process makes a call to `ChangeResourceRecordSets` and receives a successful response, the effects of that change will be visible in a subsequent call to `ListResourceRecordSets` by that process.

**Request Syntax**

```python
response = client.list_resource_record_sets(
    HostedZoneId='string',
    StartRecordName='string',
    StartRecordType='SOA'|'A'|'TXT'|'NS'|'CNAME'|'MX'|'PTR'|'SRV'|'SPF'|'AAAA',
    StartRecordIdentifier='string',
    MaxItems='string'
)
```
Parameters

- **HostedZoneId** *(string)* – [REQUIRED]
  The ID of the hosted zone that contains the resource record sets that you want to get.

- **StartRecordName** *(string)* – The first name in the lexicographic ordering of domain names that you want the ListResourceRecordSets request to list.

- **StartRecordType** *(string)* – The DNS type at which to begin the listing of resource record sets.

  Valid values: A | AAAA | CNAME | MX | NS | PTR | SOA | SPF | SRV | TXT

Values for Weighted Resource Record Sets: A | AAAA | CNAME | TXT

Values for Regional Resource Record Sets: A | AAAA | CNAME | TXT

Values for Alias Resource Record Sets: A | AAAA

Constraint: Specifying type without specifying name returns an InvalidInput error.

- **StartRecordIdentifier** *(string)* – Weighted resource record sets only: If results were truncated for a given DNS name and type, specify the value of ListResourceRecordSetsResponse$NextRecordIdentifier from the previous response to get the next resource record set that has the current DNS name and type.

- **MaxItems** *(string)* – The maximum number of records you want in the response body.

Return type **dict**

Returns

Response Syntax

```python
{
    'ResourceRecordSets': [
        {
            'Name': 'string',
            'Type': 'SOA'|'A'|'TXT'|'NS'|'CNAME'|'MX'|'PTR'|'SRV'|'SPF'|'AAAA',
            'SetIdentifier': 'string',
            'Weight': 123,
            'Region': 'us-east-1'|'us-west-1'|'us-west-2'|'eu-west-1'|'eu-central-1',
            'GeoLocation': {
                'ContinentCode': 'string',
                'CountryCode': 'string',
                'SubdivisionCode': 'string'
            },
            'Failover': 'PRIMARY'|'SECONDARY',
            'TTL': 123,
            'ResourceRecords': [
                {
                    'Value': 'string'
                }
            ],
            'AliasTarget': {
                'HostedZoneId': 'string',
                'DNSName': 'string',
                'EvaluateTargetHealth': True|False
            },
            'HealthCheckId': 'string'
        }
    ]
}
```
Response Structure

- (dict) –
  A complex type that contains information about the resource record sets that are returned by the request and information about the response.

  - ResourceRecordSets (list) –
    A complex type that contains information about the resource record sets that are returned by the request.
    - (dict) –
      A complex type that contains information about the current resource record set.
      - Name (string) –
        The domain name of the current resource record set.
      - Type (string) –
        The type of the current resource record set.
      - SetIdentifier (string) –
        Weighted, Latency, Geo, and Failover resource record sets only: An identifier that differentiates among multiple resource record sets that have the same combination of DNS name and type.
      - Weight (integer) –
        Weighted resource record sets only: Among resource record sets that have the same combination of DNS name and type, a value that determines what portion of traffic for the current resource record set is routed to the associated location.
      - Region (string) –
        Latency-based resource record sets only: Among resource record sets that have the same combination of DNS name and type, a value that specifies the AWS region for the current resource record set.
      - GeoLocation (dict) –
        Geo location resource record sets only: Among resource record sets that have the same combination of DNS name and type, a value that specifies the geo location for the current resource record set.
      - ContinentCode (string) –
        The code for a continent geo location. Note: only continent locations have a continent code.

        Valid values: \texttt{AF} | \texttt{AN} | \texttt{AS} | \texttt{EU} | \texttt{OC} | \texttt{NA} | \texttt{SA}

        Constraint: Specifying \texttt{ContinentCode} with either
CountryCode or SubdivisionCode returns an InvalidInput error.

- **CountryCode** *(string)* –

  The code for a country geo location. The default location uses ‘*’ for the country code and will match all locations that are not matched by a geo location.

  The default geo location uses a * for the country code. All other country codes follow the ISO 3166 two-character code.

- **SubdivisionCode** *(string)* –

  The code for a country’s subdivision (e.g., a province of Canada). A subdivision code is only valid with the appropriate country code.

- **Failover** *(string)* –

  *Failover resource record sets only:* Among resource record sets that have the same combination of DNS name and type, a value that indicates whether the current resource record set is a primary or secondary resource record set. A failover set may contain at most one resource record set marked as primary and one resource record set marked as secondary. A resource record set marked as primary will be returned if any of the following are true: (1) an associated health check is passing, (2) if the resource record set is an alias with the evaluate target health and at least one target resource record set is healthy, (3) both the primary and secondary resource record set are failing health checks or (4) there is no secondary resource record set. A secondary resource record set will be returned if: (1) the primary is failing a health check and either the secondary is passing a health check or has no associated health check, or (2) there is no primary resource record set.

  Valid values: PRIMARY | SECONDARY

- **TTL** *(integer)* –

  The cache time to live for the current resource record set.

- **ResourceRecords** *(list)* –

  A complex type that contains the resource records for the current resource record set.

  *(dict)* –

  A complex type that contains the value of the Value element for the current resource record set.

- **Value** *(string)* –

  The value of the Value element for the current resource record set.

- **AliasTarget** *(dict)* –

  *Alias resource record sets only:* Information about the AWS resource to which you are redirecting traffic.

- **HostedZoneId** *(string)* –
· **DNSName (string)**

*Alias resource record sets only:* The external DNS name associated with the AWS Resource.

For more information and an example, see Creating Alias Resource Record Sets in the *Amazon Route 53 Developer Guide*.

· **EvaluateTargetHealth (boolean)**

*Alias resource record sets only:* A boolean value that indicates whether this Resource Record Set should respect the health status of any health checks associated with the ALIAS target record which it is linked to.

For more information and an example, see Creating Alias Resource Record Sets in the *Amazon Route 53 Developer Guide*.

· **HealthCheckId (string)**

*Health Check resource record sets only, not required for alias resource record sets:* An identifier that is used to identify health check associated with the resource record set.

· **IsTruncated (boolean)**

A flag that indicates whether there are more resource record sets to be listed. If your results were truncated, you can make a follow-up request for the next page of results by using the ListResourceRecordSetsResponse$NextRecordName element.

Valid Values: `true` | `false`

· **NextRecordName (string)**

If the results were truncated, the name of the next record in the list. This element is present only if ListResourceRecordSetsResponse$IsTruncated is true.

· **NextRecordType (string)**

If the results were truncated, the type of the next record in the list. This element is present only if ListResourceRecordSetsResponse$IsTruncated is true.

· **NextRecordIdentifier (string)**

*Weighted resource record sets only:* If results were truncated for a given DNS name and type, the value of SetIdentifier for the next resource record set that has the current DNS name and type.

· **MaxItems (string)**

The maximum number of records you requested. The maximum value of MaxItems is 100.

**list_reusable_delegation_sets(**kwargs**)

To retrieve a list of your reusable delegation sets, send a GET request to the
2013-04-01/delegationset resource. The response to this request includes a DelegationSets element with zero, one, or multiple DelegationSet child elements. By default, the list of delegation sets is displayed on a single page. You can control the length of the page that is displayed by using the MaxItems parameter. You can use the Marker parameter to control the delegation set that the list begins with.

**Note:** Amazon Route 53 returns a maximum of 100 items. If you set MaxItems to a value greater than 100, Amazon Route 53 returns only the first 100.

### Request Syntax

```python
response = client.list_reusable_delegation_sets(
    Marker='string',
    MaxItems='string'
)
```

**Parameters**

- **Marker** *(string)* – If the request returned more than one page of results, submit another request and specify the value of NextMarker from the last response in the marker parameter to get the next page of results.

- **MaxItems** *(string)* – Specify the maximum number of reusable delegation sets to return per page of results.

**Response Syntax**

```
{
    'DelegationSets': [
        {
            'Id': 'string',
            'CallerReference': 'string',
            'NameServers': [
                'string',
            ],
        },
        {
            'Id': 'string',
            'CallerReference': 'string',
            'NameServers': [
                'string',
            ],
        },
    ],
    'Marker': 'string',
    'IsTruncated': True|False,
    'NextMarker': 'string',
    'MaxItems': 'string'
}
```

**Response Structure**

- *(dict)* – A complex type that contains the response for the request.
  - **DelegationSets** *(list)* – A complex type that contains information about the reusable delegation sets associated with the current AWS account.
    - *(dict)* – A complex type that contains name server information.
      - **Id** *(string)* –
      - **CallerReference** *(string)* –
· **NameServers** *(list)* –

A complex type that contains the authoritative name servers for the hosted zone. Use the method provided by your domain registrar to add an NS record to your domain for each NameServer that is assigned to your hosted zone.

· *(string)* –

**Marker** *(string)* –

If the request returned more than one page of results, submit another request and specify the value of `NextMarker` from the last response in the `marker` parameter to get the next page of results.

**IsTruncated** *(boolean)* –

A flag indicating whether there are more reusable delegation sets to be listed. If your results were truncated, you can make a follow-up request for the next page of results by using the `Marker` element.

Valid Values: true | false

· **NextMarker** *(string)* –

Indicates where to continue listing reusable delegation sets. If `ListReusableDelegationSetsResponse$IsTruncated` is true, make another request to `ListReusableDelegationSets` and include the value of the `NextMarker` element in the `Marker` element to get the next page of results.

· **MaxItems** *(string)* –

The maximum number of reusable delegation sets to be included in the response body. If the number of reusable delegation sets associated with this AWS account exceeds `MaxItems`, the value of `ListReusableDelegationSetsResponse$IsTruncated` in the response is true. Call `ListReusableDelegationSets` again and specify the value of `ListReusableDelegationSetsResponse$NextMarker` in the `ListReusableDelegationSetsRequest$Marker` element to get the next page of results.

```python
def list_tags_for_resource(**kwargs):
    response = client.list_tags_for_resource(
        ResourceType='healthcheck'|'hostedzone',
        ResourceId='string'
    )
```

**Parameters**

- **ResourceType** *(string)* – [REQUIRED]

  The type of the resource.
  
  – The resource type for health checks is `healthcheck`.
  
  – The resource type for hosted zones is `hostedzone`.

- **ResourceId** *(string)* – [REQUIRED]

  The ID of the resource for which you want to retrieve tags.

**Return type** dict

**Returns**

**Response Syntax**
{  
    'ResourceTagSet': {  
        'ResourceType': 'healthcheck'|'hostedzone',  
        'ResourceId': 'string',  
        'Tags': [  
            {  
                'Key': 'string',  
                'Value': 'string'  
            },  
            
        ]  
    }  
}

Response Structure

• (dict) – A complex type containing tags for the specified resource.
  
  – ResourceTagSet (dict) – A ResourceTagSet containing tags associated with the specified resource.
    
    • ResourceType (string) – The type of the resource.
      
      • The resource type for health checks is healthcheck.
      • The resource type for hosted zones is hostedzone.
    
    • ResourceId (string) – The ID for the specified resource.
    
    • Tags (list) – The tags associated with the specified resource.
      
      • (dict) – A single tag containing a key and value.
      
      • Key (string) – The key for a Tag.
      • Value (string) – The value for a Tag.

list_tags_for_resources(**kwargs)

Request Syntax

response = client.list_tags_for_resources(  
ResourceType='healthcheck'|'hostedzone',  
ResourceIds=[  
    'string',  
  ]  
)

Parameters

• ResourceType (string) – [REQUIRED]

  The type of the resources.
  
  – The resource type for health checks is healthcheck.
  – The resource type for hosted zones is hostedzone.
• **ResourceIds** *(list)* – [REQUIRED]

A complex type that contains the ResourceId element for each resource for which you want to get a list of tags.

— *(string)* –

_Return type_ **dict**

_Returns_

**Response Syntax**

```python
{
    'ResourceTagSets': [
        {
            'ResourceType': 'healthcheck'|'hostedzone',
            'ResourceId': 'string',
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                },
                ...
            ],
        },
        ...
    ],
}
```

**Response Structure**

* *(dict)* –

A complex type containing tags for the specified resources.

— **ResourceTagSets** *(list)* –

A list of ResourceTagSets containing tags associated with the specified resources.

* *(dict)* –

A complex type containing a resource and its associated tags.

· **ResourceType** *(string)* –

  The type of the resource.

· The resource type for health checks is **healthcheck**.

· The resource type for hosted zones is **hostedzone**.

· **ResourceId** *(string)* –

  The ID for the specified resource.

· **Tags** *(list)* –

  The tags associated with the specified resource.

· *(dict)* –

  A single tag containing a key and value.

· **Key** *(string)* –

  The key for a Tag.

· **Value** *(string)* –

  The value for a Tag.

$update\_health\_check\(**kwargs\)**

This action updates an existing health check.

To update a health check, send a **POST** request to the `2013-04-01/healthcheck/*health check ID*` resource. The request body must include an XML document
with an `UpdateHealthCheckRequest` element. The response returns an `UpdateHealthCheckResponse` element, which contains metadata about the health check.

**Request Syntax**

```python
response = client.update_health_check(
    HealthCheckId='string',
    HealthCheckVersion=123,
    IPAddress='string',
    Port=123,
    ResourcePath='string',
    FullyQualifiedDomainName='string',
    SearchString='string',
    FailureThreshold=123,
    Inverted=True|False,
    HealthThreshold=123,
    ChildHealthChecks=[
        'string',
    ]
)
```

**Parameters**

- **HealthCheckId** *(string) – [REQUIRED]*
  
  The ID of the health check to update.

- **HealthCheckVersion** *(integer) – Optional.*
  
  When you specify a health check version, Route 53 compares this value with the current value in the health check, which prevents you from updating the health check when the versions don’t match. Using `HealthCheckVersion` lets you prevent overwriting another change to the health check.

- **IPAddress** *(string)*
  
  The IP address of the resource that you want to check. Specify this value only if you want to change it.

- **Port** *(integer)*
  
  The port on which you want Route 53 to open a connection to perform health checks. Specify this value only if you want to change it.

- **ResourcePath** *(string)*
  
  The path that you want Amazon Route 53 to request when performing health checks. The path can be any value for which your endpoint will return an HTTP status code of 2xx or 3xx when the endpoint is healthy, for example the file `/docs/route53-health-check.html`. Specify this value only if you want to change it.

- **FullyQualifiedDomainName** *(string)*
  
  Fully qualified domain name of the instance to be health checked. Specify this value only if you want to change it.

- **SearchString** *(string)*
  
  If the value of `Type` is `HTTP_STR_MATCH` or `HTTP_STR_MATCH`, the string that you want Route 53 to search for in the response body from the specified resource. If the string appears in the response body, Route 53 considers the resource healthy. Specify this value only if you want to change it.

- **FailureThreshold** *(integer)*
  
  The number of consecutive health checks that an endpoint must pass or fail for Route 53 to change the current status of the endpoint from unhealthy to healthy or vice versa.

  Valid values are integers between 1 and 10. For more information, see “How Amazon Route 53 Determines Whether an Endpoint Is Healthy” in the Amazon
Route 53 Developer Guide.

Specify this value only if you want to change it.

- **Inverted** *(boolean)* – A boolean value that indicates whether the status of health check should be inverted. For example, if a health check is healthy but `Inverted` is `True`, then Route 53 considers the health check to be unhealthy.

Specify this value only if you want to change it.

- **HealthThreshold** *(integer)* – The minimum number of child health checks that must be healthy for Route 53 to consider the parent health check to be healthy. Valid values are integers between 0 and 256, inclusive.

Specify this value only if you want to change it.

- **ChildHealthChecks** *(list)* – For a specified parent health check, a list of `HealthCheckId` values for the associated child health checks.

Specify this value only if you want to change it.

### Response Syntax

```json
{
  'HealthCheck': {
    'Id': 'string',
    'CallerReference': 'string',
    'HealthCheckConfig': {
      'IPAddress': 'string',
      'Port': 123,
      'Type': 'HTTP'|'HTTPS'|'HTTP_STR_MATCH'|'HTTPS_STR_MATCH'|'TCP'|'CALCULATED',
      'ResourcePath': 'string',
      'FullyQualifiedDomainName': 'string',
      'SearchString': 'string',
      'RequestInterval': 123,
      'FailureThreshold': 123,
      'MeasureLatency': True|False,
      'Inverted': True|False,
      'HealthThreshold': 123,
      'ChildHealthChecks': [ 'string', ],
    },
    'HealthCheckVersion': 123
  }
}
```

### Response Structure

- *(dict)* –
  - **HealthCheck** *(dict)* –
    A complex type that contains identifying information about the health check.
    - **Id** *(string)* –
      The ID of the specified health check.
    - **CallerReference** *(string)* –
      A unique string that identifies the request to create the health check.
* **HealthCheckConfig (dict)** –

A complex type that contains the health check configuration.

- **IPAddress (string)** –
  
  IP Address of the instance being checked.

- **Port (integer)** –

  Port on which connection will be opened to the instance to health check. For HTTP and HTTP_STR_MATCH this defaults to 80 if the port is not specified. For HTTPS and HTTPS_STR_MATCH this defaults to 443 if the port is not specified.

- **Type (string)** –

  The type of health check to be performed. Currently supported types are TCP, HTTP, HTTPS, HTTP_STR_MATCH, and HTTPS_STR_MATCH.

- **ResourcePath (string)** –

  Path to ping on the instance to check the health. Required for HTTP, HTTPS, HTTP_STR_MATCH, and HTTPS_STR_MATCH health checks, HTTP request is issued to the instance on the given port and path.

- **FullyQualifiedDomainName (string)** –

  Fully qualified domain name of the instance to be health checked.

- **SearchString (string)** –

  A string to search for in the body of a health check response. Required for HTTP_STR_MATCH and HTTPS_STR_MATCH health checks.

- **RequestInterval (integer)** –

  The number of seconds between the time that Route 53 gets a response from your endpoint and the time that it sends the next health-check request.

  Each Route 53 health checker makes requests at this interval. Valid values are 10 and 30. The default value is 30.

- **FailureThreshold (integer)** –

  The number of consecutive health checks that an endpoint must pass or fail for Route 53 to change the current status of the endpoint from unhealthy to healthy or vice versa.

  Valid values are integers between 1 and 10. For more information, see “How Amazon Route 53 Determines Whether an Endpoint Is Healthy” in the Amazon Route 53 Developer Guide.

- **MeasureLatency (boolean)** –

  A Boolean value that indicates whether you want Route 53 to measure the latency between health checkers in multiple AWS regions and your endpoint and to display CloudWatch latency graphs in the Route 53 console.

- **Inverted (boolean)** –

  A boolean value that indicates whether the status of health
check should be inverted. For example, if a health check is healthy but Inverted is True, then Route 53 considers the health check to be unhealthy.

- **HealthThreshold (integer)**

  The minimum number of child health checks that must be healthy for Route 53 to consider the parent health check to be healthy. Valid values are integers between 0 and 256, inclusive.

- **ChildHealthChecks (list)**

  For a specified parent health check, a list of HealthCheckId values for the associated child health checks.

- **HealthCheckVersion (integer)**

  The version of the health check. You can optionally pass this value in a call to `UpdateHealthCheck` to prevent overwriting another change to the health check.

**update_hosted_zone_comment(**kwargs**)

To update the hosted zone comment, send a POST request to the 2013-04-01/hostedzone/*hosted zone ID* resource. The request body must include an XML document with a `UpdateHostedZoneCommentRequest` element. The response to this request includes the modified `HostedZone` element.

**Note:** The comment can have a maximum length of 256 characters.

**Request Syntax**

```
response = client.update_hosted_zone_comment(
    Id='string',
    Comment='string'
)
```

**Parameters**

- **Id (string)** – [REQUIRED]

  The ID of the hosted zone you want to update.

- **Comment (string)** – A comment about your hosted zone.

**Return type** dict

**Returns**

**Response Syntax**

```
{
    'HostedZone': {
        'Id': 'string',
        'Name': 'string',
        'CallerReference': 'string',
        'Config': {
            'Comment': 'string',
            'PrivateZone': True|False
        },
        'ResourceRecordSetCount': 123
    }
}
```
Response Structure

- **dict** –
  A complex type containing information about the specified hosted zone after the update.
  - **HostedZone (dict)** –
    A complex type that contain information about the specified hosted zone.
    - **Id (string)** –
      The ID of the specified hosted zone.
    - **Name (string)** –
      The name of the domain. This must be a fully-specified domain, for example, www.example.com. The trailing dot is optional; Route 53 assumes that the domain name is fully qualified. This means that Route 53 treats www.example.com (without a trailing dot) and www.example.com. (with a trailing dot) as identical.
      This is the name you have registered with your DNS registrar. You should ask your registrar to change the authoritative name servers for your domain to the set of NameServers elements returned in DelegationSet.
    - **CallerReference (string)** –
      A unique string that identifies the request to create the hosted zone.
    - **Config (dict)** –
      A complex type that contains the Comment element.
      - **Comment (string)** –
        An optional comment about your hosted zone. If you don't want to specify a comment, you can omit the HostedZoneConfig and Comment elements from the XML document.
      - **PrivateZone (boolean)** –
        A value that indicates whether this is a private hosted zone. The value is returned in the response; do not specify it in the request.
    - **ResourceRecordSetCount (integer)** –
      Total number of resource record sets in the hosted zone.

Paginators

The available paginators are:

- **Route53 Paginator.ListHealthChecks**
- **Route53 Paginator.ListHostedZones**
- **Route53 Paginator.ListResourceRecordSets**

```python
class Route53 Paginator.ListHealthChecks

    paginator = client.get_paginator('list_health_checks')
```
**paginate**(**kwargs**)  
Creates an iterator that will paginate through responses from Route53.Client.list_health_checks().

**Request Syntax**

```python
response_iterator = paginator.paginate(
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**  
**PaginationConfig** (**dict**) – A dictionary that provides parameters to control pagination.

- **MaxItems** (**integer**) –
  The total number of items to return. If the total number of items available is more than the value specified in max-items then a **NextToken** will be provided in the output that you can use to resume pagination.

- **PageSize** (**integer**) –
  The size of each page.

- **StartingToken** (**string**) –
  A token to specify where to start paginating. This is the **NextToken** from a previous response.

**Return type**  
**dict**

**Returns**

**Response Syntax**

```json
{
    'HealthChecks': [
        {
            'Id': 'string',
            'CallerReference': 'string',
            'HealthCheckConfig': {
                'IPAddress': 'string',
                'Port': 123,
                'Type': 'HTTP'|'HTTPS'|'HTTP_STR_MATCH'|'HTTPS_STR_MATCH'|'TCP'|'CALCULATED',
                'ResourcePath': 'string',
                'FullyQualifiedDomainName': 'string',
                'SearchString': 'string',
                'RequestInterval': 123,
                'FailureThreshold': 123,
                'MeasureLatency': True|False,
                'Inverted': True|False,
                'HealthThreshold': 123,
                'ChildHealthChecks': [
                    'string',
                ],
                'HealthCheckVersion': 123
            }
        },
        
        'HealthCheckVersion': 123
    ],

    'Marker': 'string',
    'IsTruncated': True|False,
}
```

Boto3 Documentation, Release 1.1.4

{'MaxItems': 'string',
'NextToken': 'string'}

Response Structure
- (dict) –

A complex type that contains the response for the request.
  - HealthChecks (list) –

A complex type that contains information about the health checks associated with the current AWS account.
  * (dict) –

A complex type that contains identifying information about the health check.
  - Id (string) –

The ID of the specified health check.
  - CallerReference (string) –

A unique string that identifies the request to create the health check.
  - HealthCheckConfig (dict) –

A complex type that contains the health check configuration.
  - IPAddress (string) –

IP Address of the instance being checked.
  - Port (integer) –

Port on which connection will be opened to the instance to health check. For HTTP and HTTP_STR_MATCH this defaults to 80 if the port is not specified. For HTTPS and HTTPS_STR_MATCH this defaults to 443 if the port is not specified.
  - Type (string) –

The type of health check to be performed. Currently supported types are TCP, HTTP, HTTPS, HTTP_STR_MATCH, and HTTPS_STR_MATCH.
  - ResourcePath (string) –

Path to ping on the instance to check the health. Required for HTTP, HTTPS, HTTP_STR_MATCH, and HTTPS_STR_MATCH health checks, HTTP request is issued to the instance on the given port and path.
  - FullyQualifiedDomainName (string) –

Fully qualified domain name of the instance to be health checked.
  - SearchString (string) –

A string to search for in the body of a health check response. Required for HTTP_STR_MATCH and HTTPS_STR_MATCH health checks.
  - RequestInterval (integer) –

The number of seconds between the time that Route 53 gets a response from your endpoint and the time that it sends the
Each Route 53 health checker makes requests at this interval. Valid values are 10 and 30. The default value is 30.

**· FailureThreshold** *(integer)* –

The number of consecutive health checks that an endpoint must pass or fail for Route 53 to change the current status of the endpoint from unhealthy to healthy or vice versa.

Valid values are integers between 1 and 10. For more information, see “How Amazon Route 53 Determines Whether an Endpoint Is Healthy” in the Amazon Route 53 Developer Guide.

**· MeasureLatency** *(boolean)* –

A Boolean value that indicates whether you want Route 53 to measure the latency between health checkers in multiple AWS regions and your endpoint and to display CloudWatch latency graphs in the Route 53 console.

**· Inverted** *(boolean)* –

A boolean value that indicates whether the status of health check should be inverted. For example, if a health check is healthy but Inverted is True, then Route 53 considers the health check to be unhealthy.

**· HealthThreshold** *(integer)* –

The minimum number of child health checks that must be healthy for Route 53 to consider the parent health check to be healthy. Valid values are integers between 0 and 256, inclusive.

**· ChildHealthChecks** *(list)* –

For a specified parent health check, a list of HealthCheckId values for the associated child health checks.

**· HealthCheckVersion** *(integer)* –

The version of the health check. You can optionally pass this value in a call to UpdateHealthCheck to prevent overwriting another change to the health check.

**– Marker** *(string)* –

If the request returned more than one page of results, submit another request and specify the value of NextMarker from the last response in the marker parameter to get the next page of results.

**– IsTruncated** *(boolean)* –

A flag indicating whether there are more health checks to be listed. If your results were truncated, you can make a follow-up request for the next page of results by using the Marker element.

Valid Values: true | false

**– MaxItems** *(string)* –

The maximum number of health checks to be included in the response body. If the number of health checks associated with this AWS account exceeds MaxItems, the value of ListHealthChecksResponse$IsTruncated
in the response is true. Call ListHealthChecks again and specify
the value of ListHealthChecksResponse$NextMarker in the ListHosted-
ZonesRequest$Marker element to get the next page of results.

- **NextToken (string)** –
  A token to resume pagination.

class Route53.Paginator.ListHostedZones

```python
class Route53.Paginator.ListHostedZones

    def __init__(self, client):
        self.client = client

    def paginate(self, **kwargs):
        return self._paginate('list_hosted_zones', **kwargs)
```

**Request Syntax**

```python
response_iterator = paginator.paginate(
    DelegationSetId='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **DelegationSetId (string)** –
- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize (integer)** –
    The size of each page.
  - **StartingToken (string)** –
    A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** dict

**Response Syntax**

```python
{
    'HostedZones': [
        {
            'Id': 'string',
            'Name': 'string',
            'CallerReference': 'string',
            'Config': {
                'Comment': 'string',
                'PrivateZone': True|False
            },
            'ResourceRecordSetCount': 123
        }
    ]
}
```
Response Structure

- **(dict)** –
  A complex type that contains the response for the request.
  - **HostedZones** *(list)* –
    A complex type that contains information about the hosted zones associated with the current AWS account.
    - *(dict)* –
      A complex type that contain information about the specified hosted zone.
      - **Id** *(string)* –
        The ID of the specified hosted zone.
      - **Name** *(string)* –
        The name of the domain. This must be a fully-specified domain, for example, www.example.com. The trailing dot is optional; Route 53 assumes that the domain name is fully qualified. This means that Route 53 treats www.example.com (without a trailing dot) and www.example.com (with a trailing dot) as identical.
        This is the name you have registered with your DNS registrar. You should ask your registrar to change the authoritative name servers for your domain to the set of NameServers elements returned in DelegationSet.
      - **CallerReference** *(string)* –
        A unique string that identifies the request to create the hosted zone.
      - **Config** *(dict)* –
        A complex type that contains the Comment element.
      - **Comment** *(string)* –
        An optional comment about your hosted zone. If you don’t want to specify a comment, you can omit the HostedZoneConfig and Comment elements from the XML document.
      - **PrivateZone** *(boolean)* –
        A value that indicates whether this is a private hosted zone. The value is returned in the response; do not specify it in the request.
      - **ResourceRecordSetCount** *(integer)* –
        Total number of resource record sets in the hosted zone.
    - **Marker** *(string)* –
If the request returned more than one page of results, submit another request and specify the value of NextMarker from the last response in the marker parameter to get the next page of results.

- **IsTruncated (boolean)** –
  A flag indicating whether there are more hosted zones to be listed. If your results were truncated, you can make a follow-up request for the next page of results by using the Marker element.

  Valid Values: `true` | `false`

- **MaxItems (string)** –
  The maximum number of hosted zones to be included in the response body. If the number of hosted zones associated with this AWS account exceeds MaxItems, the value of ListHostedZonesResponse$IsTruncated in the response is `true`. Call ListHostedZones again and specify the value of ListHostedZonesResponse$NextMarker in the ListHostedZonesRequest$Marker element to get the next page of results.

- **NextToken (string)** –
  A token to resume pagination.

class Route53.Paginator.ListResourceRecordSets

    paginator = client.get_paginator('list_resource_record_sets')

    @paginate(**kwargs)
    Creates an iterator that will paginate through responses from Route53.Client.list_resource_record_sets().

  Request Syntax

    response_iterator = paginator.paginate(
        HostedZoneId='string',
        PaginationConfig={
            'MaxItems': 123,
            'PageSize': 123,
            'StartingToken': 'string'
        }
    )

  Parameters

  - **HostedZoneId (string)** – [REQUIRED]
    The ID of the hosted zone that contains the resource record sets that you want to get.

  - **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
    - **MaxItems (integer)** –
      The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
    - **PageSize (integer)** –
      The size of each page.
    - **StartingToken (string)** –
A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict

Returns

Response Syntax

```json

{
    'ResourceRecordSets': [
        {
            'Name': 'string',
            'Type': 'SOA'|'A'|'TXT'|'NS'|'CNAME'|'MX'|'PTR'|'SRV'|'SPF'|'AAAA',
            'SetIdentifier': 'string',
            'Weight': 123,
            'Region': 'us-east-1'|'us-west-1'|'us-west-2'|'eu-west-1'|'eu-central-1',
            'GeoLocation': {
                'ContinentCode': 'string',
                'CountryCode': 'string',
                'SubdivisionCode': 'string'
            },
            'Failover': 'PRIMARY'|'SECONDARY',
            'TTL': 123,
            'ResourceRecords': [
                {
                    'Value': 'string'
                },
            ],
            'AliasTarget': {
                'HostedZoneId': 'string',
                'DNSName': 'string',
                'EvaluateTargetHealth': True|False
            },
            'HealthCheckId': 'string'
        },
    ],
    'IsTruncated': True|False,
    'MaxItems': 'string',
    'NextToken': 'string'
}
```
- **SetIdentifier** *(string)*

  *Weighted, Latency, Geo, and Failover resource record sets only:* An identifier that differentiates among multiple resource record sets that have the same combination of DNS name and type.

- **Weight** *(integer)*

  *Weighted resource record sets only:* Among resource record sets that have the same combination of DNS name and type, a value that determines what portion of traffic for the current resource record set is routed to the associated location.

- **Region** *(string)*

  *Latency-based resource record sets only:* Among resource record sets that have the same combination of DNS name and type, a value that specifies the AWS region for the current resource record set.

- **GeoLocation** *(dict)*

  *Geo location resource record sets only:* Among resource record sets that have the same combination of DNS name and type, a value that specifies the geo location for the current resource record set.

- **ContinentCode** *(string)*

  The code for a continent geo location. Note: only continent locations have a continent code.

  Valid values: `AF | AN | AS | EU | OC | NA | SA`

- **CountryCode** *(string)*

  The code for a country geo location. The default location uses ‘*’ for the country code and will match all locations that are not matched by a geo location.

  The default geo location uses a + for the country code. All other country codes follow the ISO 3166 two-character code.

- **SubdivisionCode** *(string)*

  The code for a country’s subdivision (e.g., a province of Canada). A subdivision code is only valid with the appropriate country code.

- **Failover** *(string)*

  *Failover resource record sets only:* Among resource record sets that have the same combination of DNS name and type, a value that indicates whether the current resource record set is a primary or secondary resource record set. A failover set may contain at most one resource record set marked as primary and one resource record set marked as secondary. A resource record set marked as primary will be returned if any of the following are true: (1) an associated health check is passing,
(2) if the resource record set is an alias with the evaluate target health and at least one target resource record set is healthy, (3) both the primary and secondary resource record set are failing health checks or (4) there is no secondary resource record set. A secondary resource record set will be returned if: (1) the primary is failing a health check and either the secondary is passing a health check or has no associated health check, or (2) there is no primary resource record set.

Valid values: PRIMARY | SECONDARY

- **TTL (integer)** –
  The cache time to live for the current resource record set.

- **ResourceRecords (list)** –
  A complex type that contains the resource records for the current resource record set.

- **Value (string)** –
  The value of the Value element for the current resource record set.

- **AliasTarget (dict)** –
  * **HostedZoneId (string)** –
    Aliases resource record sets only: Information about the AWS resource to which you are redirecting traffic.
  * **DNSName (string)** –
    Aliases resource record sets only: The external DNS name associated with the AWS Resource.

  For more information and an example, see Creating Alias Resource Record Sets in the Amazon Route 53 Developer Guide.

- **EvaluateTargetHealth (boolean)** –
  Aliases resource record sets only: A boolean value that indicates whether this Resource Record Set should respect the health status of any health checks associated with the ALIAS target record which it is linked to.

  For more information and an example, see Creating Alias Resource Record Sets in the Amazon Route 53 Developer Guide.

- **HealthCheckId (string)** –
  Health Check resource record sets only, not required for alias resource record sets: An identifier that is used to identify
health check associated with the resource record set.

- **IsTruncated** *(boolean)* –
  A flag that indicates whether there are more resource record sets to be listed. If your results were truncated, you can make a follow-up request for the next page of results by using the `ListResourceRecordSetsResponse$NextRecordName` element.
  
  Valid Values: `true` | `false`

- **MaxItems** *(string)* –
  The maximum number of records you requested. The maximum value of `MaxItems` is 100.

- **NextToken** *(string)* –
  A token to resume pagination.

### Waiters

The available waiters are:

- **Route53.Waiter.ResourceRecordSetsChanged**

```python
    class Route53.Waiter.ResourceRecordSetsChanged
```

```python
    waiter = client.get_waiter('resource_record_sets_changed')
```

```python
    waiter.wait(**kwargs)
```

Polls `Route53.Client.get_change()` every 30 seconds until a successful state is reached. An error is returned after 60 failed checks.

**Request Syntax**

```python
    waiter.wait(
        Id='string'
    )
```

**Parameters**

- **Id** *(string)* – [REQUIRED]
  The ID of the change batch request. The value that you specify here is the value that `ChangeResourceRecordSets` returned in the `Id` element when you submitted the request.

**Returns**

- None

### Route53Domains
Client

class Route53Domains.Client
    A low-level client representing Amazon Route 53 Domains:

        import boto3

        client = boto3.client('route53domains')

    These are the available methods:
        • can_paginate()
        • check_domain_availability()
        • delete_tags_for_domain()
        • disable_domain_auto_renew()
        • disable_domain_transfer_lock()
        • enable_domain_auto_renew()
        • enable_domain_transfer_lock()
        • generate_presigned_url()
        • get_domain_detail()
        • get_operation_detail()
        • get_peginator()
        • get_waiter()
        • list_domains()
        • list_operations()
        • list_tags_for_domain()
        • register_domain()
        • retrieve_domain_auth_code()
        • transfer_domain()
        • update_domain_contact()
        • update_domain_contact_privacy()
        • update_domain_nameservers()
        • update_tags_for_domain()

can_paginate(operation_name)
    Check if an operation can be paginated.
    
    Parameters operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginators("create_foo").
    
    Returns True if the operation can be paginated, False otherwise.

check_domain_availability(**kwargs)
    This operation checks the availability of one domain name. You can access this API without authenticating. Note that if the availability status of a domain is pending, you must submit another request to determine the availability of the domain name.

    Request Syntax

        response = client.check_domain_availability(  
            DomainName='string',  
            IdnLangCode='string'  
        )

    Parameters
        • DomainName (string) – [REQUIRED]
The name of a domain.
Type: String
Default: None
Constraints: The domain name can contain only the letters a through z, the numbers 0 through 9, and hyphen (-). Internationalized Domain Names are not supported.
Required: Yes

IdnLangCode (string) – Reserved for future use.

Response Syntax

```python
{ 'Availability': 'AVAILABLE'|'AVAILABLE_RESERVED'|'AVAILABLE_PREORDER'|'UNAVAILABLE'|'UNAVAILABLE_PREMIUM'|'UNAVAILABLE_RESTRICTED'|'RESERVED'|'DONT_KNOW' }
```

Response Structure

* (dict) –

The CheckDomainAvailability response includes the following elements.

  - **Availability (string)** –
    Whether the domain name is available for registering.

Note: You can only register domains designated as AVAILABLE.

Type: String
Valid values:

* AVAILABLE – The domain name is available.
* AVAILABLE_RESERVED – The domain name is reserved under specific conditions.
* AVAILABLE_PREORDER – The domain name is available and can be preordered.
* UNAVAILABLE – The domain name is not available.
* UNAVAILABLE_PREMIUM – The domain name is not available.
* UNAVAILABLE_RESTRICTED – The domain name is forbidden.
* RESERVED – The domain name has been reserved for another person or organization.
* DONT_KNOW – The TLD registry didn’t reply with a definitive answer about whether the domain name is available. Amazon Route 53 can return this response for a variety of reasons, for example, the registry is performing maintenance. Try again later.

**delete_tags_for_domain(**kwargs)**

This operation deletes the specified tags for a domain.

All tag operations are eventually consistent; subsequent operations may not immediately represent all issued operations.

Request Syntax

```python
response = client.delete_tags_for_domain(
    DomainName='string',
)```

```
Parameters

- **DomainName** *(string)* – [REQUIRED]
  
  The domain for which you want to delete one or more tags.

  The name of a domain.

  Type: String

  Default: None

  Constraints: The domain name can contain only the letters a through z, the numbers 0 through 9, and hyphen (-). Hyphens are allowed only when they are surrounded by letters, numbers, or other hyphens. You cannot specify a hyphen at the beginning or end of a label. To specify an Internationalized Domain Name, you must convert the name to Punycode.

  Required: Yes

- **TagsToDelete** *(list)* – [REQUIRED]
  
  A list of tag keys to delete.

  Type: A list that contains the keys of the tags that you want to delete.

  Default: None

  Required: No

  

Return type: `dict`

Returns

- **Response Syntax**

  ```
  {}
  ```

  - **Response Structure**

    - *(dict)* –

      disable_domain_auto_renew(**kwargs)**

      This operation disables automatic renewal of domain registration for the specified domain.

      Note: Caution! Amazon Route 53 doesn’t have a manual renewal process, so if you disable automatic renewal, registration for the domain will not be renewed when the expiration date passes, and you will lose control of the domain name.

  Request Syntax

  ```python
  response = client.disable_domain_auto_renew(
    DomainName='string'
  )
  ```

  - **Parameters**

    - **DomainName** *(string)* – [REQUIRED]

  Return type: `dict`
disable_domain_transfer_lock(**kwargs)
This operation removes the transfer lock on the domain (specifically the
clientTransferProhibited status) to allow domain transfers. We recommend you refrain
from performing this action unless you intend to transfer the domain to a different registrar. Successful
submission returns an operation ID that you can use to track the progress and completion of the action. If
the request is not completed successfully, the domain registrant will be notified by email.

Request Syntax

response = client.disable_domain_transfer_lock(
    DomainName='string'
)

Parameters  DomainName (string) – [REQUIRED]
The name of a domain.
Type: String
Default: None
Constraints: The domain name can contain only the letters a through z, the numbers 0
through 9, and hyphen (-). Internationalized Domain Names are not supported.
Required: Yes

Return type  dict

Response Syntax

{
    'OperationId': 'string'
}

Response Structure
• (dict) –
The DisableDomainTransferLock response includes the following element.
– OperationId (string) –
    Identifier for tracking the progress of the request. To use this ID to query
    the operation status, use GetOperationDetail.
    Type: String
    Default: None
    Constraints: Maximum 255 characters.

enable_domain_auto_renew(**kwargs)
This operation configures Amazon Route 53 to automatically renew the specified domain before the do-
main registration expires. The cost of renewing your domain registration is billed to your AWS account.
The period during which you can renew a domain name varies by TLD. For a list of TLDs and their renewal policies, see “Renewal, restoration, and deletion times” on the website for our registrar partner, Gandi. Route 53 requires that you renew before the end of the renewal period that is listed on the Gandi website so we can complete processing before the deadline.

Request Syntax

```python
response = client.enable_domain_auto_renew(
    DomainName='string'
)
```

**Parameters**

**DomainName** *(string) – [REQUIRED]*

**Return type**

`dict`

**Returns**

Response Syntax

```python
{}
```

**Response Structure**

- *(dict)* –

  `enable_domain_transfer_lock(**kwargs)`

This operation sets the transfer lock on the domain (specifically the `clientTransferProhibited` status) to prevent domain transfers. Successful submission returns an operation ID that you can use to track the progress and completion of the action. If the request is not completed successfully, the domain registrant will be notified by email.

Request Syntax

```python
response = client.enable_domain_transfer_lock(
    DomainName='string'
)
```

**Parameters**

**DomainName** *(string) – [REQUIRED]*

- The name of a domain.
- Type: String
- Default: None
- Constraints: The domain name can contain only the letters a through z, the numbers 0 through 9, and hyphen (-). Internationalized Domain Names are not supported.

**Required**: Yes

**Return type**

`dict`

**Returns**

Response Syntax

```python
{
    'OperationId': 'string'
}
```

**Response Structure**

- *(dict)* –

  The `EnableDomainTransferLock` response includes the following elements.
– **OperationId (string)** –

Identifier for tracking the progress of the request. To use this ID to query the operation status, use GetOperationDetail.

Type: String
Default: None

Constraints: Maximum 255 characters.

generate_presigned_url(
ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)

Generate a presigned url given a client, its method, and arguments

**Parameters**

• **ClientMethod (string)** – The client method to presign for

• **Params (dict)** – The parameters normally passed to ClientMethod.

• **ExpiresIn (int)** – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)

• **HttpMethod (string)** – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns**
The presigned url

get_domain_detail(**kwargs)

This operation returns detailed information about the domain. The domain’s contact information is also returned as part of the output.

**Request Syntax**

```python
response = client.get_domain_detail(
    DomainName='string'
)
```

**Parameters**

**DomainName (string)** – [REQUIRED]

The name of a domain.

Type: String
Default: None

Constraints: The domain name can contain only the letters a through z, the numbers 0 through 9, and hyphen (-). Internationalized Domain Names are not supported.

Required: Yes

**Return type**

dict

**Returns**

**Response Syntax**

```python

Response Structure

• (dict) –

The GetDomainDetail response includes the following elements.

  – **DomainName** *(string)* –

    The name of a domain.

    Type: String

  – **Nameservers** *(list)* –

    The name of the domain.

    Type: String

    * (dict) –

      Nameserver includes the following elements.

      • **Name** *(string)* –

        The fully qualified host name of the name server.

        Type: String

        Constraint: Maximum 255 characterss

        Parent: Nameservers

      • **GlueIps** *(list)* –

        Glue IP address of a name server entry. Glue IP addresses are required only when the name of the name server is a subdomain of the domain. For example, if your domain is example.com and the name server for the domain is ns.example.com, you need to specify the IP address for ns.example.com.

        Type: List of IP addresses.

        Constraints: The list can contain only one IPv4 and one IPv6 address.
Parent: Nameservers
  · (string) –

- **AutoRenew** (boolean) –

  Specifies whether the domain registration is set to renew automatically.

  Type: Boolean

- **AdminContact** (dict) –

  Provides details about the domain administrative contact.

  Type: Complex

  Children: FirstName, MiddleName, LastName, ContactType, OrganizationName, AddressLine1, AddressLine2, City, State, CountryCode, ZipCode, PhoneNumber, Email, Fax, ExtraParams

  * **FirstName** (string) –

    First name of contact.

    Type: String

    Default: None

    Constraints: Maximum 255 characters.

    Parents: RegistrantContact, AdminContact, TechContact

    Required: Yes

  * **LastName** (string) –

    Last name of contact.

    Type: String

    Default: None

    Constraints: Maximum 255 characters.

    Parents: RegistrantContact, AdminContact, TechContact

    Required: Yes

  * **ContactType** (string) –

    Indicates whether the contact is a person, company, association, or public organization. If you choose an option other than PERSON, you must enter an organization name, and you can’t enable privacy protection for the contact.

    Type: String

    Default: None

    Constraints: Maximum 255 characters.

    Valid values: PERSON | COMPANY | ASSOCIATION | PUBLIC_BODY

    Parents: RegistrantContact, AdminContact, TechContact

    Required: Yes
* **OrganizationName** *(string)* –
  Name of the organization for contact types other than **PERSON**.
  Type: String
  Default: None
  Constraints: Maximum 255 characters. Contact type must not be **PERSON**.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

* **AddressLine1** *(string)* –
  First line of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

* **AddressLine2** *(string)* –
  Second line of contact’s address, if any.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

* **City** *(string)* –
  The city of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

* **State** *(string)* –
  The state or province of the contact’s city.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
Parents: RegistrantContact, AdminContact, TechContact

Required: No

* **CountryCode** *(string)* —

  Code for the country of the contact’s address.

  Type: String

  Default: None

  Constraints: Maximum 255 characters.

  Parents: RegistrantContact, AdminContact, TechContact

  Required: Yes

* **ZipCode** *(string)* —

  The zip or postal code of the contact’s address.

  Type: String

  Default: None

  Constraints: Maximum 255 characters.

  Parents: RegistrantContact, AdminContact, TechContact

  Required: No

* **PhoneNumber** *(string)* —

  The phone number of the contact.

  Type: String

  Default: None

  Constraints: Phone number must be specified in the format “+[country dialing code].[number including any area code]”. For example, a US phone number might appear as "+1.1234567890".

  Parents: RegistrantContact, AdminContact, TechContact

  Required: Yes

* **Email** *(string)* —

  Email address of the contact.

  Type: String

  Default: None

  Constraints: Maximum 254 characters.

  Parents: RegistrantContact, AdminContact, TechContact

  Required: Yes

* **Fax** *(string)* —

  Fax number of the contact.

  Type: String
Default: None

Constraints: Phone number must be specified in the format “+[country dialing code].[number including any area code]”. For example, a US phone number might appear as "+1.1234567890".

Parents: RegistrantContact, AdminContact, TechContact

Required: No

* ExtraParams (list) –

A list of name-value pairs for parameters required by certain top-level domains.

Type: Complex

Default: None

Parents: RegistrantContact, AdminContact, TechContact

Children: Name, Value

Required: No

  · (dict) –

    ExtraParam includes the following elements.

    · Name (string) –

      Name of the additional parameter required by the top-level domain.

      Type: String

      Default: None

      Valid values: DUNS_NUMBER | BRAND_NUMBER | BIRTH_DEPARTMENT | BIRTH_DATE_IN_YYYY_MM_DD | BIRTH_COUNTRY | BIRTH_CITY | DOCUMENT_NUMBER | AU_ID_NUMBER | AU_ID_TYPE | CA_LEGAL_TYPE | ES_IDENTIFICATION | ES_IDENTIFICATION_TYPE | ES_LEGAL_FORM | FI_BUSINESS_NUMBER | FI_ID_NUMBER | IT_PIN | RU_PASSPORT_DATA | SE_ID_NUMBER | SG_ID_NUMBER | VAT_NUMBER

      Parent: ExtraParams

      Required: Yes

    · Value (string) –

      Values corresponding to the additional parameter names required by some top-level domains.

      Type: String

      Default: None

      Constraints: Maximum 2048 characters.

      Parent: ExtraParams

      Required: Yes
- **RegistrantContact** *(dict)* –

Provides details about the domain registrant.

Type: Complex

Children: FirstName, MiddleName, LastName, ContactType, OrganizationName, AddressLine1, AddressLine2, City, State, CountryCode, ZipCode, PhoneNumber, Email, Fax, ExtraParams

* **FirstName** *(string)* –

First name of contact.

Type: String

Default: None

Constraints: Maximum 255 characters.

Parents: RegistrantContact, AdminContact, TechContact

Required: Yes

* **LastName** *(string)* –

Last name of contact.

Type: String

Default: None

Constraints: Maximum 255 characters.

Parents: RegistrantContact, AdminContact, TechContact

Required: Yes

* **ContactType** *(string)* –

Indicates whether the contact is a person, company, association, or public organization. If you choose an option other than `PERSON`, you must enter an organization name, and you can’t enable privacy protection for the contact.

Type: String

Default: None

Constraints: Maximum 255 characters.

Valid values: PERSON | COMPANY | ASSOCIATION | PUBLIC_BODY

Parents: RegistrantContact, AdminContact, TechContact

Required: Yes

* **OrganizationName** *(string)* –

Name of the organization for contact types other than `PERSON`.

Type: String

Default: None
Constraints: Maximum 255 characters. Contact type must not be PERSON.

Parents: RegistrantContact, AdminContact, TechContact

Required: No

* AddressLine1 (string) –
  First line of the contact’s address.
  Type: String
  Default: None

Constraints: Maximum 255 characters.

Parents: RegistrantContact, AdminContact, TechContact

Required: Yes

* AddressLine2 (string) –
  Second line of contact’s address, if any.
  Type: String
  Default: None

Constraints: Maximum 255 characters.

Parents: RegistrantContact, AdminContact, TechContact

Required: No

* City (string) –
  The city of the contact’s address.
  Type: String
  Default: None

Constraints: Maximum 255 characters.

Parents: RegistrantContact, AdminContact, TechContact

Required: Yes

* State (string) –
  The state or province of the contact’s city.
  Type: String
  Default: None

Constraints: Maximum 255 characters.

Parents: RegistrantContact, AdminContact, TechContact

Required: No

* CountryCode (string) –
  Code for the country of the contact’s address.
  Type: String
Default: None
Constraints: Maximum 255 characters.
Parents: RegistrantContact, AdminContact, TechContact
Required: Yes

* **ZipCode** (string) –

The zip or postal code of the contact’s address.

Type: String
Default: None
Constraints: Maximum 255 characters.
Parents: RegistrantContact, AdminContact, TechContact
Required: No

* **PhoneNumber** (string) –

The phone number of the contact.

Type: String
Default: None
Constraints: Phone number must be specified in the format “+[country dialing code],[number including any area code]”. For example, a US phone number might appear as "+1.1234567890".
Parents: RegistrantContact, AdminContact, TechContact
Required: Yes

* **Email** (string) –

Email address of the contact.

Type: String
Default: None
Constraints: Maximum 254 characters.
Parents: RegistrantContact, AdminContact, TechContact
Required: Yes

* **Fax** (string) –

Fax number of the contact.

Type: String
Default: None
Constraints: Phone number must be specified in the format “+[country dialing code],[number including any area code]”. For example, a US phone number might appear as "+1.1234567890".
Parents: RegistrantContact, AdminContact, TechContact
Required: No

**ExtraParams (list)** –

A list of name-value pairs for parameters required by certain top-level domains.

Type: Complex

Default: None

Parents: RegistrantContact, AdminContact, TechContact

Children: Name, Value

Required: No

- **Value (string)** –

  Values corresponding to the additional parameter names required by some top-level domains.

  Type: String

  Default: None

  Constraints: Maximum 2048 characters.

  Parent: ExtraParams

Required: Yes

- **TechContact (dict)** –

  Provides details about the domain technical contact.

  Type: Complex

  Children: FirstName, MiddleName, LastName, ContactType, OrganizationName, AddressLine1, AddressLine2, City, State, CountryCode, ZipCode, PhoneNumber, Email, Fax, ExtraParams
* FirstName *(string)* –
  First name of contact.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

* LastName *(string)* –
  Last name of contact.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

* ContactType *(string)* –
  Indicates whether the contact is a person, company, association, or public organization. If you choose an option other than PERSON, you must enter an organization name, and you can’t enable privacy protection for the contact.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Valid values: PERSON | COMPANY | ASSOCIATION | PUBLIC_BODY
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

* OrganizationName *(string)* –
  Name of the organization for contact types other than PERSON.
  Type: String
  Default: None
  Constraints: Maximum 255 characters. Contact type must not be PERSON.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

* AddressLine1 *(string)* –
  First line of the contact’s address.
Type: String
Default: None
Constraints: Maximum 255 characters.
Parents: RegistrantContact, AdminContact, TechContact
Required: Yes

* AddressLine2 (string) –
Second line of contact’s address, if any.
Type: String
Default: None
Constraints: Maximum 255 characters.
Parents: RegistrantContact, AdminContact, TechContact
Required: No

* City (string) –
The city of the contact’s address.
Type: String
Default: None
Constraints: Maximum 255 characters.
Parents: RegistrantContact, AdminContact, TechContact
Required: Yes

* State (string) –
The state or province of the contact’s city.
Type: String
Default: None
Constraints: Maximum 255 characters.
Parents: RegistrantContact, AdminContact, TechContact
Required: No

* CountryCode (string) –
Code for the country of the contact’s address.
Type: String
Default: None
Constraints: Maximum 255 characters.
Parents: RegistrantContact, AdminContact, TechContact
Required: Yes
* **ZipCode** *(string)* –
  The zip or postal code of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

* **PhoneNumber** *(string)* –
  The phone number of the contact.
  Type: String
  Default: None
  Constraints: Phone number must be specified in the format “+[country dialing code].[number including any area code]”. For example, a US phone number might appear as "+1.1234567890".
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

* **Email** *(string)* –
  Email address of the contact.
  Type: String
  Default: None
  Constraints: Maximum 254 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

* **Fax** *(string)* –
  Fax number of the contact.
  Type: String
  Default: None
  Constraints: Phone number must be specified in the format “+[country dialing code].[number including any area code]”. For example, a US phone number might appear as "+1.1234567890".
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

* **ExtraParams** *(list)* –
  A list of name-value pairs for parameters required by certain top-level domains.
  Type: Complex
Default: None

Parents: RegistrantContact, AdminContact, TechContact

Children: Name, Value

Required: No

- **ExtraParam** includes the following elements.
  - **Name (string)** –
    
    Name of the additional parameter required by the top-level domain.

    Type: String
    Default: None

    Valid values:
    - DUNS_NUMBER
    - BRAND_NUMBER
    - BIRTH_DEPARTMENT
    - BIRTH_DATE_IN_YYYY_MM_DD
    - BIRTH_COUNTRY
    - BIRTH_CITY
    - DOCUMENT_NUMBER
    - AU_ID_NUMBER
    - AU_ID_TYPE
    - CA_LEGAL_TYPE
    - ES_IDENTIFICATION
    - ES_IDENTIFICATION_TYPE
    - ESLEGAL_FORM
    - FI_BUSINESS_NUMBER
    - FI_ID_NUMBER
    - IT_PIN
    - RU_PASSPORT_DATA
    - SE_ID_NUMBER
    - SG_ID_NUMBER
    - VAT_NUMBER

    Parent: ExtraParams

    Required: Yes

    - **Value (string)** –
      
      Values corresponding to the additional parameter names required by some top-level domains.

      Type: String
      Default: None

      Constraints: Maximum 2048 characters.

      Parent: ExtraParams

      Required: Yes

- **AdminPrivacy** (boolean) –

  Specifies whether contact information for the admin contact is concealed from WHOIS queries. If the value is `true`, WHOIS (“who is”) queries will return contact information for our registrar partner, Gandi, instead of the contact information that you enter.

  Type: Boolean

- **RegistrantPrivacy** (boolean) –

  Specifies whether contact information for the registrant contact is concealed from WHOIS queries. If the value is `true`, WHOIS (“who is”) queries will return contact information for our registrar partner, Gandi, instead of the contact information that you enter.

  Type: Boolean
– **TechPrivacy** *(boolean)* –

Specifies whether contact information for the tech contact is concealed from WHOIS queries. If the value is `true`, WHOIS (“who is”) queries will return contact information for our registrar partner, Gandi, instead of the contact information that you enter.

Type: Boolean

– **RegistrarName** *(string)* –

Name of the registrar of the domain as identified in the registry. Amazon Route 53 domains are registered by registrar Gandi. The value is "GANDI SAS".

Type: String

– **WhoIsServer** *(string)* –

The fully qualified name of the WHOIS server that can answer the WHOIS query for the domain.

Type: String

– **RegistrarUrl** *(string)* –

Web address of the registrar.

Type: String

– **AbuseContactEmail** *(string)* –

Email address to contact to report incorrect contact information for a domain, to report that the domain is being used to send spam, to report that someone is cybersquatting on a domain name, or report some other type of abuse.

Type: String

– **AbuseContactPhone** *(string)* –

Phone number for reporting abuse.

Type: String

– **RegistryDomainId** *(string)* –

Reserved for future use.

– **CreationDate** *(datetime)* –

The date when the domain was created as found in the response to a WHOIS query. The date format is Unix time.

– **UpdatedDate** *(datetime)* –

The last updated date of the domain as found in the response to a WHOIS query. The date format is Unix time.

– **ExpirationDate** *(datetime)* –

The date when the registration for the domain is set to expire. The date format is Unix time.

– **Reseller** *(string)* –

Reseller of the domain. Domains registered or transferred using Amazon Route 53 domains will have "Amazon" as the reseller.

Type: String

– **DnsSec** *(string)* –

Reserved for future use.
**StatusList** *(list)* –

An array of domain name status codes, also known as Extensible Provisioning Protocol (EPP) status codes.

ICANN, the organization that maintains a central database of domain names, has developed a set of domain name status codes that tell you the status of a variety of operations on a domain name, for example, registering a domain name, transferring a domain name to another registrar, renewing the registration for a domain name, and so on. All registrars use this same set of status codes.

For a current list of domain name status codes and an explanation of what each code means, go to the ICANN website and search for `epp status codes`. (Search on the ICANN website; web searches sometimes return an old version of the document.)

Type: Array of String

* *(string)* –

**get_operation_detail** (**kwargs**)

This operation returns the current status of an operation that is not completed.

Request Syntax

```python
response = client.get_operation_detail(
    OperationId='string'
)
```

**Parameters**

**OperationId** *(string)* – [REQUIRED]

The identifier for the operation for which you want to get the status. Amazon Route 53 returned the identifier in the response to the original request.

Type: String

Default: None

Required: Yes

**Return type**

dict

**Returns**

Response Syntax

```python
{
    'OperationId': 'string',
    'Status': 'SUBMITTED'|'IN_PROGRESS'|'ERROR'|'SUCCESSFUL'|'FAILED',
    'Message': 'string',
    'DomainName': 'string',
    'Type': 'REGISTER_DOMAIN'|'DELETE_DOMAIN'|'TRANSFER_IN_DOMAIN'|'UPDATE_DOMAIN_CONTACT'|'UPDATE_NAMESERVER'|'CHANGE_PRIVACY_PROTECTION'|'DOMAIN_LOCK',
    'SubmittedDate': datetime(2015, 1, 1)
}
```

**Response Structure**

* *(dict)* –

The GetOperationDetail response includes the following elements.

- **OperationId** *(string)* –

  The identifier for the operation.

  Type: String
- **Status** *(string)* –
  The current status of the requested operation in the system.
  Type: String
- **Message** *(string)* –
  Detailed information on the status including possible errors.
  Type: String
- **DomainName** *(string)* –
  The name of a domain.
  Type: String
- **Type** *(string)* –
  The type of operation that was requested.
  Type: String
- **SubmittedDate** *(datetime)* –
  The date when the request was submitted.

`get_paginator(operation_name)`

Create a paginator for an operation.

**Parameters operation_name** *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

**Raises** OperationNotPageableError Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

**Return type** L{botocore.paginate.Paginator}

**Returns** A paginator object.

`get_waiter(waiter_name)`

`list_domains(**kwargs)`

This operation returns all the domain names registered with Amazon Route 53 for the current AWS account.

**Request Syntax**

```python
response = client.list_domains(
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **Marker** *(string)* – For an initial request for a list of domains, omit this element. If the number of domains that are associated with the current AWS account is greater than the value that you specified for `MaxItems`, you can use Marker to return additional domains. Get the value of `NextPageMarker` from the previous response, and submit another request that includes the value of `NextPageMarker` in the `Marker` element.
  Type: String
  Default: None
  Constraints: The marker must match the value specified in the previous request.
Required: No

- **MaxItems** (*integer*) – Number of domains to be returned.
  
  Type: Integer
  
  Default: 20
  
  Constraints: A numeral between 1 and 100.
  
  Required: No

**Return type**  
**dict**

**Returns**

**Response Syntax**

```
{
    'Domains': [
        {
            'DomainName': 'string',
            'AutoRenew': True|False,
            'TransferLock': True|False,
            'Expiry': datetime(2015, 1, 1)
        },
    ],
    'NextPageMarker': 'string'
}
```

**Response Structure**

- (*dict*) –

  The ListDomains response includes the following elements.

  - **Domains** (*list*) –

    A summary of domains.

    Type: Complex type containing a list of domain summaries.

    **Children:** AutoRenew, DomainName, Expiry, TransferLock

    - (*dict*) –

      - **DomainName** (*string*) –

        The name of a domain.

        Type: String

      - **AutoRenew** (*boolean*) –

        Indicates whether the domain is automatically renewed upon expiration.

        Type: Boolean

        Valid values: True|False

      - **TransferLock** (*boolean*) –

        Indicates whether a domain is locked from unauthorized transfer to another party.

        Type: Boolean

        Valid values: True|False

      - **Expiry** (*datetime*) –

        Expiration date of the domain in Coordinated Universal Time (UTC).
Type: Long

- **NextPageMarker (string)**

  If there are more domains than you specified for `MaxItems` in the request, submit another request and include the value of `NextPageMarker` in the value of `Marker`.  
  
  Type: String
  
  Parent: Operations

`list_operations(**kwargs)`

This operation returns the operation IDs of operations that are not yet complete.

**Request Syntax**

```python
response = client.list_operations(
    Marker='string',
    MaxItems=123
)
```

**Parameters**

- **Marker (string)** – For an initial request for a list of operations, omit this element. If the number of operations that are not yet complete is greater than the value that you specified for `MaxItems`, you can use `Marker` to return additional operations. Get the value of `NextPageMarker` from the previous response, and submit another request that includes the value of `NextPageMarker` in the `Marker` element.

  Type: String
  
  Default: None
  
  Required: No

- **MaxItems (integer)** – Number of domains to be returned.

  Type: Integer
  
  Default: 20
  
  Constraints: A value between 1 and 100.
  
  Required: No

**Return type** dict

**Returns**

**Response Syntax**

```python
{  
    'Operations': [
      
        'OperationId': 'string',
        'Status': 'SUBMITTED'|'IN_PROGRESS'|'ERROR'|'SUCCESSFUL'|'FAILED',
        'Type': 'REGISTER_DOMAIN'|'DELETE_DOMAIN'|'TRANSFER_IN_DOMAIN'|'UPDATE_DOMAIN_CONTACT'|'UPDATE_NAMESERVER'|'CHANGE_PRIVACY_PROTECTION'|'DOMAIN_LOCK',
        'SubmittedDate': datetime(2015, 1, 1)
    ],
    'NextPageMarker': 'string'
}
```

**Response Structure**
• (dict) –

The ListOperations response includes the following elements.

– Operations (list) –

Lists summaries of the operations.

Type: Complex type containing a list of operation summaries

Children: OperationId, Status, SubmittedDate, Type

* (dict) –

OperationSummary includes the following elements.

  · OperationId (string) –

    Identifier returned to track the requested action.

    Type: String

  · Status (string) –

    The current status of the requested operation in the system.

    Type: String

  · Type (string) –

    Type of the action requested.

    Type: String

    Valid values: REGISTER_DOMAIN | DELETE_DOMAIN | TRANSFER_IN_DOMAIN | UPDATE_DOMAIN_CONTACT | UPDATE_NAMESERVER | CHANGE_PRIVACY_PROTECTION | DOMAIN_LOCK

  · SubmittedDate (datetime) –

    The date when the request was submitted.

– NextPageMarker (string) –

If there are more operations than you specified for MaxItems in the request, submit another request and include the value of NextPageMarker in the value of Marker.

Type: String

Parent: Operations

list_tags_for_domain(**kwargs)

This operation returns all of the tags that are associated with the specified domain.

All tag operations are eventually consistent; subsequent operations may not immediately represent all issued operations.

Request Syntax

response = client.list_tags_for_domain(
    DomainName='string'
)

Parameters DomainName (string) – [REQUIRED]

The domain for which you want to get a list of tags.

Return type  dict
Returns

Response Syntax

```json
{
    'TagList': [
        {
            'Key': 'string',
            'Value': 'string'
        }
    ]
}
```

Response Structure

- `dict` –

The ListTagsForDomain response includes the following elements.

  - **TagList** *(list)* –
    A list of the tags that are associated with the specified domain.
    Type: A complex type containing a list of tags
    Each tag includes the following elements.
    - **Key** *(string)* –
      The key (name) of a tag.
      Type: String
      Default: None
      Valid values: A-Z, a-z, 0-9, space, ",/.:+@”
      Constraints: Each key can be 1-128 characters long.
      Required: Yes
    - **Value** *(string)* –
      The value of a tag.
      Type: String
      Default: None
      Valid values: A-Z, a-z, 0-9, space, ",/.:+@”
      Constraints: Each value can be 0-256 characters long.
      Required: Yes

**register_domain** (**kwargs**)

This operation registers a domain. Domains are registered by the AWS registrar partner, Gandi. For some top-level domains (TLDs), this operation requires extra parameters.

When you register a domain, Amazon Route 53 does the following:

- Creates a Amazon Route 53 hosted zone that has the same name as the domain. Amazon Route 53 assigns four name servers to your hosted zone and automatically updates your domain registration with the names of these name servers.
• Enables autorenew, so your domain registration will renew automatically each year. We’ll notify you in advance of the renewal date so you can choose whether to renew the registration.
• Optionally enables privacy protection, so WHOIS queries return contact information for our registrar partner, Gandi, instead of the information you entered for registrant, admin, and tech contacts.
• If registration is successful, returns an operation ID that you can use to track the progress and completion of the action. If the request is not completed successfully, the domain registrant is notified by email.
• Charges your AWS account an amount based on the top-level domain. For more information, see Amazon Route 53 Pricing.

Request Syntax

```python
response = client.register_domain(
    DomainName='string',
    IdnLangCode='string',
    DurationInYears=123,
    AutoRenew=True|False,
    AdminContact={
        'FirstName': 'string',
        'LastName': 'string',
        'ContactType': 'PERSON'|'COMPANY'|'ASSOCIATION'|'PUBLIC_BODY'|'RESELLER',
        'OrganizationName': 'string',
        'AddressLine1': 'string',
        'AddressLine2': 'string',
        'City': 'string',
        'State': 'string',
        'CountryCode': ... 'AT'|'AU'|'AZ'|'BE'|'BG'|'BH'|'BO'|'BR'|'BY'|'BZ'|'CA'|'CC'|'CD'|'CG'|'CH'|'CI'|'CL'|'CM'|'CN'|'CO'|'CR'|'CU'|'CZ'|'DE'|'DK'|'DO'|'DZ'|'EC'|'EG'|'ES'|'ET'|'FI'|'FK'|'FM'|'FR'|'GA'|'GB'|'GD'|'GE'|'GF'|'GH'|'GI'|'GL'|'GM'|'GN'|'GQ'|'GR'|'GT'|'GU'|'GW'|'GY'|'HK'|'HN'|'HR'|'HT'|'HU'|'ID'|'IE'|'IL'|'IM'|'IN'|'IO'|'IQ'|'IR'|'IS'|'IT'|'JE'|'JM'|'JO'|'JP'|'KE'|'KG'|'KH'|'KI'|'KM'|'KN'|'KP'|'KR'|'KW'|'KY'|'KZ'|'LA'|'LB'|'LC'|'LI'|'LK'|'LR'|'LS'|'LT'|'LU'|'LV'|'LY'|'MA'|'MC'|'MD'|'ME'|'MF'|'MG'|'MH'|'MK'|'ML'|'MN'|'MO'|'MP'|'MQ'|'MR'|'MS'|'MT'|'MU'|'MV'|'MW'|'MX'|'MY'|'MZ'|'NA'|'NC'|'NE'|'NF'|'NG'|'NI'|'NL'|'NO'|'NP'|'NR'|'NU'|'NW'|'NZ'|'OM'|'PA'|'PE'|'PF'|'PG'|'PH'|'PK'|'PL'|'PM'|'PN'|'PR'|'PS'|'PT'|'PW'|'PY'|'QG'|'QR'|'RS'|'RU'|'RW'|'SA'|'SB'|'SC'|'SD'|'SE'|'SG'|'SH'|'SI'|'SJ'|'SK'|'SL'|'SM'|'SN'|'SO'|'SP'|'SR'|'ST'|'SU'|'SV'|'SW'|'SX'|'SY'|'SZ'|'TC'|'TD'|'TG'|'TH'|'TJ'|'TK'|'TM'|'TN'|'TO'|'TR'|'TT'|'TV'|'TW'|'TZ'|'UA'|'UG'|'US'|'UY'|'UZ'|'VA'|'VC'|'VE'|'VG'|'VI'|'VN'|'VU'|'WF'|'WS'|'YE'|'YT'|'ZA'|'ZM'|'ZW',
        'ZipCode': 'string',
        'PhoneNumber': 'string',
        'Email': 'string',
        'Fax': 'string',
        'ExtraParams': [
            {

                'Value': 'string'
            }
        ],
    },
    RegistrantContact={
        'FirstName': 'string',
        'LastName': 'string',
        'ContactType': 'PERSON'|'COMPANY'|'ASSOCIATION'|'PUBLIC_BODY'|'RESELLER',
        'OrganizationName': 'string',
        'AddressLine1': 'string',
        'AddressLine2': 'string',
        'City': 'string',
        'State': 'string',
        'CountryCode': ... 'AT'|'AU'|'AZ'|'BE'|'BG'|'BH'|'BO'|'BR'|'BY'|'BZ'|'CA'|'CC'|'CD'|'CG'|'CH'|'CI'|'CL'|'CM'|'CN'|'CO'|'CR'|'CU'|'CZ'|'DE'|'DK'|'DO'|'DZ'|'EC'|'EG'|'ES'|'ET'|'FI'|'FK'|'FM'|'FR'|'GA'|'GB'|'GD'|'GE'|'GF'|'GH'|'GI'|'GL'|'GM'|'GN'|'GQ'|'GR'|'GT'|'GU'|'GW'|'GY'|'HK'|'HN'|'HR'|'HT'|'HU'|'ID'|'IE'|'IL'|'IM'|'IN'|'IO'|'IQ'|'IR'|'IS'|'IT'|'JE'|'JM'|'JO'|'JP'|'KE'|'KG'|'KH'|'KI'|'KM'|'KN'|'KP'|'KR'|'KW'|'KY'|'KZ'|'LA'|'LB'|'LC'|'LI'|'LK'|'LR'|'LS'|'LT'|'LU'|'LV'|'LY'|'MA'|'MC'|'MD'|'ME'|'MF'|'MG'|'MH'|'MK'|'ML'|'MN'|'MO'|'MP'|'MQ'|'MR'|'MS'|'MT'|'MU'|'MV'|'MW'|'MX'|'MY'|'MZ'|'NA'|'NC'|'NE'|'NF'|'NG'|'NI'|'NL'|'NO'|'NP'|'NR'|'NU'|'NW'|'NZ'|'OM'|'PA'|'PE'|'PF'|'PG'|'PH'|'PK'|'PL'|'PM'|'PN'|'PR'|'PS'|'PT'|'PW'|'PY'|'QG'|'QR'|'RS'|'RU'|'RW'|'SA'|'SB'|'SC'|'SD'|'SE'|'SG'|'SH'|'SI'|'SJ'|'SK'|'SL'|'SM'|'SN'|'SO'|'SP'|'SR'|'ST'|'SU'|'SV'|'SW'|'SX'|'SY'|'SZ'|'TC'|'TD'|'TG'|'TH'|'TJ'|'TK'|'TM'|'TN'|'TO'|'TR'|'TT'|'TV'|'TW'|'TZ'|'UA'|'UG'|'US'|'UY'|'UZ'|'VA'|'VC'|'VE'|'VG'|'VI'|'VN'|'VU'|'WF'|'WS'|'YE'|'YT'|'ZA'|'ZM'|'ZW',
        'ZipCode': 'string',
        'PhoneNumber': 'string',
        'Email': 'string',
        'Fax': 'string',
        'ExtraParams': [
            {
                'Name': ... 'ES_LEGAL_FORM'|'FI_BUSINESS_NUMBER'|'FI_ID_NUMBER'|'IT_PIN'|'RU_PASSPORT_DATA'|'SE_ID_NUMBER'|'SG_ID_NUMBER'|'VAT_NUMBER',
                'Value': 'string'
            }
        ],
    },
)
```
Parameters

- **DomainName** *(string)* – [REQUIRED]
  The name of a domain.
  Type: String
  Default: None
  Constraints: The domain name can contain only the letters a through z, the numbers 0 through 9, and hyphen (-). Internationalized Domain Names are not supported.
  Required: Yes

- **IdnLangCode** *(string)* – Reserved for future use.

- **DurationInYears** *(integer)* – [REQUIRED]
  The number of years the domain will be registered. Domains are registered for a minimum of one year. The maximum period depends on the top-level domain.
  Type: Integer
  Default: 1
  Valid values: Integer from 1 to 10
  Required: Yes

- **AutoRenew** *(boolean)* – Indicates whether the domain will be automatically renewed *(true)* or not *(false)*. Autorenewal only takes effect after the account is charged.
  Type: Boolean
  Valid values: true | false
**AdminContact (dict)** – [REQUIRED]

Provides detailed contact information.

**Type:** Complex

**Children:** FirstName, MiddleName, LastName, ContactType, OrganizationName, AddressLine1, AddressLine2, City, State, CountryCode, ZipCode, PhoneNumber, Email, Fax, ExtraParams

**Required:** Yes

- **FirstName (string)** –
  
  First name of contact.
  
  **Type:** String
  
  **Default:** None
  
  **Constraints:** Maximum 255 characters.
  
  **Parents:** RegistrantContact, AdminContact, TechContact

  **Required:** Yes

- **LastName (string)** –
  
  Last name of contact.
  
  **Type:** String
  
  **Default:** None
  
  **Constraints:** Maximum 255 characters.
  
  **Parents:** RegistrantContact, AdminContact, TechContact

  **Required:** Yes

- **ContactType (string)** –
  
  Indicates whether the contact is a person, company, association, or public organization. If you choose an option other than PERSON, you must enter an organization name, and you can’t enable privacy protection for the contact.
  
  **Type:** String
  
  **Default:** None
  
  **Constraints:** Maximum 255 characters.
  
  **Valid values:** PERSON | COMPANY | ASSOCIATION | PUBLIC_BODY
  
  **Parents:** RegistrantContact, AdminContact, TechContact

  **Required:** Yes

- **OrganizationName (string)** –
  
  Name of the organization for contact types other than PERSON.
  
  **Type:** String
  
  **Default:** None
Constraints: Maximum 255 characters. Contact type must not be `PERSON`.

Parents: `RegistrantContact`, `AdminContact`, `TechContact`
Required: No

- **AddressLine1** *(string)* –
  First line of the contact’s address.
  Type: String
  Default: None

Constraints: Maximum 255 characters.
Parents: `RegistrantContact`, `AdminContact`, `TechContact`
Required: Yes

- **AddressLine2** *(string)* –
  Second line of contact’s address, if any.
  Type: String
  Default: None

Constraints: Maximum 255 characters.
Parents: `RegistrantContact`, `AdminContact`, `TechContact`
Required: No

- **City** *(string)* –
  The city of the contact’s address.
  Type: String
  Default: None

Constraints: Maximum 255 characters.
Parents: `RegistrantContact`, `AdminContact`, `TechContact`
Required: Yes

- **State** *(string)* –
  The state or province of the contact’s city.
  Type: String
  Default: None

Constraints: Maximum 255 characters.
Parents: `RegistrantContact`, `AdminContact`, `TechContact`
Required: No

- **CountryCode** *(string)* –
  Code for the country of the contact’s address.
  Type: String
  Default: None

Constraints: Maximum 255 characters.
Parents: `RegistrantContact`, `AdminContact`, `TechContact`
Required: Yes

- **ZipCode (string)** –
  The zip or postal code of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact

Required: No

- **PhoneNumber (string)** –
  The phone number of the contact.
  Type: String
  Default: None
  Constraints: Phone number must be specified in the format “+[country dialing code],[number including any area code]”. For example, a US phone number might appear as "+1.1234567890".
  Parents: RegistrantContact, AdminContact, TechContact

Required: Yes

- **Email (string)** –
  Email address of the contact.
  Type: String
  Default: None
  Constraints: Maximum 254 characters.
  Parents: RegistrantContact, AdminContact, TechContact

Required: No

- **Fax (string)** –
  Fax number of the contact.
  Type: String
  Default: None
  Constraints: Phone number must be specified in the format “+[country dialing code],[number including any area code]”. For example, a US phone number might appear as "+1.1234567890".
  Parents: RegistrantContact, AdminContact, TechContact

Required: No

- **ExtraParams (list)** –
  A list of name-value pairs for parameters required by certain top-level domains.
  Type: Complex
  Default: None
  Parents: RegistrantContact, AdminContact, TechContact
Children: Name, Value

Required: No

* (dict) –

ExtraParam includes the following elements.

- Name (string) – [REQUIRED]

  Name of the additional parameter required by the top-level domain.

  Type: String

  Default: None

  Valid values: DUNS_NUMBER, BRAND_NUMBER, BIRTH_DEPARTMENT, BIRTH_DATE_IN_YYYY_MM_DD, BIRTH_COUNTRY, BIRTH_CITY, DOCUMENT_NUMBER, AU_ID_NUMBER, AU_ID_TYPE, CA_LEGAL_TYPE, ES_IDENTIFICATION, ES_IDENTIFICATION_TYPE, ES_LEGAL_FORM, FI_BUSINESS_NUMBER, FI_ID_NUMBER, IT_PIN, RU_PASSPORT_DATA, SE_ID_NUMBER, SG_ID_NUMBER, VAT_NUMBER

Parent: ExtraParams

Required: Yes

- Value (string) – [REQUIRED]

  Values corresponding to the additional parameter names required by some top-level domains.

  Type: String

  Default: None

  Constraints: Maximum 2048 characters.

Parent: ExtraParams

Required: Yes

- RegistrantContact (dict) – [REQUIRED]

  Provides detailed contact information.

  Type: Complex

  Children: FirstName, MiddleName, LastName, ContactType, OrganizationName, AddressLine1, AddressLine2, City, State, CountryCode, ZipCode, PhoneNumber, Email, Fax, ExtraParams

Required: Yes

- FirstName (string) –

  First name of contact.

  Type: String

  Default: None

  Constraints: Maximum 255 characters.

Parents: RegistrantContact, AdminContact, TechContact
- **LastName (string)** –
  Last name of contact.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact

- **ContactType (string)** –
  Indicates whether the contact is a person, company, association, or public organization. If you choose an option other than `PERSON`, you must enter an organization name, and you can’t enable privacy protection for the contact.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Valid values: PERSON | COMPANY | ASSOCIATION | PUBLIC_BODY
  Parents: RegistrantContact, AdminContact, TechContact

- **OrganizationName (string)** –
  Name of the organization for contact types other than `PERSON`.
  Type: String
  Default: None
  Constraints: Maximum 255 characters. Contact type must not be `PERSON`.
  Parents: RegistrantContact, AdminContact, TechContact

- **AddressLine1 (string)** –
  First line of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact

- **AddressLine2 (string)** –
  Second line of contact’s address, if any.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
- **City (string)** –
  The city of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **State (string)** –
  The state or province of the contact’s city.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **CountryCode (string)** –
  Code for the country of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **ZipCode (string)** –
  The zip or postal code of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **PhoneNumber (string)** –
  The phone number of the contact.
  Type: String
  Default: None
  Constraints: Phone number must be specified in the format “+[country dialing code].[number including any area code]”. For example, a US phone number might appear as "+1.1234567890".
  Parents: RegistrantContact, AdminContact, TechContact

3.1. Services 3911
Required: Yes

- **Email (string)** –
  
  Email address of the contact.

  Type: String

  Default: None

  Constraints: Maximum 254 characters.

  Parents: RegistrantContact, AdminContact, TechContact

  Required: Yes

- **Fax (string)** –
  
  Fax number of the contact.

  Type: String

  Default: None

  Constraints: Phone number must be specified in the format “+[country dialing code].[number including any area code]”. For example, a US phone number might appear as "+1.1234567890”.

  Parents: RegistrantContact, AdminContact, TechContact

  Required: No

- **ExtraParams (list)** –
  
  A list of name-value pairs for parameters required by certain top-level domains.

  Type: Complex

  Default: None

  Parents: RegistrantContact, AdminContact, TechContact

  Children: Name, Value

  Required: No

  * (dict) –

  ExtraParam includes the following elements.

  - **Name (string)** – [REQUIRED]

    Name of the additional parameter required by the top-level domain.

    Type: String

    Default: None

    Valid values:

    - DUNS_NUMBER
    - BRAND_NUMBER
    - BIRTH_DEPARTMENT
    - BIRTH_DATE_IN_YYY_MM_DD
    - BIRTH_COUNTRY
    - BIRTH_CITY
    - DOCUMENT_NUMBER
    - AU_ID_NUMBER
    - AU_ID_TYPE
    - CA_LEGAL_TYPE
    - ES_IDENTIFICATION
    - ES_IDENTIFICATION_TYPE
    - ES_LEGAL_FORM
    - FI_BUSINESS_NUMBER
    - FI_ID_NUMBER
    - IT_PIN
    - RU_PASSPORT_DATA
    - SE_ID_NUMBER
    - SG_ID_NUMBER
    - VAT_NUMBER

    Parent: ExtraParams
• **TechContact (dict)** – [REQUIRED]

  Provides detailed contact information.

  Type: Complex

  Children: FirstName, MiddleName, LastName, ContactType, OrganizationName, AddressLine1, AddressLine2, City, State, CountryCode, ZipCode, PhoneNumber, Email, Fax, ExtraParams

  Required: Yes

  - **FirstName (string)** –

    First name of contact.

    Type: String

    Default: None

    Constraints: Maximum 255 characters.

    Parents: RegistrantContact, AdminContact, TechContact

    Required: Yes

  - **LastName (string)** –

    Last name of contact.

    Type: String

    Default: None

    Constraints: Maximum 255 characters.

    Parents: RegistrantContact, AdminContact, TechContact

    Required: Yes

  - **ContactType (string)** –

    Indicates whether the contact is a person, company, association, or public organization. If you choose an option other than PERSON, you must enter an organization name, and you can’t enable privacy protection for the contact.

    Type: String

    Default: None

    Constraints: Maximum 255 characters.

    Valid values: PERSON | COMPANY | ASSOCIATION | PUBLIC_BODY
Parents: RegistrantContact, AdminContact, TechContact

Required: Yes

- **OrganizatonName (string)**
  
  Name of the organization for contact types other than PERSON.
  
  Type: String
  
  Default: None
  
  Constraints: Maximum 255 characters. Contact type must not be PERSON.

  Parents: RegistrantContact, AdminContact, TechContact

  Required: No

- **AddressLine1 (string)**
  
  First line of the contact’s address.
  
  Type: String
  
  Default: None
  
  Constraints: Maximum 255 characters.

  Parents: RegistrantContact, AdminContact, TechContact

  Required: Yes

- **AddressLine2 (string)**
  
  Second line of contact’s address, if any.
  
  Type: String
  
  Default: None
  
  Constraints: Maximum 255 characters.

  Parents: RegistrantContact, AdminContact, TechContact

  Required: No

- **City (string)**
  
  The city of the contact’s address.
  
  Type: String
  
  Default: None
  
  Constraints: Maximum 255 characters.

  Parents: RegistrantContact, AdminContact, TechContact

  Required: Yes

- **State (string)**
  
  The state or province of the contact’s city.
  
  Type: String
  
  Default: None
  
  Constraints: Maximum 255 characters.

  Parents: RegistrantContact, AdminContact, TechContact

  Required: No
- **CountryCode** (*string*)
  Code for the country of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **ZipCode** (*string*)
  The zip or postal code of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **PhoneNumber** (*string*)
  The phone number of the contact.
  Type: String
  Default: None
  Constraints: Phone number must be specified in the format “+[country dialing code].[number including any area code]”. For example, a US phone number might appear as "+1.1234567890".
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **Email** (*string*)
  Email address of the contact.
  Type: String
  Default: None
  Constraints: Maximum 254 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **Fax** (*string*)
  Fax number of the contact.
  Type: String
  Default: None
  Constraints: Phone number must be specified in the format “+[country dialing code].[number including any area code]”. For example, a US phone number might appear as "+1.1234567890".
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No
- **ExtraParams** *(list)* –

  A list of name-value pairs for parameters required by certain top-level domains.

  Type: Complex

  Default: None

  Parents: RegistrantContact, AdminContact, TechContact

  Children: Name, Value

  Required: No

  * (dict) –

ExtraParam includes the following elements.

- **Name** *(string)* – [REQUIRED]

  Name of the additional parameter required by the top-level domain.

  Type: String

  Default: None

  Valid values: DUNS_NUMBER | BRAND_NUMBER | BIRTH_DEPARTMENT | BIRTH_DATE_IN_YYYY-MM_DD | BIRTH_COUNTRY | BIRTH_CITY | DOCUMENT_NUMBER | AU_ID_NUMBER | AU_ID_TYPE | CA_LEGAL_TYPE | ES_IDENTIFICATION | ES_IDENTIFICATION_TYPE | ES_LEGAL_FORM | FI_BUSINESS_NUMBER | FI_ID_NUMBER | IT_PIN | RU_PASSPORT_DATA | SE_ID_NUMBER | SG_ID_NUMBER | VAT_NUMBER

  Parent: ExtraParams

  Required: Yes

- **Value** *(string)* – [REQUIRED]

  Values corresponding to the additional parameter names required by some top-level domains.

  Type: String

  Default: None

  Constraints: Maximum 2048 characters.

  Parent: ExtraParams

  Required: Yes

- **PrivacyProtectAdminContact** *(boolean)* – Whether you want to conceal contact information from WHOIS queries. If you specify true, WHOIS (“who is”) queries will return contact information for our registrar partner, Gandi, instead of the contact information that you enter.

  Type: Boolean

  Default: true

  Valid values: true | false

  Required: No
• **PrivacyProtectRegistrantContact** *(boolean)* – Whether you want to conceal contact information from WHOIS queries. If you specify true, WHOIS (“who is”) queries will return contact information for our registrar partner, Gandi, instead of the contact information that you enter.

    Type: Boolean
    Default: true
    Valid values: true | false
    Required: No

• **PrivacyProtectTechContact** *(boolean)* – Whether you want to conceal contact information from WHOIS queries. If you specify true, WHOIS (“who is”) queries will return contact information for our registrar partner, Gandi, instead of the contact information that you enter.

    Type: Boolean
    Default: true
    Valid values: true | false
    Required: No

Return type: dict

Returns

Response Syntax

```
{
   'OperationId': 'string'
}
```

Response Structure

• *(dict)* –

    The RegisterDomain response includes the following element.

    • **OperationId** *(string)* –

        Identifier for tracking the progress of the request. To use this ID to query the operation status, use GetOperationDetail.

        Type: String
        Default: None
        Constraints: Maximum 255 characters.

**retrieve_domain_auth_code**(**kwargs**)

This operation returns the AuthCode for the domain. To transfer a domain to another registrar, you provide this value to the new registrar.

Request Syntax

```python
response = client.retrieve_domain_auth_code(
    DomainName='string'
)
```

Parameters

**DomainName** *(string)* – [REQUIRED]

The name of a domain.

Type: String
Default: None

Constraints: The domain name can contain only the letters a through z, the numbers 0 through 9, and hyphen (-). Internationalized Domain Names are not supported.

Required: Yes

Return type: dict

Returns:

Response Syntax

```python
{
    'AuthCode': 'string'
}
```

Response Structure

- `(dict)` –
  The RetrieveDomainAuthCode response includes the following element.
  - `AuthCode (string)` –
    The authorization code for the domain.
    Type: String

`transfer_domain(**kwargs)`

This operation transfers a domain from another registrar to Amazon Route 53. When the transfer is complete, the domain is registered with the AWS registrar partner, Gandi.

For transfer requirements, a detailed procedure, and information about viewing the status of a domain transfer, see Transferring Registration for a Domain to Amazon Route 53 in the Amazon Route 53 Developer Guide.

If the registrar for your domain is also the DNS service provider for the domain, we highly recommend that you consider transferring your DNS service to Amazon Route 53 or to another DNS service provider before you transfer your registration. Some registrars provide free DNS service when you purchase a domain registration. When you transfer the registration, the previous registrar will not renew your domain registration and could end your DNS service at any time.

**Note:** Caution! If the registrar for your domain is also the DNS service provider for the domain and you don’t transfer DNS service to another provider, your website, email, and the web applications associated with the domain might become unavailable.

If the transfer is successful, this method returns an operation ID that you can use to track the progress and completion of the action. If the transfer doesn’t complete successfully, the domain registrant will be notified by email.

Request Syntax

```python
response = client.transfer_domain(
    DomainName='string',
    IdnLangCode='string',
    DurationInYears=123,
    Nameservers=[
        {
            'Name': 'string',
            'GlueIps': [
                'string',
            ]
        },
    ],
)```

3.1. Services
Parameters

- **DomainName** *(string)* – [REQUIRED]
  The name of a domain.
  Type: String
  Default: None
  Constraints: The domain name can contain only the letters a through z, the numbers 0 through 9, and hyphen (-). Internationalized Domain Names are not supported.
  Required: Yes
- **IdnLangCode** *(string)* – Reserved for future use.
- **DurationInYears** *(integer)* – [REQUIRED]
  The number of years the domain will be registered. Domains are registered for a minimum of one year. The maximum period depends on the top-level domain.
  Type: Integer
  Default: 1
  Valid values: Integer from 1 to 10
  Required: Yes
- **Nameservers** *(list)* – Contains details for the host and glue IP addresses.
  Type: Complex
  Children: GlueIps, Name
  Required: No
  - *(dict)* –
    Nameserver includes the following elements.
    * **Name** *(string)* – [REQUIRED]
      The fully qualified host name of the name server.
      Type: String
      Constraint: Maximum 255 characters
      Parent: Nameservers
    * **GlueIps** *(list)* –
      Glue IP address of a name server entry. Glue IP addresses are required only when the name of the name server is a subdomain of the domain. For example, if your domain is example.com and the name
server for the domain is ns.example.com, you need to specify the IP address for ns.example.com.

Type: List of IP addresses.

Constraints: The list can contain only one IPv4 and one IPv6 address.

Parent: Nameservers

• **AuthCode** *(string)* – The authorization code for the domain. You get this value from the current registrar.

  Type: String

  Required: Yes

• **AutoRenew** *(boolean)* – Indicates whether the domain will be automatically renewed (true) or not (false). Autorenewal only takes effect after the account is charged.

  Type: Boolean

  Valid values: `true | false`

  Default: true

  Required: No

• **AdminContact** *(dict)* – [REQUIRED]

  Provides detailed contact information.

  Type: Complex

  Children: FirstName, MiddleName, LastName, ContactType, OrganizationName, AddressLine1, AddressLine2, City, State, CountryCode, ZipCode, PhoneNumber, Email, Fax, ExtraParams

  Required: Yes

  – **FirstName** *(string)* –

    First name of contact.

    Type: String

    Default: None

    Constraints: Maximum 255 characters.

    Parents: RegistrantContact, AdminContact, TechContact

    Required: Yes

  – **LastName** *(string)* –

    Last name of contact.

    Type: String

    Default: None

    Constraints: Maximum 255 characters.

    Parents: RegistrantContact, AdminContact, TechContact

    Required: Yes
- **ContactType** *(string)* –
  Indicates whether the contact is a person, company, association, or public organization. If you choose an option other than PERSON, you must enter an organization name, and you can’t enable privacy protection for the contact.
  
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Valid values: PERSON | COMPANY | ASSOCIATION | PUBLIC_BODY
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **OrganizationName** *(string)* –
  Name of the organization for contact types other than PERSON.
  
  Type: String
  Default: None
  Constraints: Maximum 255 characters. Contact type must not be PERSON.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **AddressLine1** *(string)* –
  First line of the contact’s address.
  
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **AddressLine2** *(string)* –
  Second line of contact’s address, if any.
  
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **City** *(string)* –
  The city of the contact’s address.
  
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
- **State** *(string)*
  The state or province of the contact’s city.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **CountryCode** *(string)*
  Code for the country of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **ZipCode** *(string)*
  The zip or postal code of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **PhoneNumber** *(string)*
  The phone number of the contact.
  Type: String
  Default: None
  Constraints: Phone number must be specified in the format "+[country dialing code],[number including any area code]". For example, a US phone number might appear as "+1.1234567890".
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **Email** *(string)*
  Email address of the contact.
  Type: String
  Default: None
  Constraints: Maximum 254 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes
- **Fax** *(string)*

  Fax number of the contact.

  Type: String

  Default: None

  Constraints: Phone number must be specified in the format "+[country dialing code].[number including any area code]". For example, a US phone number might appear as "+1.1234567890".

  Parents: RegistrantContact, AdminContact, TechContact

  Required: No

- **ExtraParams** *(list)*

  A list of name-value pairs for parameters required by certain top-level domains.

  Type: Complex

  Default: None

  Parents: RegistrantContact, AdminContact, TechContact

  Children: Name, Value

  Required: No

  * *(dict)*

    ExtraParam includes the following elements.

    - **Name** *(string)* – [REQUIRED]

      Name of the additional parameter required by the top-level domain.

      Type: String

      Default: None

      Valid values: DUNS_NUMBER | BRAND_NUMBER | BIRTH_DEPARTMENT | BIRTH_DATE_IN_YYYY_MM_DD | BIRTH_COUNTRY | BIRTH_CITY | DOCUMENT_NUMBER | AU_ID_NUMBER | AU_ID_TYPE | CA_LEGAL_TYPE | ES_IDENTIFICATION | ES_IDENTIFICATION_TYPE | ES_LEGAL_FORM | FI_BUSINESS_NUMBER | FI_ID_NUMBER | IT_PIN | RU_PASSPORT_DATA | SE_ID_NUMBER | SG_ID_NUMBER | VAT_NUMBER

      Parent: ExtraParams

      Required: Yes

    - **Value** *(string)* – [REQUIRED]

      Values corresponding to the additional parameter names required by some top-level domains.

      Type: String

      Default: None

      Constraints: Maximum 2048 characters.

      Parent: ExtraParams
• **RegistrantContact** *(dict)* – *[REQUIRED]*

Provides detailed contact information.

Type: Complex

Children: FirstName, MiddleName, LastName, ContactType, OrganizationName, AddressLine1, AddressLine2, City, State, CountryCode, ZipCode, PhoneNumber, Email, Fax, ExtraParams

Required: Yes

- **FirstName** *(string)* –

  First name of contact.

  Type: String

  Default: None

  Constraints: Maximum 255 characters.

  Parents: RegistrantContact, AdminContact, TechContact

Required: Yes

- **LastName** *(string)* –

  Last name of contact.

  Type: String

  Default: None

  Constraints: Maximum 255 characters.

  Parents: RegistrantContact, AdminContact, TechContact

Required: Yes

- **ContactType** *(string)* –

  Indicates whether the contact is a person, company, association, or public organization. If you choose an option other than PERSON, you must enter an organization name, and you can’t enable privacy protection for the contact.

  Type: String

  Default: None

  Constraints: Maximum 255 characters.

  Valid values: PERSON | COMPANY | ASSOCIATION | PUBLIC_BODY

  Parents: RegistrantContact, AdminContact, TechContact

Required: Yes

- **OrganizationName** *(string)* –

  Name of the organization for contact types other than PERSON.

  Type: String

  Default: None

  Constraints: Maximum 255 characters. Contact type must not be PERSON.
Parents: RegistrantContact, AdminContact, TechContact
Required: No

- **AddressLine1 (string)**
  First line of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **AddressLine2 (string)**
  Second line of contact’s address, if any.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **City (string)**
  The city of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **State (string)**
  The state or province of the contact’s city.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **CountryCode (string)**
  Code for the country of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes
- **ZipCode** *(string)* -
  The zip or postal code of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **PhoneNumber** *(string)* -
  The phone number of the contact.
  Type: String
  Default: None
  Constraints: Phone number must be specified in the format “+[country dialing code],[number including any area code]”. For example, a US phone number might appear as "+1.1234567890".
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **Email** *(string)* -
  Email address of the contact.
  Type: String
  Default: None
  Constraints: Maximum 254 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **Fax** *(string)* -
  Fax number of the contact.
  Type: String
  Default: None
  Constraints: Phone number must be specified in the format “+[country dialing code],[number including any area code]”. For example, a US phone number might appear as "+1.1234567890".
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **ExtraParams** *(list)* -
  A list of name-value pairs for parameters required by certain top-level domains.
  Type: Complex
  Default: None
  Parents: RegistrantContact, AdminContact, TechContact
  Children: Name, Value
ExtraParam includes the following elements.

- **Name (string)** – [REQUIRED]

  Name of the additional parameter required by the top-level domain.

  Type: String

  Default: None

  Valid values: DUNS_NUMBER | BRAND_NUMBER | BIRTH_DEPARTMENT | BIRTH_DATE_IN_YYYY_MM_DD | BIRTH_COUNTRY | BIRTH_CITY | DOCUMENT_NUMBER | AU_ID_NUMBER | AU_ID_TYPE | CALEGALTYPE | ESIDENTIFICATION | ESIDENTIFICATIONTYPE | ESLEGALFORM | FIBUSINESSNUMBER | FIIDNUMBER | ITPIN | RUPASSPORTDATA | SEIDNUMBER | SEICIENTIFICATION | SGIDNUMBER | VATNUMBER

  Parent: ExtraParams

  Required: Yes

- **Value (string)** – [REQUIRED]

  Values corresponding to the additional parameter names required by some top-level domains.

  Type: String

  Default: None

  Constraints: Maximum 2048 characters.

  Parent: ExtraParams

  Required: Yes

- **TechContact (dict)** – [REQUIRED]

  Provides detailed contact information.

  Type: Complex

  Children: FirstName, MiddleName, LastName, ContactType, OrganizationName, AddressLine1, AddressLine2, City, State, CountryCode, ZipCode, PhoneNumber, Email, Fax, ExtraParams

  Required: Yes

  - **FirstName (string)** –

    First name of contact.

    Type: String

    Default: None

    Constraints: Maximum 255 characters.

    Parents: RegistrantContact, AdminContact, TechContact

    Required: Yes
– **LastName** *(string)*

  Last name of contact.
  
  Type: String
  
  Default: None
  
  Constraints: Maximum 255 characters.
  
  Parents: RegistrantContact, AdminContact, TechContact
  
  Required: Yes

– **ContactType** *(string)*

  Indicates whether the contact is a person, company, association, or public organization. If you choose an option other than `PERSON`, you must enter an organization name, and you can’t enable privacy protection for the contact.
  
  Type: String
  
  Default: None
  
  Constraints: Maximum 255 characters.
  
  Valid values: `PERSON` | `COMPANY` | `ASSOCIATION` | `PUBLIC_BODY`
  
  Parents: RegistrantContact, AdminContact, TechContact
  
  Required: Yes

– **OrganizationName** *(string)*

  Name of the organization for contact types other than `PERSON`.
  
  Type: String
  
  Default: None
  
  Constraints: Maximum 255 characters. Contact type must not be `PERSON`.
  
  Parents: RegistrantContact, AdminContact, TechContact
  
  Required: No

– **AddressLine1** *(string)*

  First line of the contact’s address.
  
  Type: String
  
  Default: None
  
  Constraints: Maximum 255 characters.
  
  Parents: RegistrantContact, AdminContact, TechContact
  
  Required: Yes

– **AddressLine2** *(string)*

  Second line of contact’s address, if any.
  
  Type: String
  
  Default: None
  
  Constraints: Maximum 255 characters.
  
  Parents: RegistrantContact, AdminContact, TechContact
- City (string)
  
  The city of the contact’s address.
  
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- State (string)
  
  The state or province of the contact’s city.
  
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- CountryCode (string)
  
  Code for the country of the contact’s address.
  
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- ZipCode (string)
  
  The zip or postal code of the contact’s address.
  
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- PhoneNumber (string)
  
  The phone number of the contact.
  
  Type: String
  Default: None
  Constraints: Phone number must be specified in the format “+\[country dialing code\],\[number including any area code\]”. For example, a US phone number might appear as "+1.1234567890\".
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes
- **Email (string)** –
  Email address of the contact.
  Type: String
  Default: None
  Constraints: Maximum 254 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **Fax (string)** –
  Fax number of the contact.
  Type: String
  Default: None
  Constraints: Phone number must be specified in the format “+[country dialing code].[number including any area code]”. For example, a US phone number might appear as "+1.1234567890".
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **ExtraParams (list)** –
  A list of name-value pairs for parameters required by certain top-level domains.
  Type: Complex
  Default: None
  Parents: RegistrantContact, AdminContact, TechContact
  Children: Name, Value
  Required: No

  * (dict) –

  ExtraParam includes the following elements.
  · **Name (string)** – [REQUIRED]
    Name of the additional parameter required by the top-level domain.
    Type: String
    Default: None
    Valid values: DUNS_NUMBER | BRAND_NUMBER | BIRTH_DEPARTMENT | BIRTH_DATE_IN_YYYY_MM_DD | BIRTH_COUNTRY | BIRTH_CITY | DOCUMENT_NUMBER | AU_ID_NUMBER | AU_ID_TYPE | CA_LEGAL_TYPE | ES_IDENTIFICATION | ES_IDENTIFICATION_TYPE | ES_LEGAL_FORM | FI_BUSINESS_NUMBER | FI_ID_NUMBER | IT_PIN | RU_PASSPORT_DATA | SE_ID_NUMBER | SG_ID_NUMBER | VAT_NUMBER
  Parent: ExtraParams
Required: Yes

- **Value (string)** – [REQUIRED]

Values corresponding to the additional parameter names required by some top-level domains.

Type: String
Default: None
Constraints: Maximum 2048 characters.
Parent: ExtraParams

Required: Yes

- **PrivacyProtectAdminContact (boolean)** – Whether you want to conceal contact information from WHOIS queries. If you specify true, WHOIS (“who is”) queries will return contact information for our registrar partner, Gandi, instead of the contact information that you enter.

Type: Boolean
Default: true
Valid values: true | false
Required: No

- **PrivacyProtectRegistrantContact (boolean)** – Whether you want to conceal contact information from WHOIS queries. If you specify true, WHOIS (“who is”) queries will return contact information for our registrar partner, Gandi, instead of the contact information that you enter.

Type: Boolean
Default: true
Valid values: true | false
Required: No

- **PrivacyProtectTechContact (boolean)** – Whether you want to conceal contact information from WHOIS queries. If you specify true, WHOIS (“who is”) queries will return contact information for our registrar partner, Gandi, instead of the contact information that you enter.

Type: Boolean
Default: true
Valid values: true | false
Required: No

Return type: dict

Returns

Response Syntax

```python
{
    'OperationId': 'string'
}
```

Response Structure

- *(dict)* –

The TransferDomain response includes the following element.
update_domain_contact(**kwargs)

This operation updates the contact information for a particular domain. Information for at least one contact (registrant, administrator, or technical) must be supplied for update.

If the update is successful, this method returns an operation ID that you can use to track the progress and completion of the action. If the request is not completed successfully, the domain registrant will be notified by email.

Request Syntax

```python
response = client.update_domain_contact(
    DomainName='string',
    AdminContact={
        'FirstName': 'string',
        'LastName': 'string',
        'ContactType': 'PERSON'|'COMPANY'|'ASSOCIATION'|'PUBLIC_BODY'|'RESELLER',
        'OrganizationName': 'string',
        'AddressLine1': 'string',
        'AddressLine2': 'string',
        'City': 'string',
        'State': 'string',
        'CountryCode':...|
        'ZipCode': 'string',
        'PhoneNumber': 'string',
        'Email': 'string',
        'Fax': 'string',
        'ExtraParams': [
            {
                'Name': 'DUNS_NUMBER'|'BRAND_NUMBER'|'BIRTH_DEPARTMENT'|'BIRTH_DATE_IN_YYY',
                'Value': 'string'
            }
        ],
    },
    RegistrantContact={
        'FirstName': 'string',
        'LastName': 'string',
        'ContactType': 'PERSON'|'COMPANY'|'ASSOCIATION'|'PUBLIC_BODY'|'RESELLER',
        'OrganizationName': 'string',
        'AddressLine1': 'string',
        'AddressLine2': 'string',
        'City': 'string',
        'State': 'string',
        'CountryCode':...|
        'ZipCode': 'string',
        'PhoneNumber': 'string',
        'Email': 'string',
        'Fax': 'string',
        'ExtraParams': [
            {
                'Name': 'DUNS_NUMBER'|'BRAND_NUMBER'|'BIRTH_DEPARTMENT'|'BIRTH_DATE_IN_YYY',
                'Value': 'string'
            }
        ],
    }
)
```
Parameters

- **DomainName** *(string) – [REQUIRED]*
  
The name of a domain.

  Type: String

  Default: None

  Constraints: The domain name can contain only the letters a through z, the numbers 0 through 9, and hyphen (-). Internationalized Domain Names are not supported.

  Required: Yes

- **AdminContact** *(dict) – Provides detailed contact information.*

  Type: Complex

  Children: FirstName, MiddleName, LastName, ContactType, OrganizationName, AddressLine1, AddressLine2, City, State, CountryCode, ZipCode, PhoneNumber, Email, Fax, ExtraParams

  Required: Yes

  - **FirstName** *(string)* –

    First name of contact.

    Type: String

    Default: None

    Constraints: Maximum 255 characters.
Parents: RegistrantContact, AdminContact, TechContact

Required: Yes

- **LastName (string)** –

  Last name of contact.

  Type: String

  Default: None

  Constraints: Maximum 255 characters.

  Parents: RegistrantContact, AdminContact, TechContact

  Required: Yes

- **ContactType (string)** –

  Indicates whether the contact is a person, company, association, or public organization. If you choose an option other than PERSON, you must enter an organization name, and you can’t enable privacy protection for the contact.

  Type: String

  Default: None

  Constraints: Maximum 255 characters.

  Valid values: PERSON | COMPANY | ASSOCIATION | PUBLIC_BODY

  Parents: RegistrantContact, AdminContact, TechContact

  Required: Yes

- **OrganizationName (string)** –

  Name of the organization for contact types other than PERSON.

  Type: String

  Default: None

  Constraints: Maximum 255 characters. Contact type must not be PERSON.

  Parents: RegistrantContact, AdminContact, TechContact

  Required: No

- **AddressLine1 (string)** –

  First line of the contact’s address.

  Type: String

  Default: None

  Constraints: Maximum 255 characters.

  Parents: RegistrantContact, AdminContact, TechContact

  Required: Yes

- **AddressLine2 (string)** –

  Second line of contact’s address, if any.

  Type: String

  Default: None
Constraints: Maximum 255 characters.
Parents: RegistrantContact, AdminContact, TechContact
Required: No

- **City (string)** –
  The city of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **State (string)** –
  The state or province of the contact’s city.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **CountryCode (string)** –
  Code for the country of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **ZipCode (string)** –
  The zip or postal code of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **PhoneNumber (string)** –
  The phone number of the contact.
  Type: String
  Default: None
  Constraints: Phone number must be specified in the format “+[country dialing code].[number including any area code]”. For example, a US phone number might appear as "+1.1234567890".
Parents: RegistrantContact, AdminContact, TechContact

Required: Yes

- **Email (string)** –
  
  Email address of the contact.

  Type: String

  Default: None

  Constraints: Maximum 254 characters.

  Parents: RegistrantContact, AdminContact, TechContact

  Required: Yes

- **Fax (string)** –
  
  Fax number of the contact.

  Type: String

  Default: None

  Constraints: Phone number must be specified in the format “+[country dialing code],[number including any area code]”. For example, a US phone number might appear as "+1.1234567890”.

  Parents: RegistrantContact, AdminContact, TechContact

  Required: No

- **ExtraParams (list)** –
  
  A list of name-value pairs for parameters required by certain top-level domains.

  Type: Complex

  Default: None

  Parents: RegistrantContact, AdminContact, TechContact

  Children: Name, Value

  Required: No

  * (dict) –

  ExtraParam includes the following elements.

  - **Name (string)** – [REQUIRED]
    
    Name of the additional parameter required by the top-level domain.

    Type: String

    Default: None

    Valid values: DUNS_NUMBER | BRAND_NUMBER | BIRTH_DEPARTMENT | BIRTH_DATE_IN_YYYY_MM_DD | BIRTH_COUNTRY | BIRTH_CITY | DOCUMENT_NUMBER | AU_ID_NUMBER | AU_ID_TYPE | CA_LEGAL_TYPE | ES_IDENTIFICATION | ES_IDENTIFICATION_TYPE | ES_LEGAL_FORM | FI_BUSINESS_NUMBER | FI_ID_NUMBER | IT_PIN | RU_PASSPORT_DATA | SE_ID_NUMBER | SG_ID_NUMBER | VAT_NUMBER
Parent: ExtraParams
Required: Yes

- **Value (string) – [REQUIRED]**
  Values corresponding to the additional parameter names required by some top-level domains.
  
  Type: String
  
  Default: None
  
  Constraints: Maximum 2048 characters.

Parent: ExtraParams
Required: Yes

- **RegistrantContact (dict) – Provides detailed contact information.**
  
  Type: Complex
  
  Children: FirstName, MiddleName, LastName, ContactType, OrganizationName, AddressLine1, AddressLine2, City, State, CountryCode, ZipCode, PhoneNumber, Email, Fax, ExtraParams
  
  Required: Yes
  
  - **FirstName (string) –**
    
    First name of contact.
    
    Type: String
    
    Default: None
    
    Constraints: Maximum 255 characters.
    
    Parents: RegistrantContact, AdminContact, TechContact
    
    Required: Yes
    
  - **LastName (string) –**
    
    Last name of contact.
    
    Type: String
    
    Default: None
    
    Constraints: Maximum 255 characters.
    
    Parents: RegistrantContact, AdminContact, TechContact
    
    Required: Yes
    
  - **ContactType (string) –**
    
    Indicates whether the contact is a person, company, association, or public organization. If you choose an option other than PERSON, you must enter an organization name, and you can’t enable privacy protection for the contact.
    
    Type: String
    
    Default: None
    
    Constraints: Maximum 255 characters.
    
    Valid values: PERSON | COMPANY | ASSOCIATION | PUBLIC_BODY
Parents: RegistrantContact, AdminContact, TechContact
Required: Yes

- **OrganizationName** *(string)* –
  Name of the organization for contact types other than PERSON.
  Type: String
  Default: None
  Constraints: Maximum 255 characters. Contact type must not be PERSON.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **AddressLine1** *(string)* –
  First line of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **AddressLine2** *(string)* –
  Second line of contact’s address, if any.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **City** *(string)* –
  The city of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **State** *(string)* –
  The state or province of the contact’s city.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No
– **CountryCode** *(string)* –
  Code for the country of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

– **ZipCode** *(string)* –
  The zip or postal code of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

– **PhoneNumber** *(string)* –
  The phone number of the contact.
  Type: String
  Default: None
  Constraints: Phone number must be specified in the format “+[country dialing code],[number including any area code]”. For example, a US phone number might appear as "+1.1234567890".
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

– **Email** *(string)* –
  Email address of the contact.
  Type: String
  Default: None
  Constraints: Maximum 254 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

– **Fax** *(string)* –
  Fax number of the contact.
  Type: String
  Default: None
  Constraints: Phone number must be specified in the format “+[country dialing code],[number including any area code]”. For example, a US phone number might appear as "+1.1234567890".
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No
- **ExtraParams** *(list)* –

  A list of name-value pairs for parameters required by certain top-level domains.

  Type: Complex
  Default: None
  Parents: RegistrantContact, AdminContact, TechContact
  Children: Name, Value
  Required: No

* *(dict)* –

  ExtraParam includes the following elements.

  - **Name** *(string)* – [REQUIRED]

    Name of the additional parameter required by the top-level domain.

    Type: String
    Default: None

    Valid values: DUNS_NUMBER | BRAND_NUMBER | BIRTH_DEPARTMENT | BIRTH_DATE_IN_YYYY-MM_DD | BIRTH_COUNTRY | BIRTH_CITY | DOCUMENT_NUMBER | AU_ID_NUMBER | AU_ID_TYPE | CA_LEGAL_TYPE | ES_IDENTIFICATION | ES_IDENTIFICATION_TYPE | ES_LEGAL_FORM | FI_BUSINESS_NUMBER | FI_ID_NUMBER | IT_PIN | RU_PASSPORT_DATA | SE_ID_NUMBER | SG_ID_NUMBER | VAT_NUMBER

    Parent: ExtraParams
    Required: Yes

  - **Value** *(string)* – [REQUIRED]

    Values corresponding to the additional parameter names required by some top-level domains.

    Type: String
    Default: None

    Constraints: Maximum 2048 characters.

    Parent: ExtraParams
    Required: Yes

- **TechContact** *(dict)* – Provides detailed contact information.

  Type: Complex

  Children: FirstName, MiddleName, LastName, ContactType, OrganizationName, AddressLine1, AddressLine2, City, State, CountryCode, ZipCode, PhoneNumber, Email, Fax, ExtraParams

  Required: Yes
- **FirstName (string)** –
  First name of contact.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **LastName (string)** –
  Last name of contact.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **ContactType (string)** –
  Indicates whether the contact is a person, company, association, or public
  organization. If you choose an option other than PERSON, you must enter an
  organization name, and you can’t enable privacy protection for
  the contact.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Valid values: PERSON | COMPANY | ASSOCIATION | PUBLIC_BODY
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **OrganizationName (string)** –
  Name of the organization for contact types other than PERSON.
  Type: String
  Default: None
  Constraints: Maximum 255 characters. Contact type must not be PERSON.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **AddressLine1 (string)** –
  First line of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
- **AddressLine2 (string)** –
  Second line of contact’s address, if any.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **City (string)** –
  The city of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **State (string)** –
  The state or province of the contact’s city.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **CountryCode (string)** –
  Code for the country of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **ZipCode (string)** –
  The zip or postal code of the contact’s address.
  Type: String
  Default: None
  Constraints: Maximum 255 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No
- **PhoneNumber (string)** –
  The phone number of the contact.
  Type: String
  Default: None
  Constraints: Phone number must be specified in the format "+[country dialing code].[number including any area code]". For example, a US phone number might appear as "+1.1234567890".
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **Email (string)** –
  Email address of the contact.
  Type: String
  Default: None
  Constraints: Maximum 254 characters.
  Parents: RegistrantContact, AdminContact, TechContact
  Required: Yes

- **Fax (string)** –
  Fax number of the contact.
  Type: String
  Default: None
  Constraints: Phone number must be specified in the format "+[country dialing code].[number including any area code]". For example, a US phone number might appear as "+1.1234567890".
  Parents: RegistrantContact, AdminContact, TechContact
  Required: No

- **ExtraParams (list)** –
  A list of name-value pairs for parameters required by certain top-level domains.
  Type: Complex
  Default: None
  Parents: RegistrantContact, AdminContact, TechContact
  Children: Name, Value
  Required: No

  * (dict) –
  ExtraParam includes the following elements.
  - **Name (string)** – [REQUIRED]
    Name of the additional parameter required by the top-level domain.
    Type: String
    Default: None
Valid values:

- DUNS_NUMBER
- BRAND_NUMBER
- BIRTH_DEPARTMENT
- BIRTH_DATE_IN_YYYY_MM_DD
- BIRTH_COUNTRY
- BIRTH_CITY
- DOCUMENT_NUMBER
- AU_ID_NUMBER
- AU_ID_TYPE
- CA_LEGAL_TYPE
- ES_IDENTIFICATION
- ES_IDENTIFICATION_TYPE
- ES_LEGAL_FORM
- FI_BUSINESS_NUMBER
- FI_ID_NUMBER
- IT_PIN
- RU_PASSPORT_DATA
- SE_ID_NUMBER
- SG_ID_NUMBER
- VAT_NUMBER

Parent: ExtraParams

Required: Yes

- **Value (string)** – [REQUIRED]

Values corresponding to the additional parameter names required by some top-level domains.

Type: String

Default: None

Constraints: Maximum 2048 characters.

Parent: ExtraParams

Required: Yes

**Return type** dict

**Returns**

**Response Syntax**

```python
{
   'OperationId': 'string'
}
```

**Response Structure**

- (dict)

The UpdateDomainContact response includes the following element.

- **OperationId (string)** –

  Identifier for tracking the progress of the request. To use this ID to query the operation status, use GetOperationDetail.

  Type: String

  Default: None

  Constraints: Maximum 255 characters.

**update_domain_contact_privacy(**kwargs)**

This operation updates the specified domain contact’s privacy setting. When the privacy option is enabled, personal information such as postal or email address is hidden from the results of a public WHOIS query. The privacy services are provided by the AWS registrar, Gandi. For more information, see the Gandi privacy features.

This operation only affects the privacy of the specified contact type (registrant, administrator, or tech). Successful acceptance returns an operation ID that you can use with GetOperationDetail to track the progress and completion of the action. If the request is not completed successfully, the domain registrant will be notified by email.

**Request Syntax**
response = client.update_domain_contact_privacy(
    DomainName='string',
    AdminPrivacy=True|False,
    RegistrantPrivacy=True|False,
    TechPrivacy=True|False
)

**Parameters**

- **DomainName (string) – [REQUIRED]**
  
The name of a domain.
  
  Type: String
  
  Default: None

  Constraints: The domain name can contain only the letters a through z, the numbers 0 through 9, and hyphen (-). Internationalized Domain Names are not supported.

  Required: Yes

- **AdminPrivacy (boolean) –** Whether you want to conceal contact information from WHOIS queries. If you specify true, WHOIS (“who is”) queries will return contact information for our registrar partner, Gandi, instead of the contact information that you enter.

  Type: Boolean
  
  Default: None

  Valid values: true|false

  Required: No

- **RegistrantPrivacy (boolean) –** Whether you want to conceal contact information from WHOIS queries. If you specify true, WHOIS (“who is”) queries will return contact information for our registrar partner, Gandi, instead of the contact information that you enter.

  Type: Boolean
  
  Default: None

  Valid values: true|false

  Required: No

- **TechPrivacy (boolean) –** Whether you want to conceal contact information from WHOIS queries. If you specify true, WHOIS (“who is”) queries will return contact information for our registrar partner, Gandi, instead of the contact information that you enter.

  Type: Boolean
  
  Default: None

  Valid values: true|false

  Required: No

**Return type** dict

**Returns**

  **Response Syntax**
Response Structure

- **(dict)** –

The UpdateDomainContactPrivacy response includes the following element.

- **OperationId (string)** –

  Identifier for tracking the progress of the request. To use this ID to query the operation status, use GetOperationDetail.

  Type: String

  Default: None

  Constraints: Maximum 255 characters.

**update_domain_nameservers(**kwargs**)

This operation replaces the current set of name servers for the domain with the specified set of name servers. If you use Amazon Route 53 as your DNS service, specify the four name servers in the delegation set for the hosted zone for the domain.

If successful, this operation returns an operation ID that you can use to track the progress and completion of the action. If the request is not completed successfully, the domain registrant will be notified by email.

**Request Syntax**

```python
response = client.update_domain_nameservers(
    DomainName='string',
    FIAuthKey='string',
    Nameservers=[
        {
            'Name': 'string',
            'GlueIps': [ 'string',
                        'string',
                        ]
        },
    ]
)
```

**Parameters**

- **DomainName (string)** – [REQUIRED]

  The name of a domain.

  Type: String

  Default: None

  Constraints: The domain name can contain only the letters a through z, the numbers 0 through 9, and hyphen (-). Internationalized Domain Names are not supported.

  Required: Yes

- **FIAuthKey (string)** – The authorization key for .fi domains

- **Nameservers (list)** – [REQUIRED]

  A list of new name servers for the domain.

  Type: Complex
Children: Name, GlueIps

Required: Yes

- (dict)

Nameserver includes the following elements.

* Name *(string)* – [REQUIRED]

  The fully qualified host name of the name server.

  Type: String

  Constraint: Maximum 255 characters

  Parent: Nameservers

* GlueIps *(list)* –

  Glue IP address of a name server entry. Glue IP addresses are required only when the name of the name server is a subdomain of the domain. For example, if your domain is example.com and the name server for the domain is ns.example.com, you need to specify the IP address for ns.example.com.

  Type: List of IP addresses.

  Constraints: The list can contain only one IPv4 and one IPv6 address.

  Parent: Nameservers

Return type: dict

Returns

Response Syntax

{
  'OperationId': 'string'
}

Response Structure

- (dict)

  The UpdateDomainNameservers response includes the following element.

  - **OperationId** *(string)* –

    Identifier for tracking the progress of the request. To use this ID to query the operation status, use GetOperationDetail.

    Type: String

    Default: None

    Constraints: Maximum 255 characters.

*update_tags_for_domain*(**kwargs)*

This operation adds or updates tags for a specified domain.

All tag operations are eventually consistent; subsequent operations may not immediately represent all issued operations.

Request Syntax
response = client.update_tags_for_domain(
    DomainName='string',
    TagsToUpdate=[
        {'Key': 'string',
         'Value': 'string'},
    ],
)

Parameters

- **DomainName (string)** – [REQUIRED]

  The domain for which you want to add or update tags.
  The name of a domain.
  Type: String
  Default: None
  Constraints: The domain name can contain only the letters a through z, the numbers 0 through 9, and hyphen (-). Hyphens are allowed only when they are surrounded by letters, numbers, or other hyphens. You cannot specify a hyphen at the beginning or end of a label. To specify an Internationalized Domain Name, you must convert the name to Punycode.
  Required: Yes

- **TagsToUpdate (list)** – A list of the tag keys and values that you want to add or update. If you specify a key that already exists, the corresponding value will be replaced.

  Type: A complex type containing a list of tags
  Default: None
  Required: No

Each tag includes the following elements:

- **Key** The key (name) of a tag. Type: String

  Default: None
  Valid values: Unicode characters including alphanumeric, space, and ".:/=+-@"  
  Constraints: Each key can be 1-128 characters long. Required: Yes

- **Value** The value of a tag. Type: String

  Default: None
  Valid values: Unicode characters including alphanumeric, space, and ".:/=+-@"  
  Constraints: Each value can be 0-256 characters long. Required: Yes

- **(dict)**

  Each tag includes the following elements.

  - **Key** (string)

    The key (name) of a tag.

    Type: String
    Default: None
    Valid values: A-Z, a-z, 0-9, space, ":/=/+-@"
    Constraints: Each key can be 1-128 characters long.
    Required: Yes
Value (string) –
The value of a tag.
Type: String
Default: None
Valid values: A-Z, a-z, 0-9, space, ":/+=@"
Constraints: Each value can be 0-256 characters long.
Required: Yes

Return type dict

Returns

Response Syntax

{}

Response Structure

• (dict) –

Paginators

The available paginators are:

• Route53Domains.Paginator.ListDomains
• Route53Domains.Paginator.ListOperations

class Route53Domains.Paginator.ListDomains

paginator = client.get_paginator('list_domains')

paginate(**kwargs)

Creates an iterator that will paginate through responses from Route53Domains.Client.list_domains().

Request Syntax

response_iterator = paginator.paginate(
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

PaginationConfig (dict) – A dictionary that provides parameters to control pagination.

• MaxItems (integer) –
The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

• PageSize (integer) –
The size of each page.
• **StartingToken** *(string)* –

A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Domains': [
        {
            'DomainName': 'string',
            'AutoRenew': True|False,
            'TransferLock': True|False,
            'Expiry': datetime(2015, 1, 1)
        },
    ],
    'NextToken': 'string'
}
```

**Response Structure**

• (*dict*) –

The ListDomains response includes the following elements.

– **Domains** *(list)* –

A summary of domains.

  Type: Complex type containing a list of domain summaries.

  Children: `AutoRenew`, `DomainName`, `Expiry`, `TransferLock`

  • (*dict*) –

    • **DomainName** *(string)* –

      The name of a domain.

      Type: String

    • **AutoRenew** *(boolean)* –

      Indicates whether the domain is automatically renewed upon expiration.

      Type: Boolean

      Valid values: `True` | `False`

    • **TransferLock** *(boolean)* –

      Indicates whether a domain is locked from unauthorized transfer to another party.

      Type: Boolean

      Valid values: `True` | `False`

    • **Expiry** *(datetime)* –

      Expiration date of the domain in Coordinated Universal Time (UTC).

      Type: Long

– **NextToken** *(string)* –

A token to resume pagination.
class Route53Domains.Paginator.ListOperations

paginator = client.get_paginator('list_operations')

paginate(**kwargs)

Creates an iterator that will paginate through responses from Route53Domains.Client.list_operations().

Request Syntax

response_iterator = paginator.paginate(
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters PaginationConfig (dict) – A dictionary that provides parameters to control pagination.

- **MaxItems** (integer) –
  The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

- **PageSize** (integer) –
  The size of each page.

- **StartingToken** (string) –
  A token to specify where to start paginating. This is the NextToken from a previous response.

Return type dict

Returns

Response Syntax

{
    'Operations': [
        {
            'OperationId': 'string',
            'Status': 'SUBMITTED'|'IN_PROGRESS'|'ERROR'|'SUCCESSFUL'|'FAILED',
            'Type': 'REGISTER_DOMAIN'|'DELETE_DOMAIN'|'TRANSFER_IN_DOMAIN'|'UPDATE_DOMAIN_CONTACT'|'UPDATE_NAMESERVER'|'CHANGE_PRIVACY_PROTECTION'|'DOMAIN_LOCK',
            'SubmittedDate': datetime(2015, 1, 1)
        },
    ],
    'NextToken': 'string'
}

Response Structure

- (dict) –
  The ListOperations response includes the following elements.
  - **Operations** (list) –
    Lists summaries of the operations.
    Type: Complex type containing a list of operation summaries
**Children**:

- `OperationId`
- `Status`
- `SubmittedDate`
- `Type`

*(dict)* –

OperationSummary includes the following elements.

- **OperationId** *(string)* –

  Identifier returned to track the requested action.

  Type: String

- **Status** *(string)* –

  The current status of the requested operation in the system.

  Type: String

- **Type** *(string)* –

  Type of the action requested.

  Type: String

  Valid values:

  - `REGISTER_DOMAIN`
  - `DELETE_DOMAIN`
  - `TRANSFER_IN_DOMAIN`
  - `UPDATE_DOMAIN_CONTACT`
  - `UPDATE_NAMESERVER`
  - `CHANGE_PRIVACY_PROTECTION`
  - `DOMAIN_LOCK`

- **SubmittedDate** *(datetime)* –

  The date when the request was submitted.

- **NextToken** *(string)* –

  A token to resume pagination.

- `restore_object()`
- `upload_file()`
- `upload_part()`
- `upload_part_copy()`

`abort_multipart_upload(**kwargs)`

Aborts a multipart upload.

To verify that all parts have been removed, so you don’t get charged for the part storage, you should call the List Parts operation and ensure the parts list is empty.

**Request Syntax**

```python
response = client.abort_multipart_upload(
    Bucket='string',
    Key='string',
    UploadId='string',
    RequestPayer='requester'
)
```

**Parameters**

- **Bucket** *(string)* – [REQUIRED]
- **Key** *(string)* – [REQUIRED]
- **UploadId** *(string)* – [REQUIRED]
- **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html](http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html)

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'RequestCharged': 'requester'
}
```

**Response Structure**

- *(dict)* –
  - **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.
can_paginate(operation_name)
Check if an operation can be paginated.

Parameters operation_name (string) – The operation name. This is the same name as
the method name on the client. For example, if the method name is create_foo,
you'd normally invoke the operation as client.create_foo(**kwargs),
if the create_foo operation can be paginated, you can use the call
client.get_paginator("create_foo").

Returns True if the operation can be paginated, False otherwise.

complete_multipart_upload(**kwargs)
Completes a multipart upload by assembling previously uploaded parts.

Request Syntax

response = client.complete_multipart_upload(
    Bucket='string',
    Key='string',
    MultipartUpload={
        'Parts': [
            {'ETag': 'string',
             'PartNumber': 123},
        ],
    },
    UploadId='string',
    RequestPayer='requester'
)

Parameters
• Bucket (string) – [REQUIRED]
• Key (string) – [REQUIRED]
• MultipartUpload (dict) –
  – Parts (list) –
    * (dict) –
      • ETag (string) – Entity tag returned when the part was up-
        loaded.
      • PartNumber (integer) – Part number that identifies the part.
        This is a positive integer between 1 and 10,000.
• UploadId (string) – [REQUIRED]
• RequestPayer (string) – Confirms that the requester knows that
  she or he will be charged for the request. Bucket owners need
  not specify this parameter in their requests. Documentation on
  downloading objects from requester pays buckets can be found at
  http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

Return type dict

Returns

Response Syntax

{  
  'Location': 'string',
  'Bucket': 'string',
  'Key': 'string',
  'Expiration': 'string',
  'ETag': 'string',
  'ServerSideEncryption': 'AES256'|'aws:kms',
}
Response Structure

- (dict) –
  - Location (string) –
  - Bucket (string) –
  - Key (string) –
  - Expiration (string) – If the object expiration is configured, this will contain the expiration date (expiry-date) and rule ID (rule-id). The value of rule-id is URL encoded.
  - ETag (string) – Entity tag of the object.
  - ServerSideEncryption (string) – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
  - VersionId (string) – Version of the object.
  - SSEKMSKeyId (string) – If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.
  - RequestCharged (string) – If present, indicates that the requester was successfully charged for the request.

`copy_object(**kwargs)`

Creates a copy of an object that is already stored in Amazon S3.

Request Syntax

```python
response = client.copy_object(
    ACL='private'|'public-read'|'public-read-write'|'authenticated-read'|'bucket-owner-read'|'bucket-owner-full-control',
    Bucket='string',
    CacheControl='string',
    ContentDisposition='string',
    ContentEncoding='string',
    ContentLanguage='string',
    ContentType='string',
    CopySource='string',
    CopySourceIfMatch='string',
    CopySourceIfModifiedSince=datetime(2015, 1, 1),
    CopySourceIfNoneMatch='string',
    CopySourceIfUnmodifiedSince=datetime(2015, 1, 1),
    Expires=datetime(2015, 1, 1),
    GrantFullControl='string',
    GrantRead='string',
    GrantReadACP='string',
    GrantWriteACP='string',
    Key='string',
    Metadata={
        'string': 'string'
    },
    MetadataDirective='COPY'|'REPLACE',
    ServerSideEncryption='AES256'|'aws:kms',
    StorageClass='STANDARD'|'REDUCED_REDUNDANCY'|'STANDARD_IA',
    WebsiteRedirectLocation='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    SSEKMSKeyId='string',
)```
Parameters

- **ACL** *(string)* – The canned ACL to apply to the object.
- **Bucket** *(string)* – [REQUIRED]
- **CacheControl** *(string)* – Specifies caching behavior along the request/reply chain.
- **ContentDisposition** *(string)* – Specifies presentational information for the object.
- **ContentEncoding** *(string)* – Specifies what content encodings have been applied to the object and thus what decoding mechanisms must be applied to obtain the media-type referenced by the Content-Type header field.
- **ContentLanguage** *(string)* – The language the content is in.
- **ContentType** *(string)* – A standard MIME type describing the format of the object data.
- **CopySource** *(string)* – [REQUIRED] The name of the source bucket and key name of the source object, separated by a slash (/). Must be URL-encoded.
- **CopySourceIfMatch** *(string)* – Copies the object if its entity tag (ETag) matches the specified tag.
- **CopySourceIfModifiedSince** *(datetime)* – Copies the object if it has been modified since the specified time.
- **CopySourceIfNoneMatch** *(string)* – Copies the object if its entity tag (ETag) is different than the specified ETag.
- **CopySourceIfUnmodifiedSince** *(datetime)* – Copies the object if it hasn’t been modified since the specified time.
- **Expires** *(datetime)* – The date and time at which the object is no longer cacheable.
- **GrantFullControl** *(string)* – Gives the grantee READ, READ_ACP, and WRITE_ACP permissions on the object.
- **GrantRead** *(string)* – Allows grantee to read the object data and its metadata.
- **GrantReadACP** *(string)* – Allows grantee to read the object ACL.
- **GrantWriteACP** *(string)* – Allows grantee to write the ACL for the applicable object.
- **Key** *(string)* – [REQUIRED]
- **Metadata** *(dict)* – A map of metadata to store with the object in S3.
  - *(string)* – *
  - **MetadataDirective** *(string)* – Specifies whether the metadata is copied from the source object or replaced with metadata provided in the request.
- **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
- **StorageClass** *(string)* – The type of storage to use for the object. Defaults to ‘STANDARD’.
- **WebsiteRedirectLocation** *(string)* – If the bucket is configured as a website, redirects requests for this object to another object in the same bucket or to an external URL. Amazon S3 stores the value of this header in the object metadata.
- **SSECustomerAlgorithm** *(string)* – Specifies the algorithm to use when encrypting the object (e.g., AES256).
- **SSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object
and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.

- **SSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.

- **SSEKMSKeyId** *(string)* – Specifies the AWS KMS key ID to use for object encryption. All GET and PUT requests for an object protected by AWS KMS will fail if not made via SSL or using SigV4. Documentation on configuring any of the officially supported AWS SDKs and CLI can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/UsingAWSSDK.html#specify-signature-version](http://docs.aws.amazon.com/AmazonS3/latest/dev/UsingAWSSDK.html#specify-signature-version).

- **CopySourceSSECcustomerAlgorithm** *(string)* – Specifies the algorithm to use when decrypting the source object (e.g., AES256).

- **CopySourceSSECcustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use to decrypt the source object. The encryption key provided in this header must be one that was used when the source object was created.

- **CopySourceSSECcustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error.

- **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html](http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html).

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'CopyObjectResult': {
        'ETag': 'string',
        'LastModified': datetime(2015, 1, 1)
    },
    'Expiration': 'string',
    'CopySourceVersionId': 'string',
    'ServerSideEncryption': 'AES256'|'aws:kms',
    'SSECustomerAlgorithm': 'string',
    'SSECustomerKeyMD5': 'string',
    'SSEKMSKeyId': 'string',
    'RequestCharged': 'requester'
}
```

**Response Structure**

- *(dict)* –
  - **CopyObjectResult** *(dict)* –
    - **ETag** *(string)* –
    - **LastModified** *(datetime)* –
  - **Expiration** *(string)* – If the object expiration is configured, the response includes this header.
  - **CopySourceVersionId** *(string)* –
- **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
- **SSECustomerAlgorithm** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header confirming the encryption algorithm used.
- **SSECustomerKeyMD5** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header to provide round trip message integrity verification of the customer-provided encryption key.
- **SSEKMSKeyId** *(string)* – If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.
- **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.

```python
create_bucket(**kwargs)
```

Creates a new bucket.

**Request Syntax**

```python
response = client.create_bucket(
    ACL='private'|'public-read'|'public-read-write'|'authenticated-read',
    Bucket='string',
    CreateBucketConfiguration={
        'LocationConstraint': 'EU'|'eu-west-1'|'us-west-1'|'us-west-2'|'ap-southeast-1'|'ap-southeast-2'|'ap-northeast-1'|'sa-east-1'|'cn-north-1'|'eu-central-1',
    GrantFullControl='string',
    GrantRead='string',
    GrantReadACP='string',
    GrantWrite='string',
    GrantWriteACP='string'
}
```

**Parameters**

- **ACL** *(string)* – The canned ACL to apply to the bucket.
- **Bucket** *(string)* – [REQUIRED]
- **CreateBucketConfiguration** *(dict)* –
  - **LocationConstraint** *(string)* – Specifies the region where the bucket will be created. If you don’t specify a region, the bucket will be created in US Standard.
- **GrantFullControl** *(string)* – Allows grantee the read, write, read ACP, and write ACP permissions on the bucket.
- **GrantRead** *(string)* – Allows grantee to list the objects in the bucket.
- **GrantReadACP** *(string)* – Allows grantee to read the bucket ACL.
- **GrantWrite** *(string)* – Allows grantee to create, overwrite, and delete any object in the bucket.
- **GrantWriteACP** *(string)* – Allows grantee to write the ACL for the applicable bucket.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Location': 'string'
}
```
Response Structure

- (dict) –
  - Location (string) –

**create_multipart_upload(**kwargs**)

Initiates a multipart upload and returns an upload ID.

**Note:** After you initiate multipart upload and upload one or more parts, you must either complete or abort multipart upload in order to stop getting charged for storage of the uploaded parts. Only after you either complete or abort multipart upload, Amazon S3 frees up the parts storage and stops charging you for the parts storage.

**Request Syntax**

```python
response = client.create_multipart_upload(
    ACL='private'|'public-read'|'public-read-write'|'authenticated-read'|'bucket-owner-read'|'bucket-owner-full-control',
    Bucket='string',
    CacheControl='string',
    ContentDisposition='string',
    ContentEncoding='string',
    ContentLanguage='string',
    ContentType='string',
    Expires=datetime(2015, 1, 1),
    GrantFullControl='string',
    GrantRead='string',
    GrantReadACP='string',
    GrantWriteACP='string',
    Key='string',
    Metadata={
        'string': 'string'
    },
    ServerSideEncryption='AES256'|'aws:kms',
    StorageClass='STANDARD'|'REDUCED_REDUNDANCY'|'STANDARD_IA',
    WebsiteRedirectLocation='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    SSEKMSKeyId='string',
    RequestPayer='requester'
)
```

**Parameters**

- **ACL (string)** – The canned ACL to apply to the object.
- **Bucket (string)** – [REQUIRED]
- **CacheControl (string)** – Specifies caching behavior along the request/reply chain.
- **ContentDisposition (string)** – Specifies presentational information for the object.
- **ContentEncoding (string)** – Specifies what content encodings have been applied to the object and thus what decoding mechanisms must be applied to obtain the media-type referenced by the Content-Type header field.
- **ContentLanguage (string)** – The language the content is in.
- **ContentType (string)** – A standard MIME type describing the format of the object data.
- **Expires (datetime)** – The date and time at which the object is no longer cacheable.
- **GrantFullControl (string)** – Gives the grantee READ, READ_ACP, and WRITE_ACP permissions on the object.
- **GrantRead (string)** – Allows grantee to read the object data and its metadata.
• **GrantReadACP** *(string)* – Allows grantee to read the object ACL.
• **GrantWriteACP** *(string)* – Allows grantee to write the ACL for the applicable object.
• **Key** *(string)* – [REQUIRED]
• **Metadata** *(dict)* – A map of metadata to store with the object in S3.
  – *(string)* –
  * (string) –
• **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
• **StorageClass** *(string)* – The type of storage to use for the object. Defaults to ‘STANDARD’.
• **WebsiteRedirectLocation** *(string)* – If the bucket is configured as a website, redirects requests for this object to another object in the same bucket or to an external URL. Amazon S3 stores the value of this header in the object metadata.
• **SSECustomerAlgorithm** *(string)* – Specifies the algorithm to use to when encrypting the object (e.g., AES256).
• **SSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.
• **SSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.
• **SSEKMSKeyId** *(string)* – Specifies the AWS KMS key ID to use for object encryption. All GET and PUT requests for an object protected by AWS KMS will fail if not made via SSL or using SigV4. Documentation on configuring any of the officially supported AWS SDKs and CLI can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/UsingAWSSDK.html#specify-signature-version
• **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'Bucket': 'string',
    'Key': 'string',
    'UploadId': 'string',
    'ServerSideEncryption': 'AES256'|'aws:kms',
    'SSECustomerAlgorithm': 'string',
    'SSECustomerKeyMD5': 'string',
    'SSEKMSKeyId': 'string',
    'RequestCharged': 'requester'
}
```

**Response Structure**

• *(dict)* –
- **Bucket** *(string)* – Name of the bucket to which the multipart upload was initiated.
- **Key** *(string)* – Object key for which the multipart upload was initiated.
- **UploadId** *(string)* – ID for the initiated multipart upload.
- **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
- **SSECustomerAlgorithm** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header confirming the encryption algorithm used.
- **SSECustomerKeyMD5** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header to provide round trip message integrity verification of the customer-provided encryption key.
- **SSEKMSKeyId** *(string)* – If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.
- **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.

**delete_bucket(** **kwargs)**

Deletes the bucket. All objects (including all object versions and Delete Markers) in the bucket must be deleted before the bucket itself can be deleted.

**Request Syntax**

```python
response = client.delete_bucket(
    Bucket='string'
)
```

**Parameters**
- **Bucket** *(string)* – [REQUIRED]

**Returns**
- None

**delete_bucket_cors(** **kwargs)**

Deletes the cors configuration information set for the bucket.

**Request Syntax**

```python
response = client.delete_bucket_cors(
    Bucket='string'
)
```

**Parameters**
- **Bucket** *(string)* – [REQUIRED]

**Returns**
- None

**delete_bucket_lifecycle(** **kwargs)**

Deletes the lifecycle configuration from the bucket.

**Request Syntax**

```python
response = client.delete_bucket_lifecycle(
    Bucket='string'
)
```

**Parameters**
- **Bucket** *(string)* – [REQUIRED]

**Returns**
- None

**delete_bucket_policy(** **kwargs)**

Deletes the policy from the bucket.
Request Syntax

response = client.delete_bucket_policy(
    Bucket='string'
)

Parameters  
Bucket (string) – [REQUIRED]

Returns  None

delete_bucket_replication(**kwargs)

Request Syntax

response = client.delete_bucket_replication(
    Bucket='string'
)

Parameters  
Bucket (string) – [REQUIRED]

Returns  None

delete_bucket_tagging(**kwargs)

Deletes the tags from the bucket.

Request Syntax

response = client.delete_bucket_tagging(
    Bucket='string'
)

Parameters  
Bucket (string) – [REQUIRED]

Returns  None

delete_bucket_website(**kwargs)

This operation removes the website configuration from the bucket.

Request Syntax

response = client.delete_bucket_website(
    Bucket='string'
)

Parameters  
Bucket (string) – [REQUIRED]

Returns  None

delete_object(**kwargs)

Removes the null version (if there is one) of an object and inserts a delete marker, which becomes the latest version of the object. If there isn’t a null version, Amazon S3 does not remove any objects.

Request Syntax

response = client.delete_object(
    Bucket='string',
    Key='string',
    MFA='string',
    VersionId='string',
    RequestPayer='requester'
)

Parameters  

•  Bucket (string) – [REQUIRED]
• **Key** *(string)* – **[REQUIRED]**
• **MFA** *(string)* – The concatenation of the authentication device’s serial number, a space, and the value that is displayed on your authentication device.
• **VersionId** *(string)* – VersionId used to reference a specific version of the object.
• **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

Return type: **dict**

Returns:

**Response Syntax**

```py
{
    'DeleteMarker': True|False,
    'VersionId': 'string',
    'RequestCharged': 'requester'
}
```

**Response Structure**

- *(dict)* –
  - **DeleteMarker** *(boolean)* – Specifies whether the versioned object that was permanently deleted was (true) or was not (false) a delete marker.
  - **VersionId** *(string)* – Returns the version ID of the delete marker created as a result of the DELETE operation.
  - **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.

**delete_objects(**kwargs)**

This operation enables you to delete multiple objects from a bucket using a single HTTP request. You may specify up to 1000 keys.

**Request Syntax**

```py
response = client.delete_objects(
    Bucket='string',
    Delete={
        'Objects': [
            {'Key': 'string',
             'VersionId': 'string'}
        ],
        'Quiet': True|False
    },
    MFA='string',
    RequestPayer='requester'
)
```

**Parameters**

- **Bucket** *(string)* – **[REQUIRED]**
- **Delete** *(dict)* – **[REQUIRED]**
  - **Objects** *(list)* – **[REQUIRED]**
    * *(dict)* –
      - **Key** *(string)* – **[REQUIRED]** Key name of the object to delete.
· **VersionId** *(string)* – VersionId for the specific version of the object to delete.

· **Quiet** *(boolean)* – Element to enable quiet mode for the request. When you add this element, you must set its value to true.

· **MFA** *(string)* – The concatenation of the authentication device’s serial number, a space, and the value that is displayed on your authentication device.

· **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html](http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html)

**Return type** `dict`

**Returns**

**Response Syntax**

```
{
    'Deleted': [
        {
            'Key': 'string',
            'VersionId': 'string',
            'DeleteMarker': True|False,
            'DeleteMarkerVersionId': 'string'
        },
    ],
    'RequestCharged': 'requester',
    'Errors': [
        {
            'Key': 'string',
            'VersionId': 'string',
            'Code': 'string',
            'Message': 'string'
        },
    ]
}
```

**Response Structure**

· *(dict)* –
  · **Deleted** *(list)* –
    * *(dict)* –
      · **Key** *(string)* –
      · **VersionId** *(string)* –
      · **DeleteMarker** *(boolean)* –
      · **DeleteMarkerVersionId** *(string)* –
  · **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.
  · **Errors** *(list)* –
    * *(dict)* –
      · **Key** *(string)* –
      · **VersionId** *(string)* –
      · **Code** *(string)* –
      · **Message** *(string)* –

**download_file** *(Bucket, Key, Filename, ExtraArgs=None, Callback=None, Config=None)*

Download an S3 object to a file.

**Usage:**
```python
import boto3
s3 = boto3.resource('s3')
s3.meta.client.download_file('mybucket', 'hello.txt', '/tmp/hello.txt')
```

Similar behavior as S3Transfer’s `download_file()` method, except that parameters are capitalized. Detailed examples can be found at `S3Transfer’s Usage`.

`generate_presigned_post` *(Bucket, Key, Fields=None, Conditions=None, ExpiresIn=3600)*

Builds the url and the form fields used for a presigned s3 post

**Parameters**

- **Bucket** *(string)* – The name of the bucket to presign the post to. Note that bucket related conditions should not be included in the conditions parameter.
- **Key** *(string)* – Key name, optionally add `${filename}` to the end to attach the submitted filename. Note that key related conditions and fields are filled out for you and should not be included in the fields or conditions parameter.
- **Fields** *(dict)* – A dictionary of prefilled form fields to build on top of. Elements that may be included are acl, Cache-Control, Content-Type, Content-Disposition, Content-Encoding, Expires, success_action_redirect, redirect, success_action_status, and x-amz-meta-.

Note that if a particular element is included in the fields dictionary it will not be automatically added to the conditions list. You must specify a condition for the element as well.
- **Conditions** *(list)* – A list of conditions to include in the policy. Each element can be either a list or a structure. For example:
  ```
  [
  {"acl": "public-read"}, ["content-length-range", 2, 5], ["starts-with", "$success_action_redirect", ""]
  ]
  ```

Conditions that are included may pertain to acl, content-length-range, Cache-Control, Content-Type, Content-Disposition, Content-Encoding, Expires, success_action_redirect, redirect, success_action_status, and/or x-amz-meta-.

Note that if you include a condition, you must specify the a valid value in the fields dictionary as well. A value will not be added automatically to the fields dictionary based on the conditions.
- **ExpiresIn** *(int)* – The number of seconds the presigned post is valid for.

**Return type** *

dict

**Returns**

A dictionary with two elements: url and fields. Url is the url to post to. Fields is a dictionary filled with the form fields and respective values to use when submitting the post. For example:
```
{‘url’: ‘https://mybucket.s3.amazonaws.com
}
```

`generate_presigned_url` *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

**Parameters**

- **ClientMethod** *(string)* – The client method to presign for
- **Params** *(dict)* – The parameters normally passed to ClientMethod.
- **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** *(string)* – The http method to use on the generated url. By default,
the http method is whatever is used in the method’s model.

Returns The presigned url

```python
get_bucket_acl(**kwargs)
```

Gets the access control policy for the bucket.

Request Syntax

```python
response = client.get_bucket_acl(
    Bucket='string'
)
```

Parameters

- **Bucket** *(string)* – [REQUIRED]

Return type

dict

Returns

Response Syntax

```python
{
    'Owner': {
        'DisplayName': 'string',
        'ID': 'string'
    },
    'Grants': [
        {
            'Grantee': {
                'DisplayName': 'string',
                'EmailAddress': 'string',
                'ID': 'string',
                'Type': 'CanonicalUser'|'AmazonCustomerByEmail'|'Group',
                'URI': 'string'
            },
            'Permission': 'FULL_CONTROL'|'WRITE'|'WRITE_ACP'|'READ'|'READ_ACP'
        }
    ]
}
```

Response Structure

- *(dict)* –
  - **Owner** *(dict)* –
    - **DisplayName** *(string)* –
    - **ID** *(string)* –
  - **Grants** *(list)* – A list of grants.
    - *(dict)* –
      - **Grantee** *(dict)* –
        - **DisplayName** *(string)* – Screen name of the grantee.
        - **EmailAddress** *(string)* – Email address of the grantee.
        - **ID** *(string)* – The canonical user ID of the grantee.
        - **Type** *(string)* – Type of grantee
        - **URI** *(string)* – URI of the grantee group.
        - **Permission** *(string)* – Specifies the permission given to the grantee.

```python
get_bucket_cors(**kwargs)
```

Returns the cors configuration for the bucket.

Request Syntax
response = client.get_bucket_cors(
    Bucket='string'
)

**Parameters**
- **Bucket** *(string)* – [REQUIRED]

**Return type**
*dict*

**Returns**

**Response Syntax**

```python
{
    'CORSRules': [
        {
            'AllowedHeaders': [
                'string',
            ],
            'AllowedMethods': [
                'string',
            ],
            'AllowedOrigins': [
                'string',
            ],
            'ExposeHeaders': [
                'string',
            ],
            'MaxAgeSeconds': 123
        },
    ]
}
```

**Response Structure**

- *(dict)* –
  - **CORSRules** *(list)* –
    - *(dict)* –
      - **AllowedHeaders** *(list)* – Specifies which headers are allowed in a pre-flight OPTIONS request.
        - *(string)* –
      - **AllowedMethods** *(list)* – Identifies HTTP methods that the domain/origin specified in the rule is allowed to execute.
        - *(string)* –
      - **AllowedOrigins** *(list)* – One or more origins you want customers to be able to access the bucket from.
        - *(string)* –
      - **ExposeHeaders** *(list)* – One or more headers in the response that you want customers to be able to access from their applications (for example, from a JavaScript XMLHttpRequest object).
        - *(string)* –
      - **MaxAgeSeconds** *(integer)* – The time in seconds that your browser is to cache the preflight response for the specified resource.

**get_bucket_lifecycle** (**kwargs**)

Depreciated, see the GetBucketLifecycleConfiguration operation.

**Request Syntax**
response = client.get_bucket_lifecycle(
    Bucket='string'
)

Parameters
- **Bucket** *(string)* – [REQUIRED]
- **Return type** *dict*
- **Returns**

Response Syntax
```
{
    'Rules': [
        {
            'Expiration': {
                'Date': datetime(2015, 1, 1),
                'Days': 123
            },
            'ID': 'string',
            'Prefix': 'string',
            'Status': 'Enabled' | 'Disabled',
            'Transition': {
                'Date': datetime(2015, 1, 1),
                'Days': 123,
                'StorageClass': 'GLACIER' | 'STANDARD_IA'
            },
            'NoncurrentVersionTransition': {
                'NoncurrentDays': 123,
                'StorageClass': 'GLACIER' | 'STANDARD_IA'
            },
            'NoncurrentVersionExpiration': {
                'NoncurrentDays': 123
            }
        },
    ]
}
```

Response Structure
- *(dict)* –
  - **Rules** *(list)* –
    - *(dict)* –
      - **Expiration** *(dict)* –
        - **Date** *(datetime)* – Indicates at what date the object is to be moved or deleted. Should be in GMT ISO 8601 Format.
        - **Days** *(integer)* – Indicates the lifetime, in days, of the objects that are subject to the rule. The value must be a non-zero positive integer.
      - **ID** *(string)* – Unique identifier for the rule. The value cannot be longer than 255 characters.
      - **Prefix** *(string)* – Prefix identifying one or more objects to which the rule applies.
      - **Status** *(string)* – If ‘Enabled’, the rule is currently being applied. If ‘Disabled’, the rule is not currently being applied.
      - **Transition** *(dict)* –
        - **Date** *(datetime)* – Indicates at what date the object is to be moved or deleted. Should be in GMT ISO 8601 Format.
        - **Days** *(integer)* – Indicates the lifetime, in days, of the objects
that are subject to the rule. The value must be a non-zero positive integer.

- **StorageClass** *(string)* – The class of storage used to store the object.

- **NoncurrentVersionTransition** *(dict)* – Container for the transition rule that describes when noncurrent objects transition to the STANDARD_IA or GLACIER storage class. If your bucket is versioning-enabled (or versioning is suspended), you can set this action to request that Amazon S3 transition noncurrent object versions to the STANDARD_IA or GLACIER storage class at a specific period in the object’s lifetime.

  - **NoncurrentDays** *(integer)* – Specifies the number of days an object is noncurrent before Amazon S3 can perform the associated action. For information about the noncurrent days calculations, see How Amazon S3 Calculates When an Object Became Noncurrent in the Amazon Simple Storage Service Developer Guide.

- **StorageClass** *(string)* – The class of storage used to store the object.

- **NoncurrentVersionExpiration** *(dict)* – Specifies when noncurrent object versions expire. Upon expiration, Amazon S3 permanently deletes the noncurrent object versions. You set this lifecycle configuration action on a bucket that has versioning enabled (or suspended) to request that Amazon S3 delete noncurrent object versions at a specific period in the object’s lifetime.

  - **NoncurrentDays** *(integer)* – Specifies the number of days an object is noncurrent before Amazon S3 can perform the associated action. For information about the noncurrent days calculations, see How Amazon S3 Calculates When an Object Became Noncurrent in the Amazon Simple Storage Service Developer Guide.

**get_bucket_lifecycle_configuration(** kwargs **)**

Returns the lifecycle configuration information set on the bucket.

**Request Syntax**

```python
response = client.get_bucket_lifecycle_configuration(
    Bucket='string'
)
```

**Parameters**

- **Bucket** *(string)* – [REQUIRED]

**Return type**

- **dict**

**Returns**

**Response Syntax**

```python
{
    'Rules': [
        {
            'Expiration': {
                'Date': datetime(2015, 1, 1),
                'Days': 123
            }
        }
    ]
}
```
'ID': 'string',
'Prefix': 'string',
'Status': 'Enabled'|'Disabled',
'Transitions': [  
    
    'Date': datetime(2015, 1, 1),
    'Days': 123,
    'StorageClass': 'GLACIER'|'STANDARD_IA'
  ],

'NoncurrentVersionTransitions': [  
    
    'NoncurrentDays': 123,
    'StorageClass': 'GLACIER'|'STANDARD_IA'
  ],

'NoncurrentVersionExpiration': {
    'NoncurrentDays': 123
}

Response Structure
• (dict) –
  – Rules (list) –
    *(dict) –
      • Expiration (dict) –
      • Date (datetime) – Indicates at what date the object is to be moved or deleted. Should be in GMT ISO 8601 Format.
      • Days (integer) – Indicates the lifetime, in days, of the objects that are subject to the rule. The value must be a non-zero positive integer.
      • ID (string) – Unique identifier for the rule. The value cannot be longer than 255 characters.
      • Prefix (string) – Prefix identifying one or more objects to which the rule applies.
      • Status (string) – If ‘Enabled’, the rule is currently being applied. If ‘Disabled’, the rule is not currently being applied.
      • Transitions (list) –
        *(dict) –
          • Date (datetime) – Indicates at what date the object is to be moved or deleted. Should be in GMT ISO 8601 Format.
          • Days (integer) – Indicates the lifetime, in days, of the objects that are subject to the rule. The value must be a non-zero positive integer.
          • StorageClass (string) – The class of storage used to store the object.
          • NoncurrentVersionTransitions (list) –
            *(dict) – Container for the transition rule that describes when noncurrent objects transition to the STANDARD_IA or GLACIER storage class. If your bucket is versioning-enabled (or versioning is suspended), you can set this action to request that Amazon S3 transition noncurrent object versions to the STANDARD_IA or GLACIER storage class at a specific
period in the object’s lifetime.
· **NoncurrentDays (integer)** – Specifies the number of days an object is noncurrent before Amazon S3 can perform the associated action. For information about the noncurrent days calculations, see How Amazon S3 Calculates When an Object Became Noncurrent in the Amazon Simple Storage Service Developer Guide.
· **StorageClass (string)** – The class of storage used to store the object.
· **NoncurrentVersionExpiration (dict)** – Specifies when noncurrent object versions expire. Upon expiration, Amazon S3 permanently deletes the noncurrent object versions. You set this lifecycle configuration action on a bucket that has versioning enabled (or suspended) to request that Amazon S3 delete noncurrent object versions at a specific period in the object’s lifetime.
· **NoncurrentDays (integer)** – Specifies the number of days an object is noncurrent before Amazon S3 can perform the associated action. For information about the noncurrent days calculations, see How Amazon S3 Calculates When an Object Became Noncurrent in the Amazon Simple Storage Service Developer Guide.

### get_bucket_location (**kwargs**)
Returns the region the bucket resides in.

**Request Syntax**

```python
def get_bucket_location(**kwargs):
    return client.get_bucket_location(Bucket='string')
```

**Parameters**
- **Bucket (string)** – [REQUIRED]

**Return type**
- dict

**Returns**

**Response Syntax**

```python
response = client.get_bucket_location(Bucket='string')
```

**Response Structure**
- **LocationConstraint (string)** –

### get_bucket_logging (**kwargs**)
Returns the logging status of a bucket and the permissions users have to view and modify that status. To use GET, you must be the bucket owner.

**Request Syntax**

```python
def get_bucket_logging(**kwargs):
    return client.get_bucket_logging(Bucket='string')
```

**Parameters**
- **Bucket (string)** – [REQUIRED]
Return type  dict
Returns

Response Syntax

```python
{
    'LoggingEnabled': {
        'TargetBucket': 'string',
        'TargetGrants': [
            {
                'Grantee': {
                    'DisplayName': 'string',
                    'EmailAddress': 'string',
                    'ID': 'string',
                    'Type': 'CanonicalUser'|'AmazonCustomerByEmail'|'Group',
                    'URI': 'string'
                },
                'Permission': 'FULL_CONTROL'|'READ'|'WRITE'
            }
        ],
        'TargetPrefix': 'string'
    }
}
```

Response Structure

* (dict) –
  * **LoggingEnabled** (dict) –
    * TargetBucket (string) – Specifies the bucket where you want Amazon S3 to store server access logs. You can have your logs delivered to any bucket that you own, including the same bucket that is being logged. You can also configure multiple buckets to deliver their logs to the same target bucket. In this case you should choose a different TargetPrefix for each source bucket so that the delivered log files can be distinguished by key.
    * TargetGrants (list) –
      * (dict) –
        * Grantee (dict) –
          * DisplayName (string) – Screen name of the grantee.
          * EmailAddress (string) – Email address of the grantee.
          * ID (string) – The canonical user ID of the grantee.
          * Type (string) – Type of grantee
          * URI (string) – URI of the grantee group.
          * Permission (string) – Logging permissions assigned to the Grantee for the bucket.
      * TargetPrefix (string) – This element lets you specify a prefix for the keys that the log files will be stored under.

get_bucket_notification(**kwargs)
Deprecated, see the GetBucketNotificationConfiguration operation.

Request Syntax

```python
response = client.get_bucket_notification(
    Bucket='string'
)
```
**Parameters**  
**Bucket** *(string)* – [REQUIRED] Name of the bucket to get the notification configuration for.

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'TopicConfiguration': {
        'Id': 'string',
        'Events': [
        'Topic': 'string'
    },
    'QueueConfiguration': {
        'Id': 'string',
        'Events': [
        'Queue': 'string'
    },
    'CloudFunctionConfiguration': {
        'Id': 'string',
        'Events': [
        'CloudFunction': 'string',
        'InvocationRole': 'string'
    }
}
```

**Response Structure**

- *(dict)* –
  - **TopicConfiguration** *(dict)* –
    - *Id* *(string)* – Optional unique identifier for configurations in a notification configuration. If you don’t provide one, Amazon S3 will assign an ID.
    - *Events* *(list)* –
      - *(string)* – Bucket event for which to send notifications.
    - *Event* *(string)* – Bucket event for which to send notifications.
    - *Topic* *(string)* – Amazon SNS topic to which Amazon S3 will publish a message to report the specified events for the bucket.
  - **QueueConfiguration** *(dict)* –
    - *Id* *(string)* – Optional unique identifier for configurations in a notification configuration. If you don’t provide one, Amazon S3 will assign an ID.
    - *Event* *(string)* – Bucket event for which to send notifications.
    - *Events* *(list)* –
      - *(string)* – Bucket event for which to send notifications.
  - **CloudFunctionConfiguration** *(dict)* –
    - *Id* *(string)* – Optional unique identifier for configurations in a notification configuration. If you don’t provide one, Amazon S3 will assign an ID.
    - *Event* *(string)* – Bucket event for which to send notifications.
    - *Events* *(list)* –
      - *(string)* – Bucket event for which to send notifications.
assign an ID.

* `Event (string)` – Bucket event for which to send notifications.

* `Events (list)` –
  · `string` – Bucket event for which to send notifications.

* `CloudFunction (string)` –

* `InvocationRole (string)` –

**get_bucket_notification_configuration (kwargs)**

Returns the notification configuration of a bucket.

Request Syntax

```python
response = client.get_bucket_notification_configuration(
    Bucket='string'
)
```

**Parameters**

- `Bucket (string)` – [REQUIRED] Name of the bucket to get the notification configuration for.

**Return type**

- `dict`

**Returns**

Response Syntax

```json
{
    'TopicConfigurations': [
        {
            'Id': 'string',
            'TopicArn': 'string',
            'Events': [
            'Filter': {
                'Key': {
                    'FilterRules': [
                        {
                            'Name': 'prefix'|'suffix',
                            'Value': 'string'
                        }
                    ]
                }
            }
        },
    ],
    'QueueConfigurations': [
        {
            'Id': 'string',

Response Structure
  
  - (dict) – Container for specifying the notification configuration of the bucket. If this element is empty, notifications are turned off on the bucket.
  
  - TopicConfigurations (list) –
    
    * (dict) – Container for specifying the configuration when you want Amazon S3 to publish events to an Amazon Simple Notification Service (Amazon SNS) topic.
      
      - Id (string) – Optional unique identifier for configurations in a notification configuration. If you don’t provide one, Amazon S3 will assign an ID.
      
      - TopicArn (string) – Amazon SNS topic ARN to which Amazon S3 will publish a message when it detects events of specified type.
      
      - Events (list) –
        
        - (string) – Bucket event for which to send notifications.
      
      - Filter (dict) – Container for object key name filtering rules. For information about key name filtering, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.
      
      - Key (dict) – Container for object key name prefix and suffix filtering rules.
      
      - FilterRules (list) – A list of containers for key value pair that defines the criteria for the filter rule.
      
      - (dict) – Container for key value pair that defines the criteria for the filter rule.
      
      - Name (string) – Object key name prefix or suffix identifying one or more objects to which the filtering rule applies. Maximum prefix length can be up to 1,024 characters. Overlapping prefixes and suffixes are not supported. For more information, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.
· **QueueConfigurations (list)** –
  * (dict) – Container for specifying an configuration when you want Amazon S3 to publish events to an Amazon Simple Queue Service (Amazon SQS) queue.
  - **Id (string)** – Optional unique identifier for configurations in a notification configuration. If you don’t provide one, Amazon S3 will assign an ID.
  - **QueueArn (string)** – Amazon SQS queue ARN to which Amazon S3 will publish a message when it detects events of specified type.
  - **Events (list)** –
    * (string) – Bucket event for which to send notifications.
  - **Filter (dict)** – Container for object key name filtering rules. For information about key name filtering, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.
  - **Key (dict)** – Container for object key name prefix and suffix filtering rules.
  - **FilterRules (list)** – A list of containers for key value pair that defines the criteria for the filter rule.
  - (dict) – Container for key value pair that defines the criteria for the filter rule.
  - **Name (string)** – Object key name prefix or suffix identifying one or more objects to which the filtering rule applies. Maximum prefix length can be up to 1,024 characters. Overlapping prefixes and suffixes are not supported. For more information, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.

· **LambdaFunctionConfigurations (list)** –
  * (dict) – Container for specifying the AWS Lambda notification configuration.
  - **Id (string)** – Optional unique identifier for configurations in a notification configuration. If you don’t provide one, Amazon S3 will assign an ID.
  - **LambdaFunctionArn (string)** – Lambda cloud function ARN that Amazon S3 can invoke when it detects events of the specified type.
  - **Events (list)** –
    * (string) – Bucket event for which to send notifications.
  - **Filter (dict)** – Container for object key name filtering rules. For information about key name filtering, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.
  - **Key (dict)** – Container for object key name prefix and suffix filtering rules.
  - **FilterRules (list)** – A list of containers for key value pair that defines the criteria for the filter rule.
  - (dict) – Container for key value pair that defines the criteria for the filter rule.
  - **Name (string)** – Object key name prefix or suffix identifying one or more objects to which the filtering rule applies. Maximum prefix length can be up to 1,024 characters. Overlapping prefixes and suffixes are not supported. For more information, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.
prefixes and suffixes are not supported. For more information, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.

`get_bucket_policy(**kwargs)`
Returns the policy of a specified bucket.

**Request Syntax**

```python
response = client.get_bucket_policy(
    Bucket='string'
)
```

**Parameters**
- **Bucket** *(string)* – [REQUIRED]

**Return type**
- dict

**Returns**

**Response Syntax**

```python
{
    'Policy': 'string'
}
```

**Response Structure**

- *(dict)* –
  - **Policy** *(string)* – The bucket policy as a JSON document.

`get_bucket_replication(**kwargs)`

**Request Syntax**

```python
response = client.get_bucket_replication(
    Bucket='string'
)
```

**Parameters**
- **Bucket** *(string)* – [REQUIRED]

**Return type**
- dict

**Returns**

**Response Syntax**

```python
{
    'ReplicationConfiguration': {
        'Role': 'string',
        'Rules': [
            {
                'ID': 'string',
                'Prefix': 'string',
                'Status': 'Enabled'|'Disabled',
                'Destination': {
                    'Bucket': 'string',
                    'StorageClass': 'STANDARD'|'REDUCED_REDUNDANCY'|'STANDARD_IA'
                }
            }
        ]
    }
}
```

**Response Structure**
• *(dict)* –
  • **ReplicationConfiguration** *(dict)* – Container for replication rules. You can add as many as 1,000 rules. Total replication configuration size can be up to 2 MB.
  • **Role** *(string)* – Amazon Resource Name (ARN) of an IAM role for Amazon S3 to assume when replicating the objects.
  • **Rules** *(list)* – Container for information about a particular replication rule. Replication configuration must have at least one rule and can contain up to 1,000 rules.
    • *(dict)* –
      • **ID** *(string)* – Unique identifier for the rule. The value cannot be longer than 255 characters.
      • **Prefix** *(string)* – Object keyname prefix identifying one or more objects to which the rule applies. Maximum prefix length can be up to 1,024 characters. Overlapping prefixes are not supported.
      • **Status** *(string)* – The rule is ignored if status is not Enabled.
      • **Destination** *(dict)* –
        • **Bucket** *(string)* – Amazon resource name (ARN) of the bucket where you want Amazon S3 to store replicas of the object identified by the rule.
        • **StorageClass** *(string)* – The class of storage used to store the object.

**get_bucket_request_payment**( **kwargs**)

Returns the request payment configuration of a bucket.

Request Syntax

```
response = client.get_bucket_request_payment(
    Bucket='string'
)
```

**Parameters**

**Bucket** *(string)* – [REQUIRED]

**Return type**

*dict*

**Returns**

**Response Syntax**

```
{
    'Payer': 'Requester'|'BucketOwner'
}
```

**Response Structure**

• *(dict)* –
  • **Payer** *(string)* – Specifies who pays for the download and request fees.

**get_bucket_tagging**( **kwargs**)

Returns the tag set associated with the bucket.

Request Syntax

```
response = client.get_bucket_tagging(
    Bucket='string'
)
```

**Parameters**

**Bucket** *(string)* – [REQUIRED]
**Return type**  dict

**Returns**

**Response Syntax**

```plaintext
default,

[]
```

**Response Structure**

- (dict) –
  - TagSet (list) –
    * (dict) –
      - Key (string) – Name of the tag.
      - Value (string) – Value of the tag.

**get_bucket_versioning(**kwargs**)**

Returns the versioning state of a bucket.

**Request Syntax**

```python
response = client.get_bucket_versioning(
    Bucket='string'
)
```

**Parameters**

- **Bucket (string)** – [REQUIRED]

**Return type**  dict

**Returns**

**Response Syntax**

```plaintext
default,

[]
```

**Response Structure**

- (dict) –
  - Status (string) – The versioning state of the bucket.
  - MFADelete (string) – Specifies whether MFA delete is enabled in the bucket versioning configuration. This element is only returned if the bucket has been configured with MFA delete. If the bucket has never been so configured, this element is not returned.

**get_bucket_website(**kwargs**)**

Returns the website configuration for a bucket.

**Request Syntax**

```python
response = client.get_bucket_website(
    Bucket='string'
)
```

**Parameters**

- **Bucket (string)** – [REQUIRED]
Return type  dict
Returns

Response Syntax

```python
{
    'RedirectAllRequestsTo': {
        'HostName': 'string',
        'Protocol': 'http'|'https'
    },
    'IndexDocument': {
        'Suffix': 'string'
    },
    'ErrorDocument': {
        'Key': 'string'
    },
    'RoutingRules': [
        {
            'Condition': {
                'HttpErrorCodeReturnedEquals': 'string',
                'KeyPrefixEquals': 'string'
            },
            'Redirect': {
                'HostName': 'string',
                'HttpRedirectCode': 'string',
                'Protocol': 'http'|'https',
                'ReplaceKeyPrefixWith': 'string',
                'ReplaceKeyWith': 'string'
            }
        }
    ]
}
```

Response Structure

- `(dict)` –
  - **RedirectAllRequestsTo (dict)** –
    * `HostName (string)` – Name of the host where requests will be redirected.
    * `Protocol (string)` – Protocol to use (http, https) when redirecting requests. The default is the protocol that is used in the original request.
  - **IndexDocument (dict)** –
    * `Suffix (string)` – A suffix that is appended to a request that is for a directory on the website endpoint (e.g. if the suffix is index.html and you make a request to samplebucket/images/ the data that is returned will be for the object with the key name images/index.html) The suffix must not be empty and must not include a slash character.
  - **ErrorDocument (dict)** –
    * `Key (string)` – The object key name to use when a 4XX class error occurs.
  - **RoutingRules (list)** –
    * `(dict)` –
      * `Condition (dict)` – A container for describing a condition that must be met for the specified redirect to apply. For example, 1. If request is for pages in the /docs folder, redirect to the /documents folder. 2. If request results in HTTP error 4xx, redirect request to another host where you might process the
error.

- **HttpErrorCodeReturnedEquals (string)** – The HTTP error code when the redirect is applied. In the event of an error, if the error code equals this value, then the specified redirect is applied. Required when parent element `Condition` is specified and sibling `KeyPrefixEquals` is not specified. If both are specified, then both must be true for the redirect to be applied.

- **KeyPrefixEquals (string)** – The object key name prefix when the redirect is applied. For example, to redirect requests for ExamplePage.html, the key prefix will be ExamplePage.html. To redirect request for all pages with the prefix docs/, the key prefix will be /docs, which identifies all objects in the docs/ folder. Required when the parent element `Condition` is specified and sibling `HttpErrorCodeReturnedEquals` is not specified. If both conditions are specified, both must be true for the redirect to be applied.

- **Redirect (dict)** – Container for redirect information. You can redirect requests to another host, to another page, or with another protocol. In the event of an error, you can specify a different error code to return.

- **HostName (string)** – The host name to use in the redirect request.

- **HttpRedirectCode (string)** – The HTTP redirect code to use on the response. Not required if one of the siblings is present.

- **Protocol (string)** – Protocol to use (http, https) when redirecting requests. The default is the protocol that is used in the original request.

- **ReplaceKeyPrefixWith (string)** – The object key prefix to use in the redirect request. For example, to redirect requests for all pages with prefix docs/ (objects in the docs/ folder) to documents/, you can set a condition block with `KeyPrefixEquals` set to docs/ and in the `Redirect` set `ReplaceKeyPrefixWith` to documents. Not required if one of the siblings is present. Can be present only if `ReplaceKeyWith` is not provided.

- **ReplaceKeyWith (string)** – The specific object key to use in the redirect request. For example, redirect request to error.html. Not required if one of the sibling is present. Can be present only if `ReplaceKeyPrefixWith` is not provided.

```python
get_object(**kwargs)
```

Retrieves objects from Amazon S3.

**Request Syntax**

```python
response = client.get_object(
    Bucket='string',
    IfMatch='string',
    IfModifiedSince=datetime(2015, 1, 1),
    IfNoneMatch='string',
    IfUnmodifiedSince=datetime(2015, 1, 1),
    Key='string',
    Range='string',
    ResponseCacheControl='string',
    ResponseContentDisposition='string',
)```
Parameters

- **Bucket** *(string)* – [REQUIRED]
- **IfMatch** *(string)* – Return the object only if its entity tag (ETag) is the same as the one specified, otherwise return a 412 (precondition failed).
- **IfModifiedSince** *(datetime)* – Return the object only if it has been modified since the specified time, otherwise return a 304 (not modified).
- **IfNoneMatch** *(string)* – Return the object only if its entity tag (ETag) is different from the one specified, otherwise return a 304 (not modified).
- **IfUnmodifiedSince** *(datetime)* – Return the object only if it has not been modified since the specified time, otherwise return a 412 (precondition failed).
- **Key** *(string)* – [REQUIRED]
- **Range** *(string)* – Downloads the specified range bytes of an object. For more information about the HTTP Range header, go to http://www.w3.org/Protocols/rfc2616/rfc2616-sec14.html#sec14.35.
- **ResponseCacheControl** *(string)* – Sets the Cache-Control header of the response.
- **ResponseContentDisposition** *(string)* – Sets the Content-Disposition header of the response.
- **ResponseContentEncoding** *(string)* – Sets the Content-Encoding header of the response.
- **ResponseContentLanguage** *(string)* – Sets the Content-Language header of the response.
- **ResponseContentType** *(string)* – Sets the Content-Type header of the response.
- **ResponseExpires** *(datetime)* – Sets the Expires header of the response.
- **VersionId** *(string)* – VersionId used to reference a specific version of the object.
- **SSECustomerAlgorithm** *(string)* – Specifies the algorithm to use to when encrypting the object (e.g., AES256).
- **SSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.
- **SSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.
- **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

Return type: dict
Response Syntax

```python
{
   'Body': b'bytes',
   'DeleteMarker': True|False,
   'AcceptRanges': 'string',
   'Expiration': 'string',
   'Restore': 'string',
   'LastModified': datetime(2015, 1, 1),
   'ContentLength': 123,
   'ETag': 'string',
   'MissingMeta': 123,
   'VersionId': 'string',
   'CacheControl': 'string',
   'ContentDisposition': 'string',
   'ContentEncoding': 'string',
   'ContentLanguage': 'string',
   'ContentRange': 'string',
   'ContentType': 'string',
   'Expires': datetime(2015, 1, 1),
   'WebsiteRedirectLocation': 'string',
   'ServerSideEncryption': 'AES256'|'aws:kms',
   'Metadata': {
      'string': 'string'
   },
   'SSECiphertextAlgorithm': 'string',
   'SSECiphertextKeyMD5': 'string',
   'SSEKMSKeyId': 'string',
   'StorageClass': 'STANDARD'|'REDUCED_REDUndancy'|'STANDARD_IA',
   'RequestCharged': 'requester',
   'ReplicationStatus': 'COMPLETE'|'PENDING'|'FAILED'|'REPLICA'
}
```

Response Structure

- **Body** *(bytes)* – Object data.
- **DeleteMarker** *(boolean)* – Specifies whether the object retrieved was (true) or was not (false) a Delete Marker. If false, this response header does not appear in the response.
- **AcceptRanges** *(string)* –
- **Expiration** *(string)* – If the object expiration is configured (see PUT Bucket lifecycle), the response includes this header. It includes the expiry-date and rule-id key value pairs providing object expiration information. The value of the rule-id is URL encoded.
- **Restore** *(string)* – Provides information about object restoration operation and expiration time of the restored object copy.
- **LastModified** *(datetime)* – Last modified date of the object
- **ContentLength** *(integer)* – Size of the body in bytes.
- **ETag** *(string)* – An ETag is an opaque identifier assigned by a web server to a specific version of a resource found at a URL
- **MissingMeta** *(integer)* – This is set to the number of metadata entries not returned in x-amz-meta headers. This can happen if you create metadata using an API like SOAP that supports more flexible metadata than the REST API. For example, using SOAP, you can create metadata whose values are not legal HTTP headers.
- **VersionId** *(string)* – Version of the object.
- **CacheControl** *(string)* – Specifies caching behavior along the request/reply chain.
- **ContentDisposition** *(string)* – Specifies presentational information for the object.
- **ContentEncoding** *(string)* – Specifies what content encodings have been applied to the object and thus what decoding mechanisms must be applied to obtain the media-type referenced by the Content-Type header field.
- **ContentLanguage** *(string)* – The language the content is in.
- **ContentRange** *(string)* – The portion of the object returned in the response.
- **ContentType** *(string)* – A standard MIME type describing the format of the object data.
- **Expires** *(datetime)* – The date and time at which the object is no longer cacheable.
- **WebsiteRedirectLocation** *(string)* – If the bucket is configured as a website, redirects requests for this object to another object in the same bucket or to an external URL. Amazon S3 stores the value of this header in the object metadata.
- **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
- **Metadata** *(dict)* – A map of metadata to store with the object in S3.
  * *(string)* –
    - *(string)* –
  - **SSECustomerAlgorithm** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header confirming the encryption algorithm used.
  - **SSECustomerKeyMD5** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header to provide round trip message integrity verification of the customer-provided encryption key.
  - **SSEKMSKeyId** *(string)* – If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.
  - **StorageClass** *(string)* –
  - **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.
  - **ReplicationStatus** *(string)* –

### get_object_acl(**kwargs)

Returns the access control list (ACL) of an object.

#### Request Syntax

```python
response = client.get_object_acl(
    Bucket='string',
    Key='string',
    VersionId='string',
    RequestPayer='requester'
)
```

#### Parameters
- **Bucket** *(string)* – [REQUIRED]
- **Key** *(string)* – [REQUIRED]
- **VersionId** *(string)* – VersionId used to reference a specific version of the object.
- **RequestPayer** *(string)* – Confirms that the requester knows that
she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

Return type  dict

Returns

Response Syntax

```
{
  'Owner': {
    'DisplayName': 'string',
    'ID': 'string'
  },
  'Grants': [
    {
      'Grantee': {
        'DisplayName': 'string',
        'EmailAddress': 'string',
        'ID': 'string',
        'Type': 'CanonicalUser'|'AmazonCustomerByEmail'|'Group',
        'URI': 'string'
      },
      'Permission': 'FULL_CONTROL'|'WRITE'|'WRITE_ACP'|'READ'|'READ_ACP'
    }
  ],
  'RequestCharged': 'requester'
}
```

Response Structure

- (dict) –
  - Owner (dict) –
    * DisplayName (string) –
    * ID (string) –
  - Grants (list) – A list of grants.
    * (dict) –
      - Grantee (dict) –
        - DisplayName (string) – Screen name of the grantee.
        - EmailAddress (string) – Email address of the grantee.
        - ID (string) – The canonical user ID of the grantee.
        - Type (string) – Type of grantee
        - URI (string) – URI of the grantee group.
        - Permission (string) – Specifies the permission given to the grantee.
  - RequestCharged (string) – If present, indicates that the requester was successfully charged for the request.

get_object_torrent(**kwargs)

Return torrent files from a bucket.

Request Syntax

```python
response = client.get_object_torrent(
    Bucket='string',
    Key='string',
    RequestPayer='requester'
)
```

3.1. Services 3987
Parameters

- **Bucket** ([string])** – [REQUIRED]
- **Key** ([string])** – [REQUIRED]
- **RequestPayer** ([string])** – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html](http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html)

**Return type** **dict**
**Returns**

**Response Syntax**

```
{
    'Body': b'bytes',
    'RequestCharged': 'requester'
}
```

**Response Structure**

- (dict) –
  - **Body** ([bytes]** –
  - **RequestCharged** ([string]** – If present, indicates that the requester was successfully charged for the request.

**get_paginator** (**operation_name**)

Create a paginator for an operation.

**Parameters** **operation_name** ([string]** – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo` and you’d normally invoke the operation as `client.create_foo(**kwargs)` if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

**Raises** **OperationNotPageableError** Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

**Return type** **L{botocore.paginate.Paginator}**
**Returns** **A paginator object.**

**get_waiter** (**waiter_name**)

**head_bucket** (**kwargs**)

This operation is useful to determine if a bucket exists and you have permission to access it.

**Request Syntax**

```
response = client.head_bucket(
    Bucket='string'
)
```

**Parameters** **Bucket** ([string]** – [REQUIRED]

**Returns** **None**

**head_object** (**kwargs**)

The HEAD operation retrieves metadata from an object without returning the object itself. This operation is useful if you’re only interested in an object’s metadata. To use HEAD, you must have READ access to the object.

**Request Syntax**
response = client.head_object(
    Bucket='string',
    IfMatch='string',
    IfModifiedSince=datetime(2015, 1, 1),
    IfNoneMatch='string',
    IfUnmodifiedSince=datetime(2015, 1, 1),
    Key='string',
    Range='string',
    VersionId='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    RequestPayer='requester'
)

Parameters

- **Bucket (string)** – [REQUIRED]
- **IfMatch (string)** – Return the object only if its entity tag (ETag) is the same as the one specified, otherwise return a 412 (precondition failed).
- **IfModifiedSince (datetime)** – Return the object only if it has been modified since the specified time, otherwise return a 304 (not modified).
- **IfNoneMatch (string)** – Return the object only if its entity tag (ETag) is different from the one specified, otherwise return a 304 (not modified).
- **IfUnmodifiedSince (datetime)** – Return the object only if it has not been modified since the specified time, otherwise return a 412 (precondition failed).
- **Key (string)** – [REQUIRED]
- **Range (string)** – Downloads the specified range bytes of an object. For more information about the HTTP Range header, go to http://www.w3.org/Protocols/rfc2616/rfc2616-sec14.html#sec14.35.
- **VersionId (string)** – VersionId used to reference a specific version of the object.
- **SSECustomerAlgorithm (string)** – Specifies the algorithm to use to when encrypting the object (e.g., AES256).
- **SSECustomerKey (string)** – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.
- **SSECustomerKeyMD5 (string)** – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required
- **RequestPayer (string)** – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

Return type: dict

Returns

Response Syntax

```python
{
    'DeleteMarker': True|False,
    'AcceptRanges': 'string',
    'Expiration': 'string',
}
```
'Restore': 'string',
'LastModified': datetime(2015, 1, 1),
'ContentLength': 123,
'ETag': 'string',
'MissingMeta': 123,
'VersionId': 'string',
'CacheControl': 'string',
'ContentDisposition': 'string',
'ContentEncoding': 'string',
'ContentLanguage': 'string',
'ContentType': 'string',
'Expires': datetime(2015, 1, 1),
'WebsiteRedirectLocation': 'string',
'ServerSideEncryption': 'AES256'|'aws:kms',
'Metadata': {
    'string': 'string'
},
'SSECustomerAlgorithm': 'string',
'SSECustomerKeyMD5': 'string',
'SSEKMSKeyId': 'string',
'StorageClass': 'STANDARD'|'REDUCED_REDUNDANCY'|'STANDARD_IA',
'RequestCharged': 'requester',
'ReplicationStatus': 'COMPLETE'|'PENDING'|'FAILED'|'REPLICA'}

Response Structure

- **DeleteMarker** (boolean) – Specifies whether the object retrieved was (true) or was not (false) a Delete Marker. If false, this response header does not appear in the response.
- **AcceptRanges** (string) –
- **Expiration** (string) – If the object expiration is configured (see PUT Bucket lifecycle), the response includes this header. It includes the expiry-date and rule-id key value pairs providing object expiration information. The value of the rule-id is URL encoded.
- **Restore** (string) – Provides information about object restoration operation and expiration time of the restored object copy.
- **LastModified** (datetime) – Last modified date of the object
- **ContentLength** (integer) – Size of the body in bytes.
- **ETag** (string) – An ETag is an opaque identifier assigned by a web server to a specific version of a resource found at a URL
- **MissingMeta** (integer) – This is set to the number of metadata entries not returned in x-amz-meta headers. This can happen if you create metadata using an API like SOAP that supports more flexible metadata than the REST API. For example, using SOAP, you can create metadata whose values are not legal HTTP headers.
- **VersionId** (string) – Version of the object.
- **CacheControl** (string) – Specifies caching behavior along the request-reply chain.
- **ContentDisposition** (string) – Specifies presentational information for the object.
- **ContentEncoding** (string) – Specifies what content encodings have been applied to the object and thus what decoding mechanisms must be applied to obtain the media-type referenced by the Content-Type header field.
- **ContentLanguage** (string) – The language the content is in.
- **ContentType** (string) – A standard MIME type describing the format of
the object data.

- **Expires (datetime)** – The date and time at which the object is no longer cacheable.

- **WebsiteRedirectLocation (string)** – If the bucket is configured as a website, redirects requests for this object to another object in the same bucket or to an external URL. Amazon S3 stores the value of this header in the object metadata.

- **ServerSideEncryption (string)** – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).

- **Metadata (dict)** – A map of metadata to store with the object in S3.
  
  * (string) –
  
  - **SSECustomerAlgorithm (string)** – If server-side encryption with a customer-provided encryption key was requested, the response will include this header confirming the encryption algorithm used.

- **SSECustomerKeyMD5 (string)** – If server-side encryption with a customer-provided encryption key was requested, the response will include this header to provide round trip message integrity verification of the customer-provided encryption key.

- **SSEKMSKeyId (string)** – If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.

- **StorageClass (string)** –

- **RequestCharged (string)** – If present, indicates that the requester was successfully charged for the request.

- **ReplicationStatus (string)** –

### list_buckets()

Returns a list of all buckets owned by the authenticated sender of the request.

#### Request Syntax

```python
response = client.list_buckets()
```

**Return type** dict

**Returns**

#### Response Syntax

```python
{
    'Buckets': [
        
        
    ],

    'Owner': {
        
            'DisplayName': 'string',
            'ID': 'string'
    }
}
```

#### Response Structure

- **(dict)** –
  
  - **Buckets (list)** –
    
    * **(dict)** –
      
      - **Name (string)** – The name of the bucket.
· **CreationDate** *(datetime)* – Date the bucket was created.
  
  · **Owner** *(dict)* –
    * **DisplayName** *(string)* –
    * **ID** *(string)* –

**list_multipart_uploads**(**kwargs**)

This operation lists in-progress multipart uploads.

**Request Syntax**

```python
response = client.list_multipart_uploads(
    Bucket='string',
    Delimiter='string',
    EncodingType='url',
    KeyMarker='string',
    MaxUploads=123,
    Prefix='string',
    UploadIdMarker='string'
)
```

**Parameters**

- **Bucket** *(string)* – [REQUIRED]
- **Delimiter** *(string)* – Character you use to group keys.
- **EncodingType** *(string)* – Requests Amazon S3 to encode the object keys in the response and specifies the encoding method to use. An object key may contain any Unicode character; however, XML 1.0 parser cannot parse some characters, such as characters with an ASCII value from 0 to 10. For characters that are not supported in XML 1.0, you can add this parameter to request that Amazon S3 encode the keys in the response.
- **KeyMarker** *(string)* – Together with upload-id-marker, this parameter specifies the multipart upload after which listing should begin.
- **MaxUploads** *(integer)* – Sets the maximum number of multipart uploads, from 1 to 1,000, to return in the response body. 1,000 is the maximum number of uploads that can be returned in a response.
- **Prefix** *(string)* – Lists in-progress uploads only for those keys that begin with the specified prefix.
- **UploadIdMarker** *(string)* – Together with key-marker, specifies the multipart upload after which listing should begin. If key-marker is not specified, the upload-id-marker parameter is ignored.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Bucket': 'string',
    'KeyMarker': 'string',
    'UploadIdMarker': 'string',
    'NextKeyMarker': 'string',
    'Prefix': 'string',
    'Delimiter': 'string',
    'NextUploadIdMarker': 'string',
    'MaxUploads': 123,
    'IsTruncated': True|False,
    'Uploads': [
        {'UploadId': 'string'},
    ]
}
```
'Key': 'string',
'Initiated': datetime(2015, 1, 1),
'StorageClass': 'STANDARD'|'REDUCED_REUNDANCY'|'STANDARD_IA',
'Owner': {
    'DisplayName': 'string',
    'ID': 'string'
},
'Initiator': {
    'ID': 'string',
    'DisplayName': 'string'
},
'
},
'CommonPrefixes': [
{
    'Prefix': 'string'
},
],
(EncodingType': 'url'
}

Response Structure

• (dict) –
  – Bucket (string) – Name of the bucket to which the multipart upload was initiated.
  – KeyMarker (string) – The key at or after which the listing began.
  – UploadIdMarker (string) – Upload ID after which listing began.
  – NextKeyMarker (string) – When a list is truncated, this element specifies the value that should be used for the key-marker request parameter in a subsequent request.
  – Prefix (string) – When a prefix is provided in the request, this field contains the specified prefix. The result contains only keys starting with the specified prefix.
  – Delimiter (string) –
  – NextUploadIdMarker (string) – When a list is truncated, this element specifies the value that should be used for the upload-id-marker request parameter in a subsequent request.
  – MaxUploads (integer) – Maximum number of multipart uploads that could have been included in the response.
  – IsTruncated (boolean) – Indicates whether the returned list of multipart uploads is truncated. A value of true indicates that the list was truncated. The list can be truncated if the number of multipart uploads exceeds the limit allowed or specified by max uploads.
  – Uploads (list) –
    • (dict) –
      • UploadId (string) – Upload ID that identifies the multipart upload.
      • Key (string) – Key of the object for which the multipart upload was initiated.
      • Initiated (datetime) – Date and time at which the multipart upload was initiated.
      • StorageClass (string) – The class of storage used to store the object.
      • Owner (dict) –
        • DisplayName (string) –
· **ID** *(string)* –
· **Initiator** *(dict)* – Identifies who initiated the multipart upload.
· **ID** *(string)* – If the principal is an AWS account, it provides the Canonical User ID. If the principal is an IAM User, it provides a user ARN value.
· **Display Name** *(string)* – Name of the Principal.
    · **CommonPrefixes** *(list)* –
        * *(dict)* –
        · **Prefix** *(string)* –
    · **Encoding Type** *(string)* – Encoding type used by Amazon S3 to encode object keys in the response.

**list_object_versions**(**kwargs**)  
Returns metadata about all of the versions of objects in a bucket.

**Request Syntax**

```python
response = client.list_object_versions(
    Bucket='string',
    Delimiter='string',
    EncodingType='url',
    KeyMarker='string',
    MaxKeys=123,
    Prefix='string',
    VersionIdMarker='string'
)
```

**Parameters**

- **Bucket** *(string)* – [REQUIRED]
- **Delimiter** *(string)* – A delimiter is a character you use to group keys.
- **Encoding Type** *(string)* – Requests Amazon S3 to encode the object keys in the response and specifies the encoding method to use. An object key may contain any Unicode character; however, XML 1.0 parser cannot parse some characters, such as characters with an ASCII value from 0 to 10. For characters that are not supported in XML 1.0, you can add this parameter to request that Amazon S3 encode the keys in the response.
- **KeyMarker** *(string)* – Specifies the key to start with when listing objects in a bucket.
- **MaxKeys** *(integer)* – Sets the maximum number of keys returned in the response. The response might contain fewer keys but will never contain more.
- **Prefix** *(string)* – Limits the response to keys that begin with the specified prefix.
- **VersionIdMarker** *(string)* – Specifies the object version you want to start listing from.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'IsTruncated': True|False,
    'KeyMarker': 'string',
    'VersionIdMarker': 'string',
    'NextKeyMarker': 'string',
    'NextVersionIdMarker': 'string',
    'Versions': [
        'ETag': 'string',
        ...
    ]
}
```
'Size': 123,
'StorageClass': 'STANDARD',
'Key': 'string',
'VersionId': 'string',
'IsLatest': True|False,
'LastModified': datetime(2015, 1, 1),
'Owner': {
   'DisplayName': 'string',
   'ID': 'string'
 },
},
],
'DeleteMarkers': [
{
   'Owner': {
      'DisplayName': 'string',
      'ID': 'string'
   },
   'Key': 'string',
   'VersionId': 'string',
   'IsLatest': True|False,
   'LastModified': datetime(2015, 1, 1)
 },
],
'Name': 'string',
'Prefix': 'string',
'Delimiter': 'string',
'MaxKeys': 123,
'CommonPrefixes': [
{
   'Prefix': 'string'
 },
],
'EncodingType': 'url'

**Response Structure**

* (dict) –
  - **IsTruncated** (boolean) – A flag that indicates whether or not Amazon S3 returned all of the results that satisfied the search criteria. If your results were truncated, you can make a follow-up paginated request using the NextKeyMarker and NextVersionIdMarker response parameters as a starting place in another request to return the rest of the results.
  - **KeyMarker** (string) – Marks the last Key returned in a truncated response.
  - **VersionIdMarker** (string) –
  - **NextKeyMarker** (string) – Use this value for the key marker request parameter in a subsequent request.
  - **NextVersionIdMarker** (string) – Use this value for the next version id marker parameter in a subsequent request.
  - **Versions** (list) –
    * (dict) –
      - **ETag** (string) –
      - **Size** (integer) – Size in bytes of the object.
      - **StorageClass** (string) – The class of storage used to store the object.
      - **Key** (string) – The object key.
      - **VersionId** (string) – Version ID of an object.
- **IsLatest** *(boolean)* – Specifies whether the object is (true) or is not (false) the latest version of an object.
- **LastModified** *(datetime)* – Date and time the object was last modified.
- **Owner** *(dict)* –
  - **DisplayName** *(string)* –
  - **ID** *(string)* –
- **DeleteMarkers** *(list)* –
  * *(dict)* –
  - **Owner** *(dict)* –
  - **DisplayName** *(string)* –
  - **ID** *(string)* –
  - **Key** *(string)* – The object key.
  - **VersionId** *(string)* – Version ID of an object.
  - **IsLatest** *(boolean)* – Specifies whether the object is (true) or is not (false) the latest version of an object.
  - **LastModified** *(datetime)* – Date and time the object was last modified.
- **Name** *(string)* –
- **Prefix** *(string)* –
- **Delimiter** *(string)* –
- **MaxKeys** *(integer)* –
- **CommonPrefixes** *(list)* –
  * *(dict)* –
  - **Prefix** *(string)* –
- **EncodingType** *(string)* – Encoding type used by Amazon S3 to encode object keys in the response.

### `list_objects(**kwargs)`

Returns some or all (up to 1000) of the objects in a bucket. You can use the request parameters as selection criteria to return a subset of the objects in a bucket.

**Request Syntax**

```python
response = client.list_objects(
    Bucket='string',
    Delimiter='string',
    EncodingType='url',
    Marker='string',
    MaxKeys=123,
    Prefix='string'
)
```

**Parameters**

- **Bucket** *(string)* – [REQUIRED]
- **Delimiter** *(string)* – A delimiter is a character you use to group keys.
- **EncodingType** *(string)* – Requests Amazon S3 to encode the object keys in the response and specifies the encoding method to use. An object key may contain any Unicode character; however, XML 1.0 parser cannot parse some characters, such as characters with an ASCII value from 0 to 10. For characters that are not supported in XML 1.0, you can add this parameter to request that Amazon S3 encode the keys in the response.
- **Marker** *(string)* – Specifies the key to start with when listing objects in a bucket.
- **MaxKeys** *(integer)* – Sets the maximum number of keys returned in the response. The response might contain fewer keys but will never contain more.
- **Prefix** *(string)* – Limits the response to keys that begin with the specified prefix.

---

**Boto3 Documentation, Release 1.1.4**

- `IsLatest` *(boolean)* – Specifies whether the object is (true) or is not (false) the latest version of an object.
- `LastModified` *(datetime)* – Date and time the object was last modified.
- `Owner` *(dict)* –
  - `DisplayName` *(string)* –
  - `ID` *(string)* –
- `DeleteMarkers` *(list)* –
  * *(dict)* –
  - **Owner** *(dict)* –
  - **DisplayName** *(string)* –
  - **ID** *(string)* –
  - **Key** *(string)* – The object key.
  - **VersionId** *(string)* – Version ID of an object.
  - **IsLatest** *(boolean)* – Specifies whether the object is (true) or is not (false) the latest version of an object.
  - **LastModified** *(datetime)* – Date and time the object was last modified.
- `Name` *(string)* –
- `Prefix` *(string)* –
- `Delimiter` *(string)* –
- `MaxKeys` *(integer)* –
- `CommonPrefixes` *(list)* –
  * *(dict)* –
  - **Prefix** *(string)* –
- `EncodingType` *(string)* – Encoding type used by Amazon S3 to encode object keys in the response.

**list_objects(**kwargs)**

Returns some or all (up to 1000) of the objects in a bucket. You can use the request parameters as selection criteria to return a subset of the objects in a bucket.

**Request Syntax**

```python
response = client.list_objects(
    Bucket='string',
    Delimiter='string',
    EncodingType='url',
    Marker='string',
    MaxKeys=123,
    Prefix='string'
)
```

**Parameters**

- **Bucket** *(string)* – [REQUIRED]
- **Delimiter** *(string)* – A delimiter is a character you use to group keys.
- **EncodingType** *(string)* – Requests Amazon S3 to encode the object keys in the response and specifies the encoding method to use. An object key may contain any Unicode character; however, XML 1.0 parser cannot parse some characters, such as characters with an ASCII value from 0 to 10. For characters that are not supported in XML 1.0, you can add this parameter to request that Amazon S3 encode the keys in the response.
- **Marker** *(string)* – Specifies the key to start with when listing objects in a bucket.
- **MaxKeys** *(integer)* – Sets the maximum number of keys returned in the response. The response might contain fewer keys but will never contain more.
- **Prefix** *(string)* – Limits the response to keys that begin with the specified prefix.
Return type  `dict`

**Returns**

**Response Syntax**

```
{
    'IsTruncated': True|False,
    'Marker': 'string',
    'NextMarker': 'string',
    'Contents': [
        {
            'Key': 'string',
            'LastModified': datetime(2015, 1, 1),
            'ETag': 'string',
            'Size': 123,
            'StorageClass': 'STANDARD'|'REDUCED_REDUNDANCY'|'GLACIER',
            'Owner': {
                'DisplayName': 'string',
                'ID': 'string'
            }
        },
        ],
    'Name': 'string',
    'Prefix': 'string',
    'Delimiter': 'string',
    'MaxKeys': 123,
    'CommonPrefixes': [
        {
            'Prefix': 'string'
        },
    ],
    'EncodingType': 'url'
}
```

**Response Structure**

- *(dict)*
  - **IsTruncated** *(boolean)* – A flag that indicates whether or not Amazon S3 returned all of the results that satisfied the search criteria.
  - **Marker** *(string)* –
  - **NextMarker** *(string)* – When response is truncated (the IsTruncated element value in the response is true), you can use the key name in this field as marker in the subsequent request to get next set of objects. Amazon S3 lists objects in alphabetical order Note: This element is returned only if you have delimiter request parameter specified. If response does not include the NextMarker and it is truncated, you can use the value of the last Key in the response as the marker in the subsequent request to get the next set of object keys.
  - **Contents** *(list)* –
    * *(dict)* –
      - **Key** *(string)* –
      - **LastModified** *(datetime)* –
      - **ETag** *(string)* –
      - **Size** *(integer)* –
      - **StorageClass** *(string)* – The class of storage used to store the object.
      - **Owner** *(dict)* –
      - **DisplayName** *(string)* –
list_parts(**kwargs)

Lists the parts that have been uploaded for a specific multipart upload.

**Request Syntax**

```python
response = client.list_parts(
    Bucket='string',
    Key='string',
    MaxParts=123,
    PartNumberMarker=123,
    UploadId='string',
    RequestPayer='requester'
)
```

**Parameters**

- **Bucket** *(string)* – [REQUIRED]
- **Key** *(string)* – [REQUIRED]
- **MaxParts** *(integer)* – Sets the maximum number of parts to return.
- **PartNumberMarker** *(integer)* – Specifies the part after which listing should begin. Only parts with higher part numbers will be listed.
- **UploadId** *(string)* – [REQUIRED] Upload ID identifying the multipart upload whose parts are being listed.
- **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html](http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html)

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Bucket': 'string',
    'Key': 'string',
    'UploadId': 'string',
    'PartNumberMarker': 123,
    'NextPartNumberMarker': 123,
    'MaxParts': 123,
    'IsTruncated': True|False,
    'Parts': [
        
            'PartNumber': 123,
        'LastModified': datetime(2015, 1, 1),
        'ETag': 'string',
        'Size': 123
    ]
}
```
**Response Structure**

- **Bucket (string)** – Name of the bucket to which the multipart upload was initiated.
- **Key (string)** – Object key for which the multipart upload was initiated.
- **UploadId (string)** – Upload ID identifying the multipart upload whose parts are being listed.
- **PartNumberMarker (integer)** – Part number after which listing begins.
- **NextPartNumberMarker (integer)** – When a list is truncated, this element specifies the last part in the list, as well as the value to use for the part-number-marker request parameter in a subsequent request.
- **MaxParts (integer)** – Maximum number of parts that were allowed in the response.
- **IsTruncated (boolean)** – Indicates whether the returned list of parts is truncated.
- **Parts (list)** –
  - **(dict)** –
    - **PartNumber (integer)** – Part number identifying the part. This is a positive integer between 1 and 10,000.
    - **LastModified (datetime)** – Date and time at which the part was uploaded.
    - **ETag (string)** – Entity tag returned when the part was uploaded.
    - **Size (integer)** – Size of the uploaded part data.
- **Initiator (dict)** – Identifies who initiated the multipart upload.
  - **ID (string)** – If the principal is an AWS account, it provides the Canonical User ID. If the principal is an IAM User, it provides a user ARN value.
  - **DisplayName (string)** – Name of the Principal.
- **Owner (dict)** –
  - **DisplayName (string)** –
  - **ID (string)** –
- **StorageClass (string)** – The class of storage used to store the object.
- **RequestCharged (string)** – If present, indicates that the requester was successfully charged for the request.

*put_bucket_acl(**kwargs)*

Sets the permissions on a bucket using access control lists (ACL).

**Request Syntax**
response = client.put_bucket_acl(
    ACL='private'|'public-read'|'public-read-write'|'authenticated-read',
    AccessControlPolicy={
        'Grants': [
            {'Grantee': {
                'DisplayName': 'string',
                'EmailAddress': 'string',
                'ID': 'string',
                'Type': 'CanonicalUser'|'AmazonCustomerByEmail'|'Group',
                'URI': 'string'
            },
            {'Permission': 'FULL_CONTROL'|'WRITE'|'WRITE_ACP'|'READ'|'READ_ACP'}
        ],
        'Owner': {
            'DisplayName': 'string',
            'ID': 'string'
        }
    },
    Bucket='string',
    GrantFullControl='string',
    GrantRead='string',
    GrantReadACP='string',
    GrantWrite='string',
    GrantWriteACP='string'
)

Parameters

- **ACL** *(string)* – The canned ACL to apply to the bucket.
- **AccessControlPolicy** *(dict)* –
  - **Grants** *(list)* – A list of grants.
    * *(dict)* –
      - **Grantee** *(dict)* –
        - **DisplayName** *(string)* – Screen name of the grantee.
        - **EmailAddress** *(string)* – Email address of the grantee.
        - **ID** *(string)* – The canonical user ID of the grantee.
        - **Type** *(string)* – [REQUIRED] Type of grantee
        - **URI** *(string)* – URI of the grantee group.
        - **Permission** *(string)* – Specifies the permission given to the grantee.
  - **Owner** *(dict)* –
    * **DisplayName** *(string)* –
    * **ID** *(string)* –
- **Bucket** *(string)* – [REQUIRED]
- **GrantFullControl** *(string)* – Allows grantee the read, write, read ACP, and write ACP permissions on the bucket.
- **GrantRead** *(string)* – Allows grantee to list the objects in the bucket.
- **GrantReadACP** *(string)* – Allows grantee to read the bucket ACL.
- **GrantWrite** *(string)* – Allows grantee to create, overwrite, and delete any object in the bucket.
- **GrantWriteACP** *(string)* – Allows grantee to write the ACL for the applicable bucket.

Returns None

put_bucket_cors (**kwargs**)
Sets the cors configuration for a bucket.

**Request Syntax**

```python
response = client.put_bucket_cors(
    Bucket='string',
    CORSConfiguration={
        'CORSRules': [
            {
                'AllowedHeaders': [
                    'string',
                ],
                'AllowedMethods': [
                    'string',
                ],
                'AllowedOrigins': [
                    'string',
                ],
                'ExposeHeaders': [
                    'string',
                ],
                'MaxAgeSeconds': 123
            },
        ],
    },
)
```

**Parameters**

- **Bucket** *(string)* – [REQUIRED]
- **CORSConfiguration** *(dict)* – [REQUIRED]
  - **CORSRules** *(list)* – [REQUIRED]
    * (dict) –
    - **AllowedHeaders** *(list)* – Specifies which headers are allowed in a pre-flight OPTIONS request.
    - *(string)* –
    - **AllowedMethods** *(list)* – [REQUIRED] Identifies HTTP methods that the domain/origin specified in the rule is allowed to execute.
    - *(string)* –
    - **AllowedOrigins** *(list)* – [REQUIRED] One or more origins you want customers to be able to access the bucket from.
    - *(string)* –
    - **ExposeHeaders** *(list)* – One or more headers in the response that you want customers to be able to access from their applications (for example, from a JavaScript XMLHttpRequest object).
    - *(string)* –
    - **MaxAgeSeconds** *(integer)* – The time in seconds that your browser is to cache the preflight response for the specified resource.

**Returns** None

```python
put_bucket_lifecycle(**kwargs)
```

Deprecated, see the PutBucketLifecycleConfiguration operation.

**Request Syntax**
response = client.put_bucket_lifecycle(
    Bucket='string',
    LifecycleConfiguration={
        'Rules': [
            {
                'Expiration': {
                    'Date': datetime(2015, 1, 1),
                    'Days': 123
                },
                'ID': 'string',
                'Prefix': 'string',
                'Status': 'Enabled'|'Disabled',
                'Transition': {
                    'Date': datetime(2015, 1, 1),
                    'Days': 123,
                    'StorageClass': 'GLACIER'|'STANDARD_IA'
                },
                'NoncurrentVersionTransition': {
                    'NoncurrentDays': 123,
                    'StorageClass': 'GLACIER'|'STANDARD_IA'
                },
                'NoncurrentVersionExpiration': {
                    'NoncurrentDays': 123
                }
            }
        ]
    }
)

Parameters
- **Bucket** *(string)* – [REQUIRED]
- **LifecycleConfiguration** *(dict)* –
  - **Rules** *(list)* – [REQUIRED]
    - *(dict)* –
      - **Expiration** *(dict)* –
      - **Date** *(datetime)* – Indicates at what date the object is to be moved or deleted. Should be in GMT ISO 8601 Format.
      - **Days** *(integer)* – Indicates the lifetime, in days, of the objects that are subject to the rule. The value must be a non-zero positive integer.
      - **ID** *(string)* – Unique identifier for the rule. The value cannot be longer than 255 characters.
      - **Prefix** *(string)* – [REQUIRED] Prefix identifying one or more objects to which the rule applies.
      - **Status** *(string)* – [REQUIRED] If ‘Enabled’, the rule is currently being applied. If ‘Disabled’, the rule is not currently being applied.
      - **Transition** *(dict)* –
        - **Date** *(datetime)* – Indicates at what date the object is to be moved or deleted. Should be in GMT ISO 8601 Format.
        - **Days** *(integer)* – Indicates the lifetime, in days, of the objects that are subject to the rule. The value must be a non-zero positive integer.
        - **StorageClass** *(string)* – The class of storage used to store the object.
- **NoncurrentVersionTransition** (*dict*) – Container for the transition rule that describes when noncurrent objects transition to the STANDARD_IA or GLACIER storage class. If your bucket is versioning-enabled (or versioning is suspended), you can set this action to request that Amazon S3 transition noncurrent object versions to the STANDARD_IA or GLACIER storage class at a specific period in the object’s lifetime.

- **NoncurrentDays** (*integer*) – Specifies the number of days an object is noncurrent before Amazon S3 can perform the associated action. For information about the noncurrent days calculations, see How Amazon S3 Calculates When an Object Became Noncurrent in the Amazon Simple Storage Service Developer Guide.

- **StorageClass** (*string*) – The class of storage used to store the object.

- **NoncurrentVersionExpiration** (*dict*) – Specifies when noncurrent object versions expire. Upon expiration, Amazon S3 permanently deletes the noncurrent object versions. You set this lifecycle configuration action on a bucket that has versioning enabled (or suspended) to request that Amazon S3 delete noncurrent object versions at a specific period in the object’s lifetime.

- **NoncurrentDays** (*integer*) – Specifies the number of days an object is noncurrent before Amazon S3 can perform the associated action. For information about the noncurrent days calculations, see How Amazon S3 Calculates When an Object Became Noncurrent in the Amazon Simple Storage Service Developer Guide.

**Returns** None

`put_bucket_lifecycle_configuration(**kwargs)`

Sets lifecycle configuration for your bucket. If a lifecycle configuration exists, it replaces it.

**Request Syntax**

```python
response = client.put_bucket_lifecycle_configuration(
    Bucket='string',
    LifecycleConfiguration={
        'Rules': [
            {'Expiration': {'Date': datetime(2015, 1, 1), 'Days': 123},
             'ID': 'string',
             'Prefix': 'string',
             'Status': 'Enabled'|'Disabled',
             'Transitions': [
                 {'Date': datetime(2015, 1, 1),
                  'Days': 123,
                  'StorageClass': 'GLACIER'|'STANDARD_IA'},
             ],
            'NoncurrentVersionTransitions': [
```
Parameters

- **Bucket** *(string)* – [REQUIRED]
- **LifecycleConfiguration** *(dict)* –
  - **Rules** *(list)* – [REQUIRED]
    - *(dict)* –
      - **Expiration** *(dict)* –
        - **Date** *(datetime)* – Indicates at what date the object is to be moved or deleted. Should be in GMT ISO 8601 Format.
        - **Days** *(integer)* – Indicates the lifetime, in days, of the objects that are subject to the rule. The value must be a non-zero positive integer.
        - **ID** *(string)* – Unique identifier for the rule. The value cannot be longer than 255 characters.
        - **Prefix** *(string)* – [REQUIRED] Prefix identifying one or more objects to which the rule applies.
        - **Status** *(string)* – [REQUIRED] If ‘Enabled’, the rule is currently being applied. If ‘Disabled’, the rule is not currently being applied.
        - **Transitions** *(list)* –
          - *(dict)* –
            - **Date** *(datetime)* – Indicates at what date the object is to be moved or deleted. Should be in GMT ISO 8601 Format.
            - **Days** *(integer)* – Indicates the lifetime, in days, of the objects that are subject to the rule. The value must be a non-zero positive integer.
            - **StorageClass** *(string)* – The class of storage used to store the object.
        - **NoncurrentVersionTransitions** *(list)* –
          - *(dict)* – Container for the transition rule that describes when noncurrent objects transition to the STANDARD_IA or GLACIER storage class. If your bucket is versioning-enabled (or versioning is suspended), you can set this action to request that Amazon S3 transition noncurrent object versions to the STANDARD_IA or GLACIER storage class at a specific period in the object’s lifetime.
        - **NoncurrentDays** *(integer)* – Specifies the number of days an object is noncurrent before Amazon S3 can perform the associated action. For information about the noncurrent days calculations, see How Amazon S3 Calculates When an Object Became Noncurrent in the Amazon Simple Storage Service Developer Guide.
        - **StorageClass** *(string)* – The class of storage used to store the
object.

- **NoncurrentVersionExpiration (dict)** – Specifies when non-current object versions expire. Upon expiration, Amazon S3 permanently deletes the non-current object versions. You set this lifecycle configuration action on a bucket that has versioning enabled (or suspended) to request that Amazon S3 delete non-current object versions at a specific period in the object’s lifetime.

- **NoncurrentDays (integer)** – Specifies the number of days an object is noncurrent before Amazon S3 can perform the associated action. For information about the noncurrent days calculations, see How Amazon S3 Calculates When an Object Became Noncurrent in the Amazon Simple Storage Service Developer Guide.

**Returns None**

**put_bucket_logging(**kwargs**)**

Set the logging parameters for a bucket and to specify permissions for who can view and modify the logging parameters. To set the logging status of a bucket, you must be the bucket owner.

**Request Syntax**

```python
response = client.put_bucket_logging(
    Bucket='string',
    BucketLoggingStatus={
        'LoggingEnabled': {
            'TargetBucket': 'string',
            'TargetGrants': [
                {'Grantee': {
                    'DisplayName': 'string',
                    'EmailAddress': 'string',
                    'ID': 'string',
                    'Type': 'CanonicalUser'|'AmazonCustomerByEmail'|'Group',
                    'URI': 'string'
                },
                'Permission': 'FULL_CONTROL'|'READ'|'WRITE'
            ],
            'TargetPrefix': 'string'
        }
    }
)
```

**Parameters**

- **Bucket (string)** – [REQUIRED]
- **BucketLoggingStatus (dict)** – [REQUIRED]
  - **LoggingEnabled (dict)** –
    - **TargetBucket (string)** – Specifies the bucket where you want Amazon S3 to store server access logs. You can have your logs delivered to any bucket that you own, including the same bucket that is being logged. You can also configure multiple buckets to deliver their logs to the same target bucket. In this case you should choose a different TargetPrefix for each source bucket so that the delivered log files can be distinguished by key.
    - **TargetGrants (list)** –
Boto3 Documentation, Release 1.1.4

- (dict) –
- Grantee (dict) –
- DisplayName (string) – Screen name of the grantee.
- EmailAddress (string) – Email address of the grantee.
- ID (string) – The canonical user ID of the grantee.
- Type (string) – [REQUIRED] Type of grantee
- URI (string) – URI of the grantee group.
- Permission (string) – Logging permissions assigned to the Grantee for the bucket.

* TargetPrefix (string) – This element lets you specify a prefix for the keys that the log files will be stored under.

Returns None

put_bucket_notification(**kwargs)

Deprecated, see the PutBucketNotificationConfiguraiton operation.

Request Syntax

```python
response = client.put_bucket_notification(
    Bucket='string',
    NotificationConfiguration={
        'TopicConfiguration': {
            'Id': 'string',
            'Events': [
            'Topic': 'string',
        },
        'QueueConfiguration': {
            'Id': 'string',
            'Events': [
            'Queue': 'string',
        },
        'CloudFunctionConfiguration': {
            'Id': 'string',
            'Events': [
            'CloudFunction': 'string',
            'InvocationRole': 'string'
        }
    }
)
```

Parameters

- Bucket (string) – [REQUIRED]
- NotificationConfiguration (dict) – [REQUIRED]
  - TopicConfiguration (dict) –
    * Id (string) – Optional unique identifier for configurations in a notification configuration. If you don’t provide one, Amazon S3 will assign an ID.
    * Events (list) –
Bucket event for which to send notifications.

- Event (string) – Bucket event for which to send notifications.
- Topic (string) – Amazon SNS topic to which Amazon S3 will publish a message to report the specified events for the bucket.

- QueueConfiguration (dict) –
  - Id (string) – Optional unique identifier for configurations in a notification configuration. If you don’t provide one, Amazon S3 will assign an ID.
  - Event (string) – Bucket event for which to send notifications.
  - Events (list) –
    - (string) – Bucket event for which to send notifications.
  - Queue (string) –

- CloudFunctionConfiguration (dict) –
  - Id (string) – Optional unique identifier for configurations in a notification configuration. If you don’t provide one, Amazon S3 will assign an ID.
  - Event (string) – Bucket event for which to send notifications.
  - Events (list) –
    - (string) – Bucket event for which to send notifications.
  - CloudFunction (string) –
  - InvocationRole (string) –

Returns None

put_bucket_notification_configuration (**kwargs)

Enables notifications of specified events for a bucket.

Request Syntax

```python
def get_bucket_notification_configuration(**kwargs):
    response = client.put_bucket_notification_configuration(
        Bucket='string',
        NotificationConfiguration={
            'TopicConfigurations': [
                {'Id': 'string',
                 'TopicArn': 'string',
                 'Filter': {
                    'Key': {
                       'FilterRules': [
                          {'Name': 'prefix'|'suffix',
                           'Value': 'string'}
                       ]
                    },
                 }],
            'QueueConfigurations': [
                {'Id': 'string',
                 'QueueArn': 'string',
                 },
            ]
        })
```
Parameters

• **Bucket** *(string)* – [REQUIRED]

• **NotificationConfiguration** *(dict)* – [REQUIRED] Container for specifying the notification configuration of the bucket. If this element is empty, notifications are turned off on the bucket.
  
  – **TopicConfigurations** *(list)* –
    
    * *(dict)* – Container for specifying the configuration when you want Amazon S3 to publish events to an Amazon Simple Notification Service (Amazon SNS) topic.
      
      · **Id** *(string)* – Optional unique identifier for configurations in a notification configuration. If you don’t provide one, Amazon S3 will assign an ID.
      
      · **TopicArn** *(string)* – [REQUIRED] Amazon SNS topic ARN to which Amazon S3 will publish a message when it detects events of specified type.
      
      · **Events** *(list)* – [REQUIRED]
        
        · *(string)* – Bucket event for which to send notifications.
        
        · **Filter** *(dict)* – Container for object key name filtering rules. For information about key name filtering, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.
      
      · **Key** *(dict)* – Container for object key name prefix and suffix
filtering rules.
- **FilterRules** *(list)* – A list of containers for key value pair that defines the criteria for the filter rule.
- *(dict)* – Container for key value pair that defines the criteria for the filter rule.
- **Name** *(string)* – Object key name prefix or suffix identifying one or more objects to which the filtering rule applies. Maximum prefix length can be up to 1,024 characters. Overlapping prefixes and suffixes are not supported. For more information, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.
- **Value** *(string)* –
  - **QueueConfigurations** *(list)* –
    - *(dict)* – Container for specifying an configuration when you want Amazon S3 to publish events to an Amazon Simple Queue Service (Amazon SQS) queue.
      - **Id** *(string)* – Optional unique identifier for configurations in a notification configuration. If you don’t provide one, Amazon S3 will assign an ID.
      - **QueueArn** *(string)* – [REQUIRED] Amazon SQS queue ARN to which Amazon S3 will publish a message when it detects events of specified type.
      - **Events** *(list)* – [REQUIRED]
      - *(string)* – Bucket event for which to send notifications.
      - **Filter** *(dict)* – Container for object key name filtering rules.
        For information about key name filtering, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.
      - **Key** *(dict)* – Container for object key name prefix and suffix filtering rules.
      - **FilterRules** *(list)* – A list of containers for key value pair that defines the criteria for the filter rule.
      - *(dict)* – Container for key value pair that defines the criteria for the filter rule.
      - **Name** *(string)* – Object key name prefix or suffix identifying one or more objects to which the filtering rule applies. Maximum prefix length can be up to 1,024 characters. Overlapping prefixes and suffixes are not supported. For more information, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.
      - **Value** *(string)* –
  - **LambdaFunctionConfigurations** *(list)* –
    - *(dict)* – Container for specifying the AWS Lambda notification configuration.
      - **Id** *(string)* – Optional unique identifier for configurations in a notification configuration. If you don’t provide one, Amazon S3 will assign an ID.
      - **LambdaFunctionArn** *(string)* – [REQUIRED] Lambda cloud function ARN that Amazon S3 can invoke when it detects events of the specified type.
      - **Events** *(list)* – [REQUIRED]
      - *(string)* – Bucket event for which to send notifications.
      - **Filter** *(dict)* – Container for object key name filtering rules.
        For information about key name filtering, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.
Event Notifications in the Amazon Simple Storage Service Developer Guide.

- **Key (dict)** – Container for object key name prefix and suffix filtering rules.
- **FilterRules (list)** – A list of containers for key value pair that defines the criteria for the filter rule.
- **(dict)** – Container for key value pair that defines the criteria for the filter rule.
- **Name (string)** – Object key name prefix or suffix identifying one or more objects to which the filtering rule applies. Maximum prefix length can be up to 1,024 characters. Overlapping prefixes and suffixes are not supported. For more information, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.
- **Value (string)** –

**Returns None**

`put_bucket_policy(**kwargs)`

Replaces a policy on a bucket. If the bucket already has a policy, the one in this request completely replaces it.

**Request Syntax**

```python
response = client.put_bucket_policy(
    Bucket='string',
    Policy='string'
)
```

**Parameters**

- **Bucket (string)** – [REQUIRED]

**Returns None**

`put_bucket_replication(**kwargs)`

Creates a new replication configuration (or replaces an existing one, if present).

**Request Syntax**

```python
response = client.put_bucket_replication(
    Bucket='string',
    ReplicationConfiguration={
        'Role': 'string',
        'Rules': [
            
            {'ID': 'string',
            'Prefix': 'string',
            'Status': 'Enabled' | 'Disabled',
            'Destination': {
                'Bucket': 'string',
                'StorageClass': 'STANDARD' | 'REDUCED_REDUNDANCY' | 'STANDARD_IA'
            }
        ]
    }
)
```

**Parameters**

- **Bucket (string)** – [REQUIRED]
• **ReplicationConfiguration (dict)** – [REQUIRED] Container for replication rules. You can add as many as 1,000 rules. Total replication configuration size can be up to 2 MB.
  
  - **Role (string)** – [REQUIRED] Amazon Resource Name (ARN) of an IAM role for Amazon S3 to assume when replicating the objects.
  - **Rules (list)** – [REQUIRED] Container for information about a particular replication rule. Replication configuration must have at least one rule and can contain up to 1,000 rules.
    
    * (dict) –
    - **ID (string)** – Unique identifier for the rule. The value cannot be longer than 255 characters.
    - **Prefix (string)** – [REQUIRED] Object keyname prefix identifying one or more objects to which the rule applies. Maximum prefix length can be up to 1,024 characters. Overlapping prefixes are not supported.
    - **Status (string)** – [REQUIRED] The rule is ignored if status is not Enabled.
    - **Destination (dict)** – [REQUIRED]
      - **Bucket (string)** – [REQUIRED]
        Amazon resource name (ARN) of the bucket where you want Amazon S3 to store replicas of the object identified by the rule.
      - **StorageClass (string)** – The class of storage used to store the object.

Returns None

**put_bucket_request_payment (**kwargs)**

Sets the request payment configuration for a bucket. By default, the bucket owner pays for downloads from the bucket. This configuration parameter enables the bucket owner (only) to specify that the person requesting the download will be charged for the download. Documentation on requester pays buckets can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/RequesterPaysBuckets.html](http://docs.aws.amazon.com/AmazonS3/latest/dev/RequesterPaysBuckets.html)

Request Syntax

```python
response = client.put_bucket_request_payment(
    Bucket='string',
    RequestPaymentConfiguration={
        'Payer': 'Requester'|'BucketOwner'
    }
)
```

Parameters

- **Bucket (string)** – [REQUIRED]
- **RequestPaymentConfiguration (dict)** – [REQUIRED]
  
  - **Payer (string)** – [REQUIRED] Specifies who pays for the download and request fees.

Returns None

**put_bucket_tagging (**kwargs)**

Sets the tags for a bucket.

Request Syntax

```python
response = client.put_bucket_tagging(
    Bucket='string',
    Tagging={
        'TagSet': [
```
Parameters

- **Bucket** *(string)* – [REQUIRED]
- **Tagging** *(dict)* – [REQUIRED]
  - **TagSet** *(list)* – [REQUIRED]
    * (dict) –
      - **Key** *(string)* – [REQUIRED] Name of the tag.

Returns None

**put_bucket_versioning(** **kwargs**)**

Sets the versioning state of an existing bucket. To set the versioning state, you must be the bucket owner.

Request Syntax

```python
response = client.put_bucket_versioning(
    Bucket='string',
    MFA='string',
    VersioningConfiguration={
        'MFADelete': 'Enabled'|'Disabled',
        'Status': 'Enabled'|'Suspended'
    }
)
```

Parameters

- **Bucket** *(string)* – [REQUIRED]
- **MFA** *(string)* – The concatenation of the authentication device’s serial number, a space, and the value that is displayed on your authentication device.
- **VersioningConfiguration** *(dict)* – [REQUIRED]
  - **MFADelete** *(string)* – Specifies whether MFA delete is enabled in the bucket versioning configuration. This element is only returned if the bucket has been configured with MFA delete. If the bucket has never been so configured, this element is not returned.
  - **Status** *(string)* – The versioning state of the bucket.

Returns None

**put_bucket_website(** **kwargs**)**

Set the website configuration for a bucket.

Request Syntax

```python
response = client.put_bucket_website(
    Bucket='string',
    WebsiteConfiguration={
        'ErrorDocument': {  
            'Key': 'string'
        },
        'IndexDocument': {  
            'Suffix': 'string'
        }
    }
)
```
Parameters

- **Bucket** *(string)* – [REQUIRED]
- **WebsiteConfiguration** *(dict)* – [REQUIRED]
  - **ErrorDocument** *(dict)* –
    - **Key** *(string)* – [REQUIRED] The object key name to use when a 4XX class error occurs.
  - **IndexDocument** *(dict)* –
    - **Suffix** *(string)* – [REQUIRED] A suffix that is appended to a request that is for a directory on the website endpoint (e.g. if the suffix is index.html and you make a request to samplebucket/images/ the data that is returned will be for the object with the key name images/index.html) The suffix must not be empty and must not include a slash character.
  - **RedirectAllRequestsTo** *(dict)* –
    - **HostName** *(string)* – [REQUIRED] Name of the host where requests will be redirected.
    - **Protocol** *(string)* – Protocol to use (http, https) when redirecting requests. The default is the protocol that is used in the original request.
  - **RoutingRules** *(list)* –
    - *(dict)* –
      - **Condition** *(dict)* – A container for describing a condition that must be met for the specified redirect to apply. For example, 1. If request is for pages in the /docs folder, redirect to the /documents folder. 2. If request results in HTTP error 4xx, redirect request to another host where you might process the error.
      - **HttpErrorCodeReturnedEquals** *(string)* – The HTTP error code when the redirect is applied. In the event of an error, if the error code equals this value, then the specified redirect is applied. Required when parent element Condition is specified and sibling KeyPrefixEquals is not specified. If both are specified, then both must be true for the redirect to be applied.
· **KeyPrefixEquals (string)** – The object key name prefix when the redirect is applied. For example, to redirect requests for ExamplePage.html, the key prefix will be ExamplePage.html. To redirect request for all pages with the prefix docs/, the key prefix will be /docs, which identifies all objects in the docs/ folder. Required when the parent element Condition is specified and sibling HttpErrorCodeReturnedEquals is not specified. If both conditions are specified, both must be true for the redirect to be applied.

· **Redirect (dict)** – **[REQUIRED]** Container for redirect information. You can redirect requests to another host, to another page, or with another protocol. In the event of an error, you can specify a different error code to return.

· **HostName (string)** – The host name to use in the redirect request.

· **HttpRedirectCode (string)** – The HTTP redirect code to use on the response. Not required if one of the siblings is present.

· **Protocol (string)** – Protocol to use (http, https) when redirecting requests. The default is the protocol that is used in the original request.

· **ReplaceKeyPrefixWith (string)** – The object key prefix to use in the redirect request. For example, to redirect requests for all pages with prefix docs/ (objects in the docs/ folder) to documents/, you can set a condition block with KeyPrefixEquals set to docs/ and in the Redirect set ReplaceKeyPrefixWith to /documents. Not required if one of the siblings is present. Can be present only if ReplaceKeyWith is not provided.

· **ReplaceKeyWith (string)** – The specific object key to use in the redirect request. For example, redirect request to error.html. Not required if one of the sibling is present. Can be present only if ReplaceKeyPrefixWith is not provided.

**Returns** None

```python
put_object(**kwargs)
```

Adds an object to a bucket.

**Request Syntax**

```python
response = client.put_object(
    ACL='private'|'public-read'|'public-read-write'|'authenticated-read'|'bucket-owner-read'|'bucket-owner-full-control',
    Body=b'bytes',
    Bucket='string',
    CacheControl='string',
    ContentDisposition='string',
    ContentEncoding='string',
    ContentLanguage='string',
    ContentLength=123,
    ContentMD5='string',
    ContentType='string',
    Expires=datetime(2015, 1, 1),
    GrantFullControl='string',
    GrantRead='string',
    GrantReadACP='string',
    GrantWriteACP='string',
    Key='string',
)```

4014 Chapter 3. API Reference
Metadata={
    'string': 'string'
},
ServerSideEncryption='AES256'|'aws:kms',
StorageClass='STANDARD'|'REDUCED_REDUNDANCY'|'STANDARD_IA',
WebsiteRedirectLocation='string',
SSECustomerAlgorithm='string',
SSECustomerKey='string',
SSEKMSKeyId='string',
RequestPayer='requester'
}

Parameters

- **ACL (string)** – The canned ACL to apply to the object.
- **Body (bytes)** – Object data.
- **Bucket (string)** – [REQUIRED]
- **CacheControl (string)** – Specifies caching behavior along the request/reply chain.
- **ContentDisposition (string)** – Specifies presentational information for the object.
- **ContentEncoding (string)** – Specifies what content encodings have been applied to the object and thus what decoding mechanisms must be applied to obtain the media-type referenced by the Content-Type header field.
- **ContentLanguage (string)** – The language the content is in.
- **ContentLength (integer)** – Size of the body in bytes. This parameter is useful when the size of the body cannot be determined automatically.
- **ContentMD5 (string)** –
- **ContentType (string)** – A standard MIME type describing the format of the object data.
- **Expires (datetime)** – The date and time at which the object is no longer cacheable.
- **GrantFullControl (string)** – Gives the grantee READ, READ_ACP, and WRITE_ACP permissions on the object.
- **GrantRead (string)** – Allows grantee to read the object data and its metadata.
- **GrantReadACP (string)** – Allows grantee to read the object ACL.
- **GrantWriteACP (string)** – Allows grantee to write the ACL for the applicable object.
- **Key (string)** – [REQUIRED]
- **Metadata (dict)** – A map of metadata to store with the object in S3.
  - (string)
  * (string) –
- **ServerSideEncryption (string)** – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
- **StorageClass (string)** – The type of storage to use for the object. Defaults to ‘STANDARD’.
- **WebsiteRedirectLocation (string)** – If the bucket is configured as a website, redirects requests for this object to another object in the same bucket or to an external URL. Amazon S3 stores the value of this header in the object metadata.
- **SSECustomerAlgorithm (string)** – Specifies the algorithm to use to when encrypting the object (e.g., AES256).
- **SSECustomerKey (string)** – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.
- **SSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.

- **SSEKMSKeyId** *(string)* – Specifies the AWS KMS key ID to use for object encryption. All GET and PUT requests for an object protected by AWS KMS will fail if not made via SSL or using SigV4. Documentation on configuring any of the officially supported AWS SDKs and CLI can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/UsingAWSSDK.html#specify-signature-version

- **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'Expiration': 'string',
    'ETag': 'string',
    'ServerSideEncryption': 'AES256' | 'aws:kms',
    'VersionId': 'string',
    'SSECustomerAlgorithm': 'string',
    'SSECustomerKeyMD5': 'string',
    'SSEKMSKeyId': 'string',
    'RequestCharged': 'requester'
}
```

**Response Structure**

- *(dict)* –
  - **Expiration** *(string)* – If the object expiration is configured, this will contain the expiration date (expiry-date) and rule ID (rule-id). The value of rule-id is URL encoded.
  - **ETag** *(string)* – Entity tag for the uploaded object.
  - **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
  - **VersionId** *(string)* – Version of the object.
  - **SSECustomerAlgorithm** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header confirming the encryption algorithm used.
  - **SSECustomerKeyMD5** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header to provide round trip message integrity verification of the customer-provided encryption key.
  - **SSEKMSKeyId** *(string)* – If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.
  - **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.

**put_object_acl**(**kwargs**) uses the acl subresource to set the access control list (ACL) permissions for an object that already exists
in a bucket

Request Syntax

```python
response = client.put_object_acl(
    ACL='private'|'public-read'|'public-read-write'|'authenticated-read'|'bucket-owner-read'|'bucket-owner-full-control',
    AccessControlPolicy={
        'Grants': [
            {'Grantee': {
                'DisplayName': 'string',
                'EmailAddress': 'string',
                'ID': 'string',
                'Type': 'CanonicalUser'|'AmazonCustomerByEmail'|'Group',
                'URI': 'string'
            },
            'Permission': 'FULL_CONTROL'|'WRITE'|'WRITE_ACP'|'READ'|'READ_ACP'
        ],
        'Owner': {
            'DisplayName': 'string',
            'ID': 'string'
        }
    },
    Bucket='string',
    GrantFullControl='string',
    GrantRead='string',
    GrantReadACP='string',
    GrantWrite='string',
    GrantWriteACP='string',
    Key='string',
    RequestPayer='requester'
}
```

Parameters

- **ACL** *(string)* – The canned ACL to apply to the object.
- **AccessControlPolicy** *(dict)* –
  - **Grants** *(list)* – A list of grants.
    - *(dict)* –
      - **Grantee** *(dict)* –
      - **DisplayName** *(string)* – Screen name of the grantee.
      - **EmailAddress** *(string)* – Email address of the grantee.
      - **ID** *(string)* – The canonical user ID of the grantee.
      - **Type** *(string)* – [REQUIRED] Type of grantee
      - **URI** *(string)* – URI of the grantee group.
      - **Permission** *(string)* – Specifies the permission given to the grantee.
  - **Owner** *(dict)* –
  - **DisplayName** *(string)* –
  - **ID** *(string)* –
- **Bucket** *(string)* – [REQUIRED]
- **GrantFullControl** *(string)* – Allows grantee the read, write, read ACP, and write ACP permissions on the bucket.
- **GrantRead** *(string)* – Allows grantee to list the objects in the bucket.
- **GrantReadACP** *(string)* – Allows grantee to read the bucket ACL.
- **GrantWrite** *(string)* – Allows grantee to create, overwrite, and delete any object in the bucket.
• **GrantWriteACP** (**string**) – Allows grantee to write the ACL for the applicable bucket.

• **Key** (**string**) – [REQUIRED]

• **RequestPayer** (**string**) – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html](http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html)

Return type  dict

Returns

Response Syntax

```python
{
    'RequestCharged': 'requester'
}
```

Response Structure

• (dict) –
  • **RequestCharged** (**string**) – If present, indicates that the requester was successfully charged for the request.

**restore_object** (**kwargs**)

Restores an archived copy of an object back into Amazon S3

Request Syntax

```python
response = client.restore_object(
    Bucket='string',
    Key='string',
    VersionId='string',
    RestoreRequest={
        'Days': 123
    },
    RequestPayer='requester'
)
```

Parameters

• **Bucket** (**string**) – [REQUIRED]

• **Key** (**string**) – [REQUIRED]

• **VersionId** (**string**) –

• **RestoreRequest** (**dict**) –
  • **Days** (**integer**) – [REQUIRED] Lifetime of the active copy in days

• **RequestPayer** (**string**) – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html](http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html)

Return type  dict

Returns

Response Syntax

```python
{
    'RequestCharged': 'requester'
}
```
Response Structure

- (dict) –
  - RequestCharged (string) – If present, indicates that the requester was successfully charged for the request.

upload_file (Filename, Bucket, Key, ExtraArgs=None, Callback=None, Config=None)

Upload a file to an S3 object.

Usage:

```python
import boto3
s3 = boto3.resource('s3')
s3.meta.client.upload_file('/tmp/hello.txt', 'mybucket', 'hello.txt')
```

Similar behavior as S3Transfer’s upload_file() method, except that parameters are capitalized. Detailed examples can be found at S3Transfer’s Usage.

upload_part (**kwargs)

Uploads a part in a multipart upload.

Note: After you initiate multipart upload and upload one or more parts, you must either complete or abort multipart upload in order to stop getting charged for storage of the uploaded parts. Only after you either complete or abort multipart upload, Amazon S3 frees up the parts storage and stops charging you for the parts storage.

Request Syntax

```python
response = client.upload_part(
    Body=b'bytes',
    Bucket='string',
    ContentLength=123,
    ContentMD5='string',
    Key='string',
    PartNumber=123,
    UploadId='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    RequestPayer='requester'
)
```

Parameters

- **Body** (bytes) –
- **Bucket** (string) – [REQUIRED]
- **ContentLength** (integer) – Size of the body in bytes. This parameter is useful when the size of the body cannot be determined automatically.
- **ContentMD5** (string) –
- **Key** (string) – [REQUIRED]
- **PartNumber** (integer) – [REQUIRED] Part number of part being uploaded. This is a positive integer between 1 and 10,000.
- **UploadId** (string) – [REQUIRED] Upload ID identifying the multipart upload whose part is being uploaded.
- **SSECustomerAlgorithm** (string) – Specifies the algorithm to use to when encrypting the object (e.g., AES256).
- **SSECustomerKey** (string) – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key
must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header. This must be the same encryption key specified in the initiate multipart upload request.

- **SSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required

- **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

**Response Syntax**

```python
{  
    'ServerSideEncryption': 'AES256'|'aws:kms',  
    'ETag': 'string',  
    'SSECustomerAlgorithm': 'string',  
    'SSECustomerKeyMD5': 'string',  
    'SSEKMSKeyId': 'string',  
    'RequestCharged': 'requester'  
}
```

**Response Structure**

- *(dict)* –
  - **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
  - **ETag** *(string)* – Entity tag for the uploaded object.
  - **SSECustomerAlgorithm** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header confirming the encryption algorithm used.
  - **SSECustomerKeyMD5** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header to provide round trip message integrity verification of the customer-provided encryption key.
  - **SSEKMSKeyId** *(string)* – If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.
  - **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.

**upload_part_copy** *(**kwargs]*)

Uploads a part by copying data from an existing object as data source.

**Request Syntax**

```python
response = client.upload_part_copy(  
    Bucket='string',  
    CopySource='string',  
    CopySourceIfMatch='string',  
    CopySourceIfModifiedSince=datetime(2015, 1, 1),  
    CopySourceIfNoneMatch='string',  
)  
```
Parameters

- **Bucket** *(string)* – [REQUIRED]
  The name of the source bucket.
- **CopySource** *(string)* – [REQUIRED]
  The name of the source bucket and key name of the source object, separated by a slash (/). Must be URL-encoded.
- **CopySourceIfMatch** *(string)* – Copies the object if its entity tag (ETag) matches the specified tag.
- **CopySourceIfModifiedSince** *(datetime)* – Copies the object if it has been modified since the specified time.
- **CopySourceIfNoneMatch** *(string)* – Copies the object if its entity tag (ETag) is different than the specified ETag.
- **CopySourceIfUnmodifiedSince** *(datetime)* – Copies the object if it hasn’t been modified since the specified time.
- **CopySourceRange** *(string)* – The range of bytes to copy from the source object. The range value must use the form bytes=first-last, where the first and last are the zero-based byte offsets to copy. For example, bytes=0-9 indicates that you want to copy the first ten bytes of the source. You can copy a range only if the source object is greater than 5 GB.
- **Key** *(string)* – [REQUIRED]
- **PartNumber** *(integer)* – [REQUIRED]
  Part number of part being copied. This is a positive integer between 1 and 10,000.
- **UploadId** *(string)* – [REQUIRED]
  Upload ID identifying the multipart upload whose part is being copied.
- **SSECustomerAlgorithm** *(string)* – Specifies the algorithm to use when encrypting the object (e.g., AES256).
- **SSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header. This must be the same encryption key specified in the initiate multipart upload request.
- **SSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.
- **CopySourceSSECustomerAlgorithm** *(string)* – Specifies the algorithm to use when decrypting the source object (e.g., AES256).
- **CopySourceSSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use to decrypt the source object. The encryption key provided in this header must be one that was used when the source object was created.
- **CopySourceSSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 di-
gest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error.

- **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'CopySourceVersionId': 'string',
    'CopyPartResult': {
        'ETag': 'string',
        'LastModified': datetime(2015, 1, 1)
    },
    'ServerSideEncryption': 'AES256'|'aws:kms',
    'SSECustomerAlgorithm': 'string',
    'SSECustomerKeyMD5': 'string',
    'SSEKMSKeyId': 'string',
    'RequestCharged': 'requester'
}
```

**Response Structure**

- *(dict)* –
  - **CopySourceVersionId** *(string)* – The version of the source object that was copied, if you have enabled versioning on the source bucket.
  - **CopyPartResult** *(dict)* –
    - **ETag** *(string)* – Entity tag of the object.
    - **LastModified** *(datetime)* – Date and time at which the object was uploaded.
  - **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
  - **SSECustomerAlgorithm** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header confirming the encryption algorithm used.
  - **SSECustomerKeyMD5** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header to provide round trip message integrity verification of the customer-provided encryption key.
  - **SSEKMSKeyId** *(string)* – If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.
  - **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.

**Paginators**

The available paginators are:

- S3.Paginator.ListMultipartUploads
- S3.Paginator.ListObjectVersions
• S3.Paginator.ListObjects
• S3.Paginator.ListParts

class S3.Paginator.ListMultipartUploads

paginator = client.get_paginator('list_multipart_uploads')

paginate(**kwargs)
Create an iterator that will paginate through responses from
S3.Client.list_multipart_uploads().

Request Syntax

response_iterator = paginator.paginate(
    Bucket='string',
    Delimiter='string',
    EncodingType='url',
    Prefix='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

• Bucket (string) – [REQUIRED]
• Delimiter (string) – Character you use to group keys.
• EncodingType (string) – Requests Amazon S3 to encode the object keys in the
  response and specifies the encoding method to use. An object key may contain
  any Unicode character; however, XML 1.0 parser cannot parse some characters,
  such as characters with an ASCII value from 0 to 10. For characters that are not
  supported in XML 1.0, you can add this parameter to request that Amazon S3
  encode the keys in the response.
• Prefix (string) – Lists in-progress uploads only for those keys that begin with the
  specified prefix.
• PaginationConfig (dict) – A dictionary that provides parameters to control pag-
  ination.
  – MaxItems (integer) –
    The total number of items to return. If the total number of items available
    is more than the value specified in max-items then a NextToken will be
    provided in the output that you can use to resume pagination.
  – PageSize (integer) –
    The size of each page.
  – StartingToken (string) –
    A token to specify where to start paginating. This is the NextToken
    from a previous response.

Return type dict

Returns
dict

Response Syntax
{  
  'Bucket': 'string',  
  'KeyMarker': 'string',  
  'UploadIdMarker': 'string',  
  'Prefix': 'string',  
  'Delimiter': 'string',  
  'MaxUploads': 123,  
  'IsTruncated': True|False,  
  'Uploads': [  
    {  
      'UploadId': 'string',  
      'Key': 'string',  
      'Initiated': datetime(2015, 1, 1),  
      'StorageClass': 'STANDARD'|'REDUCED_REDUNDANCY'|'STANDARD_IA',  
      'Owner': {  
        'DisplayName': 'string',  
        'ID': 'string'  
      },  
      'Initiator': {  
        'ID': 'string',  
        'DisplayName': 'string'  
      }  
    },  
  ],  
  'CommonPrefixes': [  
    {  
      'Prefix': 'string'  
    }  
  ],  
  'EncodingType': 'url',  
  'NextToken': 'string'  
}

Response Structure

• (dict) –
  – Bucket (string) – Name of the bucket to which the multipart upload was initiated.
  – KeyMarker (string) – The key at or after which the listing began.
  – UploadIdMarker (string) – Upload ID after which listing began.
  – Prefix (string) – When a prefix is provided in the request, this field contains the specified prefix. The result contains only keys starting with the specified prefix.
  –Delimiter (string) –
  – MaxUploads (integer) – Maximum number of multipart uploads that could have been included in the response.
  – IsTruncated (boolean) – Indicates whether the returned list of multipart uploads is truncated. A value of true indicates that the list was truncated. The list can be truncated if the number of multipart uploads exceeds the limit allowed or specified by max uploads.
  – Uploads (list) –  
    • (dict) –
      • UploadId (string) – Upload ID that identifies the multipart upload.
      • Key (string) – Key of the object for which the multipart upload was initiated.
      • Initiated (datetime) – Date and time at which the multipart
upload was initiated.

- **StorageClass (string)** – The class of storage used to store the object.
- **Owner (dict)** –
  - **DisplayName (string)** –
  - **ID (string)** –
- **Initiator (dict)** – Identifies who initiated the multipart upload.
- **ID (string)** – If the principal is an AWS account, it provides the Canonical User ID. If the principal is an IAM User, it provides a user ARN value.
- **DisplayName (string)** – Name of the Principal.

- **CommonPrefixes (list)** –
  - ***(dict)** –
    - **Prefix (string)** –
- **EncodingType (string)** – Encoding type used by Amazon S3 to encode object keys in the response.
- **NextToken (string)** – A token to resume pagination.

```python
class S3.Paginator.ListObjectVersions

paginator = client.get_paginator('list_object_versions')
paginate(**kwargs)
```

**Request Syntax**

```python
response_iterator = paginator.paginate(
    Bucket='string',
    Delimiter='string',
    EncodingType='url',
    Prefix='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **Bucket (string)** – [REQUIRED]
- **Delimiter (string)** – A delimiter is a character you use to group keys.
- **EncodingType (string)** – Requests Amazon S3 to encode the object keys in the response and specifies the encoding method to use. An object key may contain any Unicode character; however, XML 1.0 parser cannot parse some characters, such as characters with an ASCII value from 0 to 10. For characters that are not supported in XML 1.0, you can add this parameter to request that Amazon S3 encode the keys in the response.
- **Prefix (string)** – Limits the response to keys that begin with the specified prefix.
- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  
  - **MaxItems (integer)** –
The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

- **PageSize (integer)** –
  
  The size of each page.

- **StartingToken (string)** –
  
  A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type**  dict

**Response Syntax**

```python
{
    'IsTruncated': True|False,
    'KeyMarker': 'string',
    'VersionIdMarker': 'string',
    'Versions': [
        {
            'ETag': 'string',
            'Size': 123,

        },
    ],
    'EncodingType': 'url',
    'NextToken': 'string'
}
```
Response Structure

- (dict)
  - IsTruncated (boolean) – A flag that indicates whether or not Amazon S3 returned all of the results that satisfied the search criteria. If your results were truncated, you can make a follow-up paginated request using the NextKeyMarker and NextVersionIdMarker response parameters as a starting place in another request to return the rest of the results.
  - KeyMarker (string) – Marks the last Key returned in a truncated response.
  - VersionIdMarker (string) –
  - Versions (list) –
    * (dict) –
      - ETag (string) –
      - Size (integer) – Size in bytes of the object.
      - StorageClass (string) – The class of storage used to store the object.
      - Key (string) – The object key.
      - VersionId (string) – Version ID of an object.
      - IsLatest (boolean) – Specifies whether the object is (true) or is not (false) the latest version of an object.
      - LastModified (datetime) – Date and time the object was last modified.
      - Owner (dict) –
        - DisplayName (string) –
        - ID (string) –
  - DeleteMarkers (list) –
    * (dict) –
      - Owner (dict) –
        - DisplayName (string) –
        - ID (string) –
      - Key (string) – The object key.
      - VersionId (string) – Version ID of an object.
      - IsLatest (boolean) – Specifies whether the object is (true) or is not (false) the latest version of an object.
      - LastModified (datetime) – Date and time the object was last modified.
  - Name (string) –
  - Prefix (string) –
  - Delimiter (string) –
  - MaxKeys (integer) –
  - CommonPrefixes (list) –
    * (dict) –
      - Prefix (string) –
  - EncodingType (string) – Encoding type used by Amazon S3 to encode object keys in the response.
  - NextToken (string) –

A token to resume pagination.

class S3.Paginator.ListObjects

paginator = client.get_paginator('list_objects')

paginate(**kwargs)

Creates an iterator that will paginate through responses from S3.Client.list_objects().
Request Syntax

```python
response_iterator = paginator.paginate(
    Bucket='string',
    Delimiter='string',
    EncodingType='url',
    Prefix='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **Bucket** (string) – [REQUIRED]
- **Delimiter** (string) – A delimiter is a character you use to group keys.
- **EncodingType** (string) – Requests Amazon S3 to encode the object keys in the response and specifies the encoding method to use. An object key may contain any Unicode character; however, XML 1.0 parser cannot parse some characters, such as characters with an ASCII value from 0 to 10. For characters that are not supported in XML 1.0, you can add this parameter to request that Amazon S3 encode the keys in the response.
- **Prefix** (string) – Limits the response to keys that begin with the specified prefix.
- **PaginationConfig** (dict) – A dictionary that provides parameters to control pagination.
  - **MaxItems** (integer) – The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize** (integer) – The size of each page.
  - **StartingToken** (string) – A token to specify where to start paginating. This is the `NextToken` from a previous response.

Return type `dict`

Returns

Response Syntax

```json
{
    'IsTruncated': True|False,
    'Marker': 'string',
    'NextMarker': 'string',
    'Contents': [
        {
            'Key': 'string',
            'LastModified': datetime(2015, 1, 1),
            'ETag': 'string',
            'Size': 123,
            'StorageClass': 'STANDARD'|'REDUCED_REDUNDANCY'|'GLACIER',
            'Owner': {
                'DisplayName': 'string',
                'ID': 'string'
            }
        }
    ]
}
```
Response Structure

- (dict)
  - IsTruncated (boolean) – A flag that indicates whether or not Amazon S3 returned all of the results that satisfied the search criteria.
  - Marker (string)
  - NextMarker (string) – When response is truncated (the IsTruncated element value in the response is true), you can use the key name in this field as marker in the subsequent request to get next set of objects. Amazon S3 lists objects in alphabetical order Note: This element is returned only if you have delimiter request parameter specified. If response does not include the NextMarker and it is truncated, you can use the value of the last Key in the response as the marker in the subsequent request to get the next set of object keys.
  - Contents (list)
    * (dict)
      - Key (string)
      - LastModified (datetime)
      - ETag (string)
      - Size (integer)
      - StorageClass (string) – The class of storage used to store the object.
      - Owner (dict)
        - DisplayName (string)
        - ID (string)
  - Name (string)
  - Prefix (string)
  - Delimiter (string)
  - MaxKeys (integer)
  - CommonPrefixes (list)
    * (dict)
      - Prefix (string)
  - EncodingType (string) – Encoding type used by Amazon S3 to encode object keys in the response.
  - NextToken (string)

A token to resume pagination.
paginator = client.get_paginator('list_parts')

paginate(**kwargs)

Creates an iterator that will paginate through responses from S3.Client.list_parts().

Request Syntax

response_iterator = paginator.paginate(
    Bucket='string',
    Key='string',
    UploadId='string',
    RequestPayer='requester',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

• **Bucket** (*string*) – [REQUIRED]
• **Key** (*string*) – [REQUIRED]
• **UploadId** (*string*) – [REQUIRED] Upload ID identifying the multipart upload whose parts are being listed.
• **RequestPayer** (*string*) – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html
• **PaginationConfig** (*dict*) – A dictionary that provides parameters to control pagination.
  • **MaxItems** (*integer*) –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  • **PageSize** (*integer*) –
    The size of each page.
  • **StartingToken** (*string*) –
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type: *dict*

Returns

Response Syntax

```python
{}
```

  • **Bucket** (*string*)
  • **Key** (*string*)
  • **UploadId** (*string*)
  • **PartNumberMarker** (*integer*)
  • **MaxParts** (*integer*)
  • **IsTruncated** (*boolean*)
  • **Parts** (*list*)

```python
[
}
```
'PartNumber': 123,
'LastModified': datetime(2015, 1, 1),
'ETag': 'string',
'Size': 123
},

'Initiator': {
  'ID': 'string',
  'DisplayName': 'string'
},

'Owner': {
  'DisplayName': 'string',
  'ID': 'string'
},

'StorageClass': 'STANDARD'|'REDUCED_REDUNDANCY'|'STANDARD_IA',
'RequestCharged': 'requester',
'NextToken': 'string'
}

Response Structure

* (dict) –
  – Bucket (string) – Name of the bucket to which the multipart upload was initiated.
  – Key (string) – Object key for which the multipart upload was initiated.
  – UploadId (string) – Upload ID identifying the multipart upload whose parts are being listed.
  – PartNumberMarker (integer) – Part number after which listing begins.
  – MaxParts (integer) – Maximum number of parts that were allowed in the response.
  – IsTruncated (boolean) – Indicates whether the returned list of parts is truncated.
  – Parts (list) –
    * (dict) –
      – PartNumber (integer) – Part number identifying the part. This is a positive integer between 1 and 10,000.
      – LastModified (datetime) – Date and time at which the part was uploaded.
      – ETag (string) – Entity tag returned when the part was uploaded.
      – Size (integer) – Size of the uploaded part data.
    – Initiator (dict) – Identifies who initiated the multipart upload.
      – ID (string) – If the principal is an AWS account, it provides the Canonical User ID. If the principal is an IAM User, it provides a user ARN value.
      – DisplayName (string) – Name of the Principal.
    – Owner (dict) –
      – DisplayName (string) –
      – ID (string) –
    – StorageClass (string) – The class of storage used to store the object.
    – RequestCharged (string) – If present, indicates that the requester was successfully charged for the request.
    – NextToken (string) –
      A token to resume pagination.
Waiters

The available waiters are:

- `S3.Waiter.BucketExists`
- `S3.Waiter.BucketNotExists`
- `S3.Waiter.ObjectExists`
- `S3.Waiter.ObjectNotExists`

**class S3.Waiter.BucketExists**

```python
waiter = client.get_waiter('bucket_exists')

wait(**kwargs)
    Polls `S3.Client.head_bucket()` every 5 seconds until a successful state is reached. An error is returned after 20 failed checks.

Request Syntax

waiter.wait(
    Bucket='string'
)
```

Parameters  

- **Bucket** *(string)* – [REQUIRED]

Returns  

None

**class S3.Waiter.BucketNotExists**

```python
waiter = client.get_waiter('bucket_not_exists')

wait(**kwargs)
    Polls `S3.Client.head_bucket()` every 5 seconds until a successful state is reached. An error is returned after 20 failed checks.

Request Syntax

waiter.wait(
    Bucket='string'
)
```

Parameters  

- **Bucket** *(string)* – [REQUIRED]

Returns  

None

**class S3.Waiter.ObjectExists**

```python
waiter = client.get_waiter('object_exists')

wait(**kwargs)
    Polls `S3.Client.head_object()` every 5 seconds until a successful state is reached. An error is returned after 20 failed checks.

Request Syntax

waiter.wait(
    Bucket='string'
)
```

Parameters  

- **Bucket** *(string)* – [REQUIRED]

Returns  

None
waiter.wait(
    Bucket='string',
    IfMatch='string',
    IfModifiedSince=datetime(2015, 1, 1),
    IfNoneMatch='string',
    IfUnmodifiedSince=datetime(2015, 1, 1),
    Key='string',
    Range='string',
    VersionId='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    RequestPayer='requester'
)

Parameters

- **Bucket (string) – [REQUIRED]**
- **IfMatch (string) –** Return the object only if its entity tag (ETag) is the same as the one specified, otherwise return a 412 (precondition failed).
- **IfModifiedSince (datetime) –** Return the object only if it has been modified since the specified time, otherwise return a 304 (not modified).
- **IfNoneMatch (string) –** Return the object only if its entity tag (ETag) is different from the one specified, otherwise return a 304 (not modified).
- **IfUnmodifiedSince (datetime) –** Return the object only if it has not been modified since the specified time, otherwise return a 412 (precondition failed).
- **Key (string) – [REQUIRED]**
- **VersionId (string) –** VersionId used to reference a specific version of the object.
- **SSECustomerAlgorithm (string) –** Specifies the algorithm to use to when encrypting the object (e.g., AES256).
- **SSECustomerKey (string) –** Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.
- **SSECustomerKeyMD5 (string) –** Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.
- **RequestPayer (string) –** Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html](http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html)

Returns  None

class S3.Waiter.ObjectNotExists

waiter = client.get_waiter('object_not_exists')

wait(**kwargs)

Polls S3.Client.head_object() every 5 seconds until a successful state is reached. An error is
returned after 20 failed checks.

Request Syntax

```python
waiter.wait(
    Bucket='string',
    IfMatch='string',
    IfModifiedSince=datetime(2015, 1, 1),
    IfNoneMatch='string',
    IfUnmodifiedSince=datetime(2015, 1, 1),
    Key='string',
    Range='string',
    VersionId='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    RequestPayer='requester'
)
```

Parameters

- **Bucket** *(string)* – [REQUIRED]
- **IfMatch** *(string)* – Return the object only if its entity tag (ETag) is the same as the one specified, otherwise return a 412 (precondition failed).
- **IfModifiedSince** *(datetime)* – Return the object only if it has been modified since the specified time, otherwise return a 304 (not modified).
- **IfNoneMatch** *(string)* – Return the object only if its entity tag (ETag) is different from the one specified, otherwise return a 304 (not modified).
- **IfUnmodifiedSince** *(datetime)* – Return the object only if it has not been modified since the specified time, otherwise return a 412 (precondition failed).
- **Key** *(string)* – [REQUIRED]
- **Range** *(string)* – Downloads the specified range bytes of an object. For more information about the HTTP Range header, go to http://www.w3.org/Protocols/rfc2616/rfc2616-sec14.html#sec14.35.
- **VersionId** *(string)* – VersionId used to reference a specific version of the object.
- **SSECustomerAlgorithm** *(string)* – Specifies the algorithm to use to when encrypting the object (e.g., AES256).
- **SSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.
- **SSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required
- **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

Returns None
Service Resource

**class S3.ServiceResource**

A resource representing Amazon Simple Storage Service (S3):

```python
import boto3

s3 = boto3.resource('s3')
```

These are the resource’s available actions:

- `create_bucket()`

These are the resource’s available sub-resources:

- `Bucket()`
- `BucketAcl()`
- `BucketCors()`
- `BucketLifecycle()`
- `BucketLogging()`
- `BucketNotification()`
- `BucketPolicy()`
- `BucketRequestPayment()`
- `BucketTagging()`
- `BucketVersioning()`
- `BucketWebsite()`
- `Object()`
- `ObjectAcl()`
- `ObjectSummary()`
- `ObjectVersion()`

These are the resource’s available collections:

- `buckets`

**Actions**

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide*.

**create_bucket(**kwargs**)**

Creates a new bucket.

**Request Syntax**

```python
bucket = s3.create_bucket(
    ACL='private'|'public-read'|'public-read-write'|'authenticated-read',
    Bucket='string',
    CreateBucketConfiguration={
        'LocationConstraint': 'EU'|'eu-west-1'|'us-west-1'|'us-west-2'|'ap-southeast-1'|'ap-southeast-2'|'ap-northeast-1'|'sa-east-1'|'cn-north-1'|'eu-central-1',
    'GrantFullControl': 'string',
    'GrantRead': 'string',
    'GrantReadACP': 'string',
    'GrantWrite': 'string',
    'GrantWriteACP': 'string',
}
```

**Parameters**

- **ACL** *(string)* – The canned ACL to apply to the bucket.
• **Bucket** *(string)* – [REQUIRED]
• **CreateBucketConfiguration** *(dict)* –
  – **LocationConstraint** *(string)* – Specifies the region where the bucket will be created. If you don’t specify a region, the bucket will be created in US Standard.
• **GrantFullControl** *(string)* – Allows grantee the read, write, read ACP, and write ACP permissions on the bucket.
• **GrantRead** *(string)* – Allows grantee to list the objects in the bucket.
• **GrantReadACP** *(string)* – Allows grantee to read the bucket ACL.
• **GrantWrite** *(string)* – Allows grantee to create, overwrite, and delete any object in the bucket.
• **GrantWriteACP** *(string)* – Allows grantee to write the ACL for the applicable bucket.

**Return type** `s3.Bucket`

**Returns** Bucket resource

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the `Resources Introduction Guide`.

**Bucket**(name)

Creates a Bucket resource:

```python
bucket = s3.Bucket('name')
```

**Parameters** `name` *(string)* – The Bucket’s name identifier. This **must** be set.

**Return type** `S3.Bucket`

**Returns** A Bucket resource

**BucketAcl**(bucket_name)

Creates a BucketAcl resource:

```python
bucket_acl = s3.BucketAcl('bucket_name')
```

**Parameters** `bucket_name` *(string)* – The BucketAcl’s bucket_name identifier. This **must** be set.

**Return type** `S3.BucketAcl`

**Returns** A BucketAcl resource

**BucketCors**(bucket_name)

Creates a BucketCors resource:

```python
bucket_cors = s3.BucketCors('bucket_name')
```

**Parameters** `bucket_name` *(string)* – The BucketCors’s bucket_name identifier. This **must** be set.

**Return type** `S3.BucketCors`

**Returns** A BucketCors resource

**BucketLifecycle**(bucket_name)

Creates a BucketLifecycle resource:

```python
bucket_lifecycle = s3.BucketLifecycle('bucket_name')
```

**Parameters** `bucket_name` *(string)* – The BucketLifecycle’s bucket_name identifier. This **must** be set.
Return type S3.BucketLifecycle
Returns A BucketLifecycle resource

BucketLogging (bucket_name)
Creates a BucketLogging resource:

    bucket_logging = s3.BucketLogging('bucket_name')

Parameters bucket_name (string) – The BucketLogging’s bucket_name identifier. This must be set.
Return type S3.BucketLogging
Returns A BucketLogging resource

BucketNotification (bucket_name)
Creates a BucketNotification resource:

    bucket_notification = s3.BucketNotification('bucket_name')

Parameters bucket_name (string) – The BucketNotification’s bucket_name identifier. This must be set.
Return type S3.BucketNotification
Returns A BucketNotification resource

BucketPolicy (bucket_name)
Creates a BucketPolicy resource:

    bucket_policy = s3.BucketPolicy('bucket_name')

Parameters bucket_name (string) – The BucketPolicy’s bucket_name identifier. This must be set.
Return type S3.BucketPolicy
Returns A BucketPolicy resource

BucketRequestPayment (bucket_name)
Creates a BucketRequestPayment resource:

    bucket_request_payment = s3.BucketRequestPayment('bucket_name')

Parameters bucket_name (string) – The BucketRequestPayment’s bucket_name identifier. This must be set.
Return type S3.BucketRequestPayment
Returns A BucketRequestPayment resource

BucketTagging (bucket_name)
Creates a BucketTagging resource:

    bucket_tagging = s3.BucketTagging('bucket_name')

Parameters bucket_name (string) – The BucketTagging’s bucket_name identifier. This must be set.
Return type S3.BucketTagging
Returns A BucketTagging resource

BucketVersioning (bucket_name)
Creates a BucketVersioning resource:

    bucket_versioning = s3.BucketVersioning('bucket_name')
Parameters `bucket_name` *(string)* – The BucketVersioning’s `bucket_name` identifier. This must be set.

Return type `S3.BucketVersioning`

Returns A BucketVersioning resource

**BucketWebsite** *(bucket_name)*

Creates a BucketWebsite resource:

```python
bucket_website = s3.BucketWebsite('bucket_name')
```

Parameters `bucket_name` *(string)* – The BucketWebsite’s `bucket_name` identifier. This must be set.

Return type `S3.BucketWebsite`

Returns A BucketWebsite resource

**MultipartUpload** *(bucket_name, object_key, id)*

Creates a MultipartUpload resource:

```python
multipart_upload = s3.MultipartUpload('bucket_name','object_key','id')
```

Parameters
- `bucket_name` *(string)* – The MultipartUpload’s `bucket_name` identifier. This must be set.
- `object_key` *(string)* – The MultipartUpload’s `object_key` identifier. This must be set.
- `id` *(string)* – The MultipartUpload’s `id` identifier. This must be set.

Return type `S3.MultipartUpload`

Returns A MultipartUpload resource

**MultipartUploadPart** *(bucket_name, object_key, multipart_upload_id, part_number)*

Creates a MultipartUploadPart resource:

```python
multipart_upload_part = s3.MultipartUploadPart('bucket_name','object_key','multipart_upload_id','part_number')
```

Parameters
- `bucket_name` *(string)* – The MultipartUploadPart’s `bucket_name` identifier. This must be set.
- `object_key` *(string)* – The MultipartUploadPart’s `object_key` identifier. This must be set.
- `multipart_upload_id` *(string)* – The MultipartUploadPart’s `multipart_upload_id` identifier. This must be set.
- `part_number` *(string)* – The MultipartUploadPart’s `part_number` identifier. This must be set.

Return type `S3.MultipartUploadPart`

Returns A MultipartUploadPart resource

**Object** *(bucket_name, key)*

Creates a Object resource:

```python
object = s3.Object('bucket_name','key')
```

Parameters
- `bucket_name` *(string)* – The Object’s `bucket_name` identifier. This must be set.
- `key` *(string)* – The Object’s `key` identifier. This must be set.

Return type `S3.Object`

Returns A Object resource
**ObjectAcl** *(bucket_name, object_key)*

Creates a ObjectAcl resource:

```python
object_acl = s3.ObjectAcl('bucket_name','object_key')
```

**Parameters**

- **bucket_name** *(string)* – The ObjectAcl’s bucket_name identifier. This **must** be set.
- **object_key** *(string)* – The ObjectAcl’s object_key identifier. This **must** be set.

**Return type** *S3.ObjectAcl*

**Returns**  
A ObjectAcl resource

**ObjectSummary** *(bucket_name, key)*

Creates a ObjectSummary resource:

```python
object_summary = s3.ObjectSummary('bucket_name','key')
```

**Parameters**

- **bucket_name** *(string)* – The ObjectSummary’s bucket_name identifier. This **must** be set.
- **key** *(string)* – The ObjectSummary’s key identifier. This **must** be set.

**Return type** *S3.ObjectSummary*

**Returns**  
A ObjectSummary resource

**ObjectVersion** *(bucket_name, object_key, id)*

Creates a ObjectVersion resource:

```python
object_version = s3.ObjectVersion('bucket_name','object_key','id')
```

**Parameters**

- **bucket_name** *(string)* – The ObjectVersion’s bucket_name identifier. This **must** be set.
- **object_key** *(string)* – The ObjectVersion’s object_key identifier. This **must** be set.
- **id** *(string)* – The ObjectVersion’s id identifier. This **must** be set.

**Return type** *S3.ObjectVersion*

**Returns**  
A ObjectVersion resource

**Collections**

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the *Resources Introduction Guide*.

**buckets**

**all()**

Creates an iterable of all Bucket resources in the collection.

**Request Syntax**

```python
bucket_iterator = s3.buckets.all()
```

**Return type** *list(s3.Bucket)*

**Returns**  
A list of Bucket resources
**filter()**

Creates an iterable of all Bucket resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
bucket_iterator = s3.buckets.filter()
```

**Return type** list(s3.Bucket)

**Returns** A list of Bucket resources

**limit(**kwargs**)**

Creates an iterable up to a specified amount of Bucket resources in the collection.

**Request Syntax**

```python
bucket_iterator = s3.buckets.limit()
```

**Return type** list(s3.Bucket)

**Returns** A list of Bucket resources

**page_size(**kwargs**)**

Creates an iterable of all Bucket resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
bucket_iterator = s3.buckets.page_size()
```

**Return type** list(s3.Bucket)

**Returns** A list of Bucket resources

---

**Bucket**

**class** `s3.Bucket(name)`

A resource representing an Amazon Simple Storage Service (S3) Bucket:

```python
import boto3

s3 = boto3.resource('s3')
bucket = s3.Bucket('name')
```

**Parameters** `name (string)` – The Bucket’s name identifier. This **must** be set.

These are the resource’s available identifiers:

- `name`

These are the resource’s available attributes:

- `creation_date`

These are the resource’s available actions:

- `create()`
- `delete()`
- `delete_objects()`
- `download_file()`
- `load()`
- `put_object()`
- `upload_file()`

These are the resource’s available sub-resources:

- `Acl()`
• Cors()
• Lifecycle()
• Logging()
• Notification()
• Object()
• Policy()
• RequestPayment()
• Tagging()
• Versioning()
• Website()

These are the resource’s available collections:
• multipart_uploads
• object_versions
• objects

These are the resource’s available waiters:
• wait_until_exists()
• wait_until_not_exists()

Identifiers
Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

name
(string) The Bucket’s name identifier. This must be set.

Attributes
Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

creation_date
(datetime) Date the bucket was created.

Actions
Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

download_file (Key, Filename, ExtraArgs=None, Callback=None, Config=None)

load (*args, **kwargs)

upload_file (Filename, Key, ExtraArgs=None, Callback=None, Config=None)

create (**kwargs)
Creates a new bucket.

Request Syntax

response = bucket.create(
    ACL='private'|'public-read'|'public-read-write'|'authenticated-read',
    CreateBucketConfiguration={
        'LocationConstraint': 'EU'|'eu-west-1'|'us-west-1'|'us-west-2'|'ap-southeast-1'|'ap-southeast-2'|'ap-northeast-1'|'sa-east-1'|'cn-north-1'|'eu-central-1',
        GrantFullControl='string',
        GrantRead='string',
        GrantReadACP='string',
        GrantWrite='string',
    
3.1. Services
Parameters

• **ACL** *(string)* – The canned ACL to apply to the bucket.

• **CreateBucketConfiguration** *(dict)* –
  – **LocationConstraint** *(string)* – Specifies the region where the bucket will be created. If you don’t specify a region, the bucket will be created in US Standard.

• **GrantFullControl** *(string)* – Allows grantee the read, write, read ACP, and write ACP permissions on the bucket.

• **GrantRead** *(string)* – Allows grantee to list the objects in the bucket.

• **GrantReadACP** *(string)* – Allows grantee to read the bucket ACL.

• **GrantWrite** *(string)* – Allows grantee to create, overwrite, and delete any object in the bucket.

• **GrantWriteACP** *(string)* – Allows grantee to write the ACL for the applicable bucket.

Return type dict

Response Syntax

```python
{
    'Location': 'string'
}
```

Response Structure

• *(dict)* –
  – **Location** *(string)* –

**delete()**

Deletes the bucket. All objects (including all object versions and Delete Markers) in the bucket must be deleted before the bucket itself can be deleted.

Request Syntax

```python
response = bucket.delete()
```

Returns None

**delete_objects(****kwargs**

This operation enables you to delete multiple objects from a bucket using a single HTTP request. You may specify up to 1000 keys.

Request Syntax

```python
response = bucket.delete_objects(
    Delete={
        'Objects': [
            {'Key': 'string',
             'VersionId': 'string'
            },
            ...
        ],
        'Quiet': True|False
    },
    MFA='string',
    **kwargs
)
```
RequestPayer='requester'
}

Parameters

- **Delete** *(dict)* – [REQUIRED]
  - **Objects** *(list)* – [REQUIRED]
    * *(dict)* –
      - **Key** *(string)* – [REQUIRED] Key name of the object to delete.
      - **VersionId** *(string)* – VersionId for the specific version of the object to delete.
  - **Quiet** *(boolean)* – Element to enable quiet mode for the request. When you add this element, you must set its value to true.
- **MFA** *(string)* – The concatenation of the authentication device’s serial number, a space, and the value that is displayed on your authentication device.
- **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

Return type: `dict`

Returns

Response Syntax

```python
{
    'Deleted': [
        {
            'Key': 'string',
            'VersionId': 'string',
            'DeleteMarker': True|False,
            'DeleteMarkerVersionId': 'string'
        },
    ],
    'RequestCharged': 'requester',
    'Errors': [
        {
            'Key': 'string',
            'VersionId': 'string',
            'Code': 'string',
            'Message': 'string'
        },
    ]
}
```

Response Structure

- *(dict)* –
  - **Deleted** *(list)* –
    * *(dict)* –
      - **Key** *(string)* –
      - **VersionId** *(string)* –
      - **DeleteMarker** *(boolean)* –
      - **DeleteMarkerVersionId** *(string)* –
  - **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.
  - **Errors** *(list)* –
Upload a file to an S3 object.

Usage:

```python
import boto3
s3 = boto3.resource('s3')
s3.Bucket('mybucket').upload_file('/tmp/hello.txt', 'hello.txt')
```

Similar behavior as S3Transfer's upload_file() method, except that parameters are capitalized. Detailed examples can be found at S3Transfer's Usage.

```python
put_object(**kwargs)
```

Adds an object to a bucket.

**Request Syntax**

```python
object = bucket.put_object(
    ACL='private'|'public-read'|'public-read-write'|'authenticated-read'|'bucket-owner-read'|'bucket-owner-full-control',
    Body=b'bytes',
    CacheControl='string',
    ContentDisposition='string',
    ContentEncoding='string',
    ContentLanguage='string',
    ContentLength=123,
    ContentMD5='string',
    ContentType='string',
    Expires=datetime(2015, 1, 1),
    GrantFullControl='string',
    GrantRead='string',
    GrantReadACP='string',
    GrantWriteACP='string',
    Key='string',
    Metadata={
        'string': 'string'
    },
    ServerSideEncryption='AES256'|'aws:kms',
    StorageClass='STANDARD'|'REDUCED_REDUNDANCY'|'STANDARD_IA',
    WebsiteRedirectLocation='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    SSEKMSKeyId='string',
    RequestPayer='requester'
)
```

**Parameters**

- **ACL (string)** – The canned ACL to apply to the object.
- **Body (bytes)** – Object data.
- **CacheControl (string)** – Specifies caching behavior along the request/reply chain.
- **ContentDisposition (string)** – Specifies presentational information for the object.
- **ContentEncoding (string)** – Specifies what content encodings have been applied to the object and thus
what decoding mechanisms must be applied to obtain
the media-type referenced by the Content-Type header
field.

- **ContentLanguage** *(string)* – The language the content
  is in.
- **ContentLength** *(integer)* – Size of the body in bytes. This
  parameter is useful when the size of the body cannot
  be determined automatically.
- **ContentMD5** *(string)* –
- **ContentType** *(string)* – A standard MIME type de-
  scribing the format of the object data.
- **Expires** *(datetime)* – The date and time at which the
  object is no longer cacheable.
- **GrantFullControl** *(string)* – Gives the grantee READ,
  READ_ACP, and WRITE_ACP permissions on the ob-
  ject.
- **GrantRead** *(string)* – Allows grantee to read the object
  data and its metadata.
- **GrantReadACP** *(string)* – Allows grantee to read the
  object ACL.
- **GrantWriteACP** *(string)* – Allows grantee to write the
  ACL for the applicable object.
- **Key** *(string)* – [REQUIRED]
- **Metadata** *(dict)* – A map of metadata to store with the
  object in S3.
  - *(string)* –
  - *(string)* –
- **ServerSideEncryption** *(string)* – The Server-side en-
  cryption algorithm used when storing this object in S3
  (e.g., AES256, aws:kms).
- **StorageClass** *(string)* – The type of storage to use for
  the object. Defaults to ‘STANDARD’.
- **WebsiteRedirectLocation** *(string)* – If the bucket is
  configured as a website, redirects requests for this ob-
  ject to another object in the same bucket or to an exter-
  nal URL. Amazon S3 stores the value of this header in
  the object metadata.
- **SSECustomerAlgorithm** *(string)* – Specifies the al-
  gorithm to use to when encrypting the object (e.g.,
  AES256).
- **SSECustomerKey** *(string)* – Specifies the customer-
  provided encryption key for Amazon S3 to use in en-
  crypting data. This value is used to store the object
  and then it is discarded; Amazon does not store the
  encryption key. The key must be appropriate for use
  with the algorithm specified in the x-amz-server-side-
  encryption-customer-algorithm header.
- **SSECustomerKeyMD5** *(string)* – Specifies the 128-
  bit MD5 digest of the encryption key according to RFC
  1321. Amazon S3 uses this header for a message in-
 tegrity check to ensure the encryption key was trans-
  mitted without error. Please note that this parameter is
  automatically populated if it is not provided. Including
  this parameter is not required
• **SSEKMSKeyId (string)** – Specifies the AWS KMS key ID to use for object encryption. All GET and PUT requests for an object protected by AWS KMS will fail if not made via SSL or using SigV4. Documentation on configuring any of the officially supported AWS SDKs and CLI can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/UsingAWSSDK.html#specify-signature-version

• **RequestPayer (string)** – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

**Return type** s3.Object
**Returns** Object resource

**Sub-resources**

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

**Acl()**

Creates a BucketAcl resource:

```python
bucket_acl = bucket.Acl()
```

**Return type** S3.BucketAcl
**Returns** A BucketAcl resource

**Cors()**

Creates a BucketCors resource:

```python
bucketCors = bucket.Cors()
```

**Return type** S3.BucketCors
**Returns** A BucketCors resource

**Lifecycle()**

Creates a BucketLifecycle resource:

```python
bucket_lifecycle = bucket.Lifecycle()
```

**Return type** S3.BucketLifecycle
**Returns** A BucketLifecycle resource

**Logging()**

Creates a BucketLogging resource:

```python
bucket_logging = bucket.Logging()
```

**Return type** S3.BucketLogging
**Returns** A BucketLogging resource

**Notification()**

Creates a BucketNotification resource:
bucket_notification = bucket.Notification()

    Return type S3.BucketNotification
    Returns A BucketNotification resource

Object(key)
Creates a Object resource.:

    object = bucket.Object('key')

    Parameters key (string) – The Object’s key identifier. This must be set.
    Return type S3.Object
    Returns A Object resource

Policy()
Creates a BucketPolicy resource.:

    bucket_policy = bucket.Policy()

    Return type S3.BucketPolicy
    Returns A BucketPolicy resource

RequestPayment()
Creates a BucketRequestPayment resource.:

    bucket_request_payment = bucket.RequestPayment()

    Return type S3.BucketRequestPayment
    Returns A BucketRequestPayment resource

Tagging()
Creates a BucketTagging resource.:

    bucket_tagging = bucket.Tagging()

    Return type S3.BucketTagging
    Returns A BucketTagging resource

Versioning()
Creates a BucketVersioning resource.:

    bucket_versioning = bucket.Versioning()

    Return type S3.BucketVersioning
    Returns A BucketVersioning resource

Website()
Creates a BucketWebsite resource.:

    bucket_website = bucket.Website()

    Return type S3.BucketWebsite
    Returns A BucketWebsite resource

Collections
Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the Resources Introduction Guide.
multipart_uploads

all()
Creates an iterable of all MultipartUpload resources in the collection.

Request Syntax

multipart_upload_iterator = bucket.multipart_uploads.all()

Return type list(s3.MultipartUpload)
Returns A list of MultipartUpload resources

filter(**kwargs)
Creates an iterable of all MultipartUpload resources in the collection filtered by kwargs passed to method.

Request Syntax

multipart_upload_iterator = bucket.multipart_uploads.filter(
    Delimiter='string',
    EncodingType='url',
    KeyMarker='string',
    MaxUploads=123,
    Prefix='string',
    UploadIdMarker='string'
)

Parameters

- **Delimiter (string)** – Character you use to group keys.
- **EncodingType (string)** – Requests Amazon S3 to encode the object keys in the response and specifies the encoding method to use. An object key may contain any Unicode character; however, XML 1.0 parser cannot parse some characters, such as characters with an ASCII value from 0 to 10. For characters that are not supported in XML 1.0, you can add this parameter to request that Amazon S3 encode the keys in the response.
- **KeyMarker (string)** – Together with upload-id-marker, this parameter specifies the multipart upload after which listing should begin.
- **MaxUploads (integer)** – Sets the maximum number of multipart uploads, from 1 to 1,000, to return in the response body. 1,000 is the maximum number of uploads that can be returned in a response.
- **Prefix (string)** – Lists in-progress uploads only for those keys that begin with the specified prefix.
- **UploadIdMarker (string)** – Together with key-marker, specifies the multipart upload after which listing should begin. If key-marker is not specified, the upload-id-marker parameter is ignored.

Return type list(s3.MultipartUpload)
Returns A list of MultipartUpload resources

limit(**kwargs)
Creates an iterable up to a specified amount of MultipartUpload resources in the collection.

Request Syntax

multipart_upload_iterator = bucket.multipart_uploads.limit(
    count=123
)
Parameters count (integer) – The limit to the number of resources in the iterable.
Return type list(s3.MultipartUpload)
Returns A list of MultipartUpload resources

document_size (dict)
Creates an iterable of all MultipartUpload resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

multipart_upload_iterator = bucket.multipart_uploads.page_size(
    count=123
)

Parameters count (integer) – The number of items returned by each service call
Return type list(s3.MultipartUpload)
Returns A list of MultipartUpload resources

object_versions

all()
Creates an iterable of all ObjectVersion resources in the collection.

Request Syntax

object_version_iterator = bucket.object_versions.all()

Return type list(s3.ObjectVersion)
Returns A list of ObjectVersion resources

delete (**kwargs)
This operation enables you to delete multiple objects from a bucket using a single HTTP request. You may specify up to 1000 keys.

Request Syntax

response = bucket.object_versions.delete(
    MFA='string',
    RequestPayer='requester'
)

Parameters

• MFA (string) – The concatenation of the authentication device’s serial number, a space, and the value that is displayed on your authentication device.
• RequestPayer (string) – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

Return type dict
Returns

Response Syntax
filter(**kwargs)

Creates an iterable of all ObjectVersion resources in the collection filtered by kwargs passed to method.

Request Syntax

```
object_version_iterator = bucket.object_versions.filter(
    Delimiter='string',
    EncodingType='url',
    KeyMarker='string',
    MaxKeys=123,
    Prefix='string',
    VersionIdMarker='string'
)
```

Parameters

- **Delimiter (string)** – A delimiter is a character you use to group keys.
- **EncodingType (string)** – Requests Amazon S3 to encode the object keys in the response and specifies the encoding method to use. An object key may contain any Unicode character; however, XML 1.0 parser cannot
parse some characters, such as characters with an ASCII value from 0 to 10. For characters that are not supported in XML 1.0, you can add this parameter to request that Amazon S3 encode the keys in the response.

- **KeyMarker (string)** – Specifies the key to start with when listing objects in a bucket.
- **MaxKeys (integer)** – Sets the maximum number of keys returned in the response. The response might contain fewer keys but will never contain more.
- **Prefix (string)** – Limits the response to keys that begin with the specified prefix.
- **VersionIdMarker (string)** – Specifies the object version you want to start listing from.

**Return type** list(s3.ObjectVersion)

**Returns** A list of ObjectVersion resources

**limit (**kwargs**)

Creates an iterable up to a specified amount of ObjectVersion resources in the collection.

**Request Syntax**

```python
object_version_iterator = bucket.object_versions.limit(
    count=123
)
```

**Parameters**

- **count (integer)** – The limit to the number of resources in the iterable.

**Return type** list(s3.ObjectVersion)

**Returns** A list of ObjectVersion resources

**page_size (**kwargs**)

Creates an iterable of all ObjectVersion resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
object_version_iterator = bucket.object_versions.page_size(
    count=123
)
```

**Parameters**

- **count (integer)** – The number of items returned by each service call

**Return type** list(s3.ObjectVersion)

**Returns** A list of ObjectVersion resources

**objects**

**all ()**

Creates an iterable of all ObjectSummary resources in the collection.

**Request Syntax**

```python
object_summary_iterator = bucket.objects.all()
```

**Return type** list(s3.ObjectSummary)

**Returns** A list of ObjectSummary resources

**delete (**kwargs**)

This operation enables you to delete multiple objects from a bucket using a single HTTP request. You may specify up to 1000 keys.
Request Syntax

```python
response = bucket.objects.delete(
    MFA='string',
    RequestPayer='requester'
)
```

Parameters

- **MFA** *(string)* – The concatenation of the authentication device’s serial number, a space, and the value that is displayed on your authentication device.
- **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Document on downloading objects from requester pays buckets can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html](http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html)

Return type  dict

Returns

Response Syntax

```plaintext
{
    'Deleted': [  
        {
            'Key': 'string',
            'VersionId': 'string',
            'DeleteMarker': True|False,
            'DeleteMarkerVersionId': 'string'
        },
    ],
    'RequestCharged': 'requester',
    'Errors': [  
        {
            'Key': 'string',
            'VersionId': 'string',
            'Code': 'string',
            'Message': 'string'
        },
    ]
}
```

Response Structure

- *(dict)* –
  - **Deleted** *(list)* –
    - *(dict)* –
      - **Key** *(string)* –
      - **VersionId** *(string)* –
      - **DeleteMarker** *(boolean)* –
      - **DeleteMarkerVersionId** *(string)* –
  - **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.
  - **Errors** *(list)* –
    - *(dict)* –
      - **Key** *(string)* –
      - **VersionId** *(string)* –
      - **Code** *(string)* –
· **Message (string)** –

```python
filter(**kwargs)
```

Creates an iterable of all ObjectSummary resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
object_summary_iterator = bucket.objects.filter(
    Delimiter='string',
    EncodingType='url',
    Marker='string',
    MaxKeys=123,
    Prefix='string'
)
```

**Parameters**

- **Delimiter (string)** – A delimiter is a character you use to group keys.
- **EncodingType (string)** – Requests Amazon S3 to encode the object keys in the response and specifies the encoding method to use. An object key may contain any Unicode character; however, XML 1.0 parser cannot parse some characters, such as characters with an ASCII value from 0 to 10. For characters that are not supported in XML 1.0, you can add this parameter to request that Amazon S3 encode the keys in the response.
- **Marker (string)** – Specifies the key to start with when listing objects in a bucket.
- **MaxKeys (integer)** – Sets the maximum number of keys returned in the response. The response might contain fewer keys but will never contain more.
- **Prefix (string)** – Limits the response to keys that begin with the specified prefix.

**Return type** list(s3.ObjectSummary)

**Returns** A list of ObjectSummary resources

```python
limit(**kwargs)
```

Creates an iterable up to a specified amount of ObjectSummary resources in the collection.

**Request Syntax**

```python
object_summary_iterator = bucket.objects.limit(
    count=123
)
```

**Parameters**

- **count (integer)** – The limit to the number of resources in the iterable.

**Return type** list(s3.ObjectSummary)

**Returns** A list of ObjectSummary resources

```python
page_size(**kwargs)
```

Creates an iterable of all ObjectSummary resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
object_summary_iterator = bucket.objects.page_size(
    count=123
)
```

**Parameters**

- **count (integer)** – The number of items returned by each service call
Return type
list(s3.ObjectSummary)

Returns
A list of ObjectSummary resources

Waiters
Waiters provide an interface to wait for a resource to reach a specific state. For more information about waiters refer to the Resources Introduction Guide.

wait_until_exists()
Waits until this Bucket is exists. This method calls S3.Waiter.bucket_exists.wait() which polls. S3.Client.head_bucket() every 5 seconds until a successful state is reached. An error is returned after 20 failed checks.

Request Syntax

bucket.wait_until_exists()

Returns None

wait_until_not_exists()
Waits until this Bucket is not exists. This method calls S3.Waiter.bucket_not_exists.wait() which polls. S3.Client.head_bucket() every 5 seconds until a successful state is reached. An error is returned after 20 failed checks.

Request Syntax

bucket.wait_until_not_exists()

Returns None

BucketAcl

class S3.BucketAcl(bucket_name)
A resource representing an Amazon Simple Storage Service (S3) BucketAcl:

import boto3

s3 = boto3.resource('s3')
bucket_acl = s3.BucketAcl('bucket_name')

Parameters bucket_name (string) – The BucketAcl’s bucket_name identifier. This must be set.

These are the resource’s available identifiers:
• bucket_name

These are the resource’s available attributes:
• grants
• owner

These are the resource’s available actions:
• load()
• put()
• reload()

These are the resource’s available sub-resources:
• Bucket()

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.
**bucket_name**

(string) The BucketAcl’s bucket_name identifier. This **must** be set.

**Attributes**

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the **Resources Introduction Guide**.

**grants**

(list) A list of grants.

**owner**

(dict)

**Actions**

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the **Resources Introduction Guide**.

**load()**

Calls `s3.Client.get_bucket_acl()` to update the attributes of the BucketAcl resource

**Request Syntax**

```python
bucket_acl.load()
```

**Returns** None

**put(**kwargs**)**

Sets the permissions on a bucket using access control lists (ACL).

**Request Syntax**

```python
response = bucket_acl.put(
    ACL='private'|'public-read'|'public-read-write'|'authenticated-read',
    AccessControlPolicy={
        'Grants': [
            {'Grantee': {
                'DisplayName': 'string',
                'EmailAddress': 'string',
                'ID': 'string',
                'Type': 'CanonicalUser'|'AmazonCustomerByEmail'|'Group',
                'URI': 'string'}},
            {'Permission': 'FULL_CONTROL'|'WRITE'|'WRITE_ACP'|'READ'|'READ_ACP'}
        ],
        'Owner': {
            'DisplayName': 'string',
            'ID': 'string'
        }
    },
    GrantFullControl='string',
    GrantRead='string',
    GrantReadACP='string',
    GrantWrite='string',
    GrantWriteACP='string'
)
```

**Parameters**
• ACL (string) – The canned ACL to apply to the bucket.
• AccessControlPolicy (dict) –
  – Grants (list) – A list of grants.
    * (dict) –
      · Grantee (dict) –
        · DisplayName (string) – Screen name of the grantee.
        · EmailAddress (string) – Email address of the grantee.
        · ID (string) – The canonical user ID of the grantee.
        · Type (string) – [REQUIRED] Type of grantee
        · URI (string) – URI of the grantee group.
        · Permission (string) – Specifies the permission given to the
          grantee.
    – Owner (dict) –
      * DisplayName (string) –
      * ID (string) –
• GrantFullControl (string) – Allows grantee the read, write, read ACP, and write
  ACP permissions on the bucket.
• GrantRead (string) – Allows grantee to list the objects in the bucket.
• GrantReadACP (string) – Allows grantee to read the bucket ACL.
• GrantWrite (string) – Allows grantee to create, overwrite, and delete any object
  in the bucket.
• GrantWriteACP (string) – Allows grantee to write the ACL for the applicable
  bucket.

Returns None

reload()
Calls s3.Client.get_bucket_acl() to update the attributes of the BucketAcl resource

Request Syntax

bucket_acl.reload()

Returns None

Sub-resources
Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

Bucket()
Creates a Bucket resource:

    bucket = bucket_acl.Bucket()

    Return type S3.Bucket
    Returns A Bucket resource

BucketCors

class S3.BucketCors (bucket_name)
A resource representing an Amazon Simple Storage Service (S3) BucketCors:

    import boto3
    s3 = boto3.resource('s3')
    bucket_cors = s3.BucketCors('bucket_name')
Parameters `bucket_name` *(string)* – The BucketCors’s `bucket_name` identifier. This **must** be set.

These are the resource’s available identifiers:
• `bucket_name`

These are the resource’s available attributes:
• `cors_rules`

These are the resource’s available actions:
• `delete()`
• `load()`
• `put()`
• `reload()`

These are the resource’s available sub-resources:
• `Bucket()`

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide*.

`bucket_name` *(string)* – The BucketCors’s `bucket_name` identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the *Resources Introduction Guide*.

`cors_rules` *(list)*

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide*.

`delete()`

Deletes the cors configuration information set for the bucket.

Request Syntax

```python
response = bucket_cors.delete()
```

Returns None

`load()`

Calls `s3.Client.get_bucket_cors()` to update the attributes of the BucketCors resource

Request Syntax

```python
bucket_cors.load()
```

Returns None

`put(**kwargs)`

Sets the cors configuration for a bucket.

Request Syntax

```python
response = bucket_cors.put(
    CORSConfiguration={
        'CORSRules': [],
    }
```
Parameters  CORSConfiguration (dict) – [REQUIRED]
  • CORSRules (list) – [REQUIRED]
    – (dict) –
      * AllowedHeaders (list) – Specifies which headers are allowed in a
        pre-flight OPTIONS request.
        · (string) –
      * AllowedMethods (list) – [REQUIRED] Identifies HTTP methods
        that the domain/origin specified in the rule is allowed to execute.
        · (string) –
      * AllowedOrigins (list) – [REQUIRED] One or more origins you
        want customers to be able to access the bucket from.
        · (string) –
      * ExposeHeaders (list) – One or more headers in the response that
        you want customers to be able to access from their applications (for
        example, from a JavaScript XMLHttpRequest object).
        · (string) –
      * MaxAgeSeconds (integer) – The time in seconds that your browser
        is to cache the preflight response for the specified resource.

Returns None

reload()
Calls s3.Client.get_bucket_cors() to update the attributes of the BucketCors resource

Request Syntax

bucket_cors.reload()

Returns None

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed
along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

Bucket ()
Creates a Bucket resource:

bucket = bucket_cors.Bucket()
**BucketLifecycle**

**class S3.BucketLifecycle(bucket_name)**

A resource representing an Amazon Simple Storage Service (S3) BucketLifecycle:

```python
import boto3

s3 = boto3.resource('s3')
bucket_lifecycle = s3.BucketLifecycle('bucket_name')
```

**Parameters bucket_name (string)** – The BucketLifecycle’s bucket_name identifier. This **must** be set.

These are the resource’s available identifiers:

- **bucket_name**

These are the resource’s available attributes:

- **rules**

These are the resource’s available actions:

- **delete()**
- **load()**
- **put()**
- **reload()**

These are the resource’s available sub-resources:

- **Bucket()**

**Identifiers**

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide.*

**bucket_name (string)** The BucketLifecycle’s bucket_name identifier. This **must** be set.

**Attributes**

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the **load()** method. For more information about attributes refer to the *Resources Introduction Guide.*

**rules (list)**

**Actions**

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide.*

**delete()**

Deletes the lifecycle configuration from the bucket.

**Request Syntax**

```python
response = bucket_lifecycle.delete()
```

**Returns** None
load()

Calls s3.Client.get_bucket_lifecycle() to update the attributes of the BucketLifecycle resource

Request Syntax

bucket_lifecycle.load()

Returns None

put(**kwargs)

Deprecated, see the PutBucketLifecycleConfiguration operation.

Request Syntax

response = bucket_lifecycle.put(
    LifecycleConfiguration={
        'Rules': [
            {'Expiration': {
                'Date': datetime(2015, 1, 1),
                'Days': 123
            },
            'ID': 'string',
            'Prefix': 'string',
            'Status': 'Enabled'|'Disabled',
            'Transition': {
                'Date': datetime(2015, 1, 1),
                'Days': 123,
                'StorageClass': 'GLACIER'|'STANDARD_IA'
            },
            'NoncurrentVersionTransition': {
                'NoncurrentDays': 123,
                'StorageClass': 'GLACIER'|'STANDARD_IA'
            },
            'NoncurrentVersionExpiration': {
                'NoncurrentDays': 123
            }
        ]
    }
)

Parameters LifecycleConfiguration (dict) –

• Rules (list) – [REQUIRED]
  – (dict) –
    • Expiration (dict) –
      • Date (datetime) – Indicates at what date the object is to be moved or deleted. Should be in GMT ISO 8601 Format.
      • Days (integer) – Indicates the lifetime, in days, of the objects that are subject to the rule. The value must be a non-zero positive integer.
    • ID (string) – Unique identifier for the rule. The value cannot be longer than 255 characters.
    • Prefix (string) – [REQUIRED] Prefix identifying one or more objects to which the rule applies.
    • Status (string) – [REQUIRED] If ‘Enabled’, the rule is currently being applied. If ‘Disabled’, the rule is not currently being applied.
Transition (dict) –
  · Date (datetime) – Indicates at what date the object is to be moved or deleted. Should be in GMT ISO 8601 Format.
  · Days (integer) – Indicates the lifetime, in days, of the objects that are subject to the rule. The value must be a non-zero positive integer.
  · StorageClass (string) – The class of storage used to store the object.

NoncurrentVersionTransition (dict) – Container for the transition rule that describes when noncurrent objects transition to the STANDARD_IA or GLACIER storage class. If your bucket is versioning-enabled (or versioning is suspended), you can set this action to request that Amazon S3 transition noncurrent object versions to the STANDARD_IA or GLACIER storage class at a specific period in the object’s lifetime.
  · NoncurrentDays (integer) – Specifies the number of days an object is noncurrent before Amazon S3 can perform the associated action. For information about the noncurrent days calculations, see How Amazon S3 Calculates When an Object Became Noncurrent in the Amazon Simple Storage Service Developer Guide.
  · StorageClass (string) – The class of storage used to store the object.

NoncurrentVersionExpiration (dict) – Specifies when noncurrent object versions expire. Upon expiration, Amazon S3 permanently deletes the noncurrent object versions. You set this lifecycle configuration action on a bucket that has versioning enabled (or suspended) to request that Amazon S3 delete noncurrent object versions at a specific period in the object’s lifetime.
  · NoncurrentDays (integer) – Specifies the number of days an object is noncurrent before Amazon S3 can perform the associated action. For information about the noncurrent days calculations, see How Amazon S3 Calculates When an Object Became Noncurrent in the Amazon Simple Storage Service Developer Guide.

Returns None

reload()
Calls s3.Client.get_bucket_lifecycle() to update the attributes of the BucketLifecycle resource

Request Syntax

bucket_lifecycle.reload()

Returns None

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

Bucket()

Creates a Bucket resource:

bucket = bucket_lifecycle.Bucket()
**BucketLogging**

**class** `S3.BucketLogging(bucket_name)`

A resource representing an Amazon Simple Storage Service (S3) BucketLogging:

```python
import boto3

s3 = boto3.resource('s3')
bucket_logging = s3.BucketLogging('bucket_name')
```

**Parameters**

- **bucket_name** *(string)*  
The BucketLogging’s bucket_name identifier. This **must** be set.

**These are the resource’s available identifiers:**

- `bucket_name`

**These are the resource’s available attributes:**

- `logging_enabled`

**These are the resource’s available actions:**

- `load()`
- `put()`
- `reload()`

**These are the resource’s available sub-resources:**

- `Bucket()`

**Identifiers**

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide*.

- **bucket_name** *(string)*  
The BucketLogging’s bucket_name identifier. This **must** be set.

**Attributes**

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the *Resources Introduction Guide*.

- **logging_enabled** *(dict)*  

**Actions**

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide*.

- **load()**  
  Calls `s3.Client.get_bucket_logging()` to update the attributes of the BucketLogging resource

**Request Syntax**

```python
bucket_logging.load()
```

**Returns**  
None

- **put(** **kwargs**)**  
Set the logging parameters for a bucket and to specify permissions for who can view and modify the logging parameters. To set the logging status of a bucket, you must be the bucket owner.
Request Syntax

```python
response = bucket_logging.put(
    BucketLoggingStatus={
        'LoggingEnabled': {
            'TargetBucket': 'string',
            'TargetGrants': [
                {'Grantee': {
                    'DisplayName': 'string',
                    'EmailAddress': 'string',
                    'ID': 'string',
                    'Type': 'CanonicalUser'|'AmazonCustomerByEmail'|'Group',
                    'URI': 'string'
                },
                'Permission': 'FULL_CONTROL'|'READ'|'WRITE'
            ],
            'TargetPrefix': 'string'
        }
    },
)
```

Parameters  

**BucketLoggingStatus (dict)** – [REQUIRED]

- **LoggingEnabled (dict)** –
  - **TargetBucket (string)** – Specifies the bucket where you want Amazon S3 to store server access logs. You can have your logs delivered to any bucket that you own, including the same bucket that is being logged. You can also configure multiple buckets to deliver their logs to the same target bucket. In this case you should choose a different TargetPrefix for each source bucket so that the delivered log files can be distinguished by key.
  - **TargetGrants (list)** –
    * (dict) –
      - **Grantee (dict)** –
        - **DisplayName (string)** – Screen name of the grantee.
        - **EmailAddress (string)** – Email address of the grantee.
        - **ID (string)** – The canonical user ID of the grantee.
        - **Type (string)** – [REQUIRED] Type of grantee
        - **URI (string)** – URI of the grantee group.
        - **Permission (string)** – Logging permissions assigned to the Grantee for the bucket.
  - **TargetPrefix (string)** – This element lets you specify a prefix for the keys that the log files will be stored under.

Returns  

None

`reload()`  
Calls `s3.Client.get_bucket_logging()` to update the attributes of the Bucket Logging resource

Request Syntax

```python
bucket_logging.reload()
```

Returns  

None

Sub-resources

3.1. Services
Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

**Bucket**

Creates a Bucket resource:

```python
bucket = bucket_logging.Bucket()
```

**Return type** `S3.Bucket`

**Returns** A Bucket resource

**BucketNotification**

class `S3.BucketNotification` *(bucket_name)*

A resource representing an Amazon Simple Storage Service (S3) BucketNotification:

```python
import boto3

s3 = boto3.resource('s3')
bucket_notification = s3.BucketNotification('bucket_name')
```

**Parameters** `bucket_name` *(string)*  – The BucketNotification’s bucket_name identifier. This **must** be set.

These are the resource’s available identifiers:

• `bucket_name`

These are the resource’s available attributes:

• `lambda_function_configurations`
• `queue_configurations`
• `topic_configurations`

These are the resource’s available actions:

• `load()`
• `put()`
• `reload()`

These are the resource’s available sub-resources:

• `Bucket()`

**Identifiers**

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

**bucket_name** *(string)*  – The BucketNotification’s bucket_name identifier. This **must** be set.

**Attributes**

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the Resources Introduction Guide.

**lambda_function_configurations** *(list)*

**queue_configurations** *(list)*

**topic_configurations** *(list)*
Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from
identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

load()

Calls s3.Client.get_bucket_notification_configuration() to update the attributes of
the BucketNotification resource

Request Syntax

bucket_notification.load()

Returns None

put(**kwargs)

Enables notifications of specified events for a bucket.

Request Syntax

```python
response = bucket_notification.put(
    NotificationConfiguration={
        'TopicConfigurations': [
            {'Id': 'string',
             'TopicArn': 'string',
             'Events': [
             'Filter': {
                 'Key': {
                     'FilterRules': [
                        {'Name': 'prefix'|'suffix',
                         'Value': 'string'
                     ]
                 }
             }
         },
         'QueueConfigurations': [
             {'Id': 'string',
              'QueueArn': 'string',
              'Events': [
              'Filter': {
                  'Key': {
                      'FilterRules': [
                          {'Name': 'prefix'|'suffix',
                           'Value': 'string'
                      ]
                  }
              }
          }
      ]
  })
```
Parameters NotificationConfiguration (dict) – [REQUIRED] Container for specifying the notification configuration of the bucket. If this element is empty, notifications are turned off on the bucket.

- TopicConfigurations (list) –
  - (dict) – Container for specifying the configuration when you want Amazon S3 to publish events to an Amazon Simple Notification Service (Amazon SNS) topic.
    - Id (string) – Optional unique identifier for configurations in a notification configuration. If you don’t provide one, Amazon S3 will assign an ID.
    - TopicArn (string) – [REQUIRED] Amazon SNS topic ARN to which Amazon S3 will publish a message when it detects events of specified type.
    - Events (list) – [REQUIRED]
      - (string) – Bucket event for which to send notifications.
    - Filter (dict) – Container for object key name filtering rules. For information about key name filtering, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.
      - Key (dict) – Container for object key name prefix and suffix filtering rules.
      - FilterRules (list) – A list of containers for key value pair that defines the criteria for the filter rule.
      - (dict) – Container for key value pair that defines the criteria for the filter rule.
      - Name (string) – Object key name prefix or suffix identifying one or more objects to which the filtering rule applies. Maximum prefix length can be up to 1,024 characters. Overlapping prefixes and suffixes are not supported. For more information, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.
      - Value (string) –

- QueueConfigurations (list) –
– (dict) – Container for specifying an configuration when you want Amazon S3 to publish events to an Amazon Simple Queue Service (Amazon SQS) queue.

* **Id (string)** – Optional unique identifier for configurations in a notification configuration. If you don’t provide one, Amazon S3 will assign an ID.

* **QueueArn (string)** – [REQUIRED] Amazon SQS queue ARN to which Amazon S3 will publish a message when it detects events of specified type.

* **Events (list)** – [REQUIRED]

  · **(string)** – Bucket event for which to send notifications.

* **Filter (dict)** – Container for object key name filtering rules. For information about key name filtering, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.

  · **Key (dict)** – Container for object key name prefix and suffix filtering rules.

  · **FilterRules (list)** – A list of containers for key value pair that defines the criteria for the filter rule.

  · **(dict)** – Container for key value pair that defines the criteria for the filter rule.

  · **Name (string)** – Object key name prefix or suffix identifying one or more objects to which the filtering rule applies. Maximum prefix length can be up to 1,024 characters. Overlapping prefixes and suffixes are not supported. For more information, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.

  · **Value (string)** –

* **LambdaFunctionConfigurations (list)** –

  – (dict) – Container for specifying the AWS Lambda notification configuration.

  · **Id (string)** – Optional unique identifier for configurations in a notification configuration. If you don’t provide one, Amazon S3 will assign an ID.

  · **LambdaFunctionArn (string)** – [REQUIRED] Lambda cloud function ARN that Amazon S3 can invoke when it detects events of the specified type.

  · **Events (list)** – [REQUIRED]

    · **(string)** – Bucket event for which to send notifications.

  · **Filter (dict)** – Container for object key name filtering rules. For information about key name filtering, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.

    · **Key (dict)** – Container for object key name prefix and suffix filtering rules.

    · **FilterRules (list)** – A list of containers for key value pair that defines the criteria for the filter rule.

    · **(dict)** – Container for key value pair that defines the criteria for the filter rule.

    · **Name (string)** – Object key name prefix or suffix identifying one or more objects to which the filtering rule applies. Maximum prefix length can be up to 1,024 characters. Overlapping prefixes and suffixes are not supported. For more information, go to Configuring Event Notifications in the Amazon Simple Storage Service Developer Guide.

    · **Value (string)** –
Returns None

reload()

Calls s3.Client.get_bucket_notification_configuration() to update the attributes of the BucketNotification resource

Request Syntax

bucket_notification.reload()

Returns None

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

Bucket()

Creates a Bucket resource:

```
bucket = bucket_notification.Bucket()
```

Return type S3.Bucket

Returns A Bucket resource

BucketPolicy

class S3.BucketPolicy (bucket_name)

A resource representing an Amazon Simple Storage Service (S3) BucketPolicy:

```
import boto3

s3 = boto3.resource('s3')
bucket_policy = s3.BucketPolicy('bucket_name')
```

Parameters bucket_name (string) – The BucketPolicy’s bucket_name identifier. This must be set.

These are the resource’s available identifiers:

•bucket_name

These are the resource’s available attributes:

•policy

These are the resource’s available actions:

•delete()
•load()
•put()
•reload()

These are the resource’s available sub-resources:

•Bucket()

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

bucket_name

(string) The BucketPolicy’s bucket_name identifier. This must be set.
Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the `Resources Introduction Guide`.

`policy`

*(string)* The bucket policy as a JSON document.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the `Resources Introduction Guide`.

`delete()`

Deletes the policy from the bucket.

**Request Syntax**

```python
response = bucket_policy.delete()
```

**Returns** None

`load()`

Calls `s3.Client.get_bucket_policy()` to update the attributes of the BucketPolicy resource

**Request Syntax**

```python
bucket_policy.load()
```

**Returns** None

`put(**kwargs)`

Replaces a policy on a bucket. If the bucket already has a policy, the one in this request completely replaces it.

**Request Syntax**

```python
response = bucket_policy.put(
    Policy='string'
)
```

**Parameters**

**Returns** None

`reload()`

Calls `s3.Client.get_bucket_policy()` to update the attributes of the BucketPolicy resource

**Request Syntax**

```python
bucket_policy.reload()
```

**Returns** None

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the `Resources Introduction Guide`.

`Bucket()`

Creates a Bucket resource:
bucket = bucket_policy.Bucket()

Return type: S3.Bucket
Returns: A Bucket resource

BucketRequestPayment

class S3.BucketRequestPayment(bucket_name)

A resource representing an Amazon Simple Storage Service (S3) BucketRequestPayment:

```python
import boto3

s3 = boto3.resource('s3')
bucket_request_payment = s3.BucketRequestPayment(bucket_name)
```

Parameters:
- **bucket_name** (string): The BucketRequestPayment’s bucket_name identifier. This must be set.

These are the resource’s available identifiers:
- `bucket_name`

These are the resource’s available attributes:
- `payer`

These are the resource’s available actions:
- `load()`
- `put()`
- `reload()`

These are the resource’s available sub-resources:
- `Bucket()`

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

**bucket_name**

(string) The BucketRequestPayment’s bucket_name identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the Resources Introduction Guide.

**payer**

(string) Specifies who pays for the download and request fees.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

**load()**

Calls `s3.Client.get_bucket_request_payment()` to update the attributes of the BucketRequestPayment resource.

Request Syntax

```
bucket_request_payment.load()
```

Returns: None
**put(****kwargs**)**

Sets the request payment configuration for a bucket. By default, the bucket owner pays for downloads from the bucket. This configuration parameter enables the bucket owner (only) to specify that the person requesting the download will be charged for the download. Documentation on requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/RequesterPaysBuckets.html

**Request Syntax**

```python
response = bucket_request_payment.put(
    RequestPaymentConfiguration={
        'Payer': 'Requester'|'BucketOwner'
    }
)
```

**Parameters RequestPaymentConfiguration (dict) – [REQUIRED]**

- **Payer (string) – [REQUIRED]** Specifies who pays for the download and request fees.

**Returns None**

**reload()**

Calls s3.Client.get_bucket_request_payment() to update the attributes of the BucketRequestPayment resource

**Request Syntax**

```python
bucket_request_payment.reload()
```

**Returns None**

**Sub-resources**

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

**Bucket ()**

Creates a Bucket resource:

```python
bucket = bucket_request_payment.Bucket()
```

**Return type S3.Bucket**

**Returns A Bucket resource**

**BucketTagging**

class S3.BucketTagging(bucket_name)

A resource representing an Amazon Simple Storage Service (S3) BucketTagging:

```python
import boto3

s3 = boto3.resource('s3')
bucket_tagging = s3.BucketTagging('bucket_name')
```

**Parameters bucket_name (string) – The BucketTagging’s bucket_name identifier. This must be set.**

These are the resource’s available identifiers:

- **bucket_name**

These are the resource’s available attributes:

3.1. Services
These are the resource’s available actions:

- `delete()`
- `load()`
- `put()`
- `reload()`

These are the resource’s available sub-resources:

- `Bucket()`

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

**bucket_name**

*(string)* The BucketTagging’s bucket_name identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the Resources Introduction Guide.

**tag_set**

*(list)*

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

**delete()**

Deletes the tags from the bucket.

**Request Syntax**

```python
response = bucket_tagging.delete()
```

**Returns** None

**load()**

Calls `s3.Client.get_bucket_tagging()` to update the attributes of the BucketTagging resource.

**Request Syntax**

```python
bucket_tagging.load()
```

**Returns** None

**put(****kwargs**)**

Sets the tags for a bucket.

**Request Syntax**

```python
response = bucket_tagging.put(
    Tagging={
        'TagSet': [
            {'Key': 'string',
             'Value': 'string'
            },
        ]
    }
)
```
Parameters Tagging (dict) – [REQUIRED]
  • TagSet (list) – [REQUIRED]
    – (dict) –
      • Key (string) – [REQUIRED] Name of the tag.
      • Value (string) – [REQUIRED] Value of the tag.

Returns None

reload()
Calls s3.Client.get_bucket_tagging() to update the attributes of the BucketTagging resource

Request Syntax

bucket_tagging.reload()

Returns None

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

Bucket()

Creates a Bucket resource:

    bucket = bucket_tagging.Bucket()

    Return type S3.Bucket
    Returns A Bucket resource

BucketVersioning

class S3.BucketVersioning (bucket_name)
A resource representing an Amazon Simple Storage Service (S3) BucketVersioning:

    import boto3

    s3 = boto3.resource('s3')
    bucket_versioning = s3.BucketVersioning('bucket_name')

    Parameters bucket_name (string) – The BucketVersioning’s bucket_name identifier. This must be set.

These are the resource’s available identifiers:
  • bucket_name

These are the resource’s available attributes:
  • mfa_delete
  • status

These are the resource’s available actions:
  • enable()
  • load()
  • put()
  • reload()
  • suspend()
These are the resource’s available sub-resources:

- **Bucket()**

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide.*

**bucket_name**

*(string)* The BucketVersioning’s bucket_name identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the **load()** method. For more information about attributes refer to the *Resources Introduction Guide.*

**mfa_delete**

*(string)* Specifies whether MFA delete is enabled in the bucket versioning configuration. This element is only returned if the bucket has been configured with MFA delete. If the bucket has never been so configured, this element is not returned.

**status**

*(string)* The versioning state of the bucket.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide.*

**enable(**kwargs**)

Sets the versioning state of an existing bucket. To set the versioning state, you must be the bucket owner.

**Request Syntax**

```python
response = bucket_versioning.enable(
    MFA='string',
)
```

**Parameters** **MFA** *(string)* – The concatenation of the authentication device’s serial number, a space, and the value that is displayed on your authentication device.

**Returns** None

**load()**

Calls `s3.Client.get_bucket_versioning()` to update the attributes of the BucketVersioning resource

**Request Syntax**

```python
bucket_versioning.load()
```

**Returns** None

**put(**kwargs**)

Sets the versioning state of an existing bucket. To set the versioning state, you must be the bucket owner.

**Request Syntax**

```python
response = bucket_versioning.put(
    MFA='string',
    VersioningConfiguration={
        'MFADelete': 'Enabled'|'Disabled',
        ...,
    })
```
Parameters

- **MFA** *(string)* – The concatenation of the authentication device’s serial number, a space, and the value that is displayed on your authentication device.
- **VersioningConfiguration** *(dict)* – [REQUIRED]
  - **MFADelete** *(string)* – Specifies whether MFA delete is enabled in the bucket versioning configuration. This element is only returned if the bucket has been configured with MFA delete. If the bucket has never been so configured, this element is not returned.
  - **Status** *(string)* – The versioning state of the bucket.

Returns None

**reload()**

Calls `s3.Client.get_bucket_versioning()` to update the attributes of the BucketVersioning resource.

Request Syntax

```python
bucket_versioning.reload()
```

Returns None

**suspend(**kwargs**)**

Sets the versioning state of an existing bucket. To set the versioning state, you must be the bucket owner.

Request Syntax

```python
response = bucket_versioning.suspend(
    MFA='string',
)
```

Parameters

- **MFA** *(string)* – The concatenation of the authentication device’s serial number, a space, and the value that is displayed on your authentication device.

Returns None

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the `Resources Introduction Guide`

**Bucket()**

Creates a Bucket resource:

```python
bucket = bucket_versioning.Bucket()
```

Return type `S3.Bucket`

Returns A Bucket resource

**BucketWebsite**

class `S3.BucketWebsite` *(bucket_name)*

A resource representing an Amazon Simple Storage Service (S3) BucketWebsite:
import boto3

s3 = boto3.resource('s3')
bucket_website = s3.BucketWebsite('bucket_name')

Parameters **bucket_name** *(string)* – The BucketWebsite’s bucket_name identifier. This **must** be set.

These are the resource’s available identifiers:
- **bucket_name**

These are the resource’s available attributes:
- **error_document**
- **index_document**
- **redirect_all_requests_to**
- **routing_rules**

These are the resource’s available actions:
- **delete()**
- **load()**
- **put()**
- **reload()**

These are the resource’s available sub-resources:
- **Bucket()**

Identifiers

Identifiers are properties of a resource that are set upon instantation of the resource. For more information about identifiers refer to the *Resources Introduction Guide*.

**bucket_name** *(string)* The BucketWebsite’s bucket_name identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the **load()** method. For more information about attributes refer to the *Resources Introduction Guide*.

**error_document** *(dict)*

**index_document** *(dict)*

**redirect_all_requests_to** *(dict)*

**routing_rules** *(list)*

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide*.

**delete()**

This operation removes the website configuration from the bucket.

Request Syntax

```python
response = bucket_website.delete()
```

Returns None
load()

Calls s3.Client.get_bucket_website() to update the attributes of the BucketWebsite resource

Request Syntax

bucket_website.load()

Returns None

put(**kwargs)

Set the website configuration for a bucket.

Request Syntax

response = bucket_website.put(
    WebsiteConfiguration={
        'ErrorDocument': {
            'Key': 'string'
        },
        'IndexDocument': {
            'Suffix': 'string'
        },
        'RedirectAllRequestsTo': {
            'HostName': 'string',
            'Protocol': 'http' | 'https'
        },
        'RoutingRules': [
            {
                'Condition': {
                    'HttpErrorCodeReturnedEquals': 'string',
                    'KeyPrefixEquals': 'string'
                },
                'Redirect': {
                    'HostName': 'string',
                    'HttpRedirectCode': 'string',
                    'Protocol': 'http' | 'https',
                    'ReplaceKeyPrefixWith': 'string',
                    'ReplaceKeyWith': 'string'
                }
            }
        ]
    }
)

Parameters WebsiteConfiguration (dict) – [REQUIRED]

- **ErrorDocument (dict)** –
  - **Key (string)** – [REQUIRED] The object key name to use when a 4XX class error occurs.

- **IndexDocument (dict)** –
  - **Suffix (string)** – [REQUIRED] A suffix that is appended to a request that is for a directory on the website endpoint (e.g. if the suffix is index.html and you make a request to samplebucket/images/ the data that is returned will be for the object with the key name images/index.html) The suffix must not be empty and must not include a slash character.

- **RedirectAllRequestsTo (dict)** –
  - **HostName (string)** – [REQUIRED] Name of the host where requests will be redirected.

3.1. Services
– **Protocol** *(string)* – Protocol to use (http, https) when redirecting requests. The default is the protocol that is used in the original request.

• **RoutingRules** *(list)* –
  – *(dict)* –
    – **Condition** *(dict)* – A container for describing a condition that must be met for the specified redirect to apply. For example, 1. If request is for pages in the /docs folder, redirect to the /documents folder. 2. If request results in HTTP error 4xx, redirect request to another host where you might process the error.
      - **HttpErrorCodeReturnedEquals** *(string)* – The HTTP error code when the redirect is applied. In the event of an error, if the error code equals this value, then the specified redirect is applied. Required when parent element Condition is specified and sibling KeyPrefixEquals is not specified. If both are specified, then both must be true for the redirect to be applied.
      - **KeyPrefixEquals** *(string)* – The object key name prefix when the redirect is applied. For example, to redirect requests for ExamplePage.html, the key prefix will be ExamplePage.html. To redirect request for all pages with the prefix docs/, the key prefix will be /docs, which identifies all objects in the docs/ folder. Required when the parent element Condition is specified and sibling HttpErrorCodeReturnedEquals is not specified. If both conditions are specified, both must be true for the redirect to be applied.
    – **Redirect** *(dict)* – [REQUIRED] Container for redirect information. You can redirect requests to another host, to another page, or with another protocol. In the event of an error, you can specify a different error code to return.
      - **HostName** *(string)* – The host name to use in the redirect request.
      - **HttpRedirectCode** *(string)* – The HTTP redirect code to use on the response. Not required if one of the siblings is present.
      - **Protocol** *(string)* – Protocol to use (http, https) when redirecting requests. The default is the protocol that is used in the original request.
      - **ReplaceKeyPrefixWith** *(string)* – The object key prefix to use in the redirect request. For example, to redirect requests for all pages with prefix docs/ (objects in the docs/ folder) to documents/, you can set a condition block with KeyPrefixEquals set to docs/ and in the Redirect set ReplaceKeyPrefixWith to /documents. Not required if one of the siblings is present. Can be present only if ReplaceKeyWith is not provided.
      - **ReplaceKeyWith** *(string)* – The specific object key to use in the redirect request. For example, redirect request to error.html. Not required if one of the sibling is present. Can be present only if ReplaceKeyPrefixWith is not provided.

**Returns** None

**reload()**

Calls `s3.Client.get_bucket_website()` to update the attributes of the BucketWebsite resource

**Request Syntax**
bucket_website.reload()

Returns None

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

Bucket()

Creates a Bucket resource:

bucket = bucket_website.Bucket()

Return type S3.Bucket
Returns A Bucket resource

MultipartUpload

class S3.MultipartUpload(bucket_name, object_key, id)

A resource representing an Amazon Simple Storage Service (S3) MultipartUpload:

import boto3

s3 = boto3.resource('s3')
multipart_upload = s3.MultipartUpload('bucket_name', 'object_key', 'id')

Parameters

• bucket_name (string) – The MultipartUpload’s bucket_name identifier. This must be set.
• object_key (string) – The MultipartUpload’s object_key identifier. This must be set.
• id (string) – The MultipartUpload’s id identifier. This must be set.

These are the resource’s available identifiers:
• bucket_name
• object_key
• id

These are the resource’s available attributes:
• initiated
• initiator
• key
• owner
• storage_class
• upload_id

These are the resource’s available actions:
• abort()
• complete()

These are the resource’s available sub-resources:
• Object()
• Part()

These are the resource’s available collections:
• parts

Identifiers
Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

bucket_name
   (string) The MultipartUpload’s bucket_name identifier. This must be set.

object_key
   (string) The MultipartUpload’s object_key identifier. This must be set.

id
   (string) The MultipartUpload’s id identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

initiated
   (datetime) Date and time at which the multipart upload was initiated.

initiator
   (dict) Identifies who initiated the multipart upload.

key
   (string) Key of the object for which the multipart upload was initiated.

owner
   (dict)

storage_class
   (string) The class of storage used to store the object.

upload_id
   (string) Upload ID that identifies the multipart upload.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

abort(**kwargs)
   Aborts a multipart upload.

   To verify that all parts have been removed, so you don’t get charged for the part storage, you should call the List Parts operation and ensure the parts list is empty.

Request Syntax

response = multipart_upload.abort(
    RequestPayer='requester'
)

Parameters RequestPayer (string) – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

Return type dict

Returns

Response Syntax
Response Structure
• (dict) –
  – RequestCharged (string) – If present, indicates that the requester was successfully charged for the request.

complete(**kwargs)
Completes a multipart upload by assembling previously uploaded parts.

Request Syntax

```python
object = multipart_upload.complete(
    MultipartUpload={
        'Parts': [
            {'ETag': 'string',
             'PartNumber': 123
            }
        ],
    },
    RequestPayer='requester'
)
```

Parameters
• MultipartUpload (dict) –
  – Parts (list) –
    * (dict) –
      · ETag (string) – Entity tag returned when the part was uploaded.
      · PartNumber (integer) – Part number that identifies the part.
        This is a positive integer between 1 and 10,000.
  • RequestPayer (string) – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

Return type  s3.Object
Returns  Object resource

Sub-resources
Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

Object()
Creates a Object resource:

```python
object = multipart_upload.Object()
```

Return type  S3.Object
Returns  A Object resource

Part(part_number)
Creates a MultipartUploadPart resource:
multipart_upload_part = multipart_upload.Part('part_number')

Parameters  part_number (string) – The Part’s part_number identifier. This must be set.
Return type  S3.MultipartUploadPart
Returns  A MultipartUploadPart resource

Collections

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the Resources Introduction Guide.

parts

all()

Creates an iterable of all MultipartUploadPart resources in the collection.

Request Syntax

multiline_upload_part_iter = multipart_upload.parts.all()

Return type  list(s3.MultipartUploadPart)
Returns  A list of MultipartUploadPart resources

filter(**kwargs)

Creates an iterable of all MultipartUploadPart resources in the collection filtered by kwargs passed to method.

Request Syntax

multiline_upload_part_iter = multipart_upload.parts.filter(
    MaxParts=123,
    PartNumberMarker=123,
    RequestPayer='requester'
)

Parameters

• MaxParts (integer) – Sets the maximum number of parts to return.
• PartNumberMarker (integer) – Specifies the part after which listing should begin. Only parts with higher part numbers will be listed.
• RequestPayer (string) – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

Return type  list(s3.MultipartUploadPart)
Returns  A list of MultipartUploadPart resources

limit(**kwargs)

Creates an iterable up to a specified amount of MultipartUploadPart resources in the collection.

Request Syntax

multiline_upload_part_iter = multipart_upload.parts.limit(
    count=123
)

Parameters  count (integer) – The limit to the number of resources in the iterable.
Return type  list(s3.MultipartUploadPart)
Returns A list of MultipartUploadPart resources

```python
page_size(**kwargs)
```

Creates an iterable of all MultipartUploadPart resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

```python
multipart_upload_part_iterator = multipart_upload.parts.page_size(
    count=123
)
```

Parameters

- **count (integer)** – The number of items returned by each service call
- **Return type** list(s3.MultipartUploadPart)
- **Returns** A list of MultipartUploadPart resources

### MultipartUploadPart

```python
class S3.MultipartUploadPart(bucket_name, object_key, multipart_upload_id, part_number)
```

A resource representing an Amazon Simple Storage Service (S3) MultipartUploadPart:

```python
import boto3
s3 = boto3.resource('s3')
multipart_upload_part = s3.MultipartUploadPart('bucket_name', 'object_key', 'multipart_upload_id', 'part_number')
```

Parameters

- **bucket_name (string)** – The MultipartUploadPart’s bucket_name identifier. This **must** be set.
- **object_key (string)** – The MultipartUploadPart’s object_key identifier. This **must** be set.
- **multipart_upload_id (string)** – The MultipartUploadPart’s multipart_upload_id identifier. This **must** be set.
- **part_number (string)** – The MultipartUploadPart’s part_number identifier. This **must** be set.

These are the resource’s available identifiers:

- bucket_name
- object_key
- multipart_upload_id
- part_number

These are the resource’s available attributes:

- etag
- last_modified
- size

These are the resource’s available actions:

- copy_from()
- upload()

These are the resource’s available sub-resources:

- MultipartUpload()

**Identifiers**

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide*. 

3.1. Services
bucket_name
   (string) The MultipartUploadPart's bucket_name identifier. This must be set.

object_key
   (string) The MultipartUploadPart's object_key identifier. This must be set.

multipart_upload_id
   (string) The MultipartUploadPart's multipart_upload_id identifier. This must be set.

part_number
   (string) The MultipartUploadPart's part_number identifier. This must be set.

Attributes
Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

e_tag
   (string) Entity tag returned when the part was uploaded.

last_modified
   (datetime) Date and time at which the part was uploaded.

size
   (integer) Size of the uploaded part data.

Actions
Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

copy_from(**kwargs)
   Uploads a part by copying data from an existing object as data source.

Request Syntax

response = multipart_upload_part.copy_from(
    CopySource='string',
    CopySourceIfMatch='string',
    CopySourceIfModifiedSince=datetime(2015, 1, 1),
    CopySourceIfNoneMatch='string',
    CopySourceIfUnmodifiedSince=datetime(2015, 1, 1),
    CopySourceRange='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    CopySourceSSECustomerAlgorithm='string',
    CopySourceSSECustomerKey='string',
    CopySourceSSECustomerKeyMD5='string',
    RequestPayer='requester'
)

Parameters

- CopySource (string) – [REQUIRED] The name of the source bucket and key name of the source object, separated by a slash (/). Must be URL-encoded.
- CopySourceIfMatch (string) – Copies the object if its entity tag (ETag) matches the specified tag.
- CopySourceIfModifiedSince (datetime) – Copies the object if it has been modified since the specified time.
- CopySourceIfNoneMatch (string) – Copies the object if its entity tag (ETag) is different than the specified ETag.
• **CopySourceIfUnmodifiedSince** *(datetime)* – Copies the object if it hasn’t been modified since the specified time.

• **CopySourceRange** *(string)* – The range of bytes to copy from the source object. The range value must use the form bytes=first-last, where the first and last are the zero-based byte offsets to copy. For example, bytes=0-9 indicates that you want to copy the first ten bytes of the source. You can copy a range only if the source object is greater than 5 GB.

• **SSECustomerAlgorithm** *(string)* – Specifies the algorithm to use to when encrypting the object (e.g., AES256).

• **SSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header. This must be the same encryption key specified in the initiate multipart upload request.

• **SSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required

• **CopySourceSSECustomerAlgorithm** *(string)* – Specifies the algorithm to use when decrypting the source object (e.g., AES256).

• **CopySourceSSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use to decrypt the source object. The encryption key provided in this header must be one that was used when the source object was created.

• **CopySourceSSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error.

• **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html](http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html)

Return type: `dict`

Returns 

**Response Syntax**

```
{
    'CopySourceVersionId': 'string',
    'CopyPartResult': {
        'ETag': 'string',
        'LastModified': datetime(2015, 1, 1),
    },
    'ServerSideEncryption': 'AES256'|'aws:kms',
    'SSECustomerAlgorithm': 'string',
    'SSECustomerKeyMD5': 'string',
    'SSEKMSKeyId': 'string',
    'RequestCharged': 'requester'
}
```

**Response Structure**

- *(dict)* –
- **CopySourceVersionId** (*string*) – The version of the source object that was copied, if you have enabled versioning on the source bucket.

- **CopyPartResult** (*dict*) –
  - **ETag** (*string*) – Entity tag of the object.
  - **LastModified** (*datetime*) – Date and time at which the object was uploaded.

- **ServerSideEncryption** (*string*) – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).

- **SSECustomerAlgorithm** (*string*) – If server-side encryption with a customer-provided encryption key was requested, the response will include this header confirming the encryption algorithm used.

- **SSECustomerKeyMD5** (*string*) – If server-side encryption with a customer-provided encryption key was requested, the response will include this header to provide round trip message integrity verification of the customer-provided encryption key.

- **SSEKMSKeyId** (*string*) – If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.

- **RequestCharged** (*string*) – If present, indicates that the requester was successfully charged for the request.

```python
upload(**kwargs)
```

Uploads a part in a multipart upload.

**Note:** After you initiate multipart upload and upload one or more parts, you must either complete or abort multipart upload in order to stop getting charged for storage of the uploaded parts. Only after you either complete or abort multipart upload, Amazon S3 frees up the parts storage and stops charging you for the parts storage.

**Request Syntax**

```python
response = multipart_upload_part.upload(
    Body=b'bytes',
    ContentLength=123,
    ContentMD5='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    RequestPayer='requester'
)
```

**Parameters**

- **Body** (*bytes*) –
- **ContentLength** (*integer*) – Size of the body in bytes. This parameter is useful when the size of the body cannot be determined automatically.
- **ContentMD5** (*string*) –
- **SSECustomerAlgorithm** (*string*) – Specifies the algorithm to use to when encrypting the object (e.g., AES256).
- **SSECustomerKey** (*string*) – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header. This must be the same encryption key specified in the initiate multipart upload request.
- **SSECustomerKeyMD5** (*string*) – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error.
Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required

- **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

**Return type** `dict`

**Returns**

**Response Syntax**

```
{
    'ServerSideEncryption': 'AES256'|'aws:kms',
    'ETag': 'string',
    'SSECustomerAlgorithm': 'string',
    'SSECustomerKeyMD5': 'string',
    'SSEKMSKeyId': 'string',
    'RequestCharged': 'requester'
}
```

**Response Structure**

- *(dict)*
  - **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
  - **ETag** *(string)* – Entity tag for the uploaded object.
  - **SSECustomerAlgorithm** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header confirming the encryption algorithm used.
  - **SSECustomerKeyMD5** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header to provide round trip message integrity verification of the customer-provided encryption key.
  - **SSEKMSKeyId** *(string)* – If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.
  - **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.

**Sub-resources**

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

**MultipartUpload()**

Creates a MultipartUpload resource:

```
multipart_upload = multipart_upload_part.MultipartUpload()
```

**Return type** `S3.MultipartUpload`

**Returns** A MultipartUpload resource

**Object**

**class** `S3.Object` *(bucket_name, key)*

A resource representing an Amazon Simple Storage Service (S3) Object:
import boto3

s3 = boto3.resource('s3')
object = s3.Object('bucket_name','key')

Parameters
  • bucket_name (string) – The Object’s bucket_name identifier. This must be set.
  • key (string) – The Object’s key identifier. This must be set.

These are the resource’s available identifiers:
  • bucket_name
  • key

These are the resource’s available attributes:
  • accept_ranges
  • cache_control
  • content_disposition
  • content_encoding
  • content_language
  • content_length
  • content_type
  • delete_marker
  • e_tag
  • expiration
  • expires
  • last_modified
  • metadata
  • missing_meta
  • replication_status
  • request_charged
  • restore
  • server_side_encryption
  • sse_customer_algorithm
  • sse_customer_key_md5
  • ssekms_key_id
  • storage_class
  • version_id
  • website_redirect_location

These are the resource’s available actions:
  • copy_from()
  • delete()
  • download_file()
  • get()
  • initiate_multipart_upload()
  • load()
  • put()
  • reload()
  • upload_file()

These are the resource’s available sub-resources:
  • Acl()
  • Bucket()
  • MultipartUpload()
  • Version()

These are the resource’s available waiters:
  • wait_until_exists()
Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

**bucket_name**
(string) The Object’s bucket_name identifier. This **must** be set.

**key**
(string) The Object’s key identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

**accept_ranges**
(string)

**cache_control**
(string) Specifies caching behavior along the request/reply chain.

**content_disposition**
(string) Specifies presentational information for the object.

**content_encoding**
(string) Specifies what content encodings have been applied to the object and thus what decoding mechanisms must be applied to obtain the media-type referenced by the Content-Type header field.

**content_language**
(string) The language the content is in.

**content_length**
(integer) Size of the body in bytes.

**content_type**
(string) A standard MIME type describing the format of the object data.

**delete_marker**
(boolean) Specifies whether the object retrieved was (true) or was not (false) a Delete Marker. If false, this response header does not appear in the response.

**e_tag**
(string) An ETag is an opaque identifier assigned by a web server to a specific version of a resource found at a URL.

**expiration**
(string) If the object expiration is configured (see PUT Bucket lifecycle), the response includes this header. It includes the expiry-date and rule-id key value pairs providing object expiration information. The value of the rule-id is URL encoded.

**expires**
(datetime) The date and time at which the object is no longer cacheable.

**last_modified**
(datetime) Last modified date of the object

**metadata**
(dict) A map of metadata to store with the object in S3.

**missing_meta**
(integer) This is set to the number of metadata entries not returned in x-amz-meta headers. This can
happen if you create metadata using an API like SOAP that supports more flexible metadata than the REST API. For example, using SOAP, you can create metadata whose values are not legal HTTP headers.

replication_status
(string)

request_charged
(string) If present, indicates that the requester was successfully charged for the request.

restore
(string) Provides information about object restoration operation and expiration time of the restored object copy.

server_side_encryption
(string) The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).

sse_customer_algorithm
(string) If server-side encryption with a customer-provided encryption key was requested, the response will include this header confirming the encryption algorithm used.

sse_customer_key_md5
(string) If server-side encryption with a customer-provided encryption key was requested, the response will include this header to provide round trip message integrity verification of the customer-provided encryption key.

ssekms_key_id
(string) If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.

storage_class
(string)

version_id
(string) Version of the object.

website_redirect_location
(string) If the bucket is configured as a website, redirects requests for this object to another object in the same bucket or to an external URL. Amazon S3 stores the value of this header in the object metadata.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

download_file (Filename, ExtraArgs=None, Callback=None, Config=None)

upload_file (Filename, ExtraArgs=None, Callback=None, Config=None)

copy_from (**kwargs)

Creates a copy of an object that is already stored in Amazon S3.

Request Syntax

response = object.copy_from(
    ACL='private'|'public-read'|'public-read-write'|'authenticated-read'|'bucket-owner-read'|'bucket-owner-full-control',
    CacheControl='string',
    ContentDisposition='string',
    ContentEncoding='string',
    ContentLanguage='string',
    ContentType='string',
)
copy_source='string',
copy_source_if_match='string',
copy_source_if_modified_since=datetime(2015, 1, 1),
copy_source_if_none_match='string',
copy_source_if_unmodified_since=datetime(2015, 1, 1),
expires=datetime(2015, 1, 1),
grant_full_control='string',
grant_read='string',
grant_read_acp='string',
grant_write_acp='string',
metadata={
    'string': 'string'
},
metadata_directive='COPY'|'REPLACE',
server_side_encryption='AES256'|'aws:kms',
storage_class='STANDARD'|'REDUCED_REDUNDANCY'|'STANDARD_IA',
website_redirect_location='string',
sse_customer_algorithm='string',
sse_customer_key='string',
sse_kms_key_id='string',
copy_source_sse_customer_algorithm='string',
copy_source_sse_customer_key='string',
copy_source_sse_customer_key_md5='string',
request_payer='requester'
}

Parameters

- **ACL (string)** – The canned ACL to apply to the object.
- **CacheControl (string)** – Specifies caching behavior along the request/reply chain.
- **ContentDisposition (string)** – Specifies presentational information for the object.
- **ContentEncoding (string)** – Specifies what content encodings have been applied to the object and thus what decoding mechanisms must be applied to obtain the media-type referenced by the Content-Type header field.
- **ContentLanguage (string)** – The language the content is in.
- **ContentType (string)** – A standard MIME type describing the format of the object data.
- **CopySource (string)** – [REQUIRED] The name of the source bucket and key name of the source object, separated by a slash (/). Must be URL-encoded.
- **CopySourceIfMatch (string)** – Copies the object if its entity tag (ETag) matches the specified tag.
- **CopySourceIfModifiedSince (datetime)** – Copies the object if it has been modified since the specified time.
- **CopySourceIfNoneMatch (string)** – Copies the object if its entity tag (ETag) is different than the specified ETag.
- **CopySourceIfUnmodifiedSince (datetime)** – Copies the object if it hasn’t been modified since the specified time.
- **Expires (datetime)** – The date and time at which the object is no longer cacheable.
- **GrantFullControl (string)** – Gives the grantee READ, READ_ACP, and WRITE_ACP permissions on the object.
- **GrantRead (string)** – Allows grantee to read the object data and its metadata.
- **GrantReadACP (string)** – Allows grantee to read the object ACL.
- **GrantWriteACP (string)** – Allows grantee to write the ACL for the applicable object.
• **Metadata** *(dict)* – A map of metadata to store with the object in S3.
  – *(string)* –
  * *(string)* –

• **MetadataDirective** *(string)* – Specifies whether the metadata is copied from the source object or replaced with metadata provided in the request.

• **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).

• **StorageClass** *(string)* – The type of storage to use for the object. Defaults to ‘STANDARD’.

• **WebsiteRedirectLocation** *(string)* – If the bucket is configured as a website, redirects requests for this object to another object in the same bucket or to an external URL. Amazon S3 stores the value of this header in the object metadata.

• **SSECustomerAlgorithm** *(string)* – Specifies the algorithm to use to when encrypting the object (e.g., AES256).

• **SSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.

• **SSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.

• **SEKMSKeyId** *(string)* – Specifies the AWS KMS key ID to use for object encryption. All GET and PUT requests for an object protected by AWS KMS will fail if not made via SSL or using SigV4. Documentation on configuring any of the officially supported AWS SDKs and CLI can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/UsingAWSSDK.html#specify-signature-version

• **CopySourceSSECustomerAlgorithm** *(string)* – Specifies the algorithm to use when decrypting the source object (e.g., AES256).

• **CopySourceSSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use to decrypt the source object. The encryption key provided in this header must be one that was used when the source object was created.

• **CopySourceSSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error.

• **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
'CopyObjectResult': {
  'ETag': 'string',
  'LastModified': datetime(2015, 1, 1)
}
```
Response Structure

- CopyObjectResult (dict) –
  - ETag (string) –
  - LastModified (datetime) –
  - Expiration (string) – If the object expiration is configured, the response includes this header.
  - CopySourceVersionId (string) –
  - ServerSideEncryption (string) – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
  - SSECustomerAlgorithm (string) – If server-side encryption with a customer-provided encryption key was requested, the response will include this header confirming the encryption algorithm used.
  - SSECustomerKeyMD5 (string) – If server-side encryption with a customer-provided encryption key was requested, the response will include this header to provide round trip message integrity verification of the customer-provided encryption key.
  - SSEKMSKeyId (string) – If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.
  - RequestCharged (string) – If present, indicates that the requester was successfully charged for the request.

**delete(****kwargs**)

Removes the null version (if there is one) of an object and inserts a delete marker, which becomes the latest version of the object. If there isn’t a null version, Amazon S3 does not remove any objects.

**Request Syntax**

```python
response = object.delete(
    MFA='string',
    VersionId='string',
    RequestPayer='requester'
)
```

**Parameters**

- **MFA (string)** – The concatenation of the authentication device’s serial number, a space, and the value that is displayed on your authentication device.
- **VersionId (string)** – VersionId used to reference a specific version of the object.
- **RequestPayer (string)** – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html](http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html)

**Return type** dict

**Returns**
Response Syntax

```
{
    'DeleteMarker': True|False,
    'VersionId': 'string',
    'RequestCharged': 'requester'
}
```

Response Structure

- (dict) –
  - **DeleteMarker** *(boolean)* – Specifies whether the versioned object that was permanently deleted was (true) or was not (false) a delete marker.
  - **VersionId** *(string)* – Returns the version ID of the delete marker created as a result of the DELETE operation.
  - **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.

Upload a file to an S3 object.

Usage:

```python
import boto3
s3 = boto3.resource('s3')
s3.Object('mybucket', 'hello.txt').upload_file('/tmp/hello.txt')
```

Similar behavior as S3Transfer’s upload_file() method, except that parameters are capitalized. Detailed examples can be found at [S3Transfer’s Usage](#).

### get (**kwargs)**

Retrieves objects from Amazon S3.

**Request Syntax**

```
response = object.get(
    IfMatch='string',
    IfModifiedSince=datetime(2015, 1, 1),
    IfNoneMatch='string',
    IfUnmodifiedSince=datetime(2015, 1, 1),
    Range='string',
    ResponseCacheControl='string',
    ResponseContentDisposition='string',
    ResponseContentEncoding='string',
    ResponseContentLanguage='string',
    ResponseContentType='string',
    ResponseExpires=datetime(2015, 1, 1),
    VersionId='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    RequestPayer='requester'
)
```

**Parameters**

- **IfMatch** *(string)* – Return the object only if its entity tag (ETag) is the same as the one specified, otherwise return a 412 (precondition failed).
- **IfModifiedSince** *(datetime)* – Return the object only if it has been modified since the specified time, otherwise return a 304 (not modified).
- **IfNoneMatch** *(string)* – Return the object only if its entity tag (ETag) is different from the one specified, otherwise return a 304 (not modified).
• **IfUnmodifiedSince (datetime)** – Return the object only if it has not been modified since the specified time, otherwise return a 412 (precondition failed).

• **Range (string)** – Downloads the specified range bytes of an object. For more information about the HTTP Range header, go to http://www.w3.org/Protocols/rfc2616/rfc2616-sec14.html#sec14.35.

• **ResponseCacheControl (string)** – Sets the Cache-Control header of the response.

• **ResponseContentDisposition (string)** – Sets the Content-Disposition header of the response.

• **ResponseContentEncoding (string)** – Sets the Content-Encoding header of the response.

• **ResponseContentLanguage (string)** – Sets the Content-Language header of the response.

• **ResponseContentType (string)** – Sets the Content-Type header of the response.

• **ResponseExpires (datetime)** – Sets the Expires header of the response.

• **VersionId (string)** – VersionId used to reference a specific version of the object.

• **SSECClientAlgorithm (string)** – Specifies the algorithm to use to when encrypting the object (e.g., AES256).

• **SSECClientKey (string)** – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-client-algorithm header.

• **SSECClientKeyMD5 (string)** – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.

• **RequestPayer (string)** – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsInRequesterPaysBuckets.html

Return type  dict

Returns

**Response Syntax**

```python
{
    'Body': b'bytes',
    'DeleteMarker': True|False,
    'AcceptRanges': 'string',
    'Expiration': 'string',
    'LastModified': datetime(2015, 1, 1),
    'ContentLength': 123,
    'ETag': 'string',
    'MissingMeta': 123,
    'VersionId': 'string',
    'CacheControl': 'string',
    'ContentDisposition': 'string',
    'ContentEncoding': 'string',
}```
'ContentLanguage': 'string',
'ContentRange': 'string',
'ContentType': 'string',
'Expires': datetime(2015, 1, 1),
'WebsiteRedirectLocation': 'string',
'ServerSideEncryption': 'AES256'|'aws:kms',
'Metadata': {
    'string': 'string'
},
'SSECustomerAlgorithm': 'string',
'SSECustomerKeyMD5': 'string',
'SSEKMSKeyId': 'string',
'StorageClass': 'STANDARD'|'REDUCED_REDUNDANCY'|'STANDARD_IA',
'RequestCharged': 'requester',
'ReplicationStatus': 'COMPLETE'|'PENDING'|'FAILED'|'REPLICA'

Response Structure

• (dict) –
  • **Body** *(bytes)* – Object data.
  • **DeleteMarker** *(boolean)* – Specifies whether the object retrieved was (true) or was not (false) a Delete Marker. If false, this response header does not appear in the response.
  • **AcceptRanges** *(string)*
  • **Expiration** *(string)* – If the object expiration is configured (see PUT Bucket lifecycle), the response includes this header. It includes the expiry-date and rule-id key value pairs providing object expiration information. The value of the rule-id is URL encoded.
  • **Restore** *(string)* – Provides information about object restoration operation and expiration time of the restored object copy.
  • **LastModified** *(datetime)* – Last modified date of the object
  • **ContentLength** *(integer)* – Size of the body in bytes.
  • **ETag** *(string)* – An ETag is an opaque identifier assigned by a web server to a specific version of a resource found at a URL.
  • **MissingMeta** *(integer)* – This is set to the number of metadata entries not returned in x-amz-meta headers. This can happen if you create metadata using an API like SOAP that supports more flexible metadata than the REST API. For example, using SOAP, you can create metadata whose values are not legal HTTP headers.
  • **VersionId** *(string)* – Version of the object.
  • **CacheControl** *(string)* – Specifies caching behavior along the request/reply chain.
  • **ContentDisposition** *(string)* – Specifies presentational information for the object.
  • **ContentEncoding** *(string)* – Specifies what content encodings have been applied to the object and thus what decoding mechanisms must be applied to obtain the media-type referenced by the Content-Type header field.
  • **ContentLanguage** *(string)* – The language the content is in.
  • **ContentRange** *(string)* – The portion of the object returned in the response.
  • **ContentType** *(string)* – A standard MIME type describing the format of the object data.
  • **Expires** *(datetime)* – The date and time at which the object is no longer cacheable.
- **WebsiteRedirectLocation** *(string)* – If the bucket is configured as a website, redirects requests for this object to another object in the same bucket or to an external URL. Amazon S3 stores the value of this header in the object metadata.

- **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).

- **Metadata** *(dict)* – A map of metadata to store with the object in S3.

  * *(string)*

  - *(string)*

- **SSECustomerAlgorithm** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header confirming the encryption algorithm used.

- **SSECustomerKeyMD5** *(string)* – If server-side encryption with a customer-provided encryption key was requested, the response will include this header to provide round trip message integrity verification of the customer-provided encryption key.

- **SSEKMSKeyId** *(string)* – If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.

- **StorageClass** *(string)*

- **RequestCharged** *(string)* – If present, indicates that the requester was successfully charged for the request.

- **ReplicationStatus** *(string)*

### `initiate_multipart_upload(**kwargs)`

Initiates a multipart upload and returns an upload ID.

**Note:** After you initiate multipart upload and upload one or more parts, you must either complete or abort multipart upload in order to stop getting charged for storage of the uploaded parts. Only after you either complete or abort multipart upload, Amazon S3 frees up the parts storage and stops charging you for the parts storage.

**Request Syntax**

```python
multipart_upload = object.initiate_multipart_upload(
    ACL='private'|'public-read'|'public-read-write'|'authenticated-read'|'bucket-owner-read'|'bucket-owner-full-control',
    CacheControl='string',
    ContentDisposition='string',
    ContentEncoding='string',
    ContentLanguage='string',
    ContentType='string',
    Expires=datetime(2015, 1, 1),
    GrantFullControl='string',
    GrantRead='string',
    GrantReadACP='string',
    GrantWriteACP='string',
    Metadata={
        'string': 'string'
    },
    ServerSideEncryption='AES256'|'aws:kms',
    StorageClass='STANDARD'|'REDUCED_REDUNDANCY'|'STANDARD_IA',
    WebsiteRedirectLocation='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    SSEKMSKeyId='string',
    RequestPayer='requester'
)
```
Parameters

- **ACL** *(string)* – The canned ACL to apply to the object.
- **CacheControl** *(string)* – Specifies caching behavior along the request/reply chain.
- **ContentDisposition** *(string)* – Specifies presentational information for the object.
- **ContentEncoding** *(string)* – Specifies what content encodings have been applied to the object and thus what decoding mechanisms must be applied to obtain the media-type referenced by the Content-Type header field.
- **ContentLanguage** *(string)* – The language the content is in.
- **ContentType** *(string)* – A standard MIME type describing the format of the object data.
- **Expires** *(datetime)* – The date and time at which the object is no longer cacheable.
- **GrantFullControl** *(string)* – Gives the grantee READ, READ_ACP, and WRITE_ACP permissions on the object.
- **GrantRead** *(string)* – Allows grantee to read the object data and its metadata.
- **GrantReadACP** *(string)* – Allows grantee to read the object ACL.
- **GrantWriteACP** *(string)* – Allows grantee to write the ACL for the applicable object.
- **Metadata** *(dict)* – A map of metadata to store with the object in S3.
  - *(string)*
  - *(string)*
  - **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
  - **StorageClass** *(string)* – The type of storage to use for the object. Defaults to ‘STANDARD’.
  - **WebsiteRedirectLocation** *(string)* – If the bucket is configured as a website, redirects requests for this object to another object in the same bucket or to an external URL. Amazon S3 stores the value of this header in the object metadata.
  - **SSECustomerAlgorithm** *(string)* – Specifies the algorithm to use to when encrypting the object (e.g., AES256).
  - **SSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.
  - **SSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required
  - **SSEKMSKeyId** *(string)* – Specifies the AWS KMS key ID to use for object encryption. All GET and PUT requests for an object protected by AWS KMS will fail if not made via SSL or using SigV4. Documentation on configuring any of the officially supported AWS SDKs and CLI can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/UsingAWSSDK.html#specify-signature-version](http://docs.aws.amazon.com/AmazonS3/latest/dev/UsingAWSSDK.html#specify-signature-version)
  - **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on
downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

Return type s3.MultipartUpload
Returns MultipartUpload resource

load()
Calls s3.Client.head_object() to update the attributes of the Object resource

Request Syntax

object.load()

Returns None

put (**kwargs)
Adds an object to a bucket.

Request Syntax

response = object.put(
    ACL='private'|'public-read'|'public-read-write'|'authenticated-read'|'bucket-owner-read'|'bucket-owner-full-control',
    Body=b'bytes',
    CacheControl='string',

    },
    ServerSideEncryption='AES256'|'aws:kms',
    StorageClass='STANDARD'|'REDUCED_REDUNDANCY'|'STANDARD_IA',
    WebsiteRedirectLocation='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    SSEKMSKeyId='string',
    RequestPayer='requester'
)

Parameters

- **ACL (string)** – The canned ACL to apply to the object.
- **Body (bytes)** – Object data.
- **CacheControl (string)** – Specifies caching behavior along the request/reply chain.
- **ContentDisposition (string)** – Specifies presentational information for the object.
- **ContentEncoding (string)** – Specifies what content encodings have been applied to the object and thus what decoding mechanisms must be applied to obtain the media-type referenced by the Content-Type header field.
- **ContentLanguage (string)** – The language the content is in.
• **ContentLength** *(integer)* – Size of the body in bytes. This parameter is useful when the size of the body cannot be determined automatically.

• **ContentMD5** *(string)* –

• **ContentType** *(string)* – A standard MIME type describing the format of the object data.

• **Expires** *(datetime)* – The date and time at which the object is no longer cacheable.

• **GrantFullControl** *(string)* – Gives the grantee READ, READ_ACP, and WRITE_ACP permissions on the object.

• **GrantRead** *(string)* – Allows grantee to read the object data and its metadata.

• **GrantReadACP** *(string)* – Allows grantee to read the object ACL.

• **GrantWriteACP** *(string)* – Allows grantee to write the ACL for the applicable object.

• **Metadata** *(dict)* – A map of metadata to store with the object in S3.
  – *(string)* –
  * *(string)* –

• **ServerSideEncryption** *(string)* – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).

• **StorageClass** *(string)* – The type of storage to use for the object. Defaults to ‘STANDARD’.

• **WebsiteRedirectLocation** *(string)* – If the bucket is configured as a website, redirects requests for this object to another object in the same bucket or to an external URL. Amazon S3 stores the value of this header in the object metadata.

• **SSECustomerAlgorithm** *(string)* – Specifies the algorithm to use to when encrypting the object (e.g., AES256).

• **SSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.

• **SSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.

• **SSEKMSKeyId** *(string)* – Specifies the AWS KMS key ID to use for object encryption. All GET and PUT requests for an object protected by AWS KMS will fail if not made via SSL or using SigV4. Documentation on configuring any of the officially supported AWS SDKs and CLI can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/UsingAWSSDK.html#specify-signature-version

• **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html

**Return type**  dict  
**Returns**

**Response Syntax**
{  
'Expiration': 'string',  
'ETag': 'string',  
'ServerSideEncryption': 'AES256'|'aws:kms',  
'VersionId': 'string',  
'SSECustomerAlgorithm': 'string',  
'SSECustomerKeyMD5': 'string',  
'SSEKMSKeyId': 'string',  
'RequestCharged': 'requester'  
}

Response Structure
• (dict) –
  - **Expiration (string)** – If the object expiration is configured, this will contain the expiration date (expiry-date) and rule ID (rule-id). The value of rule-id is URL encoded.
  - **ETag (string)** – Entity tag for the uploaded object.
  - **ServerSideEncryption (string)** – The Server-side encryption algorithm used when storing this object in S3 (e.g., AES256, aws:kms).
  - **VersionId (string)** – Version of the object.
  - **SSECustomerAlgorithm (string)** – If server-side encryption with a customer-provided encryption key was requested, the response will include this header confirming the encryption algorithm used.
  - **SSECustomerKeyMD5 (string)** – If server-side encryption with a customer-provided encryption key was requested, the response will include this header to provide round trip message integrity verification of the customer-provided encryption key.
  - **SSEKMSKeyId (string)** – If present, specifies the ID of the AWS Key Management Service (KMS) master encryption key that was used for the object.
  - **RequestCharged (string)** – If present, indicates that the requester was successfully charged for the request.

**reload()**

Calls `s3.Client.head_object()` to update the attributes of the Object resource.

Request Syntax

```python
object.reload()
```

**Returns** None

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

**Acl()**

Creates a ObjectAcl resource:

```python
object_acl = object.Acl()
```

**Return type** S3.ObjectAcl

**Returns** A ObjectAcl resource

**Bucket()**

Creates a Bucket resource:
bucket = object.Bucket()

    Return type  S3.Bucket
    Returns   A Bucket resource

MultipartUpload (id)
    Creates a MultipartUpload resource:

    multipart_upload = object.MultipartUpload('id')

        Parameters  id (string) – The MultipartUpload’s id identifier. This **must** be set.
        Return type  S3.MultipartUpload
        Returns   A MultipartUpload resource

Version (id)
    Creates a ObjectVersion resource:

    object_version = object.Version('id')

        Parameters  id (string) – The Version’s id identifier. This **must** be set.
        Return type  S3.ObjectVersion
        Returns   A ObjectVersion resource

Waiters

Waiters provide an interface to wait for a resource to reach a specific state. For more information about waiters refer to the *Resources Introduction Guide*.

wait_until_exists (**kwargs)
    Waits until this Object is exists. This method calls S3.Waiter.object_exists.wait() which polls. S3.Client.head_object() every 5 seconds until a successful state is reached. An error is returned after 20 failed checks.

Request Syntax

object.wait_until_exists(
    IfMatch='string',
    IfModifiedSince=datetime(2015, 1, 1),
    IfNoneMatch='string',
    IfUnmodifiedSince=datetime(2015, 1, 1),
    Range='string',
    VersionId='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    RequestPayer='requester'
)

Parameters

- **IfMatch (string)** – Return the object only if its entity tag (ETag) is the same as the one specified, otherwise return a 412 (precondition failed).
- **IfModifiedSince (datetime)** – Return the object only if it has been modified since the specified time, otherwise return a 304 (not modified).
- **IfNoneMatch (string)** – Return the object only if its entity tag (ETag) is different from the one specified, otherwise return a 304 (not modified).
- **IfUnmodifiedSince (datetime)** – Return the object only if it has not been modified since the specified time, otherwise return a 412 (precondition failed).
- **VersionId** *(string)* – VersionId used to reference a specific version of the object.
- **SSECustomerAlgorithm** *(string)* – Specifies the algorithm to use to when encrypting the object (e.g., AES256).
- **SSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.
- **SSECustomerKeyMD5** *(string)* – Specifies the 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3 uses this header for a message integrity check to ensure the encryption key was transmitted without error. Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.
- **RequestPayer** *(string)* – Confirms that the requester knows that she or he will be charged for the request. Bucket owners need not specify this parameter in their requests. Documentation on downloading objects from requester pays buckets can be found at [http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html](http://docs.aws.amazon.com/AmazonS3/latest/dev/ObjectsinRequesterPaysBuckets.html).

**Returns** None

**wait_until_not_exists**(**kwargs**)

Waits until this Object is not exists. This method calls `S3.Waiter.object_not_exists.wait()` which polls. `S3.Client.head_object()` every 5 seconds until a successful state is reached. An error is returned after 20 failed checks.

**Request Syntax**

```python
object.wait_until_not_exists(
    IfMatch='string',
    IfModifiedSince=datetime(2015, 1, 1),
    IfNoneMatch='string',
    IfUnmodifiedSince=datetime(2015, 1, 1),
    Range='string',
    VersionId='string',
    SSECustomerAlgorithm='string',
    SSECustomerKey='string',
    RequestPayer='requester'
)
```

**Parameters**

- **IfMatch** *(string)* – Return the object only if its entity tag (ETag) is the same as the one specified, otherwise return a 412 (precondition failed).
- **IfModifiedSince** *(datetime)* – Return the object only if it has been modified since the specified time, otherwise return a 304 (not modified).
- **IfNoneMatch** *(string)* – Return the object only if its entity tag (ETag) is different from the one specified, otherwise return a 304 (not modified).
- **IfUnmodifiedSince** *(datetime)* – Return the object only if it has not been modified since the specified time, otherwise return a 412 (precondition failed).
- **VersionId** *(string)* – VersionId used to reference a specific version of the object.
• **SSECustomerAlgorithm** *(string)* – Specifies the algorithm to use to when encrypting the object (e.g., AES256).

• **SSECustomerKey** *(string)* – Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon does not store the encryption key. The key must be appropriate for use with the algorithm specified in the x-amz-server-side-encryption-customer-algorithm header.
