Boto is the Amazon Web Services (AWS) SDK for Python, which allows Python developers to write software that makes use of Amazon services like S3 and EC2. Boto provides an easy to use, object-oriented API as well as low-level direct service access.
1.1 Quickstart

Getting started with Boto 3 is easy, but requires a few steps.

1.1.1 Installation

Install the latest Boto 3 release via pip:

```bash
pip install boto3
```

You may also install a specific version:

```bash
pip install boto3==1.0.0
```

**Note:** The latest development version can always be found on GitHub.

1.1.2 Configuration

Before you can begin using Boto 3, you should set up authentication credentials. Credentials for your AWS account can be found in the IAM Console. You can create or use an existing user. Go to manage access keys and generate a new set of keys.

If you have the AWS CLI installed, then you can use it to configure your credentials file:

```bash
aws configure
```

Alternatively, you can create the credential file yourself. By default, its location is at `~/.aws/credentials`:

```ini
[default]
aws_access_key_id = YOUR_ACCESS_KEY
aws_secret_access_key = YOUR_SECRET_KEY
```

You may also want to set a default region. This can be done in the configuration file. By default, its location is at `~/.aws/config`:

```ini
[default]
region=us-east-1
```
Alternatively, you can pass a region_name when creating clients and resources. This sets up credentials for the default profile as well as a default region to use when creating connections. See Configuration for in-depth configuration sources and options.

### 1.1.3 Using Boto 3

To use Boto 3, you must first import it and tell it what service you are going to use:

```python
import boto3

# Let's use Amazon S3
s3 = boto3.resource('s3')
```

Now that you have an s3 resource, you can make requests and process responses from the service. The following uses the buckets collection to print out all bucket names:

```python
# Print out bucket names
for bucket in s3.buckets.all():
    print(bucket.name)
```

It's also easy to upload and download binary data. For example, the following uploads a new file to S3. It assumes that the bucket my-bucket already exists:

```python
# Upload a new file
data = open('test.jpg', 'rb')
s3.Bucket('my-bucket').put_object(Key='test.jpg', Body=data)
```

Resources and Collections will be covered in more detail in the following sections, so don't worry if you do not completely understand the examples.

### 1.2 A Sample Tutorial

This tutorial will show you how to use Boto3 with an AWS service. In this sample tutorial, you will learn how to use Boto3 with Amazon Simple Queue Service (SQS)

#### 1.2.1 SQS

SQS allows you to queue and then process messages. This tutorial covers how to create a new queue, get and use an existing queue, push new messages onto the queue, and process messages from the queue by using Resources and Collections.

#### 1.2.2 Creating a Queue

Queues are created with a name. You may also optionally set queue attributes, such as the number of seconds to wait before an item may be processed. The examples below will use the queue name test. Before creating a queue, you must first get the SQS service resource:

```python
# Get the service resource
sqs = boto3.resource('sqs')

# Create the queue. This returns an SQS.Queue instance
queue = sqs.create_queue(QueueName='test', Attributes={'DelaySeconds': '5'})
```
# You can now access identifiers and attributes
print(queue.url)
print(queue.attributes.get('DelaySeconds'))

Reference: SQS.ServiceResource.create_queue()

Warning: The code above may throw an exception if you already have a queue named test.

## 1.2.3 Using an Existing Queue

It is possible to look up a queue by its name. If the queue does not exist, then an exception will be thrown:

```python
# Get the service resource
sqs = boto3.resource('sqs')

# Get the queue. This returns an SQS.Queue instance
queue = sqs.get_queue_by_name(QueueName='test')

# You can now access identifiers and attributes
print(queue.url)
print(queue.attributes.get('DelaySeconds'))
```

It is also possible to list all of your existing queues:

```python
# Print out each queue name, which is part of its ARN
for queue in sqs.queues.all():
    print(queue.url)
```

Note: To get the name from a queue, you must use its ARN, which is available in the queue’s attributes attribute. Using `queue.attributes['QueueArn'].split(':')[1][-1]` will return its name.

Reference: SQS.ServiceResource.get_queue_by_name(), SQS.ServiceResource.queues

## 1.2.4 Sending Messages

Sending a message adds it to the end of the queue:

```python
# Get the service resource
sqs = boto3.resource('sqs')

# Get the queue
queue = sqs.get_queue_by_name(QueueName='test')

# Create a new message
response = queue.send_message(MessageBody='world')

# The response is NOT a resource, but gives you a message ID and MD5
print(response.get('MessageId'))
print(response.get('MD5OfMessageBody'))
```

You can also create messages with custom attributes:

```python
queue.send_message(MessageBody='boto3', MessageAttributes={
    'Author': {
```
Messages can also be sent in batches. For example, sending the two messages described above in a single request would look like the following:

```python
response = queue.send_messages(Entries=[
    {'Id': '1',
     'MessageBody': 'world'},
    {'Id': '2',
     'MessageBody': 'boto3',
     'MessageAttributes': {
         'Author': {
             'StringValue': 'Daniel',
             'DataType': 'string'
         }
     }
])

# Print out any failures
print(response.get('Failed'))
```

In this case, the response contains lists of **Successful** and **Failed** messages, so you can retry failures if needed.

Reference: `SQS.Queue.send_message()`, `SQS.Queue.send_messages()`

### 1.2.5 Processing Messages

Messages are processed in batches:

```python
# Get the service resource
sqs = boto3.resource('sqs')

# Get the queue
queue = sqs.get_queue_by_name(QueueName='test')

# Process messages by printing out body and optional author name
for message in queue.receive_messages(MessageAttributeNames=['Author']):
    # Get the custom author message attribute if it was set
    author_text = ''
    if message.message_attributes is not None:
        author_name = message.message_attributes.get('Author').get('StringValue')
        if author_name:
            author_text = ' ({0})'.format(author_name)

    # Print out the body and author (if set)
    print('Hello, {0}!{1}'.format(message.body, author_text))

    # Let the queue know that the message is processed
    message.delete()
```
Given *only* the messages that were sent in a batch with `SQS.Queue.send_messages()` in the previous section, the above code will print out:

Hello, world!
Hello, boto3! (Daniel)

Reference: `SQS.Queue.receive_messages()`, `SQS.Message.delete()`
2.1 User Guides

2.1.1 Migration Guides

What's New

Boto 3 is a ground-up rewrite of Boto. It uses a data-driven approach to generate classes at runtime from JSON description files that are shared between SDKs in various languages. This includes descriptions for a high level, object oriented interface similar to those available in previous versions of Boto.

Because Boto 3 is generated from these shared JSON files, we get fast updates to the latest services and features and a consistent API across services. Community contributions to JSON description files in other SDKs also benefit Boto 3, just as contributions to Boto 3 benefit the other SDKs.

Major Features

Boto 3 consists of the following major features:

- **Resources**: a high level, object oriented interface
- **Collections**: a tool to iterate and manipulate groups of resources
- **Clients**: low level service connections
- **Paginators**: automatic paging of responses
- **Waiters**: a way to block until a certain state has been reached

Along with these major features, Boto 3 also provides sessions and per-session credentials & configuration, as well as basic components like authentication, parameter & response handling, an event system for customizations and logic to retry failed requests.

**Botocore**  Boto 3 is built atop of a library called Botocore, which is shared by the AWS CLI. Botocore provides the low level clients, session, and credential & configuration data. Boto 3 builds on top of Botocore by providing its own session, resources and collections.
Migrating from Boto 2.x

Current Boto users can begin using Boto 3 right away. The two modules can live side-by-side in the same project, which means that a piecemeal approach can be used. New features can be written in Boto 3, or existing code can be migrated over as needed, piece by piece.

High Level Concepts

Boto 2.x modules are typically split into two categories, those which include a high-level object-oriented interface and those which include only a low-level interface which matches the underlying Amazon Web Services API. Some modules are completely high-level (like Amazon S3 or EC2), some include high-level code on top of a low-level connection (like Amazon DynamoDB), and others are 100% low-level (like Amazon Elastic Transcoder).

In Boto 3 this general low-level and high-level concept hasn’t changed much, but there are two important points to understand.

Data Driven  First, in Boto 3 classes are created at runtime from JSON data files that describe AWS APIs and organizational structures built atop of them. These data files are loaded at runtime and can be modified and updated without the need of installing an entirely new SDK release.

A side effect of having all the services generated from JSON files is that there is now consistency between all AWS service modules. One important change is that all API call parameters must now be passed as keyword arguments, and these keyword arguments take the form defined by the upstream service. Though there are exceptions, this typically means UpperCamelCasing parameter names. You will see this in the service-specific migration guides linked to below.

Resource Objects  Second, while every service now uses the runtime-generated low-level client, some services additionally have high-level generated objects that we refer to as Resources. The lower-level is comparable to Boto 2.x layer 1 connection objects in that they provide a one to one mapping of API operations and return low-level responses. The higher level is comparable to the high-level customizations from Boto 2.x: an S3 Key, an EC2 Instance, and a DynamoDB Table are all considered resources in Boto 3. Just like a Boto 2.x S3Connection’s list_buckets will return Bucket objects, the Boto 3 resource interface provides actions and collections that return resources. Some services may also have hand-written customizations built on top of the runtime-generated high-level resources (such as utilities for working with S3 multipart uploads).

import boto, boto3

# Low-level connections
conn = boto.connect_elastictranscoder()
client = boto3.client('elastictranscoder')

# High-level connections & resource objects
from boto.s3.bucket import Bucket
s3_conn = boto3.resource('s3')
boto2_bucket = s3_conn.Bucket('mybucket')
s3 = s3.Bucket('mybucket')
boto3_bucket = s3.Bucket('mybucket')

Installation & Configuration

The Quickstart guide provides instructions for installing Boto 3. You can also follow the instructions there to set up new credential files, or you can continue to use your existing Boto 2.x credentials. Please note that Boto 3, the AWS
CLI, and several other SDKs all use the shared credentials file (usually at ~/.aws/credentials).

Once configured, you may begin using Boto 3:

```python
import boto3

for bucket in boto3.resource('s3').buckets.all():
    print(bucket.name)
```

See the tutorial_list and Boto 3 Documentation for more information.

The rest of this document will describe specific common usage scenarios of Boto 2 code and how to accomplish the same tasks with Boto 3.

**Services**

**Amazon S3** Boto 2.x contains a number of customizations to make working with Amazon S3 buckets and keys easy. Boto 3 exposes these same objects through its resources interface in a unified and consistent way.

**Creating the Connection** Boto 3 has both low-level clients and higher-level resources. For Amazon S3, the higher-level resources are the most similar to Boto 2.x’s s3 module:

```python
# Boto 2.x
import boto
s3_connection = boto.connect_s3()

# Boto 3
import boto3
s3 = boto3.resource('s3')
```

**Creating a Bucket** Creating a bucket in Boto 2 and Boto 3 is very similar, except that in Boto 3 all action parameters must be passed via keyword arguments and a bucket configuration must be specified manually:

```python
# Boto 2.x
s3_connection.create_bucket('mybucket')
s3_connection.create_bucket('mybucket', location=Location.USWest)

# Boto 3
s3.create_bucket(Bucket='mybucket')
s3.create_bucket(Bucket='mybucket', CreateBucketConfiguration={
    'LocationConstraint': 'us-west-1'})
```

**Storing Data** Storing data from a file, stream, or string is easy:

```python
# Boto 2.x
from boto.s3.key import Key
key = Key('hello.txt')
key.set_contents_from_file('/tmp/hello.txt')

# Boto 3
s3.Object('mybucket', 'hello.txt').put(Body=open('/tmp/hello.txt', 'rb'))
```
Accessing a Bucket  Getting a bucket is easy with Boto 3’s resources, however these do not automatically validate whether a bucket exists:

# Boto 2.x
bucket = s3_connection.get_bucket('mybucket', validate=False)
exists = s3_connection.lookup('mybucket')

# Boto 3
import botocore
bucket = s3.Bucket('mybucket')
exists = True
try:
    s3.meta.client.head_bucket(Bucket='mybucket')
except botocore.exceptions.ClientError as e:
    if int(e.response['Error']['Code']) == 404:
        exists = False

Deleting a Bucket  All of the keys in a bucket must be deleted before the bucket itself can be deleted:

# Boto 2.x
for key in bucket:
    key.delete()
bucket.delete()

# Boto 3
for key in bucket.objects.all():
    key.delete()
bucket.delete()

Iteration of Buckets and Keys  Bucket and key objects are no longer iterable, but now provide collection attributes which can be iterated:

# Boto 2.x
for bucket in s3_connection:
    for key in bucket:
        print(key.name)

# Boto 3
for bucket in s3.buckets.all():
    for key in bucket.objects.all():
        print(key.key)

Access Controls  Getting and setting canned access control values in Boto 3 operates on an ACL resource object:

# Boto 2.x
bucket.set_acl('public-read')
key.set_acl('public-read')

# Boto 3
bucket.Acl().put(ACL='public-read')
obj.put(ACL='public-read')

It’s also possible to retrieve the policy grant information:
# Boto 2.x
acp = bucket.get_acl()
for grant in acp.acl.grants:
    print(grant.display_name, grant.permission)

# Boto 3
acl = bucket.Acl()
for grant in acl.grants:
    print(grant['DisplayName'], grant['Permission'])

Boto 3 lacks the grant shortcut methods present in Boto 2.x, but it is still fairly simple to add grantees:

# Boto 2.x
bucket.add_email_grant('READ', 'user@domain.tld')

# Boto 3
bucket.Acl.put(GrantRead='emailAddress=user@domain.tld')

**Key Metadata**  It’s possible to set arbitrary metadata on keys:

# Boto 2.x
key.set_metadata('metal', 'This is my metadata value')
print(key.get_metadata('metal'))

# Boto 3
key.put(Metadata={'metal': 'This is my metadata value'})
print(key.metadata['metal'])

**Managing CORS Configuration**  Allows you to manage the cross-origin resource sharing configuration for S3 buckets:

# Boto 2.x
cors = bucket.get_cors()
config = CORSConfiguration()
config.add_rule('GET', '*')
bucket.set_cors(config)
bucket.delete_cors()

# Boto 3
cors = bucket.Cors()
config = {
    'CORSRules': [
        {
            'AllowedMethods': ['GET'],
            'AllowedOrigins': ['*']
        }
    ]
}
cors.put(CORSConfiguration=config)
cors.delete()
Amazon EC2  Boto 2.x contains a number of customizations to make working with Amazon EC2 instances, storage and networks easy. Boto 3 exposes these same objects through its resources interface in a unified and consistent way.

Creating the Connection  Boto 3 has both low-level clients and higher-level resources. For Amazon EC2, the higher-level resources are the most similar to Boto 2.x’s ec2 and vpc modules:

```
# Boto 2.x
import boto
ec2_connection = boto.connect_ec2()
vpc_connection = boto.connect_vpc()

# Boto 3
import boto3
ec2 = boto3.resource('ec2')
```

Launching New Instances  Launching new instances requires an image ID and the number of instances to launch. It can also take several optional parameters, such as the instance type and security group:

```
# Boto 2.x
ec2_connection.run_instances('<ami-image-id>')</n
# Boto 3
c2.create_instances(ImageId='<ami-image-id>', MinCount=1, MaxCount=5)
```

Stopping & Terminating Instances  Stopping and terminating multiple instances given a list of instance IDs uses Boto 3 collection filtering:

```
ids = ['instance-id-1', 'instance-id-2', ...]

# Boto 2.x
ec2_connection.stop_instances(instance_ids=ids)
ec2_connection.terminate_instances(instance_ids=ids)

# Boto 3
c2.instances.filter(InstanceIds=ids).stop()
c2.instances.filter(InstanceIds=ids).terminate()
```

Checking What Instances Are Running  Boto 3 collections come in handy when listing all your running instances as well. Every collection exposes a filter method that allows you to pass additional parameters to the underlying service API operation. The EC2 instances collection takes a parameter called Filters which is a list of names and values, for example:

```
# Boto 2.x
reservations = ec2_connection.get_all_reservations(  
    filters={'instance-state-name': 'running'})
for reservation in reservations:
    for instance in reservation.instances:
        print(instance.instance_id, instance.instance_type)

# Boto 3
# Use the filter() method of the instances collection to retrieve
# all running EC2 instances.
instances = ec2.instances.filter(  
    Filters=[{'Name': 'instance-state-name', 'Values': ['running']})
```
for instance in instances:
    print(instance.id, instance.instance_type)

Checking Health Status Of Instances  It is possible to get scheduled maintenance information for your running instances. At the time of this writing Boto 3 does not have a status resource, so you must drop down to the low-level client via ec2.meta.client:

# Boto 2.x
for status in ec2_connection.get_all_instance_statuses():
    print(status)

# Boto 3
for status in ec2.meta.client.describe_instance_status()['InstanceStatuses']:
    print(status)

Working with EBS Snapshots  Snapshots provide a way to create a copy of an EBS volume, as well as make new volumes from the snapshot which can be attached to an instance:

# Boto 2.x
snapshot = ec2_connection.create_snapshot('volume-id', 'Description')
volume = snapshot.create_volume('us-west-2')
ec2_connection.attach_volume(volume.id, 'instance-id', '/dev/sdy')
ec2_connection.delete_snapshot(snapshot.id)

# Boto 3
snapshot = ec2.create_snapshot(VolumeId='volume-id', Description='description')
volume = ec2.create_volume(SnapshotId=snapshot.id, AvailabilityZone='us-west-2a')
ec2.Instance('instance-id').attach_volume(VolumeId=volume.id, Device='/dev/sdy')
snapshot.delete()

Creating a VPC, Subnet, and Gateway  Creating VPC resources in Boto 3 is very similar to Boto 2.x:

# Boto 2.x
vpc = vpc_connection.create_vpc('10.0.0.0/24')
subnet = vpc_connection.create_subnet(vpc.id, '10.0.0.0/25')
gateway = vpc_connection.create_internet_gateway()

# Boto 3
vpc = ec2.create_vpc(CidrBlock='10.0.0.0/24')
subnet = vpc.create_subnet(CidrBlock='10.0.0.0/25')
gateway = ec2.create_internet_gateway()

Attaching and Detaching an Elastic IP and Gateway  Elastic IPs and gateways provide a way for instances inside of a VPC to communicate with the outside world:

# Boto 2.x
ec2_connection.attach_internet_gateway(gateway.id, vpc.id)
ec2_connection.detach_internet_gateway(gateway.id, vpc.id)

from boto.ec2.address import Address
address = Address()
address.allocation_id = 'eipalloc-35cf685d'
address.associate('i-71b2f60b')
address.disassociate()
# Boto 3

gateway.attach_to_vpc(VpcId=vpc.id)
gateway.detach_from_vpc(VpcId=vpc.id)

address = ec2.VpcAddress('eipalloc-35cf685d')
address.associate('i-71b2f60b')
address.association.delete()

## 2.1.2 General Feature Guides

### Resources

#### Overview

Resources represent an object-oriented interface to Amazon Web Services (AWS). They provide a higher-level abstraction than the raw, low-level calls made by service clients. To use resources, you invoke the `resource()` method of a `Session` and pass in a service name:

```python
# Get resources from the default session
sqs = boto3.resource('sqs')
s3 = boto3.resource('s3')
```

Every resource instance has a number of attributes and methods. These can conceptually be split up into identifiers, attributes, actions, references, sub-resources, and collections. Each of these is described in further detail below and in the following section.

Resources themselves can also be conceptually split into service resources (like `sqs`, `s3`, `ec2`, etc) and individual resources (like `sqs.Queue` or `s3.Bucket`). Service resources do not have identifiers or attributes. The two share the same components otherwise.

#### Identifiers & Attributes

An identifier is a unique value that is used to call actions on the resource. Resources **must** have at least one identifier, except for the top-level service resources (e.g. `sqs` or `s3`). An identifier is set at instance creation-time, and failing to provide all necessary identifiers during instantiation will result in an exception. Examples of identifiers:

```python
# SQS Queue (url is an identifier)
queue = sqs.Queue(url='http://...')
print(queue.url)

# S3 Object (bucket_name and key are identifiers)
obj = s3.Object(bucket_name='boto3', key='test.py')
print(obj.bucket_name)
print(obj.key)

# Raises exception, missing identifier: key!
obj = s3.Object(bucket_name='boto3')
```

Identifiers may also be passed as positional arguments:

```python
# SQS Queue
queue = sqs.Queue('http://...')

# S3 Object
Identifiers also play a role in resource instance equality. For two instances of a resource to be considered equal, their identifiers must be equal:

```python
>> bucket1 = s3.Bucket('boto3')
>> bucket2 = s3.Bucket('boto3')
>> bucket3 = s3.Bucket('some-other-bucket')

>> bucket1 == bucket2
True
>> bucket1 == bucket3
False
```

**Note:** Only identifiers are taken into account for instance equality. Region, account ID and other data members are not considered. When using temporary credentials or multiple regions in your code please keep this in mind.

Resources may also have attributes, which are *lazy-loaded* properties on the instance. They may be set at creation time from the response of an action on another resource, or they may be set when accessed or via an explicit call to the `load` or `reload` action. Examples of attributes:

```python
# SQS Message
message.body

# S3 Object
obj.last_modified
obj.md5
```

**Warning:** Attributes may incur a load action when first accessed. If latency is a concern, then manually calling `load` will allow you to control exactly when the load action (and thus latency) is invoked. The documentation for each resource explicitly lists its attributes. Additionally, attributes may be reloaded after an action has been performed on the resource. For example, if the `last_modified` attribute of an S3 object is loaded and then a `put` action is called, then the next time you access `last_modified` it will reload the object’s metadata.

**Actions**

An action is a method which makes a call to the service. Actions may return a low-level response, a new resource instance or a list of new resource instances. Actions automatically set the resource identifiers as parameters, but allow you to pass additional parameters via keyword arguments. Examples of actions:

```python
# SQS Queue
messages = queue.receive_messages()

# SQS Message
for message in messages:
    message.delete()

# S3 Object
obj = s3.Object(bucket_name='boto3', key='test.py')
response = obj.get()
data = response['Body'].read()
```
Examples of sending additional parameters:

```python
# SQS Service
queue = sqs.get_queue_by_name(QueueName='test')

# SQS Queue
queue.send_message(MessageBody='hello')
```

**Note:** Parameters must be passed as keyword arguments. They will not work as positional arguments.

### References

A reference is an attribute which may be None or a related resource instance. The resource instance does not share identifiers with its reference resource, that is, it is not a strict parent to child relationship. In relational terms, these can be considered many-to-one or one-to-one. Examples of references:

```python
# EC2 Instance
instance.subnet
instance.vpc
```

In the above example, an EC2 instance may have exactly one associated subnet, and may have exactly one associated VPC. The subnet does not require the instance ID to exist, hence it is not a parent to child relationship.

### Sub-resources

A sub-resource is similar to a reference, but is a related class rather than an instance. Sub-resources, when instantiated, share identifiers with their parent. It is a strict parent-child relationship. In relational terms, these can be considered one-to-many. Examples of sub-resources:

```python
# SQS
queue = sqs.Queue(url='...')
message = queue.Message(receipt_handle='...')
print(queue.url == message.queue_url)
print(message.receipt_handle)

# S3
obj = bucket.Object(key='new_file.txt')
print(obj.bucket_name)
print(obj.key)
```

Because an SQS message cannot exist without a queue, and an S3 object cannot exist without a bucket, these are parent to child relationships.

### Waiters

A waiter is similar to an action. A waiter will poll the status of a resource and suspend execution until the resource reaches the state that is being polling for or a failure occurs while polling. Waiters automatically set the resource identifiers as parameters, but allow you to pass additional parameters via keyword arguments. Examples of waiters include:

```python
# S3: Wait for a bucket to exist.
bucket.wait_until_exists()
```
# EC2: Wait for an instance to reach the running state.
instance.wait_until_running()

## Multithreading

It is recommended to create a resource instance for each thread in a multithreaded application rather than sharing a single instance among the threads. For example:

```python
import boto3
import boto3.session
import threading

class MyTask(threading.Thread):
    def __init__(self):
        self.session = boto3.session.Session()
        self.s3 = self.session.resource('s3')
        super(MyTask, self).__init__()

    def run(self):
        self.s3 = self.session.resource('s3')
        # ... do some work with S3 ...
```

In the example above, each thread would have its own Boto 3 session and its own instance of the S3 resource. This is a good idea because resources contain shared data when loaded and calling actions, accessing properties, or manually loading or reloading the resource can modify this data.

## Collections

### Overview

A collection provides an iterable interface to a group of resources. Collections behave similarly to Django QuerySets and expose a similar API. A collection seamlessly handles pagination for you, making it possible to easily iterate over all items from all pages of data. Example of a collection:

```python
# SQS list all queues
sqs = boto3.resource('sqs')
for queue in sqs.queues.all():
    print(queue.url)
```

### When Collections Make Requests

Collections can be created and manipulated without any request being made to the underlying service. A collection makes a remote service request under the following conditions:

- **Iteration:**
  ```python
  for bucket in s3.buckets.all():
      print(bucket.name)
  ```

- **Conversion to list():**
  ```python
  buckets = list(s3.buckets.all())
  ```

- **Batch actions (see below):**
  ```python
  s3.Bucket('my-bucket').objects.delete()
  ```
Filtering

Some collections support extra arguments to filter the returned data set, which are passed into the underlying service operation. Use the `filter()` method to filter the results:

```python
# S3 list all keys with the prefix '/photos'
s3 = boto3.resource('s3')
for bucket in s3.buckets.all():
    for obj in bucket.objects.filter(Prefix='/photos'):
        print('{0}:{1}'.format(bucket.name, obj.key))
```

**Warning:** Behind the scenes, the above example will call `ListBuckets`, `ListObjects`, and `HeadObject` many times. If you have a large number of S3 objects then this could incur a significant cost.

Chainability

Collection methods are chainable. They return copies of the collection rather than modifying the collection, including a deep copy of any associated operation parameters. For example, this allows you to build up multiple collections from a base which they all have in common:

```python
# EC2 find instances
ec2 = boto3.resource('ec2')
base = ec2.instances.filter(InstanceIds=['id1', 'id2', 'id3'])
filters = [{
    'name': 'tenancy',
    'value': 'dedicated'
}]
filtered1 = base.filter(Filters=filters)

# Note, this does NOT modify the filters in 'filtered1'!
filters.append({'name': 'instance-type', 'value': 't1.micro'})
filtered2 = base.filter(Filters=filters)

print('All instances:')
for instance in base:
    print(instance.id)

print('Dedicated instances:')
for instance in filtered1:
    print(instance.id)

print('Dedicated micro instances:')
for instance in filtered2:
    print(instance.id)
```

Limiting Results

It is possible to limit the number of items returned from a collection by using either the `limit()` method:

```python
# S3 iterate over first ten buckets
for bucket in s3.buckets.limit(10):
    print(bucket.name)
```
In both cases, up to 10 items total will be returned. If you do not have 10 buckets, then all of your buckets will be returned.

**Controlling Page Size**

Collections automatically handle paging through results, but you may want to control the number of items returned from a single service operation call. You can do so using the `page_size()` method:

```python
# S3 iterate over all objects 100 at a time
for obj in bucket.objects.page_size(100):
    print(obj.key)
```

By default, S3 will return 1000 objects at a time, so the above code would let you process the items in smaller batches, which could be beneficial for slow or unreliable internet connections.

**Batch Actions**

Some collections support batch actions, which are actions that operate on an entire page of results at a time. They will automatically handle pagination:

```python
# S3 delete everything in `my-bucket`
s3 = boto3.resource('s3')
s3.buckets('my-bucket').objects.delete()
```

**Danger:** The above example will **completely erase all data** in the `my-bucket` bucket! Please be careful with batch actions.

**Low-level Clients**

Clients provide a low-level interface to AWS whose methods map close to 1:1 with service APIs. All service operations are supported by clients. Clients are generated from a JSON service definition file.

**Creating Clients**

Clients are created in a similar fashion to resources:

```python
import boto3

# Create a low-level client with the service name
sqs = boto3.client('sqs')
```

It is also possible to access the low-level client from an existing resource:

```python
# Create the resource
sqs_resource = boto3.resource('sqs')

# Get the client from the resource
sqs = sqs_resource.meta.client
```
**Service Operations**

Service operations map to client methods of the same name and provide access to the same operation parameters via keyword arguments:

```python
# Make a call using the low-level client
response = sqs.send_message(QueueUrl='...', MessageBody='...')
```

As can be seen above, the method arguments map directly to the associated SQS API.

**Note:** The method names have been snake-cased for better looking Python code. Parameters **must** be sent as keyword arguments. They will not work as positional arguments.

**Handling Responses**

Responses are returned as python dictionaries. It is up to you to traverse or otherwise process the response for the data you need, keeping in mind that responses may not always include all of the expected data. In the example below, `response.get('QueueUrls', [])` is used to ensure that a list is always returned, even when the response has no key `'QueueUrls'`:

```python
# List all your queues
response = sqs.list_queues()
for url in response.get('QueueUrls', []):
    print(url)
```

The response in the example above looks something like this:

```json
{
    "QueueUrls": [ 
        "http://url1",
        "http://url2",
        "http://url3"
    ]
}
```

**Waiters**

Waiters use a client’s service operations to poll the status of an AWS resource and suspend execution until the AWS resource reaches the state that the waiter is polling for or a failure occurs while polling. Using clients, you can learn the name of each waiter that a client has access to:

```python
import boto3

s3 = boto3.client('s3')
sqs = boto3.client('sqs')

# List all of the possible waiters for both clients
print("s3 waiters:")
s3.waiter_names

print("sqs waiters:")
sqs.waiter_names
```

Note if a client does not have any waiters, it will return an empty list when accessing its `waiter_names` attribute:
s3 waiters:
[u'bucket_exists', u'bucket_not_exists', u'object_exists', u'object_not_exists']
sqs waiters:
[]

Using a client’s `get_waiter()` method, you can obtain a specific waiter from its list of possible waiters:

```python
# Retrieve waiter instance that will wait till a specified S3 bucket exists
s3_bucket_exists_waiter = s3.get_waiter('bucket_exists')
```

Then to actually start waiting, you must call the waiter’s `wait()` method with the method’s appropriate parameters passed in:

```python
# Begin waiting for the S3 bucket, mybucket, to exist
s3_bucket_exists_waiter.wait(Bucket='mybucket')
```

**Session**

A session manages state about a particular configuration. By default a session is created for you when needed. However it is possible and recommended to maintain your own session(s) in some scenarios. Sessions typically store:

- Credentials
- Region
- Other configurations

**Default Session**

The `boto3` module acts as a proxy to the default session, which is created automatically when needed. Example default session use:

```python
# Using the default session
sqs = boto3.client('sqs')
s3 = boto3.resource('s3')
```

**Custom Session**

It is also possible to manage your own session and create clients or resources from it:

```python
# Creating your own session
session = boto3.session.Session()

sqs = session.client('sqs')
s3 = session.resource('s3')
```

**Configuration**

Boto can be configured in multiple ways. Regardless of the source or sources that you choose, you must have AWS credentials and a region set in order to make requests.
Interactive Configuration

If you have the AWS CLI, then you can use its interactive `configure` command to set up your credentials and default region:

```bash
aws configure
```

Follow the prompts and it will generate configuration files in the correct locations for you.

Configuration Sources

There are multiple sources from which configuration data can be loaded. The general order in which they are checked is as follows:

1. Method parameters
2. Environment variables
3. Configuration files
4. EC2 Instance metadata

If a configuration value is set in multiple places, then the first will be used according the the order above. For example, if I have set a default region in both my environment variables and configuration file, then the environment variable is used.

Available Options

The available options for various configuration sources are listed below.

Method Parameters  When creating a session, client, or resource you can pass in credential and configuration options:

```python
from boto3.session import Session

session = Session(aws_access_key_id='<YOUR ACCESS KEY ID>',
                   aws_secret_access_key='<YOUR SECRET KEY>',
                   region_name='<REGION NAME>')
```

```python
ec2 = session.resource('ec2')
ec2_us_west_2 = session.resource('ec2', region_name='us-west-2')
```

```python
# List all of my EC2 instances in my default region.
print('Default region:')
for instance in ec2.instances.all():
    print(instance.id)
```

```python
# List all of my EC2 instances in us-west-2.
print('US West 2 region:')
for instance in ec2_us_west_2.instances.all():
    print(instance.id)
```

For a list of all options, look at the `Session` documentation.
Environment Variables

**AWS_ACCESS_KEY_ID**  The access key for your AWS account.

**AWS_SECRET_ACCESS_KEY**  The secret key for your AWS account.

**AWS_DEFAULT_REGION**  The default region to use, e.g. us-east-1.

**AWS_PROFILE**  The default credential and configuration profile to use, if any.

Configuration Files  There are two configuration files that Boto checks. The first is the shared credential file, which holds only credentials and is shared between various SDKs and tools like Boto and the AWS CLI. By default, this file is located at ~/.aws/credentials:

```
[default]
# The access key for your AWS account
aws_access_key_id=<YOUR ACCESS KEY ID>

# The secret key for your AWS account
aws_secret_access_key=<YOUR SECRET KEY>
```

Credentials can also be set for individual profiles:

```
[dev-profile]
# The access key for your dev-profile account
aws_access_key_id=<YOUR ACCESS KEY ID>

# The secret key for your dev-profile account
aws_secret_access_key=<YOUR SECRET KEY>
```

The second configuration file stores all settings which are not credentials. Its default location is ~/.aws/config:

```
[default]
# The default region when making requests
region=<REGION NAME>
```

It also supports profiles, but these are prefixed with the word profile because this file supports sections other than profiles:

```
[profile dev-profile]
# The default region when using the dev-profile account
region=<REGION NAME>
```

Extensibility Guide

All of Boto3’s resource and client classes are generated at runtime. This means that you cannot directly inherit and then extend the functionality of these classes because they do not exist until the program actually starts running. However it is still possible to extend the functionality of classes through Boto3’s event system.

An Introduction to the Event System

Boto3’s event system allows users to register a function to a specific event. Then once the running program reaches a line that emits that specific event, Boto3 will call every function registered to the event in the order in which they were registered. When Boto3 calls each of these registered functions, it will call each of them with a specific set of keyword arguments that are associated with that event. Then once the registered function is called, the function may modify the keyword arguments passed to that function or return a value. Here is an example of how the event system works:
import boto3

s3 = boto3.client('s3')

# Access the event system on the S3 client
event_system = s3.meta.events

# Create a function
def add_my_bucket(params, **kwargs):
    # Add the name of the bucket you want to default to.
    if 'Bucket' not in params:
        params['Bucket'] = 'mybucket'

# Register the function to an event
event_system.register('provide-client-params.s3.ListObjects', add_my_bucket)

response = s3.list_objects()

In this example, the handler add_my_bucket is registered such that the handler will inject the value ‘mybucket’ for the Bucket parameter whenever the the list_objects client call is made without the Bucket parameter. Note that if the same list_objects call is made without the Bucket parameter and the registered handler, it will result in a validation error.

Here are the takeaways from this example:

- All clients have their own event system that you can use to fire events and register functions. You can access the event system through the meta.events attribute on the client.

- All functions registered to the event system must have **kwargs in the function signature. This is because emitting an event can have any number of keyword arguments emitted along side it, and so if your function is called without **kwargs, its signature will have to match every keyword argument emitted by the event. This also allows for more keyword arguments to be added to the emitted event in the future without breaking existing handlers.

- To register a function to an event, call the register method on the event system with the name of the event you want to register the function to and the function handle. Note that if you register the event after the event is emitted, the function will not be called unless the event is emitted again. In the example, the add_my_bucket handler was registered to the ‘provide-client-params.s3.ListObjects’ event, which is an event that can be used to inject and modify parameters passed in by the client method. To read more about the event refer to provide-client-params

A Hierarchical Structure

The event system also provides a hierarchy for registering events such that you can register a function to a set of events depending on the event name hierarchy.

An event name can have its own hierarchy by specifying . in its name. For example, take the event name ‘general.specific.more_specific’. When this event is emitted, the registered functions will be called in the order from most specific to least specific registration. So in this example, the functions will be called in the following order:

1. Functions registered to ‘general.specific.more_specific’
2. Functions registered to ‘general.specific’
3. Functions registered to ‘general’

Here is a deeper example of how the event system works with respect to its hierarchical structure:
import boto3

s3 = boto3.client('s3')

# Access the event system on the S3 client
event_system = s3.meta.events

def add_my_general_bucket(params, **kwargs):
    if 'Bucket' not in params:
        params['Bucket'] = 'mybucket'

def add_my_specific_bucket(params, **kwargs):
    if 'Bucket' not in params:
        params['Bucket'] = 'myspecificbucket'

event_system.register('provide-client-params.s3', add_my_general_bucket)
event_system.register('provide-client-params.s3.ListObjects', add_my_specific_bucket)

list_obj_response = s3.list_objects()
put_obj_response = s3.put_object(Key='mykey', Body=b'my body')

In this example, the list_objects method call will use the 'myspecificbucket' for the bucket instead of 'mybucket' because the add_my_specific_bucket method was registered to the 'provide-client-params.s3.ListObjects' event which is more specific than the 'provide-client-params.s3' event. Thus, the add_my_specific_bucket function is called before the add_my_general_bucket function is called when the event is emitted.

However for the put_object call, the bucket used is 'mybucket'. This is because the event emitted for the put_object client call is 'provide-client-params.s3.PutObject' and the add_my_general_bucket method is called via its registration to 'provide-client-params.s3'. The 'provide-client-params.s3.ListObjects' event is never emitted so the registered add_my_specific_bucket function is never called.

**Wildcard Matching**

Another aspect of Boto3’s event system is that it has the capability to do wildcard matching using the ‘*’ notation. Here is an example of using wildcards in the event system:

import boto3

s3 = boto3.client('s3')

# Access the event system on the S3 client
event_system = s3.meta.events

def add_my_wildcard_bucket(params, **kwargs):
    if 'Bucket' not in params:
        params['Bucket'] = 'mybucket'

event_system.register('provide-client-params.s3.*', add_my_wildcard_bucket)
response = s3.list_objects()

The ‘*’ allows you to register to a group of events without having to know the actual name of the event. This is useful when you have to apply the same handler in multiple places. Also note that if the wildcard is used, it must be isolated. It does not handle globbing with additional characters. So in the previous example, if the my_wildcard_function was registered to 'provide-client-params.s3.*objects', the handler would not be called because it will consider 'provide-client-params.s3.*objects' to be a specific event.
The wildcard also respects the hierarchical structure of the event system. If another handler was registered to the ‘provide-client-params.s3’ event, the add_my_wildcard_bucket would be called first because it is registered to ‘provide-client-params.s3.*’ which is more specific than the event ‘provide-client.s3’.

Isolation of Event Systems

The event system in Boto3 has the notion of isolation: all clients maintain their own set of registered handlers. For example if a handler is registered to one client’s event system, it will not be registered to another client’s event system:

```
import boto3

client1 = boto3.client('s3')
client2 = boto3.client('s3')

def add_my_bucket(params, **kwargs):
    if 'Bucket' not in params:
        params['Bucket'] = 'mybucket'

def add_my_other_bucket(params, **kwargs):
    if 'Bucket' not in params:
        params['Bucket'] = 'myotherbucket'

client1.meta.events.register(
    'provide-client-params.s3.ListObjects', add_my_bucket)
client2.meta.events.register(
    'provide-client-params.s3.ListObjects', add_my_other_bucket)

client1_response = client1.list_objects()
client2_response = client2.list_objects()
```

Thanks to the isolation of clients’ event systems, client1 will inject ‘mybucket’ for its list_objects method call while client2 will inject ‘myotherbucket’ for its list_objects method call because add_my_bucket was registered to client1 while add_my_other_bucket was registered to client2.

Boto3 Specific Events

Boto3 emits a set of events that users can register to customize clients or resources and modify the behavior of method calls.

Here is the list of events that users of boto3 can register handlers to:

- ’creating-client-class
- ’creating-resource-class
- ’provide-client-params’

creating-client-class

**Full Event Name** ’creating-client-class.service-name’

**Note:** service-name refers to the value used to instantiate a client i.e. boto3.client(‘service-name’)

---

28 Chapter 2. User Guide
Description  This event is emitted upon creation of the client class for a service. The client class for a service is not created until the first instantiation of the client class. Use this event for adding methods to the client class or adding classes for the client class to inherit from.

Keyword Arguments Emitted

- **class_attributes**  
  *type* : dict  
  *param*  
  A dictionary where the keys are the names of the attributes of the class and the values are the actual attributes of the class.

- **base_classes**  
  *type* : list  
  *param*  
  A list of classes that the client class will inherit from where the order of inheritance is the same as the order of the list.

Expected Return Value  Do not return anything.

Example  Here is an example of how to add a method to the client class:

```python
from boto3.session import Session

def custom_method(self):
    print('This is my custom method')

def add_custom_method(class_attributes, **kwargs):
    class_attributes['my_method'] = custom_method

session = Session()
session.events.register('creating-client-class.s3', add_custom_method)

client = session.client('s3')
client.my_method()

This should output:
This is my custom method
```

Here is an example of how to add a new class for the client class to inherit from:

```python
from boto3.session import Session

class MyClass(object):
    def __init__(self, *args, **kwargs):
        super(MyClass, self).__init__(*args, **kwargs)
        print('Client instantiated!')

def add_custom_class(base_classes, **kwargs):
    base_classes.insert(0, MyClass)

session = Session()
session.events.register('creating-client-class.s3', add_custom_class)

client = session.client('s3')

This should output:
Client instantiated!
```

creating-resource-class
Full Event Name 'creating-resource-class.service-name.resource-name'

Note: service-name refers to the value used to instantiate a service resource i.e. boto3.resource('service-name') and resource-name refers to the name of the resource class.

Description This event is emitted upon creation of the resource class. The resource class is not created until the first instantiation of the resource class. Use this event for adding methods to the resource class or adding classes for the resource class to inherit from.

Keyword Arguments Emitted

- type class_attributes dict
  - param class_attributes A dictionary where the keys are the names of the attributes of the class and the values are the actual attributes of the class.
- type base_classes list
  - param base_classes A list of classes that the resource class will inherit from where the order of inheritance is the same as the order of the list.

Expected Return Value Do not return anything.

Example Here is an example of how to add a method to a resource class:

```python
from boto3.session import Session

def custom_method(self):
    print('This is my custom method')

def add_custom_method(class_attributes, **kwargs):
    class_attributes['my_method'] = custom_method

session = Session()
session.events.register('creating-resource-class.s3.ServiceResource',
                        add_custom_method)

resource = session.resource('s3')
resource.my_method()

This should output:
This is my custom method
```

Here is an example of how to add a new class for a resource class to inherit from:

```python
from boto3.session import Session

class MyClass(object):
    def __init__(self, *args, **kwargs):
        super(MyClass, self).__init__(*args, **kwargs)
        print('Resource instantiated!')

def add_custom_class(base_classes, **kwargs):
    base_classes.insert(0, MyClass)

session = Session()
session.events.register('creating-resource-class.s3.ServiceResource',
                        add_custom_class)

resource = session.resource('s3')
```
This should output:

Resource instantiated!

provide-client-params

**Full Event Name** 'provide-client.service-name.operation-name'

**Note:** service-name refers to the value used to instantiate a client i.e. boto3.client('service-name'). operation-name refers to the underlying API operation of the corresponding client method. To access the operation API name, retrieve the value from the client.meta.method_to_api_mapping dictionary using the name of the desired client method as the key.

**Description** This event is emitted before validation of the parameters passed to client method. Use this event to inject or modify parameters prior to the parameters being validated and built into a request that is sent over the wire.

**Keyword Arguments Emitted**

- **type params** dict
  - **param params** A dictionary where the keys are the names of the parameters passed through the client method and the values are the values of those parameters.
- **type model** botocore.model.OperationModel
  - **param model** A model representing the underlying API operation of the client method.

**Expected Return Value** Do not return anything or return a new dictionary of parameters to use when making the request.

**Example** Here is an example of how to inject a parameter using the event:

```python
import boto3

s3 = boto3.client('s3')

# Access the event system on the S3 client
event_system = s3.meta.events

# Create a function
def add_my_bucket(params, **kwargs):
    # Add the name of the bucket you want to default to.
    if 'Bucket' not in params:
        params['Bucket'] = 'mybucket'

# Register the function to an event
event_system.register('provide-client-params.s3.ListObjects', add_my_bucket)

response = s3.list_objects()
```

---

**2.1.3 Service Feature Guides**

**DynamoDB**

By following this guide, you will learn how to use the DynamoDB.ServiceResource and DynamoDB.Table resources in order to create tables, write items to tables, modify existing items, retrieve items, and query/filter the items in the table.
Creating a New Table

In order to create a new table, use the `DynamoDB.ServiceResource.create_table()` method:

```python
import boto3

# Get the service resource.
dynamodb = boto3.resource('dynamodb')

# Create the DynamoDB table.
table = dynamodb.create_table(
    TableName='users',
    KeySchema=[
        {'AttributeName': 'username',
         'KeyType': 'HASH'},
        {'AttributeName': 'last_name',
         'KeyType': 'RANGE'}
    ],
    AttributeDefinitions=[
        {'AttributeName': 'username',
         'AttributeType': 'S'},
        {'AttributeName': 'last_name',
         'AttributeType': 'S'}
    ],
    ProvisionedThroughput={
        'ReadCapacityUnits': 5,
        'WriteCapacityUnits': 5
    }
)

# Wait until the table exists.
table.meta.client.get_waiter('table_exists').wait(TableName='users')

# Print out some data about the table.
print(table.item_count)
```

Expected Output:

0

This creates a table named `users` that respectively has the hash and range primary keys `username` and `last_name`. This method will return a `DynamoDB.Table` resource to call additional methods on the created table.

Using an Existing Table

It is also possible to create a `DynamoDB.Table` resource from an existing table:
import boto3

# Get the service resource.
dynamodb = boto3.resource('dynamodb')

# Instantiate a table resource object without actually
# creating a DynamoDB table. Note that the attributes of this table
# are lazy-loaded: a request is not made nor are the attribute
# values populated until the attributes
# on the table resource are accessed or its load() method is called.
table = dynamodb.Table('users')

# Print out some data about the table.
# This will cause a request to be made to DynamoDB and its attribute
# values will be set based on the response.
print(table.creation_date_time)

Expected Output (Please note that probably the actual times will not match up):

2015-06-26 12:42:45.149000-07:00

Creating a New Item

Once you have a DynamoDB.Table resource you can add new items to the table using
DynamoDB.Table.put_item():

```python
table.put_item(
    Item={
        'username': 'janedoe',
        'first_name': 'Jane',
        'last_name': 'Doe',
        'age': 25,
        'account_type': 'standard_user',
    }
)
```

For all of the valid types that can be used for an item, refer to Valid DynamoDB Types.

Getting an Item

You can then retrieve the object using DynamoDB.Table.get_item():

```python
response = table.get_item(
    Key={'
        'username': 'janedoe',
        'last_name': 'Doe'
    }
)
item = response['Item']
print(item)
```

Expected Output:

```python
{u'username': u'janedoe',
 u'first_name': u'Jane',
 u'last_name': u'Doe',
```
u'account_type': u'standard_user',
u'age': Decimal('25')}

Updating Item

Using the retrieved item, you can update attributes of the item in the table:

```python
item['age'] = 26
```
```
item = table.put_item(Item=item)
```

Then if you retrieve the item again, it will be updated appropriately:

```python
response = table.get_item(
    Key={
        'username': 'janedoe',
        'last_name': 'Doe'
    }
)
item = response['Item']
```
```
print(item)
```

Expected Output:

```python
{u'username': u'janedoe',
 u'first_name': u'Jane',
 u'last_name': u'Doe',
 u'account_type': u'standard_user',
 u'age': Decimal('26')}
```

Deleting Item

You can also delete the item using `DynamoDB.Table.delete_item()`:

```python
table.delete_item(
    Key={
        'username': 'janedoe',
        'last_name': 'Doe'
    }
)
```

Batch Writing

If you are loading a lot of data at a time, you can make use of `DynamoDB.Table.batch_writer()` so you can both speed up the process and reduce the number of write requests made to the service.

This method returns a handle to a batch writer object that will automatically handle buffering and sending items in batches. In addition, the batch writer will also automatically handle any unprocessed items and resend them as needed. All you need to do is call `put_item` for any items you want to add, and `delete_item` for any items you want to delete:

```python
with table.batch_writer() as batch:
    batch.put_item(
        Item={
            'account_type': 'standard_user',
            'username': 'johndoe',
```
{'first_name': 'John',
'last_name': 'Doe',
'age': 25,
'address': {
    'road': '1 Jefferson Street',
    'city': 'Los Angeles',
    'state': 'CA',
    'zipcode': 90001
}
}
batch.put_item{
    Item={
        'account_type': 'super_user',
        'username': 'janedoering',
        'first_name': 'Jane',
        'last_name': 'Doering',
        'age': 40,
        'address': {
            'road': '2 Washington Avenue',
            'city': 'Seattle',
            'state': 'WA',
            'zipcode': 98109
        }
    }
}
batch.put_item{
    Item={
        'account_type': 'standard_user',
        'username': 'bobsmith',
        'first_name': 'Bob',
        'last_name': 'Smith',
        'age': 18,
        'address': {
            'road': '3 Madison Lane',
            'city': 'Louisville',
            'state': 'KY',
            'zipcode': 40213
        }
    }
}
batch.put_item{
    Item={
        'account_type': 'super_user',
        'username': 'alicedoe',
        'first_name': 'Alice',
        'last_name': 'Doe',
        'age': 27,
        'address': {
            'road': '1 Jefferson Street',
            'city': 'Los Angeles',
            'state': 'CA',
            'zipcode': 90001
        }
    }
}

The batch writer is even able to handle a very large amount of writes to the table.

2.1. User Guides
with table.batch_writer() as batch:
    for i in range(50):
        batch.put_item(
            Item={
                'account_type': 'anonymous',
                'username': 'user' + str(i),
                'first_name': 'unknown',
                'last_name': 'unknown'
            }
        )

Querying and Scanning

With the table full of items, you can then query or scan the items in the table using the `DynamoDB.Table.query()` or `DynamoDB.Table.scan()` methods respectively. To add conditions to scanning and querying the table, you will need to import the `boto3.dynamodb.conditions.Key` and `boto3.dynamodb.conditions.Attr` classes. The `boto3.dynamodb.conditions.Key` should be used when the condition is related to the key of the item. The `boto3.dynamodb.conditions.Attr` should be used when the condition is related to an attribute of the item:

```python
from boto3.dynamodb.conditions import Key, Attr
```

This queries for all of the users whose `username` key equals `johndoe`:

```python
response = table.query(
    KeyConditionExpression=Key('username').eq('johndoe')
)
items = response['Items']
print(items)
```

Expected Output:

```python
[{
    'username': 'johndoe',
    'first_name': 'John',
    'last_name': 'Doe',
    'account_type': 'standard_user',
    'age': Decimal('25'),
    'address': {
        'city': 'Los Angeles',
        'state': 'CA',
        'zipcode': Decimal('90001'),
        'road': '1 Jefferson Street'
    }
}]
```

Similarly you can scan the table based on attributes of the items. For example, this scans for all the users whose `age` is less than 27:

```python
response = table.scan(
    FilterExpression=Attr('age').lt(27)
)
items = response['Items']
print(items)
```

Expected Output:

```python
[{
    'username': 'johndoe',
    'first_name': 'John',
    'last_name': 'Doe',
    'account_type': 'standard_user',
    'age': Decimal('25'),
    'address': {
        'city': 'Los Angeles',
        'state': 'CA',
        'zipcode': Decimal('90001'),
        'road': '1 Jefferson Street'
    }
}]
```
You are also able to chain conditions together using the logical operators: & (and), | (or), and ~ (not). For example, this scans for all users whose first_name starts with J and whose account_type is super_user:

```python
response = table.scan(
    FilterExpression=Attr('first_name').begins_with('J') & Attr('account_type').eq('super_user')
)
items = response['Items']
print(items)
```

Expected Output:
```json
[
{
    'username': 'janedoering',
    'first_name': 'Jane',
    'last_name': 'Doering',
    'account_type': 'super_user',
    'age': Decimal('40'),
    'address': {u'city': u'Seattle',
                u'state': u'WA',
                u'zipcode': Decimal('98109'),
                u'road': u'2 Washington Avenue'}
}
]
```

You can even scan based on conditions of a nested attribute. For example this scans for all users whose state in their address is CA:

```python
response = table.scan(
    FilterExpression=Attr('address.state').eq('CA')
)
items = response['Items']
print(items)
```

Expected Output:
```json
[
{
    'username': 'johndoe',
    'first_name': 'John',
    'last_name': 'Doe',
    'account_type': 'standard_user',
    'age': Decimal('25'),
    'address': {u'city': u'Los Angeles',
                u'state': u'CA',
                u'zipcode': Decimal('90001'),
                u'road': u'1 Jefferson Street'}},
{
    'username': 'alicedoe',
    'first_name': 'Alice',
    'last_name': 'Doe',
    'account_type': 'standard_user',
    'age': Decimal('25'),
    'address': {u'city': u'Los Angeles',
                u'state': u'CA',
                u'zipcode': Decimal('90001'),
                u'road': u'1 Jefferson Street'}},
]
```
u'account_type': u'super_user',
    u'age': Decimal('27'),
    u'address': {u'city': u'Los Angeles',
                 u'state': u'CA',
                 u'zipcode': Decimal('90001'),
                 u'road': u'1 Jefferson Street'}}

For more information on the various conditions you can use for queries and scans, refer to *DynamoDB Conditions*.

**Deleting a Table**

Finally, if you want to delete your table call `DynamoDB.Table.delete()`:

table.delete()
3.1 Services

3.1.1 Available Services

AutoScaling

**Table of Contents**

- AutoScaling
  - Client
  - Paginators

**Client**

```python
import boto3

client = boto3.client('autoscaling')
```

These are the available methods:

- `attach_instances()`
- `attach_load_balancers()`
- `can_paginate()`
- `complete_lifecycle_action()`
- `create_auto_scaling_group()`
- `create_launch_configuration()`
- `create_or_update_tags()`
- `delete_auto_scaling_group()`
- `delete_launch_configuration()`
• delete_lifecycle_hook()
• delete_notification_configuration()
• delete_policy()
• delete_scheduled_action()
• delete_tags()
• describe_account_limits()
• describe_adjustment_types()
• describe_auto_scaling_groups()
• describe_auto_scaling_instances()
• describe_auto_scaling_notification_types()
• describe_launch_configurations()
• describe_lifecycle_hook_types()
• describe_lifecycle_hooks()
• describe_load_balancers()
• describe_metric_collection_types()
• describe_notification_configurations()
• describe_policies()
• describe_scaling_activities()
• describe_scaling_process_types()
• describe_scheduled_actions()
• describe_tags()
• describe_termination_policy_types()
• detach_instances()
• detach_load_balancers()
• disable_metrics_collection()
• enable_metrics_collection()
• enter_standby()
• execute_policy()
• exit_standby()
• generate_presigned_url()
• get_paginators()
• get_waiter()
• put_lifecycle_hook()
• put_notification_configuration()
• put_scaling_policy()
• put_scheduled_update_group_action()
• record_lifecycle_action_heartbeat()
• resume_processes()
• set_desired_capacity()
• set_instance_health()
• suspend_processes()
• terminate_instance_in_auto_scaling_group()
• update_auto_scaling_group()

**attach_instances(**kwargs\)**
Attaches one or more EC2 instances to the specified Auto Scaling group.

For more information, see Attach EC2 Instances to Your Auto Scaling Group in the Auto Scaling Developer Guide.

Request Syntax

```
response = client.attach_instances(
    InstanceIds=[
        'string',
    ],
    AutoScalingGroupName='string'
)
```

Parameters

- **InstanceIds** *(list)* – One or more EC2 instance IDs.
  
  - *(string)* –

- **AutoScalingGroupName** *(string)* – [REQUIRED]
  The name of the group.

Returns
None

**attach_load_balancers(**kwargs\)**
Attaches one or more load balancers to the specified Auto Scaling group.

To describe the load balancers for an Auto Scaling group, use DescribeLoadBalancers . To detach the load balancer from the Auto Scaling group, use DetachLoadBalancers .

For more information, see Attach a Load Balancer to Your Auto Scaling Group in the Auto Scaling Developer Guide.

Request Syntax

```
response = client.attach_load_balancers(
    AutoScalingGroupName='string',
    LoadBalancerNames=[
        'string',
    ]
)
```

Parameters

- **AutoScalingGroupName** *(string)* – The name of the group.

- **LoadBalancerNames** *(list)* – One or more load balancer names.
Return type: dict

Returns

Response Syntax

{}

Response Structure

• (dict) –

can_paginate(operation_name)

Check if an operation can be paginated.

Parameters

operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

Returns: True if the operation can be paginated, False otherwise.

complete_lifecycle_action(**kwargs)

Completes the lifecycle action for the associated token initiated under the given lifecycle hook with the specified result.

This operation is a part of the basic sequence for adding a lifecycle hook to an Auto Scaling group:

• Create a notification target. A target can be either an Amazon SQS queue or an Amazon SNS topic.
• Create an IAM role. This role allows Auto Scaling to publish lifecycle notifications to the designated SQS queue or SNS topic.
• Create the lifecycle hook. You can create a hook that acts when instances launch or when instances terminate.
• If necessary, record the lifecycle action heartbeat to keep the instance in a pending state.

• Complete the lifecycle action .

For more information, see Auto Scaling Pending State and Auto Scaling Terminating State in the Auto Scaling Developer Guide .

Request Syntax

response = client.complete_lifecycle_action(
    LifecycleHookName='string',
    AutoScalingGroupName='string',
    LifecycleActionToken='string',
    LifecycleActionResult='string'
)

Parameters

• LifecycleHookName (string) – [REQUIRED]

    The name of the lifecycle hook.

• AutoScalingGroupName (string) – [REQUIRED]

    The name of the group for the lifecycle hook.
• **LifecycleActionToken** *(string) – [REQUIRED]*

A universally unique identifier (UUID) that identifies a specific lifecycle action associated with an instance. Auto Scaling sends this token to the notification target you specified when you created the lifecycle hook.

• **LifecycleActionResult** *(string) – [REQUIRED]*

The action for the group to take. This parameter can be either **CONTINUE** or **ABANDON**.

**Return type** dict

**Returns**

**Response Syntax**

```
{}
```

**Response Structure**

• *(dict)* –

```python
create_auto_scaling_group(**kwargs)
```

Creates an Auto Scaling group with the specified name and attributes.

If you exceed your maximum limit of Auto Scaling groups, which by default is 20 per region, the call fails. For information about viewing and updating this limit, see DescribeAccountLimits.

For more information, see Auto Scaling Groups in the Auto Scaling Developer Guide.

**Request Syntax**

```python
response = client.create_auto_scaling_group(
    AutoScalingGroupName='string',
    LaunchConfigurationName='string',
    InstanceId='string',
    MinSize=123,
    MaxSize=123,
    DesiredCapacity=123,
    DefaultCooldown=123,
    AvailabilityZones=[
        'string',
    ],
    LoadBalancerNames=[
        'string',
    ],
    HealthCheckType='string',
    HealthCheckGracePeriod=123,
    PlacementGroup='string',
    VPCZoneIdentifier='string',
    TerminationPolicies=[
        'string',
    ],
    Tags=[
        {
            'ResourceId': 'string',
            'ResourceType': 'string',
            'Key': 'string',
            'Value': 'string',
            'PropagateAtLaunch': True|False
        },
    ],
```

---

3.1. Services
Parameters

- **AutoScalingGroupName** *(string)* – [REQUIRED]
  
  The name of the group. This name must be unique within the scope of your AWS account.

- **LaunchConfigurationName** *(string)* – The name of the launch configuration. Alternatively, use the `InstanceId` parameter to specify an EC2 instance instead of a launch configuration.

- **InstanceId** *(string)* – The ID of the EC2 instance used to create a launch configuration for the group. Alternatively, use the `LaunchConfigurationName` parameter to specify a launch configuration instead of an EC2 instance.

  When you specify an ID of an instance, Auto Scaling creates a new launch configuration and associates it with the group. This launch configuration derives its attributes from the specified instance, with the exception of the block device mapping.

  For more information, see Create an Auto Scaling Group from an EC2 Instance in the *Auto Scaling Developer Guide*.

- **MinSize** *(integer)* – [REQUIRED]
  
  The minimum size of the group.

- **MaxSize** *(integer)* – [REQUIRED]
  
  The maximum size of the group.

- **DesiredCapacity** *(integer)* – The number of EC2 instances that should be running in the group. This number must be greater than or equal to the minimum size of the group and less than or equal to the maximum size of the group.

- **DefaultCooldown** *(integer)* – The amount of time, in seconds, after a scaling activity completes before another scaling activity can start.

  If this parameter is not specified, the default value is 300. For more information, see Understanding Auto Scaling Cooldowns in the *Auto Scaling Developer Guide*.

- **AvailabilityZones** *(list)* – One or more Availability Zones for the group. This parameter is optional if you specify subnets using the `VPCZoneIdentifier` parameter.

  - *(string)* –

- **LoadBalancerNames** *(list)* – One or more load balancers.

  For more information, see Load Balance Your Auto Scaling Group in the *Auto Scaling Developer Guide*.

  - *(string)* –

- **HealthCheckType** *(string)* – The service to use for the health checks. The valid values are `EC2` and `ELB`.

  By default, health checks use Amazon EC2 instance status checks to determine the health of an instance. For more information, see Health Checks.

- **HealthCheckGracePeriod** *(integer)* – The amount of time, in seconds, after an EC2 instance comes into service that Auto Scaling starts checking its health. During this time, any health check failures for the instance are ignored.
This parameter is required if you are adding an **ELB** health check. Frequently, new instances need to warm up, briefly, before they can pass a health check. To provide ample warm-up time, set the health check grace period of the group to match the expected startup period of your application.

For more information, see Add an Elastic Load Balancing Health Check to Your Auto Scaling Group in the Auto Scaling Developer Guide.

- **PlacementGroup** *(string)* – The name of the placement group into which you’ll launch your instances, if any. For more information, see Placement Groups in the Amazon Elastic Compute Cloud User Guide.

- **VPCZoneIdentifier** *(string)* – A comma-separated list of subnet identifiers for your virtual private cloud (VPC).

  If you specify subnets and Availability Zones with this call, ensure that the subnets’ Availability Zones match the Availability Zones specified.

  For more information, see Auto Scaling and Amazon Virtual Private Cloud in the Auto Scaling Developer Guide.

- **TerminationPolicies** *(list)* – One or more termination policies used to select the instance to terminate. These policies are executed in the order that they are listed.

  For more information, see Choosing a Termination Policy for Your Auto Scaling Group in the Auto Scaling Developer Guide.

  - *(string)* –

- **Tags** *(list)* – The tag to be created or updated. Each tag should be defined by its resource type, resource ID, key, value, and a propagate flag. Valid values: key=*value*, value=*value*, propagate=*true* or *false*. Value and propagate are optional parameters.

  For more information, see Tagging Auto Scaling Groups and Instances in the Auto Scaling Developer Guide.

  - *(dict)* –

    Describes a tag for an Auto Scaling group.

    - **ResourceId** *(string)* –
      The name of the group.

    - **ResourceType** *(string)* –
      The type of resource. The only supported value is *auto-scaling-group*.

    - **Key** *(string)* – [REQUIRED]
      The tag key.

    - **Value** *(string)* –
      The tag value.

    - **PropagateAtLaunch** *(boolean)* –
      Determines whether the tag is added to new instances as they are launched in the group.

**Returns** None

create_launch_configuration(**kwargs)**

Creates a launch configuration.
If you exceed your maximum limit of launch configurations, which by default is 100 per region, the call fails. For information about viewing and updating this limit, see DescribeAccountLimits.

For more information, see Launch Configurations in the Auto Scaling Developer Guide.

Request Syntax

```python
response = client.create_launch_configuration(
    LaunchConfigurationName='string',
    ImageId='string',
    KeyName='string',
    SecurityGroups=[
        'string',
    ],
    ClassicLinkVPCId='string',
    ClassicLinkVPCSecurityGroups=[
        'string',
    ],
    UserData='string',
    InstanceId='string',
    InstanceType='string',
    KernelId='string',
    RamdiskId='string',
    BlockDeviceMappings=[
        {
            'VirtualName': 'string',
            'DeviceName': 'string',
            'Ebs': {
                'SnapshotId': 'string',
                'VolumeSize': 123,
                'VolumeType': 'string',
                'DeleteOnTermination': True|False,
                'Iops': 123
            },
            'NoDevice': True|False
        },
    ],
    InstanceMonitoring={
        'Enabled': True|False
    },
    SpotPrice='string',
    IamInstanceProfile='string',
    EbsOptimized=True|False,
    AssociatePublicIpAddress=True|False,
    PlacementTenancy='string'
)
```

Parameters

- **LaunchConfigurationName** *(string)* – [REQUIRED]
  The name of the launch configuration. This name must be unique within the scope of your AWS account.

- **ImageId** *(string)* – The ID of the Amazon Machine Image (AMI) to use to launch your EC2 instances. For more information, see Finding an AMI in the Amazon Elastic Compute Cloud User Guide.

- **KeyName** *(string)* – The name of the key pair. For more information, see Amazon EC2 Key Pairs in the Amazon Elastic Compute Cloud User Guide.
• **SecurityGroups** *(list)* – One or more security groups with which to associate the instances.

If your instances are launched in EC2-Classic, you can either specify security group names or the security group IDs. For more information about security groups for EC2-Classic, see Amazon EC2 Security Groups in the Amazon Elastic Compute Cloud User Guide.

If your instances are launched into a VPC, specify security group IDs. For more information, see Security Groups for Your VPC in the Amazon Virtual Private Cloud User Guide.

– *(string)* –

• **ClassicLinkVPCId** *(string)* – The ID of a ClassicLink-enabled VPC to link your EC2-Classic instances to. This parameter is supported only if you are launching EC2-Classic instances. For more information, see ClassicLink in the Amazon Elastic Compute Cloud User Guide.

• **ClassicLinkVPCSecurityGroups** *(list)* – The IDs of one or more security groups for the VPC specified in ClassicLinkVPCId. This parameter is required if ClassicLinkVPCId is specified, and is not supported otherwise. For more information, see ClassicLink in the Amazon Elastic Compute Cloud User Guide.

– *(string)* –

• **UserData** *(string)* – The user data to make available to the launched EC2 instances. For more information, see Instance Metadata and User Data in the Amazon Elastic Compute Cloud User Guide.

At this time, launch configurations don’t support compressed (zipped) user data files. **This value will be base64 encoded automatically. Do not base64 encode this value prior to performing the operation.**

• **InstanceId** *(string)* – The ID of the EC2 instance to use to create the launch configuration.

The new launch configuration derives attributes from the instance, with the exception of the block device mapping.

To create a launch configuration with a block device mapping or override any other instance attributes, specify them as part of the same request.

For more information, see Create a Launch Configuration Using an EC2 Instance in the Auto Scaling Developer Guide.

• **InstanceType** *(string)* – The instance type of the EC2 instance. For information about available instance types, see Available Instance Types in the Amazon Elastic Cloud Compute User Guide.

• **KernelId** *(string)* – The ID of the kernel associated with the AMI.

• **RamdiskId** *(string)* – The ID of the RAM disk associated with the AMI.

• **BlockDeviceMappings** *(list)* – One or more mappings that specify how block devices are exposed to the instance. For more information, see Block Device Mapping in the Amazon Elastic Compute Cloud User Guide.

– *(dict)* –

  Describes a block device mapping.
* **VirtualName** *(string)* –
  The name of the virtual device, ephemeral0 to ephemeral3.

* **DeviceName** *(string)* – [REQUIRED]
  The device name exposed to the EC2 instance (for example, /dev/sdh or xvdh).

* **Ebs** *(dict)* –
  The information about the Amazon EBS volume.
  - **SnapshotId** *(string)* –
    The ID of the snapshot.
  - **VolumeSize** *(integer)* –
    The volume size, in gigabytes.
    Valid values: If the volume type is io1, the minimum size of the volume is 10 GiB. If you specify SnapshotId and VolumeSize, VolumeSize must be equal to or larger than the size of the snapshot.
    Default: If you create a volume from a snapshot and you don’t specify a volume size, the default is the size of the snapshot.
    Required: Required when the volume type is io1.
  - **VolumeType** *(string)* –
    The volume type.
    Valid values: standard | io1 | gp2
    Default: standard
  - **DeleteOnTermination** *(boolean)* –
    Indicates whether to delete the volume on instance termination.
    Default: true
  - **Iops** *(integer)* –
    For Provisioned IOPS (SSD) volumes only. The number of I/O operations per second (IOPS) to provision for the volume.
    Valid values: Range is 100 to 4000.
    Default: None

* **NoDevice** *(boolean)* –
  Suppresses a device mapping.
  If this parameter is true for the root device, the instance might fail the EC2 health check. Auto Scaling launches a replacement instance if the instance fails the health check.

* **InstanceMonitoring** *(dict)* – Enables detailed monitoring if it is disabled. Detailed monitoring is enabled by default.
  When detailed monitoring is enabled, Amazon CloudWatch generates metrics every minute and your account is charged a fee. When you disable detailed monitoring, by specifying False, CloudWatch generates metrics every 5 minutes. For more
information, see Monitor Your Auto Scaling Instances in the Auto Scaling Developer Guide.

- **Enabled (boolean)** –
  
  If True, instance monitoring is enabled.

- **SpotPrice (string)** – The maximum hourly price to be paid for any Spot Instance launched to fulfill the request. Spot Instances are launched when the price you specify exceeds the current Spot market price. For more information, see Launch Spot Instances in Your Auto Scaling Group in the Auto Scaling Developer Guide.

- **IamInstanceProfile (string)** – The name or the Amazon Resource Name (ARN) of the instance profile associated with the IAM role for the instance.

  EC2 instances launched with an IAM role will automatically have AWS security credentials available. You can use IAM roles with Auto Scaling to automatically enable applications running on your EC2 instances to securely access other AWS resources. For more information, see Launch Auto Scaling Instances with an IAM Role in the Auto Scaling Developer Guide.

- **EbsOptimized (boolean)** – Indicates whether the instance is optimized for Amazon EBS I/O. By default, the instance is not optimized for EBS I/O. The optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal I/O performance. This optimization is not available with all instance types. Additional usage charges apply. For more information, see Amazon EBS-Optimized Instances in the Amazon Elastic Compute Cloud User Guide.

- **AssociatePublicIpAddress (boolean)** – Used for groups that launch instances into a virtual private cloud (VPC). Specifies whether to assign a public IP address to each instance. For more information, see Auto Scaling and Amazon Virtual Private Cloud in the Auto Scaling Developer Guide.

  If you specify a value for this parameter, be sure to specify at least one subnet using the VPCZoneIdentifier parameter when you create your group.

  Default: If the instance is launched into a default subnet, the default is true. If the instance is launched into a nondefault subnet, the default is false. For more information, see Supported Platforms in the Amazon Elastic Compute Cloud User Guide.

- **PlacementTenancy (string)** – The tenancy of the instance. An instance with a tenancy of dedicated runs on single-tenant hardware and can only be launched into a VPC.

  You must set the value of this parameter to dedicated if you want to launch Dedicated Instances into a shared tenancy VPC (VPC with instance placement tenancy attribute set to default).

  If you specify a value for this parameter, be sure to specify at least one subnet using the VPCZoneIdentifier parameter when you create your group.

  For more information, see Auto Scaling and Amazon Virtual Private Cloud in the Auto Scaling Developer Guide.

  Valid values: default | dedicated

**create_or_update_tags (**kwargs)**

Creates or updates tags for the specified Auto Scaling group.
A tag is defined by its resource ID, resource type, key, value, and propagate flag. The value and the propagate flag are optional parameters. The only supported resource type is `auto-scaling-group`, and the resource ID must be the name of the group. The `PropagateAtLaunch` flag determines whether the tag is added to instances launched in the group. Valid values are `true` or `false`.

When you specify a tag with a key that already exists, the operation overwrites the previous tag definition, and you do not get an error message.

For more information, see Tagging Auto Scaling Groups and Instances in the Auto Scaling Developer Guide.

Request Syntax

```python
response = client.create_or_update_tags(
    Tags=[
        {
            'ResourceId': 'string',
            'ResourceType': 'string',
            'Key': 'string',
            'Value': 'string',
            'PropagateAtLaunch': True|False
        },
    ]
)
```

**Parameters**

**Tags** *(list) – [REQUIRED]***

One or more tags.

- *(dict) –

  Describes a tag for an Auto Scaling group.

  - **ResourceId** *(string) –*
    
    The name of the group.

  - **ResourceType** *(string) –*
    
    The type of resource. The only supported value is `auto-scaling-group`.

  - **Key** *(string) – [REQUIRED]***
    
    The tag key.

  - **Value** *(string) –*
    
    The tag value.

  - **PropagateAtLaunch** *(boolean) –*
    
    Determines whether the tag is added to new instances as they are launched in the group.

**Returns**

None

*delete_auto_scaling_group**(**kwargs)

Deletes the specified Auto Scaling group.

The group must have no instances and no scaling activities in progress.

To remove all instances before calling `DeleteAutoScalingGroup`, call `UpdateAutoScalingGroup` to set the minimum and maximum size of the Auto Scaling group to zero.
Request Syntax

```python
response = client.delete_auto_scaling_group(
    AutoScalingGroupName='string',
    ForceDelete=True|False
)
```

**Parameters**

- **AutoScalingGroupName** (*string*) – [REQUIRED]
  The name of the group to delete.

- **ForceDelete** (*boolean*) – Specifies that the group will be deleted along with all instances associated with the group, without waiting for all instances to be terminated. This parameter also deletes any lifecycle actions associated with the group.

**Returns** None

**delete_launch_configuration(**kwargs**)**

Deletes the specified launch configuration.

The launch configuration must not be attached to an Auto Scaling group. When this call completes, the launch configuration is no longer available for use.

**Request Syntax**

```python
response = client.delete_launch_configuration(
    LaunchConfigurationName='string'
)
```

**Parameters** **LaunchConfigurationName** (*string*) – [REQUIRED]

The name of the launch configuration.

**Returns** None

**delete_lifecycle_hook(**kwargs**)**

Deletes the specified lifecycle hook.

If there are any outstanding lifecycle actions, they are completed first (ABANDON for launching instances, CONTINUE for terminating instances).

**Request Syntax**

```python
response = client.delete_lifecycle_hook(
    LifecycleHookName='string',
    AutoScalingGroupName='string'
)
```

**Parameters**

- **LifecycleHookName** (*string*) – [REQUIRED]
  The name of the lifecycle hook.

- **AutoScalingGroupName** (*string*) – [REQUIRED]
  The name of the Auto Scaling group for the lifecycle hook.

**Return type** `dict`
Returns
Response Syntax
{}

Response Structure
• (dict) –

`delete_notification_configuration(**kwargs)`
Deletes the specified notification.

Request Syntax
```python
response = client.delete_notification_configuration(
    AutoScalingGroupName='string',
    TopicARN='string'
)
```

Parameters
• `AutoScalingGroupName (string) – [REQUIRED]`
The name of the Auto Scaling group.
• `TopicARN (string) – [REQUIRED]`
The Amazon Resource Name (ARN) of the Amazon Simple Notification Service (SNS) topic.

Returns  None

`delete_policy(**kwargs)`
Deletes the specified Auto Scaling policy.

Request Syntax
```python
response = client.delete_policy(
    AutoScalingGroupName='string',
    PolicyName='string'
)
```

Parameters
• `AutoScalingGroupName (string) – [REQUIRED]`
The name of the Auto Scaling group.
• `PolicyName (string) – [REQUIRED]`
The name or Amazon Resource Name (ARN) of the policy.

Returns  None

`delete_scheduled_action(**kwargs)`
Deletes the specified scheduled action.

Request Syntax
```python
response = client.delete_scheduled_action(
    AutoScalingGroupName='string',
    ScheduledActionName='string'
)
```
Parameters

- **AutoScalingGroupName** (*string*) – The name of the Auto Scaling group.
- **ScheduledActionName** (*string*) – [REQUIRED]
  The name of the action to delete.

Returns None

delete_tags(**kwargs)**

Deletes the specified tags.

Request Syntax

```python
response = client.delete_tags(
    Tags=[
        {
            'ResourceId': 'string',
            'ResourceType': 'string',
            'Key': 'string',
            'Value': 'string',
            'PropagateAtLaunch': True|False
        }
    ]
)
```

Parameters  **Tags** (*list*) – [REQUIRED]

Each tag should be defined by its resource type, resource ID, key, value, and a propagate flag. Valid values are: Resource type = `auto-scaling-group`, Resource ID = `AutoScalingGroupName`, key=*value*, value=*value*, propagate=*true* or *false*.

- (dict) –
  Describes a tag for an Auto Scaling group.
  - **ResourceId** (*string*) –
    The name of the group.
  - **ResourceType** (*string*) –
    The type of resource. The only supported value is `auto-scaling-group`.
  - **Key** (*string*) – [REQUIRED]
    The tag key.
  - **Value** (*string*) –
    The tag value.
  - **PropagateAtLaunch** (*boolean*) –
    Determines whether the tag is added to new instances as they are launched in the group.

Returns None

describe_account_limits()

Describes the current Auto Scaling resource limits for your AWS account.
For information about requesting an increase in these limits, see AWS Service Limits in the Amazon Web Services General Reference.

Request Syntax

```python
response = client.describe_account_limits()
```

Return type  `dict`

Returns

Response Syntax

```python
{
    'MaxNumberOfAutoScalingGroups': 123,
    'MaxNumberOfLaunchConfigurations': 123
}
```

Response Structure

- `(dict)` –
  - `MaxNumberOfAutoScalingGroups` *(integer)* –
    - The maximum number of groups allowed for your AWS account. The default limit is 20 per region.
  - `MaxNumberOfLaunchConfigurations` *(integer)* –
    - The maximum number of launch configurations allowed for your AWS account. The default limit is 100 per region.

```python
describe_adjustment_types()
```

Describes the policy adjustment types for use with PutScalingPolicy.

Request Syntax

```python
response = client.describe_adjustment_types()
```

Return type  `dict`

Returns

Response Syntax

```python
{
    'AdjustmentTypes': [
        {
            'AdjustmentType': 'string'
        }
    ]
}
```

Response Structure

- `(dict)` –
  - `AdjustmentTypes` *(list)* –
    - The policy adjustment types.
  - *(dict)* –
    - Describes a policy adjustment type.
For more information, see Dynamic Scaling in the Auto Scaling Developer Guide.

- **AdjustmentType** *(string)* –
  The policy adjustment type. The valid values are ChangeInCapacity, ExactCapacity, and PercentChangeInCapacity.

**describe_auto_scaling_groups** (**kwargs)**
Describes one or more Auto Scaling groups. If a list of names is not provided, the call describes all Auto Scaling groups.

**Request Syntax**
```python
response = client.describe_auto_scaling_groups(
    AutoScalingGroupNames=[
        'string',
    ],
    NextToken='string',
    MaxRecords=123
)
```

**Parameters**
- **AutoScalingGroupNames** *(list)* – The group names.
  - *(string)* –
- **NextToken** *(string)* – The token for the next set of items to return. (You received this token from a previous call.)
- **MaxRecords** *(integer)* – The maximum number of items to return with this call.

**Return type** `dict`

**Returns**

**Response Syntax**
```python
{
    'AutoScalingGroups': [
        {
            'AutoScalingGroupName': 'string',
            'AutoScalingGroupARN': 'string',
            'LaunchConfigurationName': 'string',
            'MinSize': 123,
            'MaxSize': 123,
            'DesiredCapacity': 123,
            'DefaultCooldown': 123,
            'AvailabilityZones': [
                'string',
            ],
            'LoadBalancerNames': [
                'string',
            ],
            'HealthCheckType': 'string',
            'HealthCheckGracePeriod': 123,
            'Instances': [
                {
                    'InstanceId': 'string',
                    'AvailabilityZone': 'string',
                    'LifecycleState': 'Pending'|'Pending:Wait'|'Pending:Proceed'|'Quarantined'|'InService'|'Terminating'|'Terminating:Wait'|'Terminating:Proceed'|'Terminated'|'Detaching'|'Detached'|'EnteringStandby'|'Standby',
                }
            ],
        }
    ]
}
```
'HealthStatus': 'string',
    'LaunchConfigurationName': 'string'
},
    'CreatedTime': datetime(2015, 1, 1),
    'SuspendedProcesses': [  
        {  
            'ProcessName': 'string',
            'SuspensionReason': 'string'
        },
    ],
    'PlacementGroup': 'string',
    'VPCZoneIdentifier': 'string',
    'EnabledMetrics': [  
        {  
            'Metric': 'string',
            'Granularity': 'string'
        },
    ],
    'Status': 'string',
    'Tags': [  
        {  
            'ResourceId': 'string',
            'ResourceType': 'string',
            'Key': 'string',
            'Value': 'string',
            'PropagateAtLaunch': True|False
        },
    ],
    'TerminationPolicies': [  
        'string',
    ],
    'NextToken': 'string'
}

Response Structure

* (dict) –
  
  – **AutoScalingGroups** (list) –

    The groups.

    # (dict) –

    Describes an Auto Scaling group.

    • **AutoScalingGroupName** (string) –

    The name of the group.

    • **AutoScalingGroupARN** (string) –

    The Amazon Resource Name (ARN) of the group.

    • **LaunchConfigurationName** (string) –

    The name of the associated launch configuration.

    • **MinSize** (integer) –

The minimum size of the group.

- **MaxSize (integer)** –
  The maximum size of the group.

- **DesiredCapacity (integer)** –
  The desired size of the group.

- **DefaultCooldown (integer)** –
  The number of seconds after a scaling activity completes before any further scaling activities can start.

- **AvailabilityZones (list)** –
  One or more Availability Zones for the group.

- **LoadBalancerNames (list)** –
  One or more load balancers associated with the group.

- **HealthCheckType (string)** –
  The service of interest for the health status check, which can be either EC2 for Amazon EC2 or ELB for Elastic Load Balancing.

- **HealthCheckGracePeriod (integer)** –
  The amount of time that Auto Scaling waits before checking an instance’s health status. The grace period begins when an instance comes into service.

- **Instances (list)** –
  The EC2 instances associated with the group.

- **InstanceId (string)** –
  The ID of the instance.

- **AvailabilityZone (string)** –
  The Availability Zone in which the instance is running.

- **LifecycleState (string)** –
  A description of the current lifecycle state. Note that the Quarantined state is not used.

- **HealthStatus (string)** –
  The health status of the instance.

- **LaunchConfigurationName (string)** –
  The launch configuration associated with the instance.

- **CreatedTime (datetime)** –
  The date and time the group was created.
- **SuspendedProcesses** (*list*) –
  The suspended processes associated with the group.
- *(dict)* –
  Describes an Auto Scaling process that has been suspended. For more information, see `ProcessType`.
- **ProcessName** (*string*) –
  The name of the suspended process.
- **SuspensionReason** (*string*) –
  The reason that the process was suspended.
- **PlacementGroup** (*string*) –
  The name of the placement group into which you'll launch your instances, if any. For more information, see `Placement Groups`.
- **VPCZoneIdentifier** (*string*) –
  One or more subnet IDs, if applicable, separated by commas.
  If you specify `VPCZoneIdentifier` and `AvailabilityZone`, ensure that the Availability Zones of the subnets match the values for `AvailabilityZone`.
- **EnabledMetrics** (*list*) –
  The metrics enabled for the group.
  *(dict)* –
  Describes an enabled metric.
- **Metric** (*string*) –
  The name of the metric.
- **GroupMinSize**
- **GroupMaxSize**
- **GroupDesiredCapacity**
- **GroupInServiceInstances**
- **GroupPendingInstances**
- **GroupStandbyInstances**
- **GroupTerminatingInstances**
- **GroupTotalInstances**
- **Granularity** (*string*) –
  The granularity of the metric. The only valid value is `1Minute`.
- **Status** (*string*) –
  The current state of the group when `DeleteAutoScalingGroup` is in progress.
- **Tags** (*list*) –
  The tags for the group.
· *(dict)* –
  Describes a tag for an Auto Scaling group.
· **ResourceId** *(string)* –
  The name of the group.
· **ResourceType** *(string)* –
  The type of resource. The only supported value is `auto-scaling-group`.
· **Key** *(string)* –
  The tag key.
· **Value** *(string)* –
  The tag value.
· **PropagateAtLaunch** *(boolean)* –
  Determines whether the tag is added to new instances as they are launched in the group.
· **TerminationPolicies** *(list)* –
  The termination policies for the group.
· *(string)* –
  – **NextToken** *(string)* –
    The token to use when requesting the next set of items. If there are no additional items to return, the string is empty.

**describe_auto_scaling_instances** (**kwargs**)

Describes one or more Auto Scaling instances. If a list is not provided, the call describes all instances.

**Request Syntax**

```python
response = client.describe_auto_scaling_instances(
    InstanceIds=[
        'string',
    ],
    MaxRecords=123,
    NextToken='string'
)
```

**Parameters**

- **InstanceIds** *(list)* – One or more Auto Scaling instances to describe, up to 50 instances. If you omit this parameter, all Auto Scaling instances are described. If you specify an ID that does not exist, it is ignored with no error.
  - *(string)* –
- **MaxRecords** *(integer)* – The maximum number of items to return with this call.
- **NextToken** *(string)* – The token for the next set of items to return. (You received this token from a previous call.)

**Return type**  dict

**Returns**

**Response Syntax**
{  
  'AutoScalingInstances': [  
    {  
      'InstanceId': 'string',  
      'AutoScalingGroupName': 'string',  
      'AvailabilityZone': 'string',  
      'LifecycleState': 'string',  
      'HealthStatus': 'string',  
      'LaunchConfigurationName': 'string'  
    },  
  ],  
  'NextToken': 'string'  
}

Response Structure

- (dict) –
  - AutoScalingInstances (list) –
    The instances.
      - (dict) –
        Describes an EC2 instance associated with an Auto Scaling group.
          - InstanceId (string) –
            The ID of the instance.
          - AutoScalingGroupName (string) –
            The name of the Auto Scaling group associated with the instance.
          - AvailabilityZone (string) –
            The Availability Zone for the instance.
          - LifecycleState (string) –
            The lifecycle state for the instance. For more information, see Auto Scaling Instance States in the Auto Scaling Developer Guide.
          - HealthStatus (string) –
            The health status of this instance. “Healthy” means that the instance is healthy and should remain in service. “Unhealthy” means that the instance is unhealthy and Auto Scaling should terminate and replace it.
          - LaunchConfigurationName (string) –
            The launch configuration associated with the instance.
  - NextToken (string) –
    The token to use when requesting the next set of items. If there are no additional items to return, the string is empty.

describe_auto_scaling_notification_types()

Describes the notification types that are supported by Auto Scaling.

Request Syntax

response = client.describe_auto_scaling_notification_types()

Return type  dict
Returns

Response Syntax

```python
{
    'AutoScalingNotificationTypes': [ 'string',
    ]
}
```

Response Structure

- (dict) –
  - **AutoScalingNotificationTypes** (list) –
    One or more of the following notification types:
    - autoscaling:EC2_INSTANCE_LAUNCH
    - autoscaling:EC2_INSTANCE_LAUNCH_ERROR
    - autoscaling:EC2_INSTANCE_TERMINATE
    - autoscaling:EC2_INSTANCE_TERMINATE_ERROR
    - autoscaling:TEST_NOTIFICATION
    - (string) –

describe_launch_configurations(**kwargs)

Describes one or more launch configurations. If you omit the list of names, then the call describes all launch configurations.

Request Syntax

```python
response = client.describe_launch_configurations(
    LaunchConfigurationNames=['string'],
    NextToken='string',
    MaxRecords=123
)
```

Parameters

- **LaunchConfigurationNames** (list) – The launch configuration names.
  - (string) –
- **NextToken** (string) – The token for the next set of items to return. (You received this token from a previous call.)
- **MaxRecords** (integer) – The maximum number of items to return with this call. The default is 100.

Return type: dict

Returns

Response Syntax

```python
{
    'LaunchConfigurations': [
    {
        'LaunchConfigurationName': 'string',
        'LaunchConfigurationARN': 'string',
        'ImageId': 'string',
        'KeyName': 'string',
        'SecurityGroups': ['string',
    
```
`Response Structure`

- *(dict)* –
  - **LaunchConfigurations** *(list)* –
    - The launch configurations.
      - *(dict)* –
        - **LaunchConfigurationName** *(string)* –
          - The name of the launch configuration.
        - **LaunchConfigurationARN** *(string)* –
          - The Amazon Resource Name (ARN) of the launch configuration.
        - **ImageId** *(string)* –
          - The ID of the Amazon Machine Image (AMI).
        - **KeyName** *(string)* –
          - The name of the key pair.
        - **SecurityGroups** *(list)* –
          - The security groups associated with the launch configuration.
        - **UserData** *(string)* –
          - User data to be passed to the instance.
        - **InstanceType** *(string)* –
          - The instance type of the launch configuration.
        - **KernelId** *(string)* –
          - The kernel ID to be used.
        - **RamdiskId** *(string)* –
          - The ramdisk ID to be used.
        - **BlockDeviceMappings** *(list)* –
          - A list of block device mappings.
            - *(dict)* –
              - **VirtualName** *(string)* –
                - The virtual name of the block device.
              - **DeviceName** *(string)* –
                - The device name of the block device.
              - **Ebs** *(dict)* –
                - A dictionary containing EBS settings.
                  - **SnapshotId** *(string)* –
                    - The snapshot ID of the EBS volume.
                  - **VolumeSize** *(int)* –
                    - The size of the EBS volume.
                  - **VolumeType** *(string)* –
                    - The type of the EBS volume.
                  - **DeleteOnTermination** *(bool)* –
                    - Whether the EBS volume should be deleted on termination.
                  - **Iops** *(int)* –
                    - The IOPS of the EBS volume.
              - **NoDevice** *(bool)* –
                - Whether the device should be mapped.
        - **InstanceMonitoring** *(dict)* –
          - A dictionary containing instance monitoring settings.
            - **Enabled** *(bool)* –
              - Whether instance monitoring is enabled.
        - **SpotPrice** *(string)* –
          - The spot price for the instance.
        - **IamInstanceProfile** *(string)* –
          - The IAM instance profile to be used.
        - **CreatedTime** *(datetime)* –
          - The creation time of the launch configuration.
        - **EbsOptimized** *(bool)* –
          - Whether the instance is EBS optimized.
        - **AssociatePublicIpAddress** *(bool)* –
          - Whether a public IP address should be associated.
        - **PlacementTenancy** *(string)* –
          - The tenancy of the placement.
The security groups to associate with the instances.

- (string) –
- ClassicLinkVPCId (string) –

The ID of a ClassicLink-enabled VPC to link your EC2-Classic instances to. This parameter can only be used if you are launching EC2-Classic instances. For more information, see ClassicLink in the Amazon Elastic Compute Cloud User Guide.

- ClassicLinkVPCSecurityGroups (list) –

The IDs of one or more security groups for the VPC specified in ClassicLinkVPCId. This parameter is required if ClassicLinkVPCId is specified, and cannot be used otherwise. For more information, see ClassicLink in the Amazon Elastic Compute Cloud User Guide.

- (string) –
- UserData (string) –

The user data available to the instances.

- InstanceType (string) –

The instance type for the instances.

- KernelId (string) –

The ID of the kernel associated with the AMI.

- RamdiskId (string) –

The ID of the RAM disk associated with the AMI.

- BlockDeviceMappings (list) –

A block device mapping, which specifies the block devices for the instance.

- (dict) –

Describes a block device mapping.

- VirtualName (string) –

The name of the virtual device, ephemeral0 to ephemeral3.

- DeviceName (string) –

The device name exposed to the EC2 instance (for example, /dev/sdh or xvdh).

- Ebs (dict) –

The information about the Amazon EBS volume.

- SnapshotId (string) –

The ID of the snapshot.

- VolumeSize (integer) –

The volume size, in gigabytes.

Valid values: If the volume type is io1, the minimum size of the volume is 10 GiB. If you specify SnapshotId and VolumeSize, VolumeSize must be equal to or larger than the size of the snapshot.

Default: If you create a volume from a snapshot and you don’t specify a volume size, the default is the size of the snapshot.
Required: Required when the volume type is io1.

- **VolumeType (string)**
  
  The volume type.

  Valid values: `standard` | `io1` | `gp2`

  Default: `standard`

- **DeleteOnTermination (boolean)**
  
  Indicates whether to delete the volume on instance termination.

  Default: `true`

- **Iops (integer)**
  
  For Provisioned IOPS (SSD) volumes only. The number of I/O operations per second (IOPS) to provision for the volume.

  Valid values: Range is 100 to 4000.

  Default: None

- **NoDevice (boolean)**
  
  Suppresses a device mapping.

  If this parameter is true for the root device, the instance might fail the EC2 health check. Auto Scaling launches a replacement instance if the instance fails the health check.

- **InstanceMonitoring (dict)**
  
  Controls whether instances in this group are launched with detailed monitoring.

  - **Enabled (boolean)**
    
    If `True`, instance monitoring is enabled.

- **SpotPrice (string)**
  
  The price to bid when launching Spot Instances.

- **IamInstanceProfile (string)**
  
  The name or Amazon Resource Name (ARN) of the instance profile associated with the IAM role for the instance.

- **CreatedTime (datetime)**
  
  The creation date and time for the launch configuration.

- **EbsOptimized (boolean)**
  
  Controls whether the instance is optimized for EBS I/O (`true`) or not (`false`).

- **AssociatePublicIpAddress (boolean)**
  
  Specifies whether the instances are associated with a public IP address (`true`) or not (`false`).

- **PlacementTenancy (string)**
  
  The tenancy of the instance, either `default` or `dedicated`. An instance with `dedicated` tenancy runs in an isolated, single-tenant hardware and can only be launched into a VPC.

- **NextToken (string)**
  
  The token to use when requesting the next set of items. If there are no additional items to return, the string is empty.
describe_lifecycle_hook_types()
Describes the available types of lifecycle hooks.

Request Syntax

```python
response = client.describe_lifecycle_hook_types()
```

Return type  dict

Returns

Response Syntax

```python
{
    'LifecycleHookTypes': [ string,
    ]
}
```

Response Structure

- (dict) –
  - LifecycleHookTypes (list) –
    One or more of the following notification types:
    * autoscaling:EC2_INSTANCE_LAUNCHING
    * autoscaling:EC2_INSTANCE_TERMINATING
    * (string) –

describe_lifecycle_hooks(**kwargs)
Describes the lifecycle hooks for the specified Auto Scaling group.

Request Syntax

```python
response = client.describe_lifecycle_hooks(
    AutoScalingGroupName='string',
    LifecycleHookNames=[
        'string',
    ]
)
```

Parameters

- AutoScalingGroupName (string) – [REQUIRED]
  The name of the group.
- LifecycleHookNames (list) – The names of one or more lifecycle hooks.

- (string) –

Return type  dict

Returns

Response Syntax

```python
{
    'LifecycleHooks': [
        {
            'LifecycleHookName': 'string',
            'AutoScalingGroupName': 'string',
            'LifecycleTransition': 'string',
            'NotificationTargetARN': 'string',
            'RoleARN': 'string',
        }
    ]
}
```
'NotificationMetadata': 'string',
'HeartbeatTimeout': 123,
'GlobalTimeout': 123,
'DefaultResult': 'string'
},
]
}

Response Structure

- (dict) –
  - LifecycleHooks (list) –
    The lifecycle hooks for the specified group.
  *

(dict) –

Describes a lifecycle hook, which tells Auto Scaling that you want to perform an action when an instance launches or terminates. When you have a lifecycle hook in place, the Auto Scaling group will either:

- Pause the instance after it launches, but before it is put into service
- Pause the instance as it terminates, but before it is fully terminated

For more information, see Auto Scaling Pending State and Auto Scaling Terminating State in the Auto Scaling Developer Guide.

- LifecycleHookName (string) –
  The name of the lifecycle hook.
- AutoScalingGroupName (string) –
  The name of the Auto Scaling group for the lifecycle hook.
- LifecycleTransition (string) –
  The state of the EC2 instance to which you want to attach the lifecycle hook. For a list of lifecycle hook types, see DescribeLifecycleHookTypes.
- NotificationTargetARN (string) –
  The ARN of the notification target that Auto Scaling uses to notify you when an instance is in the transition state for the lifecycle hook. This ARN target can be either an SQS queue or an SNS topic. The notification message sent to the target includes the following:
  - Lifecycle action token
  - User account ID
  - Name of the Auto Scaling group
  - Lifecycle hook name
  - EC2 instance ID
  - Lifecycle transition
  - Notification metadata
- RoleARN (string) –
  The ARN of the IAM role that allows the Auto Scaling group to publish to the specified notification target.
- NotificationMetadata (string) –
  Additional information that you want to include any time Auto Scaling sends a message to the notification target.
· **HeartbeatTimeout** *(integer)* –
  The amount of time that can elapse before the lifecycle hook times out. When the lifecycle hook times out, Auto Scaling performs the action defined in the **DefaultResult** parameter. You can prevent the lifecycle hook from timing out by calling `RecordLifecycleActionHeartbeat`.

· **GlobalTimeout** *(integer)* –
  The maximum length of time an instance can remain in a **Pending:Wait** or **Terminating:Wait** state. Currently, the maximum is set to 48 hours.

· **DefaultResult** *(string)* –
  Defines the action the Auto Scaling group should take when the lifecycle hook timeout elapses or if an unexpected failure occurs. The valid values are **CONTINUE** and **ABANDON**. The default value is **CONTINUE**.

### `describe_load_balancers(**kwargs)`
Describes the load balancers for the specified Auto Scaling group.

**Request Syntax**

```python
response = client.describe_load_balancers(
    AutoScalingGroupName='string',
    NextToken='string',
    MaxRecords=123
)
```

**Parameters**

- **AutoScalingGroupName** *(string)* – [REQUIRED]
  The name of the group.
- **NextToken** *(string)* – The token for the next set of items to return. (You received this token from a previous call.)
- **MaxRecords** *(integer)* – The maximum number of items to return with this call.

**Return type**  dict

**Response Syntax**

```python
{
    'LoadBalancers': [
        {
            'LoadBalancerName': 'string',
            'State': 'string'
        },
        
        'NextToken': 'string'
    ]
}
```

**Response Structure**

- *(dict)* –
  - **LoadBalancers** *(list)* –
    The load balancers.
    * *(dict)* –
      Describes the state of a load balancer.
- **LoadBalancerName** *(string)* –
  The name of the load balancer.
- **State** *(string)* –
  The state of the load balancer.
- **Adding** - The instances in the group are being registered with the load balancer.
- **Added** - All instances in the group are registered with the load balancer.
- **InService** - At least one instance in the group passed an ELB health check.
- **Removing** - The instances are being deregistered from the load balancer. If connection draining is enabled, Elastic Load Balancing waits for in-flight requests to complete before deregistering the instances.
- **NextToken** *(string)* –
  The token to use when requesting the next set of items. If there are no additional items to return, the string is empty.

**describe_metric_collection_types()**
Describes the available CloudWatch metrics for Auto Scaling.

Note that the `GroupStandbyInstances` metric is not returned by default. You must explicitly request this metric when calling `EnableMetricsCollection`.

**Request Syntax**

```python
response = client.describe_metric_collection_types()
```

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Metrics': [
        {
            'Metric': 'string'
        },
    ],
    'Granularities': [
        {
            'Granularity': 'string'
        }
    ]
}
```

**Response Structure**

- *(dict)* –
  - **Metrics** *(list)* –
    One or more metrics.
    - *(dict)* –
      Describes a metric.
      - **Metric** *(string)* –
        The metric.
The granularities for the metrics.

* (dict) –

Describes a granularity of a metric.

- **Granularity** (string) –

  The granularity. The only valid value is **1Minute**.

### describe_notification_configurations(**kwargs)**

Describes the notification actions associated with the specified Auto Scaling group.

**Request Syntax**

```python
response = client.describe_notification_configurations(
    AutoScalingGroupNames=[
        'string',
    ],
    NextToken='string',
    MaxRecords=123
)
```

**Parameters**

- **AutoScalingGroupNames** (list) – The name of the group.
  - (string) –
- **NextToken** (string) – The token for the next set of items to return. (You received this token from a previous call.)
- **MaxRecords** (integer) – The maximum number of items to return with this call.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'NotificationConfigurations': [
        {
            'AutoScalingGroupName': 'string',
            'TopicARN': 'string',
            'NotificationType': 'string'
        },
        {
            'AutoScalingGroupName': 'string',
            'TopicARN': 'string',
            'NotificationType': 'string'
        }
    ],
    'NextToken': 'string'
}
```

**Response Structure**

- (dict) –
  - **NotificationConfigurations** (list) –
    - The notification configurations.
* (dict) –

Describes a notification.

- **AutoScalingGroupName** *(string)* –
  The name of the group.

- **TopicARN** *(string)* –
  The Amazon Resource Name (ARN) of the Amazon Simple Notification Service (SNS) topic.

- **NotificationType** *(string)* –
  The types of events for an action to start.
  - autoscaling:EC2_INSTANCE_LAUNCH
  - autoscaling:EC2_INSTANCE_LAUNCH_ERROR
  - autoscaling:EC2_INSTANCE_TERMINATE
  - autoscaling:EC2_INSTANCE_TERMINATE_ERROR
  - autoscaling:TEST_NOTIFICATION

- **NextToken** *(string)* –
  The token to use when requesting the next set of items. If there are no additional items to return, the string is empty.

**describe_policies** (**kwargs**)

Describes the policies for the specified Auto Scaling group.

**Request Syntax**

```python
response = client.describe_policies(
    AutoScalingGroupName='string',
    PolicyNames=['string'],
    PolicyTypes=['string'],
    NextToken='string',
    MaxRecords=123
)
```

**Parameters**

- **AutoScalingGroupName** *(string)* – The name of the group.
- **PolicyNames** *(list)* – One or more policy names or policy ARNs to be described. If you omit this list, all policy names are described. If an group name is provided, the results are limited to that group. This list is limited to 50 items. If you specify an unknown policy name, it is ignored with no error.
  - *(string)* –
- **PolicyTypes** *(list)* – One or more policy types. Valid values are SimpleScaling and StepScaling.
  - *(string)* –
- **NextToken** *(string)* – The token for the next set of items to return. (You received this token from a previous call.)
- **MaxRecords** *(integer)* – The maximum number of items to be returned with each call.

**Return type** `dict`

**Response Syntax**
"ScalingPolicies": [
    {
        'AutoScalingGroupName': 'string',
        'PolicyName': 'string',
        'PolicyARN': 'string',
        'PolicyType': 'string',
        'AdjustmentType': 'string',
        'MinAdjustmentStep': 123,
        'MinAdjustmentMagnitude': 123,
        'ScalingAdjustment': 123,
        'Cooldown': 123,
        'StepAdjustments': [
            {
                'MetricIntervalLowerBound': 123.0,
                'MetricIntervalUpperBound': 123.0,
                'ScalingAdjustment': 123
            }
        ],
        'MetricAggregationType': 'string',
        'EstimatedInstanceWarmup': 123,
        'Alarms': [
            {
                'AlarmName': 'string',
                'AlarmARN': 'string'
            }
        ]
    }
],
'NextToken': 'string'

Response Structure
* (dict) –
  – ScalingPolicies (list) –
  The scaling policies.
    * (dict) –
      Describes a scaling policy.
      * AutoScalingGroupName (string) –
        The name of the Auto Scaling group associated with this scaling policy.
      * PolicyName (string) –
        The name of the scaling policy.
      * PolicyARN (string) –
        The Amazon Resource Name (ARN) of the policy.
      * PolicyType (string) –
        The policy type. Valid values are SimpleScaling and StepScaling.
      * AdjustmentType (string) –
        The adjustment type, which specifies how ScalingAdjustment is interpreted. Valid values are ChangeInCapacity, ExactCapacity, and
PercentChangeInCapacity.

- **MinAdjustmentStep (integer)** –
  
  Available for backward compatibility. Use MinAdjustmentMagnitude instead.

- **MinAdjustmentMagnitude (integer)** –
  
  The minimum number of instances to scale. If the value of AdjustmentType is PercentChangeInCapacity, the scaling policy changes the DesiredCapacity of the Auto Scaling group by at least this many instances. Otherwise, the error is ValidationError.

- **ScalingAdjustment (integer)** –
  
  The amount by which to scale, based on the specified adjustment type. A positive value adds to the current capacity while a negative number removes from the current capacity.

- **Cooldown (integer)** –
  
  The amount of time, in seconds, after a scaling activity completes before any further trigger-related scaling activities can start.

- **StepAdjustments (list)** –
  
  A set of adjustments that enable you to scale based on the size of the alarm breach.

  - **(dict)** –
    
    Describes an adjustment based on the difference between the value of the aggregated CloudWatch metric and the breach threshold that you’ve defined for the alarm.

    For the following examples, suppose that you have an alarm with a breach threshold of 50:

    - If you want the adjustment to be triggered when the metric is greater than or equal to 50 and less than 60, specify a lower bound of 0 and an upper bound of 10.
    - If you want the adjustment to be triggered when the metric is greater than 40 and less than or equal to 50, specify a lower bound of -10 and an upper bound of 0.

    There are a few rules for the step adjustments for your step policy:

    - The ranges of your step adjustments can’t overlap or have a gap.
    - At most one step adjustment can have a null lower bound. If one step adjustment has a negative lower bound, then there must be a step adjustment with a null lower bound.
    - At most one step adjustment can have a null upper bound. If one step adjustment has a positive upper bound, then there must be a step adjustment with a null upper bound.
    - The upper and lower bound can’t be null in the same step adjustment.

- **MetricIntervalLowerBound (float)** –
  
  The lower bound for the difference between the alarm threshold and the CloudWatch metric. If the metric value is above the breach threshold, the lower bound is inclusive (the metric must be greater than or equal to the threshold plus the lower
The upper bound for the difference between the alarm threshold and the CloudWatch metric. If the metric value is above the breach threshold, the upper bound is exclusive (the metric must be less than the threshold plus the upper bound). Otherwise, it is inclusive (the metric must be less than or equal to the threshold plus the upper bound). A null value indicates positive infinity.

The upper bound must be greater than the lower bound.

- **ScalingAdjustment** (integer) –

  The amount by which to scale, based on the specified adjustment type. A positive value adds to the current capacity while a negative number removes from the current capacity.

- **MetricAggregationType** (string) –

  The aggregation type for the CloudWatch metrics. Valid values are Minimum, Maximum, and Average.

- **EstimatedInstanceWarmup** (integer) –

  The estimated time, in seconds, until a newly launched instance can contribute to the CloudWatch metrics.

- **Alarms** (list) –

  The CloudWatch alarms related to the policy.

  - (dict) –

    Describes an alarm.

    - **AlarmName** (string) –

      The name of the alarm.

    - **AlarmARN** (string) –

      The Amazon Resource Name (ARN) of the alarm.

- **NextToken** (string) –

  The token to use when requesting the next set of items. If there are no additional items to return, the string is empty.

describe_scaling_activities(**kwargs)**

Describes one or more scaling activities for the specified Auto Scaling group. If you omit the ActivityIds, the call returns all activities from the past six weeks. Activities are sorted by the start time. Activities still in progress appear first on the list.

**Request Syntax**

```python
response = client.describe_scaling_activities(
    ActivityIds=[
        'string',
    ],
    AutoScalingGroupName='string',
    MaxRecords=123,
    NextToken='string'
)
```

**Parameters**
• **ActivityIds (list)** – The activity IDs of the desired scaling activities. If this list is omitted, all activities are described. If the `AutoScalingGroupName` parameter is provided, the results are limited to that group. The list of requested activities cannot contain more than 50 items. If unknown activities are requested, they are ignored with no error.

– (string)

• **AutoScalingGroupName (string)** – The name of the group.

• **MaxRecords (integer)** – The maximum number of items to return with this call.

• **NextToken (string)** – The token for the next set of items to return. (You received this token from a previous call.)

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Activities': [
        {
            'ActivityId': 'string',
            'AutoScalingGroupName': 'string',
            'Description': 'string',
            'Cause': 'string',
            'StartTime': datetime(2015, 1, 1),
            'EndTime': datetime(2015, 1, 1),
            'StatusCode': 'WaitingForSpotInstanceRequestId'|'WaitingForSpotInstanceId'|'WaitingForInstanceId'|'PreInService'|'InProgress'|'WaitingForELBConnectionDraining'|'MidLifecycleAction'|'WaitingForInstanceWarmup'|'Successful'|'Failed'|'Cancelled',
            'StatusMessage': 'string',
            'Progress': 123,
            'Details': 'string'
        },
    ],
    'NextToken': 'string'
}
```

**Response Structure**

• (dict) –

– **Activities (list)** –

The scaling activities.

* (dict) –

Describes scaling activity, which is a long-running process that represents a change to your Auto Scaling group, such as changing its size or replacing an instance.

• **ActivityId (string)** –

The ID of the activity.

• **AutoScalingGroupName (string)** –

The name of the Auto Scaling group.

• **Description (string)** –

A friendly, more verbose description of the activity.

• **Cause (string)** –

The reason the activity began.

• **StartTime (datetime)** –

The start time of the activity.

• **EndTime (datetime)** –
The end time of the activity.

- **StatusCode (string)** –
  The current status of the activity.

- **StatusMessage (string)** –
  A friendly, more verbose description of the activity status.

- **Progress (integer)** –
  A value between 0 and 100 that indicates the progress of the activity.

- **Details (string)** –
  The details about the activity.

- **NextToken (string)** –
  The token to use when requesting the next set of items. If there are no additional items to return, the string is empty.

### describe_scaling_process_types()

Describes the scaling process types for use with ResumeProcesses and SuspendProcesses.

**Request Syntax**

```python
response = client.describe_scaling_process_types()
```

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'Processes': [
        {
            'ProcessName': 'string'
        },
    ]
}
```

**Response Structure**

- *(dict)* –
  - **Processes (list)** –

    The names of the process types.

    - *(dict)* –
      Describes a process type.

      For more information, see Auto Scaling Processes in the Auto Scaling Developer Guide.

      - **ProcessName (string)** –
        The name of the process.

      - **Launch**
      - **Terminate**
      - **AddToLoadBalancer**
      - **AlarmNotification**
      - **AZRebalance**
      - **HealthCheck**
      - **ReplaceUnhealthy**
      - **ScheduledActions**
describe_scheduled_actions(**kwargs)

Describes the actions scheduled for your Auto Scaling group that haven’t run. To describe the actions that have already run, use DescribeScalingActivities.

Request Syntax

```python
response = client.describe_scheduled_actions(
    AutoScalingGroupName='string',
    ScheduledActionNames=[
        'string',
    ],
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    NextToken='string',
    MaxRecords=123
)
```

Parameters

- **AutoScalingGroupName** *(string)* – The name of the group.
- **ScheduledActionNames** *(list)* – Describes one or more scheduled actions. If you omit this list, the call describes all scheduled actions. If you specify an unknown scheduled action it is ignored with no error.

You can describe up to a maximum of 50 instances with a single call. If there are more items to return, the call returns a token. To get the next set of items, repeat the call with the returned token in the `NextToken` parameter.

- **StartTime** *(datetime)* – The earliest scheduled start time to return. If scheduled action names are provided, this parameter is ignored.
- **EndTime** *(datetime)* – The latest scheduled start time to return. If scheduled action names are provided, this parameter is ignored.
- **NextToken** *(string)* – The token for the next set of items to return. (You received this token from a previous call.)
- **MaxRecords** *(integer)* – The maximum number of items to return with this call.

Return type **dict**

Returns

Response Syntax

```python
{
    'ScheduledUpdateGroupActions': [
        {
            'AutoScalingGroupName': 'string',
            'ScheduledActionName': 'string',
            'ScheduledActionARN': 'string',
            'Time': datetime(2015, 1, 1),
            'StartTime': datetime(2015, 1, 1),
            'EndTime': datetime(2015, 1, 1),
            'Recurrence': 'string',
            'MinSize': 123,
            'MaxSize': 123,
            'DesiredCapacity': 123
        },
    ],
    'NextToken': 'string'
}
```

Response Structure
• (dict) –
  – ScheduledUpdateGroupActions (list) –
  The scheduled actions.
    * (dict) –
      Describes a scheduled update to an Auto Scaling group.
        · AutoScalingGroupName (string) –
          The name of the group.
        · ScheduledActionName (string) –
          The name of the scheduled action.
        · ScheduledActionARN (string) –
          The Amazon Resource Name (ARN) of the scheduled action.
        · Time (datetime) –
          This parameter is deprecated; use StartTime instead.
        · StartTime (datetime) –
          The date and time that the action is scheduled to begin. This
date and time can be up to one month in the future.
          When StartTime and EndTime are specified with
          Recurrence, they form the boundaries of when the recur-
          ring action will start and stop.
        · EndTime (datetime) –
          The date and time that the action is scheduled to end. This
date and time can be up to one month in the future.
        · Recurrence (string) –
          The recurring schedule for the action.
        · MinSize (integer) –
          The minimum size of the group.
        · MaxSize (integer) –
          The maximum size of the group.
        · DesiredCapacity (integer) –
          The number of instances you prefer to maintain in the group.
      – NextToken (string) –
        The token to use when requesting the next set of items. If there are no
        additional items to return, the string is empty.

describe_tags (**kwargs)
Describes the specified tags.

You can use filters to limit the results. For example, you can query for the tags for a specific Auto Scaling
group. You can specify multiple values for a filter. A tag must match at least one of the specified values
for it to be included in the results.

You can also specify multiple filters. The result includes information for a particular tag only if it matches
all the filters. If there’s no match, no special message is returned.

Request Syntax

response = client.describe_tags(
  Filters=[

3.1. Services
Parameters

- **Filters** *(list)* – A filter used to scope the tags to return.
  
  - *(dict)* –

  Describes a filter.

  - **Name** *(string)* –

    The name of the filter. The valid values are:
    "auto-scaling-group", "key", "value", and 
    "propagate-at-launch".

  - **Values** *(list)* –

    The value of the filter.

  - *(string)* –

- **NextToken** *(string)* – The token for the next set of items to return. (You received this token from a previous call.)

- **MaxRecords** *(integer)* – The maximum number of items to return with this call.

Return type  *dict*

Returns

**Response Syntax**

```json
{
'Tags': [
   {
      'ResourceId': 'string',
      'ResourceType': 'string',
      'Key': 'string',
      'Value': 'string',
      'PropagateAtLaunch': True|False
   },
   
   NextToken: 'string'
}
```

**Response Structure**

- *(dict)* –

  - **Tags** *(list)* –

    The tags.

    - *(dict)* –

      Describes a tag for an Auto Scaling group.

      - **ResourceId** *(string)* –

        The name of the group.

      - **ResourceType** *(string)* –

        The type of resource. The only supported value is 
        "auto-scaling-group".
Key (string) –

The tag key.

Value (string) –

The tag value.

PropagateAtLaunch (boolean) –

Determines whether the tag is added to new instances as they are launched in the group.

NextToken (string) –

The token to use when requesting the next set of items. If there are no additional items to return, the string is empty.

describe_termination_policy_types()

Describes the termination policies supported by Auto Scaling.

Request Syntax

response = client.describe_termination_policy_types()

Return type  dict

Returns

Response Syntax

{
    'TerminationPolicyTypes': [
        'string',
    ]
}

Response Structure

* (dict) –

– TerminationPolicyTypes (list) –

The termination policies supported by Auto Scaling (OldestInstance, OldestLaunchConfiguration, NewestInstance, ClosestToNextInstanceHour, and Default).

* (string) –
detach_instances(**kwargs)

Removes one or more instances from the specified Auto Scaling group. After the instances are detached, you can manage them independently from the rest of the Auto Scaling group.

For more information, see Detach EC2 Instances from Your Auto Scaling Group in the Auto Scaling Developer Guide.

Request Syntax

response = client.detach_instances(
    InstanceIds=[
        'string',
    ],
    AutoScalingGroupName='string',
    ShouldDecrementDesiredCapacity=True|False
)

Parameters

* InstanceIds (list) – One or more instance IDs.
• **AutoScalingGroupName** *(string)* – [REQUIRED]
  
  The name of the group.

• **ShouldDecrementDesiredCapacity** *(boolean)* – [REQUIRED]

  If True, the Auto Scaling group decrements the desired capacity value by the number of instances detached.

**Return type**  
dict

**Returns**

**Response Syntax**

```
{
    'Activities': [
        {
            'ActivityId': 'string',
            'AutoScalingGroupName': 'string',
            'Description': 'string',
            'Cause': 'string',
            'StartTime': datetime(2015, 1, 1),
            'EndTime': datetime(2015, 1, 1),
            'StatusCode': 'WaitingForSpotInstanceRequestId'|'WaitingForSpotInstanceId'|'WaitingForInstanceId'|'PreInService'|'InProgress'|'WaitingForELBConnectionDraining'|'MidLifecycleAction'|'WaitingForInstanceWarmup'|'Successful'|'Failed'|'Cancelled',
            'StatusMessage': 'string',
            'Progress': 123,
            'Details': 'string'
        },
    ]
}
```

**Response Structure**

• *(dict)* –

  − **Activities** *(list)* –

  The activities related to detaching the instances from the Auto Scaling group.

  • *(dict)* –

    Describes scaling activity, which is a long-running process that represents a change to your Auto Scaling group, such as changing its size or replacing an instance.

    • **ActivityId** *(string)* –

      The ID of the activity.

    • **AutoScalingGroupName** *(string)* –

      The name of the Auto Scaling group.

    • **Description** *(string)* –

      A friendly, more verbose description of the activity.

    • **Cause** *(string)* –

      The reason the activity began.

    • **StartTime** *(datetime)* –

      The start time of the activity.

    • **EndTime** *(datetime)* –

      The end time of the activity.

    • **StatusCode** *(string)* –
The current status of the activity.

- **StatusMessage (string)** –
  A friendly, more verbose description of the activity status.

- **Progress (integer)** –
  A value between 0 and 100 that indicates the progress of the activity.

- **Details (string)** –
  The details about the activity.

### `detach_load_balancers(**kwargs)`
Removes one or more load balancers from the specified Auto Scaling group.

When you detach a load balancer, it enters the **Removing** state while deregistering the instances in the group. When all instances are deregistered, then you can no longer describe the load balancer using `DescribeLoadBalancers`. Note that the instances remain running.

#### Request Syntax

```python
response = client.detach_load_balancers(
    AutoScalingGroupName='string',
    LoadBalancerNames=['string'],
)
```

#### Parameters

- **AutoScalingGroupName (string)** – The name of the group.
- **LoadBalancerNames (list)** – One or more load balancer names.

#### Return type
dict

#### Returns

- **Response Syntax**

  ```
  {}
  ```

- **Response Structure**

  ```
  (dict)
  ```

### `disable_metrics_collection(**kwargs)`
Disables monitoring of the specified metrics for the specified Auto Scaling group.

#### Request Syntax

```python
response = client.disable_metrics_collection(
    AutoScalingGroupName='string',
    Metrics=['string'],
)
```

#### Parameters

- **AutoScalingGroupName (string)** – [REQUIRED]
  The name or Amazon Resource Name (ARN) of the group.
- **Metrics (list)** – One or more metrics. If you omit this parameter, all metrics are disabled.
enable_metrics_collection(**kwargs)

Enables monitoring of the specified metrics for the specified Auto Scaling group.

You can only enable metrics collection if InstanceMonitoring in the launch configuration for the group is set to True.

Request Syntax

response = client.enable_metrics_collection(
    AutoScalingGroupName='string',
    Metrics=[
        'string',
    ],
    Granularity='string'
)

Parameters

- **AutoScalingGroupName (string)** – [REQUIRED]
  
The name or ARN of the Auto Scaling group.

- **Metrics (list)** – One or more metrics. If you omit this parameter, all metrics are enabled.
  
  - GroupMinSize
  - GroupMaxSize
  - GroupDesiredCapacity
  - GroupInServiceInstances
  - GroupPendingInstances
  - GroupStandbyInstances
  - GroupTerminatingInstances
  - GroupTotalInstances

  Note that the GroupStandbyInstances metric is not enabled by default. You must explicitly request this metric.

  - (string) –

- **Granularity (string)** – [REQUIRED]
  
The granularity to associate with the metrics to collect. The only valid value is 1Minute.

Returns

None

terminate_instances(**kwargs)

Terminates the specified instances.

For more information, see Auto Scaling Terminating State in the Auto Scaling Developer Guide.
response = client.enter_standby(
    InstanceIds=[
        'string',
    ],
    AutoScalingGroupName='string',
    ShouldDecrementDesiredCapacity=True|False
)

Parameters

• **InstanceIds** (*list*) – One or more instances to move into Standby mode. You must specify at least one instance ID.
  
  – (*string*) –

• **AutoScalingGroupName** (*string*) – [REQUIRED]
  The name of the Auto Scaling group.

• **ShouldDecrementDesiredCapacity** (*boolean*) – [REQUIRED]
  Specifies whether the instances moved to Standby mode count as part of the Auto Scaling group’s desired capacity. If set, the desired capacity for the Auto Scaling group decrements by the number of instances moved to Standby mode.

Return type  dict

Returns

Response Syntax

```
{
    'Activities': [
        {
            'ActivityId': 'string',
            'AutoScalingGroupName': 'string',
            'Description': 'string',
            'Cause': 'string',
            'StartTime': datetime(2015, 1, 1),
            'EndTime': datetime(2015, 1, 1),
            'StatusCode': 'WaitingForSpotInstanceRequestId'|'WaitingForSpotInstanceId'|'WaitingForInstanceId'|'PreInService'|'InProgress'|'WaitingForELBConnectionDraining'|'MidLifecycleAction'|'WaitingForInstanceWarmup'|'Successful'|'Failed'|'Cancelled',
            'StatusMessage': 'string',
            'Progress': 123,
            'Details': 'string'
        },
    ],
}
```

Response Structure

• (*dict*) –
  
  – **Activities** (*list*) –
    
    The activities related to moving instances into Standby mode.
    
    – (*dict*) –

    Describes scaling activity, which is a long-running process that represents a change to your Auto Scaling group, such as changing its size or replacing an instance.

    • **ActivityId** (*string*) –

      The ID of the activity.

    • **AutoScalingGroupName** (*string*) –

      The name of the Auto Scaling group.
- **Description** *(string)*
  A friendly, more verbose description of the activity.

- **Cause** *(string)*
  The reason the activity began.

- **StartTime** *(datetime)*
  The start time of the activity.

- **EndTime** *(datetime)*
  The end time of the activity.

- **StatusCode** *(string)*
  The current status of the activity.

- **StatusMessage** *(string)*
  A friendly, more verbose description of the activity status.

- **Progress** *(integer)*
  A value between 0 and 100 that indicates the progress of the activity.

- **Details** *(string)*
  The details about the activity.

```
execute_policy(**kwargs)
```
Executes the specified policy.

**Request Syntax**

```python
response = client.execute_policy(
    AutoScalingGroupName='string',
    PolicyName='string',
    HonorCooldown=True|False,
    MetricValue=123.0,
    BreachThreshold=123.0
)
```

**Parameters**

- **AutoScalingGroupName** *(string)* – The name or Amazon Resource Name (ARN) of the Auto Scaling group.

- **PolicyName** *(string)* – [REQUIRED]
The name or ARN of the policy.

- **HonorCooldown** *(boolean)* – If this parameter is true, Auto Scaling waits for the cooldown period to complete before executing the policy. Otherwise, Auto Scaling executes the policy without waiting for the cooldown period to complete.

  This parameter is not supported if the policy type is **StepScaling**.

  For more information, see Understanding Auto Scaling Cooldowns in the Auto Scaling Developer Guide.

- **MetricValue** *(float)* – The metric value to compare to BreachThreshold. This enables you to execute a policy of type **StepScaling** and determine which step adjustment to use. For example, if the breach threshold is 50 and you want to use a step adjustment with a lower bound of 0 and an upper bound of 10, you can set the metric value to 59.

  If you specify a metric value that doesn’t correspond to a step adjustment for the policy, the call returns an error.
This parameter is required if the policy type is StepScaling and not supported otherwise.

- **BreachThreshold** (float) – The breach threshold for the alarm.
  
  This parameter is required if the policy type is StepScaling and not supported otherwise.

**Returns** None

__exit_standby__(**kwargs)

Moves the specified instances out of Standby mode.

For more information, see Auto Scaling InService State in the Auto Scaling Developer Guide.

**Request Syntax**

```python
response = client.exit_standby(
    InstanceIds=[
        'string',
    ],
    AutoScalingGroupName='string'
)
```

**Parameters**

- **InstanceIds** (list) – One or more instance IDs. You must specify at least one instance ID.
  
  - (string) –

- **AutoScalingGroupName** (string) – [REQUIRED]
  
  The name of the Auto Scaling group.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Activities': [
        {
            'ActivityId': 'string',
            'AutoScalingGroupName': 'string',
            'Description': 'string',
            'Cause': 'string',
            'StartTime': datetime(2015, 1, 1),
            'EndTime': datetime(2015, 1, 1),
            'StatusCode': 'WaitingForSpotInstanceRequestId'|'WaitingForSpotInstanceId'|'WaitingForInstanceId'|'PreInService'|'InProgress'|'WaitingForELBConnectionDraining'|'MidLifecycleAction'|'WaitingForInstanceWarmup'|'Successful'|'Failed'|'Cancelled',
            'StatusMessage': 'string',
            'Progress': 123,
            'Details': 'string'
        },
    ]
}
```

**Response Structure**

- (dict) –
  
  - **Activities** (list) –

    The activities related to moving instances out of Standby mode.

- (dict) –
Describes scaling activity, which is a long-running process that represents a change to your Auto Scaling group, such as changing its size or replacing an instance.

- **ActivityId** *(string)* – The ID of the activity.
- **AutoScalingGroupName** *(string)* – The name of the Auto Scaling group.
- **Description** *(string)* – A friendly, more verbose description of the activity.
- **Cause** *(string)* – The reason the activity began.
- **StartTime** *(datetime)* – The start time of the activity.
- **EndTime** *(datetime)* – The end time of the activity.
- **StatusCode** *(string)* – The current status of the activity.
- **StatusMessage** *(string)* – A friendly, more verbose description of the activity status.
- **Progress** *(integer)* – A value between 0 and 100 that indicates the progress of the activity.
- **Details** *(string)* – The details about the activity.

**generate_presigned_url** *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

**Parameters**
- **ClientMethod** *(string)* – The client method to presign for
- **Params** *(dict)* – The parameters normally passed to ClientMethod.
- **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns** The presigned url

**get_paginator** *(operation_name)*

Create a paginator for an operation.

**Parameters** **operation_name** *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

**Raises** **OperationNotPageableError** Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

**Return type** L{botocore.paginate.Paginator}

**Returns** A paginator object.

**get_waiter** *(waiter_name)*
put_lifecycle_hook(**kwargs)

Creates or updates a lifecycle hook for the specified Auto Scaling Group.

A lifecycle hook tells Auto Scaling that you want to perform an action on an instance that is not actively in service; for example, either when the instance launches or before the instance terminates.

This operation is a part of the basic sequence for adding a lifecycle hook to an Auto Scaling group:

- Create a notification target. A target can be either an Amazon SQS queue or an Amazon SNS topic.
- Create an IAM role. This role allows Auto Scaling to publish lifecycle notifications to the designated SQS queue or SNS topic.
- Create the lifecycle hook. You can create a hook that acts when instances launch or when instances terminate.
- If necessary, record the lifecycle action heartbeat to keep the instance in a pending state.
- Complete the lifecycle action.

For more information, see Auto Scaling Pending State and Auto Scaling Terminating State in the Auto Scaling Developer Guide.

If you exceed your maximum limit of lifecycle hooks, which by default is 50 per region, the call fails. For information about updating this limit, see AWS Service Limits in the Amazon Web Services General Reference.

Request Syntax

```python
response = client.put_lifecycle_hook(
    LifecycleHookName='string',
    AutoScalingGroupName='string',
    LifecycleTransition='string',
    RoleARN='string',
    NotificationTargetARN='string',
    NotificationMetadata='string',
    HeartbeatTimeout=123,
    DefaultResult='string'
)
```

Parameters

- **LifecycleHookName (string)** – [REQUIRED]
  
  The name of the lifecycle hook.

- **AutoScalingGroupName (string)** – [REQUIRED]
  
  The name of the Auto Scaling group to which you want to assign the lifecycle hook.

- **LifecycleTransition (string)** – The instance state to which you want to attach the lifecycle hook. For a list of lifecycle hook types, see DescribeLifecycleHookTypes.

  This parameter is required for new lifecycle hooks, but optional when updating existing hooks.

- **RoleARN (string)** – The ARN of the IAM role that allows the Auto Scaling group to publish to the specified notification target.

  This parameter is required for new lifecycle hooks, but optional when updating existing hooks.

- **NotificationTargetARN (string)** – The ARN of the notification target that Auto Scaling will use to notify you when an instance is in the transition state for the lifecycle hook. This ARN target can be either an SQS queue or an SNS topic.

  This parameter is required for new lifecycle hooks, but optional when updating existing hooks.
The notification message sent to the target will include:

- **LifecycleActionToken**. The Lifecycle action token.
- **AccountId**. The user account ID.
- **AutoScalingGroupName**. The name of the Auto Scaling group.
- **LifecycleHookName**. The lifecycle hook name.
- **EC2InstanceId**. The EC2 instance ID.
- **LifecycleTransition**. The lifecycle transition.
- **NotificationMetadata**. The notification metadata.

This operation uses the JSON format when sending notifications to an Amazon SQS queue, and an email key/value pair format when sending notifications to an Amazon SNS topic.

When you call this operation, a test message is sent to the notification target. This test message contains an additional key/value pair:

```plaintext
Event:autoscaling:TEST_NOTIFICATION
```

- **NotificationMetadata** (*string*) – Contains additional information that you want to include any time Auto Scaling sends a message to the notification target.
- **HeartbeatTimeout** (*integer*) – Defines the amount of time, in seconds, that can elapse before the lifecycle hook times out. When the lifecycle hook times out, Auto Scaling performs the action defined in the **DefaultResult** parameter. You can prevent the lifecycle hook from timing out by calling **RecordLifecycleActionHeartbeat**. The default value for this parameter is 3600 seconds (1 hour).
- **DefaultResult** (*string*) – Defines the action the Auto Scaling group should take when the lifecycle hook timeout elapses or if an unexpected failure occurs. The value for this parameter can be either **CONTINUE** or **ABANDON**. The default value for this parameter is **ABANDON**.

**Return type** dict

**Returns**

**Response Syntax**

```plaintext
{}
```

**Response Structure**

- *(dict)* –

**put_notification_configuration(**kwargs**)**

Configures an Auto Scaling group to send notifications when specified events take place. Subscribers to this topic can have messages for events delivered to an endpoint such as a web server or email address.

For more information see Getting Notifications When Your Auto Scaling Group Changes in the Auto Scaling Developer Guide.

This configuration overwrites an existing configuration.

**Request Syntax**

```python
response = client.put_notification_configuration(
    AutoScalingGroupName='string',
    TopicARN='string',
    NotificationTypes=[
        'string',
    ],
)
```

**Parameters**

---

**Boto3 Documentation, Release 1.1.4**
put_scaling_policy(**kwargs)

Creates or updates a policy for an Auto Scaling group. To update an existing policy, use the existing policy name and set the parameters you want to change. Any existing parameter not changed in an update to an existing policy is not changed in this update request.

If you exceed your maximum limit of step adjustments, which by default is 20 per region, the call fails. For information about updating this limit, see AWS Service Limits in the Amazon Web Services General Reference.

Request Syntax

def response = client.put_scaling_policy(
    AutoScalingGroupName='string',
    PolicyName='string',
    PolicyType='string',
    AdjustmentType='string',
    MinAdjustmentStep=123,
    MinAdjustmentMagnitude=123,
    ScalingAdjustment=123,
    Cooldown=123,
    MetricAggregationType='string',
    StepAdjustments=[
        {'MetricIntervalLowerBound': 123.0,
         'MetricIntervalUpperBound': 123.0,
         'ScalingAdjustment': 123},
    ],
    EstimatedInstanceWarmup=123
)

Parameters

- **AutoScalingGroupName (string)** – [REQUIRED]
  
The name of the Auto Scaling group.

- **PolicyName (string)** – [REQUIRED]
  
The name of the policy.

- **PolicyType (string)** – The policy type. Valid values are SimpleScaling and StepScaling. If the policy type is null, the value is treated as SimpleScaling.

- **AdjustmentType (string)** – [REQUIRED]
  
The adjustment type. Valid values are ChangeInCapacity, ExactCapacity, and PercentChangeInCapacity.
For more information, see **Dynamic Scaling** in the *Auto Scaling Developer Guide*.

- **MinAdjustmentStep** *(integer)* – Available for backward compatibility. Use *MinAdjustmentMagnitude* instead.
- **MinAdjustmentMagnitude** *(integer)* – The minimum number of instances to scale. If the value of *AdjustmentType* is *PercentChangeInCapacity*, the scaling policy changes the *DesiredCapacity* of the Auto Scaling group by at least this many instances. Otherwise, the error is *ValidationError*.
- **ScalingAdjustment** *(integer)* – The amount by which to scale, based on the specified adjustment type. A positive value adds to the current capacity while a negative number removes from the current capacity.

This parameter is required if the policy type is *SimpleScaling* and not supported otherwise.

- **Cooldown** *(integer)* – The amount of time, in seconds, after a scaling activity completes and before the next scaling activity can start. If this parameter is not specified, the default cooldown period for the group applies.

This parameter is not supported unless the policy type is *SimpleScaling*.

For more information, see **Understanding Auto Scaling Cooldowns** in the *Auto Scaling Developer Guide*.

- **MetricAggregationType** *(string)* – The aggregation type for the CloudWatch metrics. Valid values are *Minimum*, *Maximum*, and *Average*. If the aggregation type is null, the value is treated as *Average*.

This parameter is not supported if the policy type is *SimpleScaling*.

- **StepAdjustments** *(list)* – A set of adjustments that enable you to scale based on the size of the alarm breach.

This parameter is required if the policy type is *StepScaling* and not supported otherwise.

- *(dict)* –

  Describes an adjustment based on the difference between the value of the aggregated CloudWatch metric and the breach threshold that you’ve defined for the alarm.

  For the following examples, suppose that you have an alarm with a breach threshold of 50:

  * If you want the adjustment to be triggered when the metric is greater than or equal to 50 and less than 60, specify a lower bound of 0 and an upper bound of 10.
  * If you want the adjustment to be triggered when the metric is greater than 40 and less than or equal to 50, specify a lower bound of -10 and an upper bound of 0.

  There are a few rules for the step adjustments for your step policy:

  * The ranges of your step adjustments can’t overlap or have a gap.
  * At most one step adjustment can have a null lower bound. If one step adjustment has a negative lower bound, then there must be a step adjustment with a null lower bound.
  * At most one step adjustment can have a null upper bound. If one step adjustment has a positive upper bound, then there must be a step adjustment with a null upper bound.
  * The upper and lower bound can’t be null in the same step adjustment.

  - **MetricIntervalLowerBound** *(float)* –
The lower bound for the difference between the alarm threshold and the CloudWatch metric. If the metric value is above the breach threshold, the lower bound is inclusive (the metric must be greater than or equal to the threshold plus the lower bound). Otherwise, it is exclusive (the metric must be greater than the threshold plus the lower bound). A null value indicates negative infinity.

* MetricIntervalUpperBound (float) –

The upper bound for the difference between the alarm threshold and the CloudWatch metric. If the metric value is above the breach threshold, the upper bound is exclusive (the metric must be less than the threshold plus the upper bound). Otherwise, it is inclusive (the metric must be less than or equal to the threshold plus the upper bound). A null value indicates positive infinity.

The upper bound must be greater than the lower bound.

* ScalingAdjustment (integer) – [REQUIRED]

The amount by which to scale, based on the specified adjustment type. A positive value adds to the current capacity while a negative number removes from the current capacity.

* EstimatedInstanceWarmup (integer) – The estimated time, in seconds, until a newly launched instance can contribute to the CloudWatch metrics. The default is to use the value specified for the default cooldown period for the group.

This parameter is not supported if the policy type is SimpleScaling.

Return type  dict

Returns

Response Syntax

```
{
  'PolicyARN': 'string'
}
```

Response Structure

- (dict) –
  - PolicyARN (string) –

  The Amazon Resource Name (ARN) of the policy.

put_scheduled_update_group_action(**kwargs)

Creates or updates a scheduled scaling action for an Auto Scaling group. When updating a scheduled scaling action, if you leave a parameter unspecified, the corresponding value remains unchanged in the affected Auto Scaling group.

For more information, see Scheduled Scaling in the Auto Scaling Developer Guide.

Request Syntax

```python
response = client.put_scheduled_update_group_action(
    AutoScalingGroupName='string',
    ScheduledActionName='string',
    Time=datetime(2015, 1, 1),
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    Recurrence='string',
    MinSize=123,
    MaxSize=123,
)```
Parameters

- **AutoScalingGroupName (string)** – [REQUIRED]
  The name or Amazon Resource Name (ARN) of the Auto Scaling group.

- **ScheduledActionName (string)** – [REQUIRED]
  The name of this scaling action.

- **Time (datetime)** – This parameter is deprecated; use **StartTime** instead.
  The time for this action to start. If both **Time** and **StartTime** are specified, their values must be identical.

- **StartTime (datetime)** – The time for this action to start, in “YYYY-MM-DDThh:mm:ssZ” format in UTC/GMT only (for example, 2014-06-01T00:00:00Z).
  If you try to schedule your action in the past, Auto Scaling returns an error message.

  When **StartTime** and **EndTime** are specified with **Recurrence**, they form the boundaries of when the recurring action starts and stops.

- **EndTime (datetime)** – The time for this action to end.

- **Recurrence (string)** – The time when recurring future actions will start. Start time is specified by the user following the Unix cron syntax format. For more information, see Cron in Wikipedia.

  When **StartTime** and **EndTime** are specified with **Recurrence**, they form the boundaries of when the recurring action will start and stop.

- **MinSize (integer)** – The minimum size for the Auto Scaling group.

- **MaxSize (integer)** – The maximum size for the Auto Scaling group.

- **DesiredCapacity (integer)** – The number of EC2 instances that should be running in the group.

Returns

None

`record_lifecycle_action_heartbeat(**kwargs)`

Records a heartbeat for the lifecycle action associated with a specific token. This extends the timeout by the length of time defined by the `HeartbeatTimeout` parameter of `PutLifecycleHook`.

This operation is a part of the basic sequence for adding a lifecycle hook to an Auto Scaling group:

- Create a notification target. A target can be either an Amazon SQS queue or an Amazon SNS topic.
- Create an IAM role. This role allows Auto Scaling to publish lifecycle notifications to the designated SQS queue or SNS topic.
- Create the lifecycle hook. You can create a hook that acts when instances launch or when instances terminate.

  **If necessary, record the lifecycle action heartbeat to keep the instance in a pending state.**

- Complete the lifecycle action.

For more information, see Auto Scaling Pending State and Auto Scaling Terminating State in the Auto Scaling Developer Guide.

Request Syntax

```python
response = client.record_lifecycle_action_heartbeat(
    LifecycleHookName='string',
    AutoScalingGroupName='string',
    LifecycleActionToken='string'
)
```
Parameters

- **LifecycleHookName** *(string)* – [REQUIRED]
  
  The name of the lifecycle hook.

- **AutoScalingGroupName** *(string)* – [REQUIRED]
  
  The name of the Auto Scaling group for the hook.

- **LifecycleActionToken** *(string)* – [REQUIRED]
  
  A token that uniquely identifies a specific lifecycle action associated with an instance. Auto Scaling sends this token to the notification target you specified when you created the lifecycle hook.

Return type  dict

Returns

Response Syntax

```
{}
```

Response Structure

- *(dict)* –

  **resume_processes** (**kwargs**)
  
  Resumes the specified suspended Auto Scaling processes for the specified Auto Scaling group. To resume specific processes, use the `ScalingProcesses` parameter. To resume all processes, omit the `ScalingProcesses` parameter. For more information, see Suspend and Resume Auto Scaling Processes in the *Auto Scaling Developer Guide* .

Request Syntax

```python
response = client.resume_processes(
    AutoScalingGroupName='string',
    ScalingProcesses=[
        'string',
    ]
)
```

Parameters

- **AutoScalingGroupName** *(string)* – [REQUIRED]
  
  The name or Amazon Resource Name (ARN) of the Auto Scaling group.

- **ScalingProcesses** *(list)* – One or more of the following processes:
  - Launch
  - Terminate
  - HealthCheck
  - ReplaceUnhealthy
  - AZRebalance
  - AlarmNotification
  - ScheduledActions
  - AddToLoadBalancer
  - *(string)* –

Returns  None

**set_desired_capacity** (**kwargs**)

Sets the size of the specified Auto Scaling group.

For more information about desired capacity, see What Is Auto Scaling? in the *Auto Scaling Developer Guide* .
Request Syntax

```python
response = client.set_desired_capacity(
    AutoScalingGroupName='string',
    DesiredCapacity=123,
    HonorCooldown=True|False
}
```

Parameters

- **AutoScalingGroupName (string) – [REQUIRED]**

  The name of the Auto Scaling group.

- **DesiredCapacity (integer) – [REQUIRED]**

  The number of EC2 instances that should be running in the Auto Scaling group.

- **HonorCooldown (boolean) –** By default, SetDesiredCapacity overrides any cooldown period associated with the Auto Scaling group. Specify True to make Auto Scaling to wait for the cool-down period associated with the Auto Scaling group to complete before initiating a scaling activity to set your Auto Scaling group to its new capacity.

Returns

None

```python
set_instance_health(**kwargs)
```

Sets the health status of the specified instance.

For more information, see Health Checks in the Auto Scaling Developer Guide.

Request Syntax

```python
response = client.set_instance_health(
    InstanceId='string',
    HealthStatus='string',
    ShouldRespectGracePeriod=True|False
}
```

Parameters

- **InstanceId (string) – [REQUIRED]**

  The ID of the EC2 instance.

- **HealthStatus (string) – [REQUIRED]**

  The health status of the instance. Set to Healthy if you want the instance to remain in service. Set to Unhealthy if you want the instance to be out of service. Auto Scaling will terminate and replace the unhealthy instance.

- **ShouldRespectGracePeriod (boolean) –** If the Auto Scaling group of the specified instance has a HealthCheckGracePeriod specified for the group, by default, this call will respect the grace period. Set this to False, if you do not want the call to respect the grace period associated with the group.

For more information, see the HealthCheckGracePeriod parameter description for CreateAutoScalingGroup.

Returns

None

```python
suspend_processes(**kwargs)
```

Suspends the specified Auto Scaling processes for the specified Auto Scaling group. To suspend specific processes, use the ScalingProcesses parameter. To suspend all processes, omit the ScalingProcesses parameter.

Note that if you suspend either the Launch or Terminate process types, it can prevent other process types from functioning properly.
To resume processes that have been suspended, use `ResumeProcesses`.

For more information, see Suspend and Resume Auto Scaling Processes in the Auto Scaling Developer Guide.

**Request Syntax**

```python
terminate_instance_in_auto_scaling_group(**kwargs)
```

This call simply makes a termination request. The instances is not terminated immediately.

**Parameters**

- **InstanceId (string)** – [REQUIRED]
  The ID of the EC2 instance.
- **ShouldDecrementDesiredCapacity (boolean)** – [REQUIRED]
  If `true`, terminating this instance also decrements the size of the Auto Scaling group.

**Returns**

**Response Syntax**

```python
{
    'Activity': {
        'ActivityId': 'string',
        'AutoScalingGroupName': 'string',
```
'Description': 'string',
'Cause': 'string',
'StartTime': datetime(2015, 1, 1),
'EndTime': datetime(2015, 1, 1),
'StatusCode': 'WaitingForSpotInstanceRequestId'|'WaitingForSpotInstanceId'|'WaitingForInstanceId'|'PreInService'|'InProgress'|'WaitingForELBConnectionDraining'|'MidLifecycleAction'|'WaitingForInstanceWarmup'|'Successful'|'Failed'|'Cancelled',
'StatusMessage': 'string',
'Progress': 123,
'Details': 'string'
}
}

Response Structure

• (dict) –
  – Activity (dict) –
     A scaling activity.
       • ActivityId (string) –
           The ID of the activity.
       • AutoScalingGroupName (string) –
           The name of the Auto Scaling group.
       • Description (string) –
           A friendly, more verbose description of the activity.
       • Cause (string) –
           The reason the activity began.
       • StartTime (datetime) –
           The start time of the activity.
       • EndTime (datetime) –
           The end time of the activity.
       • StatusCode (string) –
           The current status of the activity.
       • StatusMessage (string) –
           A friendly, more verbose description of the activity status.
       • Progress (integer) –
           A value between 0 and 100 that indicates the progress of the activity.
       • Details (string) –
           The details about the activity.

update_auto_scaling_group(**kwargs)

Updates the configuration for the specified Auto Scaling group.

To update an Auto Scaling group with a launch configuration with InstanceMonitoring set to False, you must first disable the collection of group metrics. Otherwise, you will get an error. If you have previously enabled the collection of group metrics, you can disable it using DisableMetricsCollection.

The new settings are registered upon the completion of this call. Any launch configuration settings take effect on any triggers after this call returns. Scaling activities that are currently in progress aren’t affected.

Note the following:

• If you specify a new value for MinSize without specifying a value for DesiredCapacity, and the new MinSize is larger than the current size of the group, we implicitly call SetDesiredCapacity to set the size of the group to the new value of MinSize.
• If you specify a new value for MaxSize without specifying a value for DesiredCapacity, and the new MaxSize is smaller than the current size of the group, we implicitly call SetDesiredCapacity to set the size of the group to the new value of MaxSize.

• All other optional parameters are left unchanged if not specified.

Request Syntax

```python
response = client.update_auto_scaling_group(
    AutoScalingGroupName='string',
    LaunchConfigurationName='string',
    MinSize=123,
    MaxSize=123,
    DesiredCapacity=123,
    DefaultCooldown=123,
    AvailabilityZones=[
        'string',
    ],
    HealthCheckType='string',
    HealthCheckGracePeriod=123,
    PlacementGroup='string',
    VPCZoneIdentifier='string',
    TerminationPolicies=[
        'string',
    ]
)
```

Parameters

- **AutoScalingGroupName (string)** – [REQUIRED]
  
  The name of the Auto Scaling group.

- **LaunchConfigurationName (string)** – The name of the launch configuration.

- **MinSize (integer)** – The minimum size of the Auto Scaling group.

- **MaxSize (integer)** – The maximum size of the Auto Scaling group.

- **DesiredCapacity (integer)** – The number of EC2 instances that should be running in the Auto Scaling group. This number must be greater than or equal to the minimum size of the group and less than or equal to the maximum size of the group.

- **DefaultCooldown (integer)** – The amount of time, in seconds, after a scaling activity completes before another scaling activity can start. For more information, see Understanding Auto Scaling Cooldowns.

- **AvailabilityZones (list)** – One or more Availability Zones for the group. (string)

- **HealthCheckType (string)** – The type of health check for the instances in the Auto Scaling group. The health check type can either be EC2 for Amazon EC2 or ELB for Elastic Load Balancing.

- **HealthCheckGracePeriod (integer)** – The amount of time, in seconds, that Auto Scaling waits before checking the health status of an instance. The grace period begins when the instance passes the system status and instance status checks from Amazon EC2. For more information, see ‘

- **PlacementGroup (string)** – The name of the placement group into which you’ll launch your instances, if any. For more information, see Placement Groups.

- **VPCZoneIdentifier (string)** – The ID of the subnet, if you are launching into a VPC. You can specify several subnets in a comma-separated list.

When you specify VPCZoneIdentifier with AvailabilityZones, ensure that the subnets’ Availability Zones match the values you specify for AvailabilityZones.
For more information, see Auto Scaling and Amazon Virtual Private Cloud in the Auto Scaling Developer Guide.

- **TerminationPolicies** *(list)* – A standalone termination policy or a list of termination policies used to select the instance to terminate. The policies are executed in the order that they are listed.
  
  For more information, see Choosing a Termination Policy for Your Auto Scaling Group in the Auto Scaling Developer Guide.

  - *(string)* –

  Returns None

### Paginators

The available paginators are:

- `AutoScaling.Paginator.DescribeAutoScalingGroups`
- `AutoScaling.Paginator.DescribeAutoScalingInstances`
- `AutoScaling.Paginator.DescribeLaunchConfigurations`
- `AutoScaling.Paginator.DescribeNotificationConfigurations`
- `AutoScaling.Paginator.DescribePolicies`
- `AutoScaling.Paginator.DescribeScalingActivities`
- `AutoScaling.Paginator.DescribeScheduledActions`
- `AutoScaling.Paginator.DescribeTags`

```python
class AutoScaling.Paginator.DescribeAutoScalingGroups

paginator = client.get_paginator('describe_auto_scaling_groups')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `AutoScaling.Client.describe_auto_scaling_groups()`.

#### Request Syntax

```python
response_iterator = paginator.paginate(
    AutoScalingGroupNames=[
        'string',
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

#### Parameters

- **AutoScalingGroupNames** *(list)* – The group names.
  - *(string)* –

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
- **MaxItems (integer)** –

  The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.

- **PageSize (integer)** –

  The size of each page.

- **StartingToken (string)** –

  A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'AutoScalingGroups': [
        {
            'AutoScalingGroupName': 'string',
            'AutoScalingGroupARN': 'string',
            'LaunchConfigurationName': 'string',
            'MinSize': 123,
            'MaxSize': 123,
            'DesiredCapacity': 123,
            'DefaultCooldown': 123,
            'AvailabilityZones': [
                'string',
            ],
            'LoadBalancerNames': [
                'string',
            ],
            'HealthCheckType': 'string',
            'HealthCheckGracePeriod': 123,
            'Instances': [
                {
                    'InstanceId': 'string',
                    'AvailabilityZone': 'string',
                    'LifecycleState': 'Pending'|'Pending:Wait'|'Pending:Proceed'|'Quarantined'|'InService'|'Terminating'|'Terminating:Wait'|'Terminating:Proceed'|'Terminated'|'Detaching'|'Detached'|'EnteringStandby'|'Standby',
                    'HealthStatus': 'string',
                    'LaunchConfigurationName': 'string',
                }
            ],
            'CreatedTime': datetime(2015, 1, 1),
            'SuspendedProcesses': [
                {
                    'ProcessName': 'string',
                    'SuspensionReason': 'string'
                }
            ],
            'PlacementGroup': 'string',
            'VPCZoneIdentifier': 'string',
            'EnabledMetrics': [
                {
                    'Metric': 'string',
                    'Granularity': 'string'
                }
            ],
        }
    ],
    '3.1. Services 99'
}
'Status': 'string',
'Tags': [
    {
        'ResourceId': 'string',
        'ResourceType': 'string',
        'Key': 'string',
        'Value': 'string',
        'PropagateAtLaunch': True|False
    },
],
'TerminationPolicies': [
    'string',
],
],

Response Structure

• (dict) –
  – AutoScalingGroups (list) –

The groups.

* (dict) –

  Describes an Auto Scaling group.
  • AutoScalingGroupName (string) –
    The name of the group.
  • AutoScalingGroupARN (string) –
    The Amazon Resource Name (ARN) of the group.
  • LaunchConfigurationName (string) –
    The name of the associated launch configuration.
  • MinSize (integer) –
    The minimum size of the group.
  • MaxSize (integer) –
    The maximum size of the group.
  • DesiredCapacity (integer) –
    The desired size of the group.
  • DefaultCooldown (integer) –
    The number of seconds after a scaling activity completes before any further scaling activities can start.
  • AvailabilityZones (list) –
    One or more Availability Zones for the group.
  • (string) –
    • LoadBalancerNames (list) –
      One or more load balancers associated with the group.
  • (string) –
    • HealthCheckType (string) –
      The service of interest for the health status check, which can be either EC2 for Amazon EC2 or ELB for Elastic Load Balancing.
- **HealthCheckGracePeriod** *(integer)* –
  The amount of time that Auto Scaling waits before checking an instance’s health status. The grace period begins when an instance comes into service.

- **Instances** *(list)* –
  The EC2 instances associated with the group.
  *(dict)* –
  Describes an EC2 instance.
  - **InstanceId** *(string)* –
    The ID of the instance.
  - **AvailabilityZone** *(string)* –
    The Availability Zone in which the instance is running.
  - **LifecycleState** *(string)* –
    A description of the current lifecycle state. Note that the Quarantined state is not used.
  - **HealthStatus** *(string)* –
    The health status of the instance.
  - **LaunchConfigurationName** *(string)* –
    The launch configuration associated with the instance.
  - **CreatedTime** *(datetime)* –
    The date and time the group was created.
  - **SuspendedProcesses** *(list)* –
    The suspended processes associated with the group.
    *(dict)* –
    Describes an Auto Scaling process that has been suspended. For more information, see ProcessType.
  - **ProcessName** *(string)* –
    The name of the suspended process.
  - **SuspensionReason** *(string)* –
    The reason that the process was suspended.
  - **PlacementGroup** *(string)* –
    The name of the placement group into which you’ll launch your instances, if any. For more information, see Placement Groups.
  - **VPCZoneIdentifier** *(string)* –
    One or more subnet IDs, if applicable, separated by commas.

If you specify VPCZoneIdentifier and AvailabilityZones, ensure that the Availability Zones of the subnets match the values for AvailabilityZones.

- **EnabledMetrics** *(list)* –
  The metrics enabled for the group.
  *(dict)* –
  Describes an enabled metric.
· **Metric** *(string)* –
  The name of the metric.
· GroupMinSize
· GroupMaxSize
· GroupDesiredCapacity
· GroupInServiceInstances
· GroupPendingInstances
· GroupStandbyInstances
· GroupTerminatingInstances
· GroupTotalInstances
· **Granularity** *(string)* –
  The granularity of the metric. The only valid value is `1Minute`.
· **Status** *(string)* –
  The current state of the group when `DeleteAutoScalingGroup` is in progress.
· **Tags** *(list)* –
  The tags for the group.
  *(dict)* –
  Describes a tag for an Auto Scaling group.
· **ResourceId** *(string)* –
  The name of the group.
· **ResourceType** *(string)* –
  The type of resource. The only supported value is `auto-scaling-group`.
· **Key** *(string)* –
  The tag key.
· **Value** *(string)* –
  The tag value.
· **PropagateAtLaunch** *(boolean)* –
  Determines whether the tag is added to new instances as they are launched in the group.
· **TerminationPolicies** *(list)* –
  The termination policies for the group.
  *(string)* –

```python
class AutoScaling.Paginator.DescribeAutoScalingInstances

paginator = client.get_paginator('describe_auto_scaling_instances')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `AutoScaling.Client.describe_auto_scaling_instances()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    InstanceIds=[
```
Parameters

- **InstanceIds** *(list)* – One or more Auto Scaling instances to describe, up to 50 instances. If you omit this parameter, all Auto Scaling instances are described. If you specify an ID that does not exist, it is ignored with no error.
  - *(string)* –
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* – The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* – The size of each page.
  - **StartingToken** *(string)* – A token to specify where to start paginating. This is the `NextToken` from a previous response.

Return type  **dict**

Returns

Response Syntax

```python
{
    'AutoScalingInstances': [
    {
        'InstanceId': 'string',
        'AutoScalingGroupName': 'string',
        'AvailabilityZone': 'string',
        'LifecycleState': 'string',
        'HealthStatus': 'string',
        'LaunchConfigurationName': 'string'
    },
    ],
}
```

Response Structure

- *(dict)* –
  - **AutoScalingInstances** *(list)* – The instances.
    - *(dict)* –
      - **InstanceId** *(string)* – Describes an EC2 instance associated with an Auto Scaling group.
        - **InstanceId** *(string)* – The ID of the instance.
- **AutoScalingGroupName** *(string)* –
  The name of the Auto Scaling group associated with the instance.
- **AvailabilityZone** *(string)* –
  The Availability Zone for the instance.
- **LifecycleState** *(string)* –
  The lifecycle state for the instance. For more information, see *Auto Scaling Instance States* in the *Auto Scaling Developer Guide*.
- **HealthStatus** *(string)* –
  The health status of this instance. “Healthy” means that the instance is healthy and should remain in service. “Unhealthy” means that the instance is unhealthy and Auto Scaling should terminate and replace it.
- **LaunchConfigurationName** *(string)* –
  The launch configuration associated with the instance.

```python
class AutoScaling.Paginator.DescribeLaunchConfigurations

paginator = client.get_paginator('describe_launch_configurations')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `AutoScaling.Client.describe_launch_configurations()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    LaunchConfigurationNames=[
        'string',
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **LaunchConfigurationNames** *(list)* – The launch configuration names.
  - *(string)* –
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –
    The size of each page.
  - **StartingToken** *(string)* –
A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'LaunchConfigurations': [
        {
            'LaunchConfigurationName': 'string',
            'LaunchConfigurationARN': 'string',
            'ImageId': 'string',
            'KeyName': 'string',
            'SecurityGroups': [
                'string',
            ],
            'ClassicLinkVPCId': 'string',
            'ClassicLinkVPCSecurityGroups': [
                'string',
            ],
            'UserData': 'string',
            'InstanceType': 'string',
            'KernelId': 'string',
            'RamdiskId': 'string',
            'UserData': 'string',
            'InstanceMonitoring': {
                'Enabled': True|False,
            },
            'SpotPrice': 'string',
            'IamInstanceProfile': 'string',
            'CreatedTime': datetime(2015, 1, 1),
            'EbsOptimized': True|False,
            'AssociatePublicIpAddress': True|False,
            'PlacementTenancy': 'string'
        },
    ],
}
```

**Response Structure**

- *(dict)*
  - **LaunchConfigurations** *(list)*
    - The launch configurations.
Describes a launch configuration.

- **LaunchConfigurationName** *(string)*
  The name of the launch configuration.

- **LaunchConfigurationARN** *(string)*
  The Amazon Resource Name (ARN) of the launch configuration.

- **ImageId** *(string)*
  The ID of the Amazon Machine Image (AMI).

- **KeyName** *(string)*
  The name of the key pair.

- **SecurityGroups** *(list)*
  The security groups to associate with the instances.

- **InstanceType** *(string)*
  The instance type for the instances.

- **KernelId** *(string)*
  The ID of the kernel associated with the AMI.

- **RamdiskId** *(string)*
  The ID of the RAM disk associated with the AMI.

- **BlockDeviceMappings** *(list)*
  A block device mapping, which specifies the block devices for the instance.

- **VirtualName** *(string)*
  The name of the virtual device, ephemeral0 to ephemeral3.

- **DeviceName** *(string)*
  The device name exposed to the EC2 instance (for example, /dev/sdh or xvdh).
· **Ebs (dict)** –
  The information about the Amazon EBS volume.
  · **SnapshotId (string)** –
    The ID of the snapshot.
  · **VolumeSize (integer)** –
    The volume size, in gigabytes.
    Valid values: If the volume type is `io1`, the minimum size of the volume is 10 GiB. If you specify `SnapshotId` and `VolumeSize`, `VolumeSize` must be equal to or larger than the size of the snapshot.
    Default: If you create a volume from a snapshot and you don’t specify a volume size, the default is the size of the snapshot.
    Required: Required when the volume type is `io1`.
  · **VolumeType (string)** –
    The volume type.
    Valid values: `standard` | `io1` | `gp2`
    Default: `standard`
  · **DeleteOnTermination (boolean)** –
    Indicates whether to delete the volume on instance termination.
    Default: `true`
  · **iops (integer)** –
    For Provisioned IOPS (SSD) volumes only. The number of I/O operations per second (IOPS) to provision for the volume.
    Valid values: Range is 100 to 4000.
    Default: None
  · **NoDevice (boolean)** –
    Suppresses a device mapping.
    If this parameter is true for the root device, the instance might fail the EC2 health check. Auto Scaling launches a replacement instance if the instance fails the health check.
  · **InstanceMonitoring (dict)** –
    Controls whether instances in this group are launched with detailed monitoring.
  · **Enabled (boolean)** –
    If `True`, instance monitoring is enabled.
  · **SpotPrice (string)** –
    The price to bid when launching Spot Instances.
  · **IamInstanceProfile (string)** –
    The name or Amazon Resource Name (ARN) of the instance profile associated with the IAM role for the instance.
  · **CreatedTime (datetime)** –
    The creation date and time for the launch configuration.
· **EbsOptimized** *(boolean)* –
  Controls whether the instance is optimized for EBS I/O *(true)* or not *(false)*.

· **AssociatePublicIpAddress** *(boolean)* –
  Specifies whether the instances are associated with a public IP address *(true)* or not *(false)*.

· **PlacementTenancy** *(string)* –
  The tenancy of the instance, either *default* or *dedicated*. An instance with *dedicated* tenancy runs in an isolated, single-tenant hardware and can only be launched into a VPC.

```python
class AutoScaling.Paginator.DescribeNotificationConfigurations

paginator = client.get_paginator('describe_notification_configurations')

paginate(**kwargs)
Creates an iterator that will paginate through responses from
AutoScaling.Client.describe_notification_configurations().

Request Syntax

response_iterator = paginator.paginate(
    AutoScalingGroupNames=[
        'string',
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **AutoScalingGroupNames** *(list)* – The name of the group.
  - *(string)* –

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –
    The size of each page.
  - **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  **dict**

Returns

**Response Syntax**
{  
  'NotificationConfigurations': [  
    {  
      'AutoScalingGroupName': 'string',  
      'TopicARN': 'string',  
      'NotificationType': 'string'  
    },  
  ],  
}

Response Structure
* (dict) –
  – **NotificationConfigurations** (list) –

The notification configurations.
* (dict) –

  Describes a notification.
  · **AutoScalingGroupName** (string) –

    The name of the group.
  · **TopicARN** (string) –

    The Amazon Resource Name (ARN) of the Amazon Simple Notification Service (SNS) topic.
  · **NotificationType** (string) –

    The types of events for an action to start.
    · autoscaling:EC2_INSTANCE_LAUNCH
    · autoscaling:EC2_INSTANCE_LAUNCH_ERROR
    · autoscaling:EC2_INSTANCE_TERMINATE
    · autoscaling:EC2_INSTANCE_TERMINATE_ERROR
    · autoscaling:TEST_NOTIFICATION

class AutoScaling.Paginator.DescribePolicies

paginator = client.get_paginator('describe_policies')

**paginate** (**kwargs)

Creates an iterator that will paginate through responses from `AutoScaling.Client.describe_policies()`.

Request Syntax

response_iterator = paginator.paginate(
  AutoScalingGroupName='string',
  PolicyNames=['string',
               'string'],
  PolicyTypes=['string',
               'string'],
  PaginationConfig={
    'MaxItems': 123,
    'PageSize': 123,
    'StartingToken': 'string'  
}
Parameters

- **AutoScalingGroupName** *(string)* – The name of the group.
- **PolicyNames** *(list)* – One or more policy names or policy ARNs to be described. If you omit this list, all policy names are described. If an group name is provided, the results are limited to that group. This list is limited to 50 items. If you specify an unknown policy name, it is ignored with no error.
  - *(string)*
- **PolicyTypes** *(list)* – One or more policy types. Valid values are `SimpleScaling` and `StepScaling`.
  - *(string)*
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* – The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* – The size of each page.
  - **StartingToken** *(string)* – A token to specify where to start paginating. This is the `NextToken` from a previous response.

Return type  *dict*

Returns

**Response Syntax**

```python
{
    'ScalingPolicies': [
        {
            'AutoScalingGroupName': 'string',
            'PolicyName': 'string',
            'PolicyARN': 'string',
            'PolicyType': 'string',
            'AdjustmentType': 'string',
            'MinAdjustmentStep': 123,
            'MinAdjustmentMagnitude': 123,
            'ScalingAdjustment': 123,
            'Cooldown': 123,
            'StepAdjustments': [*
                {
                    'MetricIntervalLowerBound': 123.0,
                    'MetricIntervalUpperBound': 123.0,
                    'ScalingAdjustment': 123
                },
            ],
            'MetricAggregationType': 'string',
            'EstimatedInstanceWarmup': 123,
            'Alarms': [*
                {
                    'AlarmName': 'string',
                    'AlarmARN': 'string'
                },
            ],
        }
    ]
}
```
Response Structure

- (dict)
  - ScalingPolicies (list)
    The scaling policies.
      - (dict)
        Describes a scaling policy.
          - AutoScalingGroupName (string)
            The name of the Auto Scaling group associated with this scaling policy.
          - PolicyName (string)
            The name of the scaling policy.
          - PolicyARN (string)
            The Amazon Resource Name (ARN) of the policy.
          - PolicyType (string)
            The policy type. Valid values are SimpleScaling and StepScaling.
          - AdjustmentType (string)
            The adjustment type, which specifies how ScalingAdjustment is interpreted. Valid values are ChangeInCapacity, ExactCapacity, and PercentChangeInCapacity.
          - MinAdjustmentStep (integer)
            Available for backward compatibility. Use MinAdjustmentMagnitude instead.
          - MinAdjustmentMagnitude (integer)
            The minimum number of instances to scale. If the value of AdjustmentType is PercentChangeInCapacity, the scaling policy changes the DesiredCapacity of the Auto Scaling group by at least this many instances. Otherwise, the error is ValidationError.
          - ScalingAdjustment (integer)
            The amount by which to scale, based on the specified adjustment type. A positive value adds to the current capacity while a negative number removes from the current capacity.
          - Cooldown (integer)
            The amount of time, in seconds, after a scaling activity completes before any further trigger-related scaling activities can start.
          - StepAdjustments (list)
            A set of adjustments that enable you to scale based on the size of the alarm breach.
· (dict) –

  Describes an adjustment based on the difference between the value of the aggregated CloudWatch metric and the breach threshold that you’ve defined for the alarm.

For the following examples, suppose that you have an alarm with a breach threshold of 50:
· If you want the adjustment to be triggered when the metric is greater than or equal to 50 and less than 60, specify a lower bound of 0 and an upper bound of 10.
· If you want the adjustment to be triggered when the metric is greater than 40 and less than or equal to 50, specify a lower bound of -10 and an upper bound of 0.

There are a few rules for the step adjustments for your step policy:
· The ranges of your step adjustments can’t overlap or have a gap.
· At most one step adjustment can have a null lower bound. If one step adjustment has a negative lower bound, then there must be a step adjustment with a null lower bound.
· At most one step adjustment can have a null upper bound. If one step adjustment has a positive upper bound, then there must be a step adjustment with a null upper bound.
· The upper and lower bound can’t be null in the same step adjustment.

· MetricIntervalLowerBound (float) –

  The lower bound for the difference between the alarm threshold and the CloudWatch metric. If the metric value is above the breach threshold, the lower bound is inclusive (the metric must be greater than or equal to the threshold plus the lower bound). Otherwise, it is exclusive (the metric must be greater than the threshold plus the lower bound). A null value indicates negative infinity.

· MetricIntervalUpperBound (float) –

  The upper bound for the difference between the alarm threshold and the CloudWatch metric. If the metric value is above the breach threshold, the upper bound is exclusive (the metric must be less than the threshold plus the upper bound). Otherwise, it is inclusive (the metric must be less than or equal to the threshold plus the upper bound). A null value indicates positive infinity.

  The upper bound must be greater than the lower bound.

· ScalingAdjustment (integer) –

  The amount by which to scale, based on the specified adjustment type. A positive value adds to the current capacity while a negative number removes from the current capacity.

· MetricAggregationType (string) –

  The aggregation type for the CloudWatch metrics. Valid values are Minimum, Maximum, and Average.

· EstimatedInstanceWarmup (integer) –

  The estimated time, in seconds, until a newly launched in-
A Boto3 instance can contribute to the CloudWatch metrics.

- **Alarms** *(list)* –
  The CloudWatch alarms related to the policy.

- **alarm** *(dict)* –
  Describes an alarm.

  - **AlarmName** *(string)* –
    The name of the alarm.

  - **AlarmARN** *(string)* –
    The Amazon Resource Name (ARN) of the alarm.

```python
class AutoScaling.Paginator.DescribeScalingActivities

    paginator = client.get_paginator('describe_scaling_activities')
    paginate(**kwargs)

    Creates an iterator that will paginate through responses from
    AutoScaling.Client.describe_scaling_activities().

    Request Syntax

    response_iterator = paginator.paginate(
        ActivityIds=[
            'string',
        ],
        AutoScalingGroupName='string',
        PaginationConfig={
            'MaxItems': 123,
            'PageSize': 123,
            'StartingToken': 'string'
        }
    )

    Parameters

    - **ActivityIds** *(list)* – The activity IDs of the desired scaling activities. If this
      list is omitted, all activities are described. If the
      AutoScalingGroupName parameter is provided, the results are limited to that group. The list of requested
      activities cannot contain more than 50 items. If unknown activities are requested,
      they are ignored with no error.

    - **AutoScalingGroupName** *(string)* – The name of the group.

    - **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pag-
      ination.

        - **MaxItems** *(integer)* –
          The total number of items to return. If the total number of items available
          is more than the value specified in max-items then a NextToken will be
          provided in the output that you can use to resume pagination.

        - **PageSize** *(integer)* –
          The size of each page.

        - **StartingToken** *(string)* –
          A token to specify where to start paginating. This is the NextToken
          from a previous response.
```

3.1. Services 113
Return type: dict

Returns

Response Syntax

```
{
    'Activities': [
        {
            'ActivityId': 'string',
            'AutoScalingGroupName': 'string',
            'Description': 'string',
            'Cause': 'string',
            'StartTime': datetime(2015, 1, 1),
            'EndTime': datetime(2015, 1, 1),
            'StatusCode': 'WaitingForSpotInstanceRequestId'|'WaitingForSpotInstanceId'|'WaitingForInstanceId'|'PreInService'|'InProgress'|'WaitingForELBConnectionDraining'|'MidLifecycleAction'|'WaitingForInstanceWarmup'|'Successful'|'Failed'|'Cancelled',
            'StatusMessage': 'string',
            'Progress': 123,
            'Details': 'string'
        },
    ],
}
```

Response Structure

* (dict) –
  * Activities (list) –

The scaling activities.

* (dict) –

Describes scaling activity, which is a long-running process that represents a change to your Auto Scaling group, such as changing its size or replacing an instance.

- **ActivityId (string)** –
  The ID of the activity.

- **AutoScalingGroupName (string)** –
  The name of the Auto Scaling group.

- **Description (string)** –
  A friendly, more verbose description of the activity.

- **Cause (string)** –
  The reason the activity began.

- **StartTime (datetime)** –
  The start time of the activity.

- **EndTime (datetime)** –
  The end time of the activity.

- **StatusCode (string)** –
  The current status of the activity.

- **StatusMessage (string)** –
  A friendly, more verbose description of the activity status.

- **Progress (integer)** –
  A value between 0 and 100 that indicates the progress of the activity.
class AutoScaling.Paginator.DescribeScheduledActions

```python
paginator = client.get_paginator('describe_scheduled_actions')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `AutoScaling.Client.describe_scheduled_actions()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    AutoScalingGroupName='string',
    ScheduledActionNames=[
        'string',
    ],
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **AutoScalingGroupName** *(string)* – The name of the group.
- **ScheduledActionNames** *(list)* – Describes one or more scheduled actions. If you omit this list, the call describes all scheduled actions. If you specify an unknown scheduled action it is ignored with no error.

You can describe up to a maximum of 50 instances with a single call. If there are more items to return, the call returns a token. To get the next set of items, repeat the call with the returned token in the `NextToken` parameter.

- **StartTime** *(datetime)* – The earliest scheduled start time to return. If scheduled action names are provided, this parameter is ignored.
- **EndTime** *(datetime)* – The latest scheduled start time to return. If scheduled action names are provided, this parameter is ignored.
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –
    The size of each page.
  - **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`
Returns

Response Syntax

```python
{
    'ScheduledUpdateGroupActions': [
        {
            'AutoScalingGroupName': 'string',
            'ScheduledActionName': 'string',
            'ScheduledActionARN': 'string',
            'Time': datetime(2015, 1, 1),
            'StartTime': datetime(2015, 1, 1),
            'EndTime': datetime(2015, 1, 1),
            'Recurrence': 'string',
            'MinSize': 123,
            'MaxSize': 123,
            'DesiredCapacity': 123
        },
    ],
}
```

Response Structure

- *(dict)* –
  - **ScheduledUpdateGroupActions** *(list)* –
    
    The scheduled actions.
    
    * *(dict)* –
      
      Describes a scheduled update to an Auto Scaling group.
      
      - **AutoScalingGroupName** *(string)* –
        
        The name of the group.
      
      - **ScheduledActionName** *(string)* –
        
        The name of the scheduled action.
      
      - **ScheduledActionARN** *(string)* –
        
        The Amazon Resource Name (ARN) of the scheduled action.
      
      - **Time** *(datetime)* –
        
        This parameter is deprecated; use StartTime instead.
      
      - **StartTime** *(datetime)* –
        
        The date and time that the action is scheduled to begin. This date and time can be up to one month in the future.

        When StartTime and EndTime are specified with Recurrence, they form the boundaries of when the recurring action will start and stop.

      - **EndTime** *(datetime)* –
        
        The date and time that the action is scheduled to end. This date and time can be up to one month in the future.
      
      - **Recurrence** *(string)* –
        
        The recurring schedule for the action.
      
      - **MinSize** *(integer)* –
        
        The minimum size of the group.
· **MaxSize** *(integer)* –
  The maximum size of the group.

· **DesiredCapacity** *(integer)* –
  The number of instances you prefer to maintain in the group.

```python
class AutoScaling.Paginator.

paginator = client.get_paginator('describe_tags')
paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `AutoScaling.Client.describe_tags()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    Filters=[
        {
            'Name': 'string',
            'Values': [ 'string',
        ]
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **Filters** *(list)* – A filter used to scope the tags to return.
  - *(dict)* –
    Describes a filter.
    - **Name** *(string)* –
      The name of the filter. The valid values are: "auto-scaling-group", "key", "value", and "propagate-at-launch".
    - **Values** *(list)* –
      The value of the filter.
  - **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
    - **MaxItems** *(integer)* –
      The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
    - **PageSize** *(integer)* –
      The size of each page.
– **StartingToken** *(string)* –

A token to specify where to start paginating. This is the *NextToken* from a previous response.

**Return type**  **dict**

**Returns**

**Response Syntax**

```python
{
    'Tags': [
        {
            'ResourceId': 'string',
            'ResourceType': 'string',
            'Key': 'string',
            'Value': 'string',
            'PropagateAtLaunch': True|False
        },
    ],
}
```

**Response Structure**

- *(dict)* –
  - **Tags** *(list)* –

The tags.

* *(dict)* –

Describes a tag for an Auto Scaling group.

- **ResourceId** *(string)* –

The name of the group.

- **ResourceType** *(string)* –

The type of resource. The only supported value is *auto-scaling-group*.

- **Key** *(string)* –

The tag key.

- **Value** *(string)* –

The tag value.

- **PropagateAtLaunch** *(boolean)* –

Determines whether the tag is added to new instances as they are launched in the group.

**CloudFormation**
Client

class CloudFormation.Client
A low-level client representing AWS CloudFormation:

```python
import boto3

client = boto3.client('cloudformation')
```

These are the available methods:

- `can_paginate()`  
- `cancel_update_stack(**kwargs)`  
- `create_stack()`  
- `delete_stack()`  
- `describe_stack_events()`  
- `describe_stack_resource()`  
- `describe_stack_resources()`  
- `describe_stacks()`  
- `estimate_template_cost()`  
- `generate_presigned_url()`  
- `get_paginator()`  
- `get_stack_policy()`  
- `get_template()`  
- `get_template_summary()`  
- `get_waiter()`  
- `list_stack_resources()`  
- `list_stacks()`  
- `set_stack_policy()`  
- `signal_resource()`  
- `update_stack()`  
- `validate_template()`

can_paginate(operation_name)
Check if an operation can be paginated.

Parameters:
operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get Paginator("create_foo")`.

Returns:
True if the operation can be paginated, False otherwise.

cancel_update_stack(**kwargs)
Cancels an update on the specified stack. If the call completes successfully, the stack will roll back the
update and revert to the previous stack configuration.

**Note:** Only stacks that are in the UPDATE_IN_PROGRESS state can be canceled.

### Request Syntax

```python
response = client.cancel_update_stack(
    StackName='string'
)
```

**Parameters StackName** *(string) – [REQUIRED]*

The name or the unique stack ID that is associated with the stack.

**Returns** None

### create_stack(**kwargs)**

Creates a stack as specified in the template. After the call completes successfully, the stack creation starts.
You can check the status of the stack via the DescribeStacks API.

### Request Syntax

```python
response = client.create_stack(
    StackName='string',
    TemplateBody='string',
    TemplateURL='string',
    Parameters=[
        {
            'ParameterKey': 'string',
            'ParameterValue': 'string',
            'UsePreviousValue': True|False
        },
    ],
    DisableRollback=True|False,
    TimeoutInMinutes=123,
    NotificationARNs=[
        'string',
    ],
    Capabilities=[
        'CAPABILITY_IAM',
    ],
    OnFailure='DO_NOTHING'|'ROLLBACK'|'DELETE',
    StackPolicyBody='string',
    StackPolicyURL='string',
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

**Parameters**

- **StackName** *(string) – [REQUIRED]*

  The name that is associated with the stack. The name must be unique in the region in which you are creating the stack.

**Note:** A stack name can contain only alphanumeric characters (case sensitive)
and hyphens. It must start with an alphabetic character and cannot be longer than 255 characters.

- **TemplateBody (string)** – Structure containing the template body with a minimum length of 1 byte and a maximum length of 51,200 bytes. For more information, go to Template Anatomy in the AWS CloudFormation User Guide.

Conditional: You must specify either the TemplateBody or the TemplateURL parameter, but not both.

- **TemplateURL (string)** – Location of file containing the template body. The URL must point to a template (max size: 460,800 bytes) located in an S3 bucket in the same region as the stack. For more information, go to the Template Anatomy in the AWS CloudFormation User Guide.

Conditional: You must specify either the TemplateBody or the TemplateURL parameter, but not both.

- **Parameters (list)** – A list of Parameter structures that specify input parameters for the stack.
  - (dict)

  The Parameter data type.
  
  - **ParameterKey (string)** –
    
    The key associated with the parameter. If you don’t specify a key and value for a particular parameter, AWS CloudFormation uses the default value that is specified in your template.
  
  - **ParameterValue (string)** –
    
    The value associated with the parameter.
  
  - **UsePreviousValue (boolean)** –
    
    During a stack update, use the existing parameter value that the stack is using for a given parameter key. If you specify true, do not specify a parameter value.

- **DisableRollback (boolean)** – Set to true to disable rollback of the stack if stack creation failed. You can specify either DisableRollback or OnFailure, but not both.

Default: false

- **TimeoutInMinutes (integer)** – The amount of time that can pass before the stack status becomes CREATE_FAILED; if DisableRollback is not set or is set to false, the stack will be rolled back.

- **NotificationARNs (list)** – The Simple Notification Service (SNS) topic ARNs to publish stack related events. You can find your SNS topic ARNs using the SNS console or your Command Line Interface (CLI).
  
  - (string)

- **Capabilities (list)** – A list of capabilities that you must specify before AWS CloudFormation can create or update certain stacks. Some stack templates might include resources that can affect permissions in your AWS account. For those stacks, you must explicitly acknowledge their capabilities by specifying this parameter.

Currently, the only valid value is CAPABILITY_IAM, which is required for the following resources: AWS::IAM::AccessKey, AWS::IAM::Group, AWS::IAM::InstanceProfile, AWS::IAM::Policy, AWS::IAM::Role, AWS::IAM::User, and AWS::IAM::UserToGroupAddition. If your stack template contains these resources, we recommend that you review any permissions associated with them. If you don’t specify this parameter, this action returns an
InsufficientCapabilities error.
   – (string) –

• **OnFailure** *(string)* – Determines what action will be taken if stack creation fails. This must be one of: DO NOTHING, ROLLBACK, or DELETE. You can specify either **OnFailure** or **DisableRollback**, but not both.

  Default: ROLLBACK

• **StackPolicyBody** *(string)* – Structure containing the stack policy body. For more information, go to Prevent Updates to Stack Resources in the AWS CloudFormation User Guide. You can specify either the **StackPolicyBody** or the **StackPolicyURL** parameter, but not both.

• **StackPolicyURL** *(string)* – Location of a file containing the stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. You can specify either the **StackPolicyBody** or the **StackPolicyURL** parameter, but not both.

• **Tags** *(list)* – A set of user-defined Tags to associate with this stack, represented by key/value pairs. Tags defined for the stack are propagated to EC2 resources that are created as part of the stack. A maximum number of 10 tags can be specified.

  – (dict) –

  The Tag type is used by CreateStack in the Tags parameter. It allows you to specify a key/value pair that can be used to store information related to cost allocation for an AWS CloudFormation stack.

  * **Key** *(string)* –

    Required. A string used to identify this tag. You can specify a maximum of 128 characters for a tag key. Tags owned by Amazon Web Services (AWS) have the reserved prefix: aws:

  * **Value** *(string)* –

    Required. A string containing the value for this tag. You can specify a maximum of 256 characters for a tag value.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'StackId': 'string'
}
```

**Response Structure**

• (dict) –

  The output for a CreateStack action.

  – **StackId** *(string)* –

    Unique identifier of the stack.

**delete_stack** (**kwargs**)

Deletes a specified stack. Once the call completes successfully, stack deletion starts. Deleted stacks do not show up in the DescribeStacks API if the deletion has been completed successfully.

**Request Syntax**

```python
response = client.delete_stack(
    StackName='string'
)
```
Parameters  **StackName** *(string)* – [REQUIRED]

The name or the unique stack ID that is associated with the stack.

Returns  None

**describe_stack_events** (**kwargs**)

Returns all stack related events for a specified stack. For more information about a stack’s event history, go to Stacks in the AWS CloudFormation User Guide.

**Note:** You can list events for stacks that have failed to create or have been deleted by specifying the unique stack identifier (stack ID).

Request Syntax

```python
response = client.describe_stack_events(
    StackName='string',
    NextToken='string'
)
```

Parameters

- **StackName** *(string)* – The name or the unique stack ID that is associated with the stack, which are not always interchangeable:
  - Running stacks: You can specify either the stack’s name or its unique stack ID.
  - Deleted stacks: You must specify the unique stack ID.
  Default: There is no default value.

- **NextToken** *(string)* – String that identifies the start of the next list of events, if there is one.
  Default: There is no default value.

Return type  dict

Returns

Response Syntax

```python
{
    'StackEvents': [
        {
            'StackId': 'string',
            'EventId': 'string',
            'StackName': 'string',
            'LogicalResourceId': 'string',
            'PhysicalResourceId': 'string',
            'ResourceType': 'string',
            'Timestamp': datetime(2015, 1, 1),
            'ResourceStatus': 'CREATE_IN_PROGRESS'|'CREATE_FAILED'|'CREATE_COMPLETE'|'DELETE_IN_PROGRESS'|'DELETE_FAILED'|'DELETE_COMPLETE'|'DELETE_SKIPPED'|'UPDATE_IN_PROGRESS'|'UPDATE_FAILED'|'UPDATE_COMPLETE',
            'ResourceStatusReason': 'string',
            'ResourceProperties': 'string'
        },
    ],
    'NextToken': 'string'
}
```

Response Structure

- *(dict)* –

  The output for a DescribeStackEvents action.
– **StackEvents** *(list)* –

A list of **StackEvents** structures.

* *(dict)* –

The StackEvent data type.

- **StackId** *(string)* –
  The unique ID name of the instance of the stack.

- **EventId** *(string)* –
  The unique ID of this event.

- **StackName** *(string)* –
  The name associated with a stack.

- **LogicalResourceId** *(string)* –
  The logical name of the resource specified in the template.

- **PhysicalResourceId** *(string)* –
  The name or unique identifier associated with the physical instance of the resource.

- **ResourceType** *(string)* –
  Type of resource. (For more information, go to AWS Resource Types Reference in the AWS CloudFormation User Guide.)

- **Timestamp** *(datetime)* –
  Time the status was updated.

- **ResourceStatus** *(string)* –
  Current status of the resource.

- **ResourceStatusReason** *(string)* –
  Success/failure message associated with the resource.

- **ResourceProperties** *(string)* –
  BLOB of the properties used to create the resource.

– **NextToken** *(string)* –

String that identifies the start of the next list of events, if there is one.

describe_stack_resource(**kwargs)**

Returns a description of the specified resource in the specified stack.

For deleted stacks, DescribeStackResource returns resource information for up to 90 days after the stack has been deleted.

**Request Syntax**

```python
response = client.describe_stack_resource(
    StackName='string',
    LogicalResourceId='string'
)
```

**Parameters**

- **StackName** *(string)* – [REQUIRED]
  The name or the unique stack ID that is associated with the stack, which are not always interchangeable:
  – Running stacks: You can specify either the stack’s name or its unique stack ID.
– Deleted stacks: You must specify the unique stack ID.
  Default: There is no default value.
* **LogicalResourceId** *(string)* – [REQUIRED]

  The logical name of the resource as specified in the template.
  
  Default: There is no default value.

Return type  **dict**

Returns

Response Syntax

```
{
  'StackResourceDetail': {
    'StackName': 'string',
    'StackId': 'string',
    'LogicalResourceId': 'string',
    'PhysicalResourceId': 'string',
    'ResourceType': 'string',
    'LastUpdatedTimestamp': datetime(2015, 1, 1),
    'ResourceStatus': 'CREATE_IN_PROGRESS'|'CREATE_FAILED'|'CREATE_COMPLETE'|'DELETE_IN_PROGRESS'|'DELETE_FAILED'|'DELETE_COMPLETE'|'DELETE_SKIPPED'|'UPDATE_IN_PROGRESS'|'UPDATE_FAILED'|'UPDATE_COMPLETE',
    'ResourceStatusReason': 'string',
    'Description': 'string',
    'Metadata': 'string'
  }
}
```

Response Structure

* **(dict)** –

  The output for a DescribeStackResource action.

  – **StackResourceDetail** *(dict)* –

    A **StackResourceDetail** structure containing the description of the specified resource in the specified stack.

    * **StackName** *(string)* –

      The name associated with the stack.

    * **StackId** *(string)* –

      Unique identifier of the stack.

    * **LogicalResourceId** *(string)* –

      The logical name of the resource specified in the template.

    * **PhysicalResourceId** *(string)* –

      The name or unique identifier that corresponds to a physical instance ID of a resource supported by AWS CloudFormation.

    * **ResourceType** *(string)* –

      Type of resource. (For more information, go to AWS Resource Types Reference in the AWS CloudFormation User Guide.)

    * **LastUpdatedTimestamp** *(datetime)* –

      Time the status was updated.

    * **ResourceStatus** *(string)* –

      Current status of the resource.

    * **ResourceStatusReason** *(string)* –

      Success/failure message associated with the resource.
* Description *(string)* –  
User defined description associated with the resource.

* Metadata *(string)* –  
The JSON format content of the Metadata attribute declared for  
the resource. For more information, see Metadata Attribute in the  
AWS CloudFormation User Guide.

**describe_stack_resources **(****kwargs**)

Returns AWS resource descriptions for running and deleted stacks. If StackName is specified, all the  
associated resources that are part of the stack are returned. If PhysicalResourceId is specified, the  
associated resources of the stack that the resource belongs to are returned.

**Note:** Only the first 100 resources will be returned. If your stack has more resources than this, you  
should use ListStackResources instead.

For deleted stacks, DescribeStackResources returns resource information for up to 90 days after  
the stack has been deleted.

You must specify either StackName or PhysicalResourceId, but not both. In addition, you can  
specify LogicalResourceId to filter the returned result. For more information about resources, the  
LogicalResourceId and PhysicalResourceId, go to the AWS CloudFormation User Guide.

**Note:** A ValidationError is returned if you specify both StackName and  
PhysicalResourceId in the same request.

**Request Syntax**

```python
response = client.describe_stack_resources(
    StackName='string',
    LogicalResourceId='string',
    PhysicalResourceId='string'
)
```

**Parameters**

- **StackName** *(string)* – The name or the unique stack ID that is associated with  
  the stack, which are not always interchangeable:  
  - Running stacks: You can specify either the stack’s name or its unique stack  
    ID.  
  - Deleted stacks: You must specify the unique stack ID.  
    Default: There is no default value.  
    Required: Conditional. If you do not specify StackName, you must specify  
    PhysicalResourceId.

- **LogicalResourceId** *(string)* – The logical name of the resource as specified in  
  the template.  
  Default: There is no default value.

- **PhysicalResourceId** *(string)* – The name or unique identifier that corresponds  
  to a physical instance ID of a resource supported by AWS CloudFormation.  
  For example, for an Amazon Elastic Compute Cloud (EC2) instance,  
  PhysicalResourceId corresponds to the InstanceId. You can pass  
  the EC2 InstanceId to DescribeStackResources to find which stack  
  the instance belongs to and what other resources are part of the stack.
Required: Conditional. If you do not specify PhysicalResourceId, you must specify StackName.

Default: There is no default value.

Return type  dict

Returns

Response Syntax

```
{
'StackResources': [
{
   'StackName': 'string',
   'StackId': 'string',
   'LogicalResourceId': 'string',
   'PhysicalResourceId': 'string',
   'ResourceType': 'string',
   'Timestamp': datetime(2015, 1, 1),
   'ResourceStatus': 'CREATE_IN_PROGRESS'|'CREATE_FAILED'|'CREATE_COMPLETE'|'DELETE_IN_PROGRESS'|'DELETE_FAILED'|'DELETE_COMPLETE'|'DELETE_SKIPPED'|'UPDATE_IN_PROGRESS'|'UPDATE_FAILED'|'UPDATE_COMPLETE',
   'ResourceStatusReason': 'string',
   'Description': 'string'
},
]
}
```

Response Structure

- (dict) –

The output for a DescribeStackResources action.

  - StackResources (list) –

    A list of StackResource structures.

      * (dict) –

      The StackResource data type.

        - StackName (string) –

          The name associated with the stack.

        - StackId (string) –

          Unique identifier of the stack.

        - LogicalResourceId (string) –

          The logical name of the resource specified in the template.

        - PhysicalResourceId (string) –

          The name or unique identifier that corresponds to a physical instance ID of a resource supported by AWS CloudFormation.

        - ResourceType (string) –

          Type of resource. (For more information, go to AWS Resource Types Reference in the AWS CloudFormation User Guide.)

        - Timestamp (datetime) –

          Time the status was updated.

        - ResourceStatus (string) –

          Current status of the resource.

        - ResourceStatusReason (string) –

          Success/failure message associated with the resource.
**Description (string)** –
User defined description associated with the resource.

**describe_stacks (**\*kwargs**)**
Returns the description for the specified stack; if no stack name was specified, then it returns the description for all the stacks created.

**Request Syntax**

```python
response = client.describe_stacks(
    StackName='string',
    NextToken='string'
)
```

**Parameters**

- **StackName (string)** – The name or the unique stack ID that is associated with the stack, which are not always interchangeable:
  - Running stacks: You can specify either the stack’s name or its unique stack ID.
  - Deleted stacks: You must specify the unique stack ID.
  Default: There is no default value.
- **NextToken (string)** – String that identifies the start of the next list of stacks, if there is one.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'Stacks': [
        {
            'StackId': 'string',
            'StackName': 'string',
            'Description': 'string',
            'Parameters': [
                {
                    'ParameterKey': 'string',
                    'ParameterValue': 'string',
                    'UsePreviousValue': True|False
                }
            ],
            'CreationTime': datetime(2015, 1, 1),
            'LastUpdatedTime': datetime(2015, 1, 1),
            'StackStatus': \*\*_ROLLBACK_IN_PROGRESS'|'UPDATE_ROLLBACK_FAILED'|'UPDATE_ROLLBACK_COMPLETE_CLEANUP_IN_PROGRESS'|'UPDATE_ROLLBACK_COMPLETE',
            'StackStatusReason': 'string',
            'DisableRollback': True|False,
            'NotificationARNs': ['string'],
            'TimeoutInMinutes': 123,
            'Capabilities': ['CAPABILITY_IAM'],
            'Outputs': [
                {
                    'OutputKey': 'string',
                    'OutputValue': 'string'
                }
            ]
        }
    ]
}
```
Response Structure

- (dict) –
  The output for a DescribeStacks action.

  - Stacks (list) –
    A list of stack structures.

        * (dict) –
          The Stack data type.

            - StackId (string) –
              Unique identifier of the stack.

            - StackName (string) –
              The name associated with the stack.

            - Description (string) –
              User defined description associated with the stack.

            - Parameters (list) –
              A list of Parameter structures.

            * (dict) –
              The Parameter data type.

                - ParameterKey (string) –
                  The key associated with the parameter. If you don’t specify a key and value for a particular parameter, AWS CloudFormation uses the default value that is specified in your template.

                - ParameterValue (string) –
                  The value associated with the parameter.

                - UsePreviousValue (boolean) –
                  During a stack update, use the existing parameter value that the stack is using for a given parameter key. If you specify true, do not specify a parameter value.

                - CreationTime (datetime) –
                  Time at which the stack was created.

                - LastUpdatedTime (datetime) –
                  The time the stack was last updated. This field will only be returned if the stack has been updated at least once.

                - StackStatus (string) –
                  Current status of the stack.
- **StackStatusReason** *(string)* –
  Success/failure message associated with the stack status.
- **DisableRollback** *(boolean)* –
  Boolean to enable or disable rollback on stack creation failures:
  - `true`: disable rollback
  - `false`: enable rollback
- **NotificationARNs** *(list)* –
  SNS topic ARNs to which stack related events are published.
  - *(string)* –
- **TimeoutInMinutes** *(integer)* –
  The amount of time within which stack creation should complete.
- **Capabilities** *(list)* –
  The capabilities allowed in the stack.
  - *(string)* –
- **Outputs** *(list)* –
  A list of output structures.
  - *(dict)* –
  The Output data type.
- **OutputKey** *(string)* –
  The key associated with the output.
- **OutputValue** *(string)* –
  The value associated with the output.
- **Description** *(string)* –
  User defined description associated with the output.
- **Tags** *(list)* –
  A list of Tags that specify cost allocation information for the stack.
  - *(dict)* –
  The Tag type is used by CreateStack in the Tags parameter. It allows you to specify a key/value pair that can be used to store information related to cost allocation for an AWS CloudFormation stack.
  - **Key** *(string)* –
    *Required*. A string used to identify this tag. You can specify a maximum of 128 characters for a tag key. Tags owned by Amazon Web Services (AWS) have the reserved prefix: `aws:`.
  - **Value** *(string)* –
    *Required*. A string containing the value for this tag. You can specify a maximum of 256 characters for a tag value.
- **NextToken** *(string)* – String that identifies the start of the next list of stacks, if there is one.

**estimate_template_cost(** **kwargs**)**

Returns the estimated monthly cost of a template. The return value is an AWS Simple Monthly Calculator
URL with a query string that describes the resources required to run the template.

**Request Syntax**

```python
response = client.estimate_template_cost(
    TemplateBody='string',
    TemplateURL='string',
    Parameters=[
        {
            'ParameterKey': 'string',
            'ParameterValue': 'string',
            'UsePreviousValue': True|False
        },
    ],
)
```

**Parameters**

- **TemplateBody** (*string*) – Structure containing the template body with a minimum length of 1 byte and a maximum length of 51,200 bytes. (For more information, go to Template Anatomy in the AWS CloudFormation User Guide.)

  Conditional: You must pass `TemplateBody` or `TemplateURL`. If both are passed, only `TemplateBody` is used.

- **TemplateURL** (*string*) – Location of file containing the template body. The URL must point to a template located in an S3 bucket in the same region as the stack. For more information, go to Template Anatomy in the AWS CloudFormation User Guide.

  Conditional: You must pass `TemplateURL` or `TemplateBody`. If both are passed, only `TemplateBody` is used.

- **Parameters** (*list*) – A list of `Parameter` structures that specify input parameters.

  ```
  - (dict) – 
  
  The Parameter data type.
  
  * **ParameterKey** (*string*) –
    
    The key associated with the parameter. If you don’t specify a key and value for a particular parameter, AWS CloudFormation uses the default value that is specified in your template.
  
  * **ParameterValue** (*string*) –
    
    The value associated with the parameter.
  
  * **UsePreviousValue** (*boolean*) –
    
    During a stack update, use the existing parameter value that the stack is using for a given parameter key. If you specify `true`, do not specify a parameter value.
  
**Return type** dict

**Returns**

- **Response Syntax**

  ```
  {
      'Url': 'string'
  }
  ```

**Response Structure**
• (dict) –
  The output for a EstimateTemplateCost action.
  – Url (string) –
    An AWS Simple Monthly Calculator URL with a query string that de-
    scribes the resources required to run the template.

generate_presigned_url (ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)
Generate a presigned url given a client, its method, and arguments

Parameters
  • ClientMethod (string) – The client method to presign for
  • Params (dict) – The parameters normally passed to ClientMethod.
  • ExpiresIn (int) – The number of seconds the presigned url is valid for. By
default it expires in an hour (3600 seconds)
  • HttpMethod (string) – The http method to use on the generated url. By default,
    the http method is whatever is used in the method’s model.

Returns
  The presigned url

get Paginator (operation_name)
Create a paginator for an operation.

Parameters operation_name (string) – The operation name. This is the same name as
the method name on the client. For example, if the method name is create_foo,
and you’d normally invoke the operation as client.create_foo(**kwargs),
if the create_foo operation can be paginated, you can use the call
client.get Paginator("create_foo")

Raises OperationNotPageableError Raised if the operation is not pageable. You can use
the client.canpaginate method to check if an operation is pageable.

Return type L{botocore.paginate.Paginator}
Returns A paginator object.

get_stack_policy(**kwargs)
Returns the stack policy for a specified stack. If a stack doesn’t have a policy, a null value is returned.

Request Syntax

response = client.get_stack_policy(
    StackName='string'
)

Parameters
  StackName (string) – [REQUIRED]
  The name or unique stack ID that is associated with the stack whose policy you want
to get.

Return type
dict
Returns

Response Syntax

{
    'StackPolicyBody': 'string'
}

Response Structure
  • (dict) –
    The output for the GetStackPolicy action.
– **StackPolicyBody** *(string)* –

Structure containing the stack policy body. (For more information, go to Prevent Updates to Stack Resources in the AWS CloudFormation User Guide.)

**get_template** (**kwargs**)

Returns the template body for a specified stack. You can get the template for running or deleted stacks. For deleted stacks, GetTemplate returns the template for up to 90 days after the stack has been deleted.

**Note:** If the template does not exist, a **ValidationError** is returned.

**Request Syntax**

```python
response = client.get_template(
    StackName='string'
)
```

**Parameters**

**StackName** *(string)* – [REQUIRED]

The name or the unique stack ID that is associated with the stack, which are not always interchangeable:
  • Running stacks: You can specify either the stack’s name or its unique stack ID.
  • Deleted stacks: You must specify the unique stack ID.

**Default:** There is no default value.

**Return type**

**dict**

**Returns**

**Response Syntax**

```python
{
    'TemplateBody': 'string'
}
```

**Response Structure**

- *(dict)* –

The output for GetTemplate action.

– **TemplateBody** *(string)* –

Structure containing the template body. (For more information, go to Template Anatomy in the AWS CloudFormation User Guide.)

**get_template_summary** (**kwargs**)

Returns information about a new or existing template. The GetTemplateSummary action is useful for viewing parameter information, such as default parameter values and parameter types, before you create or update a stack.

You can use the GetTemplateSummary action when you submit a template, or you can get template information for a running or deleted stack.

For deleted stacks, GetTemplateSummary returns the template information for up to 90 days after the stack has been deleted. If the template does not exist, a **ValidationError** is returned.

**Request Syntax**

```python
response = client.get_template_summary(
    TemplateBody='string',
    TemplateURL='string',
)
```
StackName='string'

Parameters

- **TemplateBody** *(string)* – Structure containing the template body with a minimum length of 1 byte and a maximum length of 51,200 bytes. For more information about templates, see Template Anatomy in the AWS CloudFormation User Guide.

  Conditional: You must specify only one of the following parameters: StackName, TemplateBody, or TemplateURL.

- **TemplateURL** *(string)* – Location of file containing the template body. The URL must point to a template (max size: 460,800 bytes) located in an Amazon S3 bucket. For more information about templates, see Template Anatomy in the AWS CloudFormation User Guide.

  Conditional: You must specify only one of the following parameters: StackName, TemplateBody, or TemplateURL.

- **StackName** *(string)* – The name or the stack ID that is associated with the stack, which are not always interchangeable. For running stacks, you can specify either the stack’s name or its unique stack ID. For deleted stack, you must specify the unique stack ID.

  Conditional: You must specify only one of the following parameters: StackName, TemplateBody, or TemplateURL.

Return type **dict**

Returns

Response Syntax

```python
{
    'Parameters': [
        {
            'ParameterKey': 'string',
            'DefaultValue': 'string',
            'ParameterType': 'string',
            'NoEcho': True|False,
            'Description': 'string',
            'ParameterConstraints': {
                'AllowedValues': ['string'],
            }
        },
    ],
    'Description': 'string',
    'Capabilities': ['CAPABILITY_IAM'],
    'CapabilitiesReason': 'string',
    'Version': 'string',
    'Metadata': 'string'
}
```

Response Structure

- *(dict)* –

  The output for the GetTemplateSummary action.
– **Parameters** *(list)* –

A list of parameter declarations that describe various properties for each parameter.

* *(dict)* –

The ParameterDeclaration data type.

- **ParameterKey** *(string)* –
  The name that is associated with the parameter.

- **DefaultValue** *(string)* –
  The default value of the parameter.

- **ParameterType** *(string)* –
  The type of parameter.

- **NoEcho** *(boolean)* –
  Flag that indicates whether the parameter value is shown as plain text in logs and in the AWS Management Console.

- **Description** *(string)* –
  The description that is associated with the parameter.

- **ParameterConstraints** *(dict)* –
  The criteria that AWS CloudFormation uses to validate parameter values.

- **AllowedValues** *(list)* –
  A list of values that are permitted for a parameter.

– **Description** *(string)* –

The value that is defined in the Description property of the template.

– **Capabilities** *(list)* –

The capabilities found within the template. Currently, AWS CloudFormation supports only the CAPABILITY_IAM capability. If your template contains IAM resources, you must specify the CAPABILITY_IAM value for this parameter when you use the CreateStack or UpdateStack actions with your template; otherwise, those actions return an InsufficientCapabilities error.

* *(string)* –

– **CapabilitiesReason** *(string)* –

The list of resources that generated the values in the Capabilities response element.

– **Version** *(string)* –

The AWS template format version, which identifies the capabilities of the template.

– **Metadata** *(string)* –

The value that is defined for the Metadata property of the template.

**get_waiter** *(waiter_name)*

**list_stack_resources** *(**kwargs)*

Returns descriptions of all resources of the specified stack.

For deleted stacks, ListStackResources returns resource information for up to 90 days after the stack has been deleted.
Request Syntax

```python
response = client.list_stack_resources(
    StackName='string',
    NextToken='string'
)
```

Parameters

- **StackName (string)** – [REQUIRED]

  The name or the unique stack ID that is associated with the stack, which are not always interchangeable:
  - Running stacks: You can specify either the stack’s name or its unique stack ID.
  - Deleted stacks: You must specify the unique stack ID.

  Default: There is no default value.

- **NextToken (string)** – String that identifies the start of the next list of stack resource summaries, if there is one.

  Default: There is no default value.

Return type  dict

Returns

Response Syntax

```json
{
    'StackResourceSummaries': [
        {
            'LogicalResourceId': 'string',
            'PhysicalResourceId': 'string',
            'ResourceType': 'string',
            'LastUpdatedTimestamp': datetime(2015, 1, 1),
            'ResourceStatus': 'CREATE_IN_PROGRESS'|'CREATE_FAILED'|'CREATE_COMPLETE'|'DELETE_IN_PROGRESS'|'DELETE_FAILED'|'DELETE_COMPLETE'|'DELETE_SKIPPED'|'UPDATE_IN_PROGRESS'|'UPDATE_FAILED'|'UPDATE_COMPLETE',
            'ResourceStatusReason': 'string'
        },
    ],
    'NextToken': 'string'
}
```

Response Structure

- `(dict)` –

  The output for a ListStackResources action.

  - **StackResourceSummaries (list)** –

    A list of StackResourceSummary structures.

      * `(dict)` –

        Contains high-level information about the specified stack resource.

        - **LogicalResourceId (string)** –

          The logical name of the resource specified in the template.

        - **PhysicalResourceId (string)** –

          The name or unique identifier that corresponds to a physical instance ID of the resource.

        - **ResourceType (string)** –
Type of resource. (For more information, go to AWS Resource Types Reference in the AWS CloudFormation User Guide.)

- LastUpdatedTimestamp (datetime)
  Time the status was updated.

- ResourceStatus (string)
  Current status of the resource.

- ResourceStatusReason (string)
  Success/failure message associated with the resource.

- NextToken (string)
  String that identifies the start of the next list of stack resources, if there is one.

list_stacks(**kwargs)
Returns the summary information for stacks whose status matches the specified StackStatusFilter. Summary information for stacks that have been deleted is kept for 90 days after the stack is deleted. If no StackStatusFilter is specified, summary information for all stacks is returned (including existing stacks and stacks that have been deleted).

Request Syntax

```
response = client.list_stacks(
    NextToken='string',
    StackStatusFilter=[
        'CREATE_IN_PROGRESS'|'CREATE_FAILED'|'CREATE_COMPLETE'|'ROLLBACK_IN_PROGRESS'|'ROLLBACK_FAILED'|'ROLLBACK_COMPLETE'|'UPDATE_IN_PROGRESS'|'UPDATE_FAILED'|'UPDATE_COMPLETE'|'UPDATE_ROLLBACK_IN_PROGRESS'|'UPDATE_ROLLBACK_FAILED'|'UPDATE_ROLLBACK_COMPLETE_CLEANUP_IN_PROGRESS'|'UPDATE_ROLLBACK_COMPLETE',
    ]
)
```

Parameters

- NextToken (string) – String that identifies the start of the next list of stacks, if there is one.
  Default: There is no default value.

- StackStatusFilter (list) – Stack status to use as a filter. Specify one or more stack status codes to list only stacks with the specified status codes. For a complete list of stack status codes, see the StackStatus parameter of the Stack data type.

Return type dict

Returns

Response Syntax

```
{
    'StackSummaries': [
        {
            'StackId': 'string',
            'StackName': 'string',
            'TemplateDescription': 'string',
            'CreationTime': datetime(2015, 1, 1),
            'LastUpdatedTime': datetime(2015, 1, 1),
            'DeletionTime': datetime(2015, 1, 1),
            'StackStatus': ... _ROLLBACK_IN_PROGRESS'|'UPDATE_ROLLBACK_FAILED'|'UPDATE_ROLLBACK_COMPLETE_CLEANUP_IN_PROGRESS'|'UPDATE_ROLLBACK_COMPLETE',
            'StackStatusReason': 'string'
        },
    ]
}
```
Response Structure

- (dict) – The output for ListStacks action.
  - StackSummaries (list) – A list of StackSummary structures containing information about the specified stacks.
    * (dict) – The StackSummary Data Type
      - StackId (string) – Unique stack identifier.
      - StackName (string) – The name associated with the stack.
      - TemplateDescription (string) – The template description of the template used to create the stack.
      - CreationTime (datetime) – The time the stack was created.
      - LastUpdatedTime (datetime) – The time the stack was last updated. This field will only be returned if the stack has been updated at least once.
      - DeletionTime (datetime) – The time the stack was deleted.
      - StackStatus (string) – The current status of the stack.
      - StackStatusReason (string) – Success/Failure message associated with the stack status.
    - NextToken (string) – String that identifies the start of the next list of stacks, if there is one.

set_stack_policy(**kwargs)
Sets a stack policy for a specified stack.

Request Syntax

response = client.set_stack_policy(
    StackName='string',
    StackPolicyBody='string',
    StackPolicyURL='string'
)

Parameters

- StackName (string) – [REQUIRED]
  The name or unique stack ID that you want to associate a policy with.
• **StackPolicyBody** (*string*) – Structure containing the stack policy body. For more information, go to Prevent Updates to Stack Resources in the AWS CloudFormation User Guide. You can specify either the `StackPolicyBody` or the `StackPolicyURL` parameter, but not both.

• **StackPolicyURL** (*string*) – Location of a file containing the stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. You can specify either the `StackPolicyBody` or the `StackPolicyURL` parameter, but not both.

**Returns** None

### `signal_resource(**kwargs)`

Sends a signal to the specified resource with a success or failure status. You can use the SignalResource API in conjunction with a creation policy or update policy. AWS CloudFormation doesn’t proceed with a stack creation or update until resources receive the required number of signals or the timeout period is exceeded. The SignalResource API is useful in cases where you want to send signals from anywhere other than an Amazon EC2 instance.

**Request Syntax**

```python
response = client.signal_resource(
    StackName='string',
    LogicalResourceId='string',
    UniqueId='string',
    Status='SUCCESS' | 'FAILURE'
)
```

**Parameters**

- **StackName** (*string*) – [REQUIRED]
  
  The stack name or unique stack ID that includes the resource that you want to signal.

- **LogicalResourceId** (*string*) – [REQUIRED]
  
  The logical ID of the resource that you want to signal. The logical ID is the name of the resource that given in the template.

- **UniqueId** (*string*) – [REQUIRED]
  
  A unique ID of the signal. When you signal Amazon EC2 instances or Auto Scaling groups, specify the instance ID that you are signaling as the unique ID. If you send multiple signals to a single resource (such as signaling a wait condition), each signal requires a different unique ID.

- **Status** (*string*) – [REQUIRED]
  
  The status of the signal, which is either success or failure. A failure signal causes AWS CloudFormation to immediately fail the stack creation or update.

**Returns** None

### `update_stack(**kwargs)`

Updates a stack as specified in the template. After the call completes successfully, the stack update starts. You can check the status of the stack via the DescribeStacks action.

To get a copy of the template for an existing stack, you can use the GetTemplate action.

Tags that were associated with this stack during creation time will still be associated with the stack after an UpdateStack operation.

For more information about creating an update template, updating a stack, and monitoring the progress of the update, see Updating a Stack.

**Request Syntax**
```
response = client.update_stack(
    StackName='string',
    TemplateBody='string',
    TemplateURL='string',
    UsePreviousTemplate=True|False,
    StackPolicyDuringUpdateBody='string',
    StackPolicyDuringUpdateURL='string',
    Parameters=[
        {  
            'ParameterKey': 'string',
            'ParameterValue': 'string',
            'UsePreviousValue': True|False
        },
    ],
    Capabilities=[  
        'CAPABILITY_IAM',
    ],
    StackPolicyBody='string',
    StackPolicyURL='string',
    NotificationARNs=[  
        'string',
    ]
)
```

**Parameters**

- **StackName (string)** – [REQUIRED]
  
  The name or unique stack ID of the stack to update.

- **TemplateBody (string)** – Structure containing the template body with a minimum length of 1 byte and a maximum length of 51,200 bytes. (For more information, go to Template Anatomy in the AWS CloudFormation User Guide.)

  Conditional: You must specify either the TemplateBody or the TemplateURL parameter, but not both.

- **TemplateURL (string)** – Location of file containing the template body. The URL must point to a template located in an S3 bucket in the same region as the stack. For more information, go to Template Anatomy in the AWS CloudFormation User Guide.

  Conditional: You must specify either the TemplateBody or the TemplateURL parameter, but not both.

- **UsePreviousTemplate (boolean)** – Reuse the existing template that is associated with the stack that you are updating.

- **StackPolicyDuringUpdateBody (string)** – Structure containing the temporary overriding stack policy body. You can specify either the StackPolicyDuringUpdateBody or the StackPolicyDuringUpdateURL parameter, but not both.

  If you want to update protected resources, specify a temporary overriding stack policy during this update. If you do not specify a stack policy, the current policy that is associated with the stack will be used.

- **StackPolicyDuringUpdateURL (string)** – Location of a file containing the temporary overriding stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. You can specify either the StackPolicyDuringUpdateBody or the StackPolicyDuringUpdateURL parameter, but not both.

  If you want to update protected resources, specify a temporary overriding stack policy during this update. If you do not specify a stack policy, the current policy that is associated with the stack will be used.
policy during this update. If you do not specify a stack policy, the current policy that is associated with the stack will be used.

- **Parameters** *(list)* – A list of Parameter structures that specify input parameters for the stack. For more information, see the Parameter data type.
  - *(dict)* –
    
    The Parameter data type.
    
    * **ParameterKey** *(string)* –
      
      The key associated with the parameter. If you don’t specify a key and value for a particular parameter, AWS CloudFormation uses the default value that is specified in your template.
    
    * **ParameterValue** *(string)* –
      
      The value associated with the parameter.
    
    * **UsePreviousValue** *(boolean)* –
      
      During a stack update, use the existing parameter value that the stack is using for a given parameter key. If you specify true, do not specify a parameter value.

- **Capabilities** *(list)* – A list of capabilities that you must specify before AWS CloudFormation can create or update certain stacks. Some stack templates might include resources that can affect permissions in your AWS account. For those stacks, you must explicitly acknowledge their capabilities by specifying this parameter. Currently, the only valid value is `CAPABILITY_IAM`, which is required for the following resources: AWS::IAM::AccessKey, AWS::IAM::Group, AWS::IAM::InstanceProfile, AWS::IAM::Policy, AWS::IAM::Role, AWS::IAM::User, and AWS::IAM::UserToGroupAddition. If your stack template contains these resources, we recommend that you review any permissions associated with them. If you don’t specify this parameter, this action returns an InsufficientCapabilities error.
  - *(string)* –

- **StackPolicyBody** *(string)* – Structure containing a new stack policy body. You can specify either the StackPolicyBody or the StackPolicyURL parameter, but not both.

  You might update the stack policy, for example, in order to protect a new resource that you created during a stack update. If you do not specify a stack policy, the current policy that is associated with the stack is unchanged.

- **StackPolicyURL** *(string)* – Location of a file containing the updated stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. You can specify either the StackPolicyBody or the StackPolicyURL parameter, but not both.

  You might update the stack policy, for example, in order to protect a new resource that you created during a stack update. If you do not specify a stack policy, the current policy that is associated with the stack is unchanged.

- **NotificationARNs** *(list)* – Update the ARNs for the Amazon SNS topics that are associated with the stack.
  - *(string)* –

Return type: dict

Returns:

**Response Syntax**

```json
{
  'StackId': 'string'
}
```
validate_template(**kwargs)

Validates a specified template.

Request Syntax

```python
response = client.validate_template(
    TemplateBody='string',
    TemplateURL='string'
)
```

Parameters

- **TemplateBody** (*string*) – Structure containing the template body with a minimum length of 1 byte and a maximum length of 51,200 bytes. For more information, go to Template Anatomy in the AWS CloudFormation User Guide.

  Conditional: You must pass `TemplateURL` or `TemplateBody`. If both are passed, only `TemplateBody` is used.

- **TemplateURL** (*string*) – Location of file containing the template body. The URL must point to a template (max size: 460,800 bytes) located in an S3 bucket in the same region as the stack. For more information, go to Template Anatomy in the AWS CloudFormation User Guide.

  Conditional: You must pass `TemplateURL` or `TemplateBody`. If both are passed, only `TemplateBody` is used.

Return type  dict

Returns

Response Syntax

```python
{
    'Parameters': [
        {
            'ParameterKey': 'string',
            'DefaultValue': 'string',
            'NoEcho': True|False,
            'Description': 'string'
        },
        {
            'ParameterKey': 'string',
            'DefaultValue': 'string',
            'NoEcho': True|False,
            'Description': 'string'
        },
    ],
    'Description': 'string',
    'Capabilities': [
        'CAPABILITY_IAM',
    ],
    'CapabilitiesReason': 'string'
}
```

Response Structure

- *(dict)* –

  The output for ValidateTemplate action.
– **Parameters** *(list)* –

A list of `TemplateParameter` structures.

* *(dict)* –

The `TemplateParameter` data type.

  · **ParameterKey** *(string)* –

    The name associated with the parameter.

  · **DefaultValue** *(string)* –

    The default value associated with the parameter.

  · **NoEcho** *(boolean)* –

    Flag indicating whether the parameter should be displayed as plain text in logs and UIs.

  · **Description** *(string)* –

    User defined description associated with the parameter.

– **Description** *(string)* –

The description found within the template.

– **Capabilities** *(list)* –

The capabilities found within the template. Currently, AWS CloudFormation supports only the `CAPABILITY_IAM` capability. If your template contains IAM resources, you must specify the `CAPABILITY_IAM` value for this parameter when you use the `CreateStack` or `UpdateStack` actions with your template; otherwise, those actions return an `InsufficientCapabilities` error.

* *(string)* –

– **CapabilitiesReason** *(string)* –

The list of resources that generated the values in the `Capabilities` response element.

**Paginators**

The available paginators are:

* `CloudFormation.Paginator.DescribeStackEvents`
* `CloudFormation.Paginator.DescribeStacks`
* `CloudFormation.Paginator.ListStackResources`
* `CloudFormation.Paginator.ListStacks`

class `CloudFormation.Paginator.DescribeStackEvents`

    paginator = client.get_paginator('describe_stack_events')

    paginate(**kwargs)
    
    Creates an iterator that will paginate through responses from `CloudFormation.Client.describe_stack_events()`.

**Request Syntax**
response_iterator = paginator.paginate(
    StackName='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **StackName** (*string*) – The name or the unique stack ID that is associated with the stack, which are not always interchangeable:
  - Running stacks: You can specify either the stack’s name or its unique stack ID.
  - Deleted stacks: You must specify the unique stack ID.
  Default: There is no default value.

- **PaginationConfig** (*dict*) – A dictionary that provides parameters to control pagination.
  - **MaxItems** (*integer*) –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize** (*integer*) –
    The size of each page.
  - **StartingToken** (*string*) –
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

Return type **dict**

Returns

Response Syntax

```python
{
    'StackEvents': [
        {
            'StackId': 'string',
            'EventId': 'string',
            'StackName': 'string',
            'LogicalResourceId': 'string',
            'PhysicalResourceId': 'string',
            'ResourceType': 'string',
            'Timestamp': datetime(2015, 1, 1),
            'ResourceStatus': 'CREATE_IN_PROGRESS'|'CREATE_FAILED'|'CREATE_COMPLETE'|'DELETE_IN_PROGRESS'|'DELETE_FAILED'|'DELETE_COMPLETE'|'DELETE_SKIPPED'|'UPDATE_IN_PROGRESS'|'UPDATE_FAILED'|'UPDATE_COMPLETE',
            'ResourceStatusReason': 'string',
            'ResourceProperties': 'string'
        },
    ],
}
```

Response Structure

- **(dict)** –
  The output for a DescribeStackEvents action.
  - **StackEvents** (*list*) –
A list of `StackEvents` structures.

*(dict)* –

The `StackEvent` data type.

- **StackId (string)** – 
  The unique ID name of the instance of the stack.

- **EventId (string)** – 
  The unique ID of this event.

- **StackName (string)** – 
  The name associated with a stack.

- **LogicalResourceId (string)** – 
  The logical name of the resource specified in the template.

- **PhysicalResourceId (string)** – 
  The name or unique identifier associated with the physical instance of the resource.

- **ResourceType (string)** – 
  Type of resource. (For more information, go to AWS Resource Types Reference in the AWS CloudFormation User Guide.)

- **Timestamp (datetime)** – 
  Time the status was updated.

- **ResourceStatus (string)** – 
  Current status of the resource.

- **ResourceStatusReason (string)** – 
  Success/failure message associated with the resource.

- **ResourceProperties (string)** – 
  BLOB of the properties used to create the resource.

```python
class CloudFormation.Paginator.DescribeStacks

paginator = client.get_paginator('describe_stacks')

paginate(**kwargs)

Creates an iterator that will paginate through responses from
`CloudFormation.Client.describe_stacks()`.

Request Syntax

```python
response_iterator = paginator.paginate(
    StackName='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **StackName (string)** – The name or the unique stack ID that is associated with the stack, which are not always interchangeable:
Running stacks: You can specify either the stack’s name or its unique stack ID.

Deleted stacks: You must specify the unique stack ID.

Default: There is no default value.

- **PaginationConfig** (*dict*) — A dictionary that provides parameters to control pagination.
  - **MaxItems** (*integer*) —
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** (*integer*) —
    The size of each page.
  - **StartingToken** (*string*) —
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type: dict

Returns

**Response Syntax**

```json
{
    'Stacks': [
        {
            'StackId': 'string',
            'StackName': 'string',
            'Description': 'string',
            'Parameters': [
                {
                    'ParameterKey': 'string',
                    'ParameterValue': 'string',
                    'UsePreviousValue': True|False
                }
            ],
            'CreationTime': datetime(2015, 1, 1),
            'LastUpdatedTime': datetime(2015, 1, 1),
            'StackStatus': 'CREATE_IN_PROGRESS'|'CREATE_FAILED'|'CREATE_COMPLETE'|'UPDATE_IN_PROGRESS'|'UPDATE_COMPLETE_CLEANUP_IN_PROGRESS'|'UPDATE_COMPLETE'|'DELETE_IN_PROGRESS'|'DELETE_FAILED'|'DELETE_COMPLETE',
            'StackStatusReason': 'string',
            'DisableRollback': True|False,
            'NotificationARNs': [
                'string',
            ],
            'TimeoutInMinutes': 123,
            'Capabilities': [
                'CAPABILITY_IAM',
            ],
            'Outputs': [
                {
                    'OutputKey': 'string',
                    'OutputValue': 'string',
                    'Description': 'string'
                }
            ],
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                }
            ]
        }
    ]
}
```
Response Structure

- (dict) –

  The output for a DescribeStacks action.

  - Stacks (list) –

    A list of stack structures.

      * (dict) –

        The Stack data type.

        - StackId (string) –

          Unique identifier of the stack.

        - StackName (string) –

          The name associated with the stack.

        - Description (string) –

          User defined description associated with the stack.

        - Parameters (list) –

          A list of Parameter structures.

            * (dict) –

              The Parameter data type.

              - ParameterKey (string) –

                The key associated with the parameter. If you don’t specify a key and value for a particular parameter, AWS CloudFormation uses the default value that is specified in your template.

              - ParameterValue (string) –

                The value associated with the parameter.

              - UsePreviousValue (boolean) –

                During a stack update, use the existing parameter value that the stack is using for a given parameter key. If you specify true, do not specify a parameter value.

              - CreationTime (datetime) –

                Time at which the stack was created.

              - LastUpdatedTime (datetime) –

                The time the stack was last updated. This field will only be returned if the stack has been updated at least once.

              - StackStatus (string) –

                Current status of the stack.

              - StackStatusReason (string) –

                Success/failure message associated with the stack status.

              - DisableRollback (boolean) –

                Boolean to enable or disable rollback on stack creation failures:
- **true**: disable rollback
- **false**: enable rollback

**NotificationARNs (list)** –

SNS topic ARNs to which stack related events are published.

- **(string)** –
- **TimeoutInMinutes (integer)** –

The amount of time within which stack creation should complete.

**Capabilities (list)** –

The capabilities allowed in the stack.

- **(string)** –
- **Outputs (list)** –

  A list of output structures.

  - **(dict)** –

    The Output data type.

- **OutputKey (string)** –

  The key associated with the output.

- **OutputValue (string)** –

  The value associated with the output.

- **Description (string)** –

  User defined description associated with the output.

- **Tags (list)** –

  A list of Tags that specify cost allocation information for the stack.

  - **(dict)** –

    The Tag type is used by `CreateStack` in the `Tags` parameter. It allows you to specify a key/value pair that can be used to store information related to cost allocation for an AWS CloudFormation stack.

- **Key (string)** –

  *Required*. A string used to identify this tag. You can specify a maximum of 128 characters for a tag key. Tags owned by Amazon Web Services (AWS) have the reserved prefix: `aws:`.

- **Value (string)** –

  *Required*. A string containing the value for this tag. You can specify a maximum of 256 characters for a tag value.

```python
class CloudFormation.Paginator.ListStackResources

paginator = client.get_paginator('list_stack_resources')

paginate(**kwargs)

Creates an iterator that will paginate through responses from CloudFormation.Client.list_stack_resources().

Request Syntax
response_iterator = paginator.paginate(
    StackName='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

• **StackName (string)** – [REQUIRED]
  The name or the unique stack ID that is associated with the stack, which are not always interchangeable:
  – Running stacks: You can specify either the stack’s name or its unique stack ID.
  – Deleted stacks: You must specify the unique stack ID.

  Default: There is no default value.

• **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  – **MaxItems (integer)** –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  – **PageSize (integer)** –
    The size of each page.
  – **StartingToken (string)** –
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict

Returns

**Response Syntax**

```python
{
    'StackResourceSummaries': [
        {
            'LogicalResourceId': 'string',
            'PhysicalResourceId': 'string',
            'ResourceType': 'string',
            'LastUpdatedTimestamp': datetime(2015, 1, 1),
            'ResourceStatus': 'CREATE_IN_PROGRESS'|'CREATE_FAILED'|'CREATE_COMPLETE'|'DELETE_IN_PROGRESS'|'DELETE_FAILED'|'DELETE_COMPLETE'|'DELETE_SKIPPED'|'UPDATE_IN_PROGRESS'|'UPDATE_FAILED'|'UPDATE_COMPLETE',
            'ResourceStatusReason': 'string'
        },
    ],
}
```

**Response Structure**

• **(dict)** –
  The output for a ListStackResources action.
  – **StackResourceSummaries (list)** –
    A list of StackResourceSummary structures.
* (dict) –

Contains high-level information about the specified stack resource.
- **LogicalResourceId** (string) –
  The logical name of the resource specified in the template.
- **PhysicalResourceId** (string) –
  The name or unique identifier that corresponds to a physical instance ID of the resource.
- **ResourceType** (string) –
  Type of resource. (For more information, go to AWS Resource Types Reference in the AWS CloudFormation User Guide.)
- **LastUpdatedTimestamp** (datetime) –
  Time the status was updated.
- **ResourceStatus** (string) –
  Current status of the resource.
- **ResourceStatusReason** (string) –
  Success/failure message associated with the resource.

```
class CloudFormation.Paginator.ListStacks

paginator = client.get_paginated('list_stacks')

paginate(**kwargs)

Creates an iterator that will paginate through responses from
CloudFormation.Client.list_stacks().

Request Syntax
```
response_iterator = paginator.paginate(
    StackStatusFilter=[
        'CREATE_IN_PROGRESS'|'CREATE_FAILED'|'CREATE_COMPLETE'|'ROLLBACK_IN_PROGRESS'|'ROLLBACK_FAILED'|'ROLLBACK_COMPLETE'|'UPDATE_IN_PROGRESS'|'UPDATE_FAILED'|'UPDATE_COMPLETE'|'UPDATE_ROLLBACK_IN_PROGRESS'|'UPDATE_ROLLBACK_FAILED'|'UPDATE_ROLLBACK_COMPLETE_CLEANUP_IN_PROGRESS'|'UPDATE_ROLLBACK_COMPLETE',
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters
- **StackStatusFilter** (list) – Stack status to use as a filter. Specify one or more stack status codes to list only stacks with the specified status codes. For a complete list of stack status codes, see the StackStatus parameter of the Stack data type.
  - (string) –
- **PaginationConfig** (dict) – A dictionary that provides parameters to control pagination.
  - **MaxItems** (integer) –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
- **PageSize** *(integer)* –
  The size of each page.

- **StartingToken** *(string)* –
  A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** `dict`

**Response Syntax**

```
{
    'StackSummaries': [
        {
            'StackId': 'string',
            'StackName': 'string',
            'TemplateDescription': 'string',
            'CreationTime': datetime(2015, 1, 1),
            'LastUpdatedTime': datetime(2015, 1, 1),
            'DeletionTime': datetime(2015, 1, 1),
            'StackStatus': ... _ROLLBACK_IN_PROGRESS'|'UPDATE_ROLLBACK_FAILED'|'UPDATE_ROLLBACK_COMPLETE'|'UPDATE_ROLLBACK_COMPLETE_CLEANUP_IN_PROGRESS'|'CREATE_IN_PROGRESS'|'CREATE_FAILED'|'CREATE_COMPLETE'|'DELETE_IN_PROGRESS'|'DELETE_FAILED'|'DELETE_COMPLETE',
            'StackStatusReason': 'string'
        },
        
    ],

}
```

**Response Structure**

- *(dict)* –
  The output for ListStacks action.

- **StackSummaries** *(list)* –
  A list of `StackSummary` structures containing information about the specified stacks.
    - *(dict)* –
      The `StackSummary` Data Type
      - **StackId** *(string)* –
        Unique stack identifier.
      - **StackName** *(string)* –
        The name associated with the stack.
      - **TemplateDescription** *(string)* –
        The template description of the template used to create the stack.
      - **CreationTime** *(datetime)* –
        The time the stack was created.
      - **LastUpdatedTime** *(datetime)* –
        The time the stack was last updated. This field will only be returned if the stack has been updated at least once.
      - **DeletionTime** *(datetime)* –
        The time the stack was deleted.
      - **StackStatus** *(string)* –
        The current status of the stack.
Service Resource

class CloudFormation.ServiceResource
A resource representing AWS CloudFormation:

```python
import boto3

cloudformation = boto3.resource('cloudformation')
```

These are the resource’s available actions:

• `create_stack()`

These are the resource’s available sub-resources:

• `Event()`
• `Stack()`
• `StackResource()`
• `StackResourceSummary()`

These are the resource’s available collections:

• `stacks`

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

`create_stack(**kwargs)`

Creates a stack as specified in the template. After the call completes successfully, the stack creation starts. You can check the status of the stack via the DescribeStacks API.

**Request Syntax**

```python
stack = cloudformation.create_stack(
    StackName='string',
    TemplateBody='string',
    TemplateURL='string',
    Parameters=[
        {'ParameterKey': 'string',
         'ParameterValue': 'string',
         'UsePreviousValue': True|False}
    ],
    DisableRollback=True|False,
    TimeoutInMinutes=123,
    NotificationARNs=['string'],
   Capabilities=[
        'CAPABILITY_IAM',
    ],
    OnFailure='DO NOTHING'|'ROLLBACK'|'DELETE',
    StackPolicyBody='string',
    StackPolicyURL='string',
    Tags=[
        {
```
Parameters

• **StackName (string)** – [REQUIRED]
  The name that is associated with the stack. The name must be unique in the region in which you are creating the stack.

  **Note:** A stack name can contain only alphanumeric characters (case sensitive) and hyphens. It must start with an alphabetic character and cannot be longer than 255 characters.

• **TemplateBody (string)** – Structure containing the template body with a minimum length of 1 byte and a maximum length of 51,200 bytes. For more information, go to Template Anatomy in the AWS CloudFormation User Guide.

  Conditional: You must specify either the TemplateBody or the TemplateURL parameter, but not both.

• **TemplateURL (string)** – Location of file containing the template body. The URL must point to a template (max size: 460,800 bytes) located in an S3 bucket in the same region as the stack. For more information, go to the Template Anatomy in the AWS CloudFormation User Guide.

  Conditional: You must specify either the TemplateBody or the TemplateURL parameter, but not both.

• **Parameters (list)** – A list of Parameter structures that specify input parameters for the stack.
  – (dict) –
    The Parameter data type.
    * **ParameterKey (string)** –
      The key associated with the parameter. If you don’t specify a key and value for a particular parameter, AWS CloudFormation uses the default value that is specified in your template.
    * **ParameterValue (string)** –
      The value associated with the parameter.
    * **UsePreviousValue (boolean)** –
      During a stack update, use the existing parameter value that the stack is using for a given parameter key. If you specify true, do not specify a parameter value.

• **DisableRollback (boolean)** – Set to true to disable rollback of the stack if stack creation failed. You can specify either DisableRollback or OnFailure, but not both.

  Default: false

• **TimeoutInMinutes (integer)** – The amount of time that can pass before the stack status becomes CREATE_FAILED; if DisableRollback is not set or is set to false, the stack will be rolled back.

• **NotificationARNs (list)** – The Simple Notification Service (SNS) topic ARNs to publish stack related events. You can find your SNS topic ARNs using the SNS console or your Command Line Interface (CLI).
• **Capabilities (list)** – A list of capabilities that you must specify before AWS CloudFormation can create or update certain stacks. Some stack templates might include resources that can affect permissions in your AWS account. For those stacks, you must explicitly acknowledge their capabilities by specifying this parameter.

Currently, the only valid value is `CAPABILITY_IAM`, which is required for the following resources: `AWS::IAM::AccessKey`, `AWS::IAM::Group`, `AWS::IAM::InstanceProfile`, `AWS::IAM::Policy`, `AWS::IAM::Role`, `AWS::IAM::User`, and `AWS::IAM::UserToGroupAddition`. If your stack template contains these resources, we recommend that you review any permissions associated with them. If you don’t specify this parameter, this action returns an `InsufficientCapabilities` error.

• **OnFailure (string)** – Determines what action will be taken if stack creation fails. This must be one of: `DO NOTHING`, `ROLLBACK`, or `DELETE`. You can specify either `OnFailure` or `DisableRollback`, but not both.

  Default: `ROLLBACK`

• **StackPolicyBody (string)** – Structure containing the stack policy body. For more information, go to Prevent Updates to Stack Resources in the AWS CloudFormation User Guide. You can specify either the `StackPolicyBody` or the `StackPolicyURL` parameter, but not both.

• **StackPolicyURL (string)** – Location of a file containing the stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. You can specify either the `StackPolicyBody` or the `StackPolicyURL` parameter, but not both.

• **Tags (list)** – A set of user-defined tags to associate with this stack, represented by key/value pairs. Tags defined for the stack are propagated to EC2 resources that are created as part of the stack. A maximum number of 10 tags can be specified.

  • **(dict)** –

  The Tag type is used by `CreateStack` in the Tags parameter. It allows you to specify a key/value pair that can be used to store information related to cost allocation for an AWS CloudFormation stack.

    • **Key (string)** –
      
      Required. A string used to identify this tag. You can specify a maximum of 128 characters for a tag key. Tags owned by Amazon Web Services (AWS) have the reserved prefix: `aws:`.

    • **Value (string)** –
      
      Required. A string containing the value for this tag. You can specify a maximum of 256 characters for a tag value.

  Return type `cloudformation.Stack`

  Returns Stack resource

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

**Event (id)**

  Creates a Event resource.
event = cloudformation.Event('id')

Parameters id (string) – The Event’s id identifier. This must be set.
Return type CloudFormation.Event
Returns A Event resource

Stack (name)
Creates a Stack resource:

stack = cloudformation.Stack('name')

Parameters name (string) – The Stack’s name identifier. This must be set.
Return type CloudFormation.Stack
Returns A Stack resource

StackResource (stack_name, logical_id)
Creates a StackResource resource:

stack_resource = cloudformation.StackResource('stack_name','logical_id')

Parameters
• stack_name (string) – The StackResource’s stack_name identifier. This must be set.
• logical_id (string) – The StackResource’s logical_id identifier. This must be set.
Return type CloudFormation.StackResource
Returns A StackResource resource

StackResourceSummary (stack_name, logical_id)
Creates a StackResourceSummary resource:

stack_resource_summary = cloudformation.StackResourceSummary('stack_name','logical_id')

Parameters
• stack_name (string) – The StackResourceSummary’s stack_name identifier. This must be set.
• logical_id (string) – The StackResourceSummary’s logical_id identifier. This must be set.
Return type CloudFormation.StackResourceSummary
Returns A StackResourceSummary resource

Collections
Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the Resources Introduction Guide.

stacks

all ()
Creates an iterable of all Stack resources in the collection.

Request Syntax

stack_iterator = cloudformation.stacks.all()

Return type list(cloudformation.Stack)
Returns A list of Stack resources
**filter(**kwargs)**

Creates an iterable of all Stack resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
stack_iterator = cloudformation.stacks.filter(
    StackName='string',
    NextToken='string'
)
```

**Parameters**

- **StackName (string)** – The name or the unique stack ID that is associated with the stack, which are not always interchangeable:
  - Running stacks: You can specify either the stack’s name or its unique stack ID.
  - Deleted stacks: You must specify the unique stack ID.
  
- **NextToken (string)** – String that identifies the start of the next list of stacks, if there is one.

**Return type** list(cloudformation.Stack)

**Returns**
A list of Stack resources

**limit(**kwargs)**

Creates an iterable up to a specified amount of Stack resources in the collection.

**Request Syntax**

```python
stack_iterator = cloudformation.stacks.limit(
    count=123
)
```

**Parameters**

- **count (integer)** – The limit to the number of resources in the iterable.

**Return type** list(cloudformation.Stack)

**Returns**
A list of Stack resources

**page_size(**kwargs)**

Creates an iterable of all Stack resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
stack_iterator = cloudformation.stacks.page_size(
    count=123
)
```

**Parameters**

- **count (integer)** – The number of items returned by each service call

**Return type** list(cloudformation.Stack)

**Returns**
A list of Stack resources

**Event**

```python
class CloudFormation.Event(id)
```

A resource representing an AWS CloudFormation Event:
import boto3

cloudformation = boto3.resource('cloudformation')
event = cloudformation.Event('id')

Parameters

id (string) – The Event’s id identifier. This must be set.

These are the resource’s available identifiers:

- id

These are the resource’s available attributes:

- event_id
- logical_resource_id
- physical_resource_id
- resource_properties
- resource_status
- resource_status_reason
- resource_type
- stack_id
- stack_name
- timestamp

Identifiers

Identifiers are properties of a resource that are set upon instantation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

id

(string) The Event’s id identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

event_id

(string)

The unique ID of this event.

logical_resource_id

(string)

The logical name of the resource specified in the template.

physical_resource_id

(string)

The name or unique identifier associated with the physical instance of the resource.

resource_properties

(string)

BLOB of the properties used to create the resource.

resource_status

(string)

Current status of the resource.

resource_status_reason

(string)

Success/failure message associated with the resource.
resource_type
(string)
Type of resource. (For more information, go to AWS Resource Types Reference in the AWS CloudFormation User Guide.)

stack_id
(string)
The unique ID name of the instance of the stack.

stack_name
(string)
The name associated with a stack.

timestamp
(datetime)
Time the status was updated.

Stack
class CloudFormation.Stack(name)
A resource representing an AWS CloudFormation Stack:

import boto3

cloudformation = boto3.resource('cloudformation')
stack = cloudformation.Stack('name')

Parameters name (string) – The Stack’s name identifier. This must be set.

These are the resource’s available identifiers:
• name

These are the resource’s available attributes:
• capabilities
• creation_time
• description
• disable_rollback
• last_updated_time
• notification_arns
• outputs
• parameters
• stack_id
• stack_name
• stack_status
• stack_status_reason
• tags
• timeout_in_minutes

These are the resource’s available actions:
• cancel_update()
• delete()
• load()
• reload()
• update()

These are the resource’s available sub-resources:
Resource()

These are the resource’s available collections:

- events
- resource_summaries

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

**name**

*(string)* The Stack’s name identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the Resources Introduction Guide.

**capabilities**

*(list)*

The capabilities allowed in the stack.

**creation_time**

*(datetime)*

Time at which the stack was created.

**description**

*(string)*

User defined description associated with the stack.

**disable_rollback**

*(boolean)*

Boolean to enable or disable rollback on stack creation failures:

- **true**: disable rollback
- **false**: enable rollback

**last_updated_time**

*(datetime)*

The time the stack was last updated. This field will only be returned if the stack has been updated at least once.

**notification_arns**

*(list)*

SNS topic ARNs to which stack related events are published.

**outputs**

*(list)*

A list of output structures.

**parameters**

*(list)*

A list of Parameter structures.

**stack_id**

*(string)*

Unique identifier of the stack.
stack_name
   (string)
   The name associated with the stack.

stack_status
   (string)
   Current status of the stack.

stack_status_reason
   (string)
   Success/failure message associated with the stack status.

tags
   (list)
   A list of Tag s that specify cost allocation information for the stack.

timeout_in_minutes
   (integer)
   The amount of time within which stack creation should complete.

Actions
Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

cancel_update()
Cancels an update on the specified stack. If the call completes successfully, the stack will roll back the update and revert to the previous stack configuration.

Note: Only stacks that are in the UPDATE_IN_PROGRESS state can be canceled.

Request Syntax
response = stack.cancel_update()

Returns None

delete()
Deletes a specified stack. Once the call completes successfully, stack deletion starts. Deleted stacks do not show up in the DescribeStacks API if the deletion has been completed successfully.

Request Syntax
response = stack.delete()

Returns None

load()
Calls cloudformation.Client.describe_stacks() to update the attributes of the Stack resource.

Request Syntax
stack.load()

Returns None
reload()

Calls cloudformation.Client.describe_stacks() to update the attributes of the Stack resource

Request Syntax

stack.reload()

Returns None

update(**kwargs)

Updates a stack as specified in the template. After the call completes successfully, the stack update starts. You can check the status of the stack via the DescribeStacks action.

To get a copy of the template for an existing stack, you can use the GetTemplate action.

Tags that were associated with this stack during creation time will still be associated with the stack after an UpdateStack operation.

For more information about creating an update template, updating a stack, and monitoring the progress of the update, see Updating a Stack.

Request Syntax

response = stack.update(
    TemplateBody='string',
    TemplateURL='string',
    UsePreviousTemplate=True|False,
    StackPolicyDuringUpdateBody='string',
    StackPolicyDuringUpdateURL='string',
    Parameters=[
      {
        'ParameterKey': 'string',
        'ParameterValue': 'string',
        'UsePreviousValue': True|False
      },
    ],
    Capabilities=[
      'CAPABILITY_IAM',
    ],
    StackPolicyBody='string',
    StackPolicyURL='string',
    NotificationARNs=[
      'string',
    ]
)

Parameters

- **TemplateBody** *(string)* – Structure containing the template body with a minimum length of 1 byte and a maximum length of 51,200 bytes. (For more information, go to Template Anatomy in the AWS CloudFormation User Guide.)

  Conditional: You must specify either the TemplateBody or the TemplateURL parameter, but not both.

- **TemplateURL** *(string)* – Location of file containing the template body. The URL must point to a template located in an S3 bucket in the same region as the stack. For more information, go to Template Anatomy in the AWS CloudFormation User Guide.
Conditional: You must specify either the `TemplateBody` or the `TemplateURL` parameter, but not both.

- **UsePreviousTemplate** (`boolean`) – Reuse the existing template that is associated with the stack that you are updating.

- **StackPolicyDuringUpdateBody** (`string`) – Structure containing the temporary overriding stack policy body. You can specify either the `StackPolicyDuringUpdateBody` or the `StackPolicyDuringUpdateURL` parameter, but not both.

If you want to update protected resources, specify a temporary overriding stack policy during this update. If you do not specify a stack policy, the current policy that is associated with the stack will be used.

- **StackPolicyDuringUpdateURL** (`string`) – Location of a file containing the temporary overriding stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. You can specify either the `StackPolicyDuringUpdateBody` or the `StackPolicyDuringUpdateURL` parameter, but not both.

If you want to update protected resources, specify a temporary overriding stack policy during this update. If you do not specify a stack policy, the current policy that is associated with the stack will be used.

- **Parameters** (`list`) – A list of `Parameter` structures that specify input parameters for the stack. For more information, see the `Parameter` data type.

  - (`dict`) –

    The Parameter data type.

    - **ParameterKey** (`string`) –

      The key associated with the parameter. If you don’t specify a key and value for a particular parameter, AWS CloudFormation uses the default value that is specified in your template.

    - **ParameterValue** (`string`) –

      The value associated with the parameter.

    - **UsePreviousValue** (`boolean`) –

      During a stack update, use the existing parameter value that the stack is using for a given parameter key. If you specify `true`, do not specify a parameter value.

- **Capabilities** (`list`) – A list of capabilities that you must specify before AWS CloudFormation can create or update certain stacks. Some stack templates might include resources that can affect permissions in your AWS account. For those stacks, you must explicitly acknowledge their capabilities by specifying this parameter. Currently, the only valid value is `CAPABILITY_IAM`, which is required for the following resources: `AWS::IAM::AccessKey`, `AWS::IAM::Group`, `AWS::IAM::InstanceProfile`, `AWS::IAM::Policy`, `AWS::IAM::Role`, `AWS::IAM::User`, and `AWS::IAM::UserToGroupAddition`. If your stack template contains these resources, we recommend that you review any permissions associated with them. If you don’t specify this parameter, this action returns an InsufficientCapabilities error.

  - (`string`) –

    - **StackPolicyBody** (`string`) – Structure containing a new stack policy body. You can specify either the `StackPolicyBody` or the `StackPolicyURL` parameter, but not both.

You might update the stack policy, for example, in order to protect a new resource that you created during a stack update. If you do not specify a stack policy, the
current policy that is associated with the stack is unchanged.

- **StackPolicyURL (string)** – Location of a file containing the updated stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. You can specify either the StackPolicyBody or the StackPolicyURL parameter, but not both.

You might update the stack policy, for example, in order to protect a new resource that you created during a stack update. If you do not specify a stack policy, the current policy that is associated with the stack is unchanged.

- **NotificationARNs (list)** – Update the ARNs for the Amazon SNS topics that are associated with the stack.

  - *(string)* –

  **Return type**  
  **dict**

  **Returns**

  **Response Syntax**

  ```
  {
      'StackId': 'string'
  }
  ```

  **Response Structure**

  - *(dict)* –

    The output for a UpdateStack action.

    - **StackId (string)** –

        Unique identifier of the stack.

**Sub-resources**

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the *Resources Introduction Guide.*

**Resource** *(logical_id)*

Creates a StackResource resource:

```python
stack_resource = stack.Resource('logical_id')
```

**Parameters**  

- **logical_id (string)** – The Resource’s logical_id identifier. This **must** be set.

  **Return type**  
  **CloudFormation.StackResource**

  **Returns**  
  A StackResource resource

**Collections**

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the *Resources Introduction Guide.*

**events**

**all ()**

Creates an iterable of all Event resources in the collection.

**Request Syntax**

```python
event_iterator = stack.events.all()
```

**Return type**  

**list(cloudformation.Event)**

**Returns**  
A list of Event resources
filter(**kwargs)
Creates an iterable of all Event resources in the collection filtered by kwargs passed to method.

Request Syntax

event_iterator = stack.events.filter(
    NextToken='string'
)

Parameters
NextToken (string) – String that identifies the start of the next list of events, if there is one.
Default: There is no default value.

Returns
list(cloudformation.Event)

limit(**kwargs)
Creates an iterable up to a specified amount of Event resources in the collection.

Request Syntax

event_iterator = stack.events.limit(
    count=123
)

Parameters
count (integer) – The limit to the number of resources in the iterable.

Returns
list(cloudformation.Event)

page_size(**kwargs)
Creates an iterable of all Event resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

event_iterator = stack.events.page_size(
    count=123
)

Parameters
count (integer) – The number of items returned by each service call

Returns
list(cloudformation.Event)

resource_summaries

all()
Creates an iterable of all StackResourceSummary resources in the collection.

Request Syntax

stack_resource_summary_iterator = stack.resource_summaries.all()

Returns
list(cloudformation.StackResourceSummary)

filter(**kwargs)
Creates an iterable of all StackResourceSummary resources in the collection filtered by kwargs passed to method.
Request Syntax

```
stack_resource_summary_iterator = stack.resource_summaries.filter(
    NextToken='string'
)
```

**Parameters**

NextToken *(string)* — String that identifies the start of the next list of stack resource summaries, if there is one.

Default: There is no default value.

**Return type**

```
list(cloudformation.StackResourceSummary)
```

**Returns**

A list of StackResourceSummary resources

---

**limit(**

```
stack_resource_summary_iterator = stack.resource_summaries.limit(
    count=123
)
```

**Parameters**

count *(integer)* — The limit to the number of resources in the iterable.

**Return type**

```
list(cloudformation.StackResourceSummary)
```

**Returns**

A list of StackResourceSummary resources

---

**page_size(**

```
stack_resource_summary_iterator = stack.resource_summaries.page_size(
    count=123
)
```

**Parameters**

count *(integer)* — The number of items returned by each service call

**Return type**

```
list(cloudformation.StackResourceSummary)
```

**Returns**

A list of StackResourceSummary resources

---

**StackResource**

```
class CloudFormation.StackResource(stack_name, logical_id)
```

A resource representing an AWS CloudFormation StackResource:

```
import boto3

cloudformation = boto3.resource('cloudformation')
stack_resource = cloudformation.StackResource('stack_name','logical_id')
```

**Parameters**

- **stack_name (string)** — The StackResource’s stack_name identifier. This **must** be set.
- **logical_id (string)** — The StackResource’s logical_id identifier. This **must** be set.

These are the resource’s available identifiers:

- stack_name
- logical_id

---

3.1. Services
These are the resource’s available attributes:

- `description`
- `last_updated_timestamp`
- `logical_resource_id`
- `metadata`
- `physical_resource_id`
- `resource_status`
- `resource_status_reason`
- `resource_type`
- `stack_id`

These are the resource’s available sub-resources:

- `Stack()`

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide*.

- `stack_name`
  
  *(string)* The StackResource’s stack_name identifier. This **must** be set.

- `logical_id`
  
  *(string)* The StackResource’s logical_id identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the *Resources Introduction Guide*.

- `description`
  
  *(string)*

  User defined description associated with the resource.

- `last_updated_timestamp`
  
  *(datetime)*

  Time the status was updated.

- `logical_resource_id`
  
  *(string)*

  The logical name of the resource specified in the template.

- `metadata`
  
  *(string)*

  The JSON format content of the Metadata attribute declared for the resource. For more information, see Metadata Attribute in the AWS CloudFormation User Guide.

- `physical_resource_id`
  
  *(string)*

  The name or unique identifier that corresponds to a physical instance ID of a resource supported by AWS CloudFormation.

- `resource_status`
  
  *(string)*

  Current status of the resource.

- `resource_status_reason`
  
  *(string)*
Success/failure message associated with the resource.

```python
resource_type
(string)
```

Type of resource. (For more information, go to AWS Resource Types Reference in the AWS CloudFormation User Guide.)

```python
stack_id
(string)
```

Unique identifier of the stack.

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

Stack()

Creates a Stack resource:

```python
stack = stack_resource.Stack()

Return type CloudFormation.Stack

Returns A Stack resource
```

StackResourceSummary

```python
class CloudFormation.StackResourceSummary(stack_name, logical_id)
```

A resource representing an AWS CloudFormation StackResourceSummary:

```python
import boto3

cloudformation = boto3.resource('cloudformation')

stack_resource_summary = cloudformation.StackResourceSummary('stack_name','logical_id')
```

Parameters

- **stack_name (string)** – The StackResourceSummary’s stack_name identifier. This must be set.
- **logical_id (string)** – The StackResourceSummary’s logical_id identifier. This must be set.

These are the resource’s available identifiers:

- **stack_name**
- **logical_id**

These are the resource’s available attributes:

- **last_updated_timestamp**
- **logical_resource_id**
- **physical_resource_id**
- **resource_status**
- **resource_status_reason**
- **resource_type**

These are the resource’s available sub-resources:

- **Resource()**

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.
stack_name

(string) The StackResourceSummary’s stack_name identifier. This must be set.

logical_id

(string) The StackResourceSummary’s logical_id identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

last_updated_timestamp

(datetime)

Time the status was updated.

logical_resource_id

(string)

The logical name of the resource specified in the template.

physical_resource_id

(string)

The name or unique identifier that corresponds to a physical instance ID of the resource.

resource_status

(string)

Current status of the resource.

resource_status_reason

(string)

Success/failure message associated with the resource.

resource_type

(string)

Type of resource. (For more information, go to AWS Resource Types Reference in the AWS CloudFormation User Guide.)

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

Resource()

Creates a StackResource resource:

```
stack_resource = stack_resource_summary.Resource()
```

Return type CloudFormation.StackResource

Returns A StackResource resource

CloudFront
Table of Contents

- CloudFront
  - Client
  - Paginators
  - Waiters

Client

class CloudFront.Client

A low-level client representing Amazon CloudFront:

```python
import boto3

client = boto3.client('cloudfront')
```

These are the available methods:

- `can_paginate()`
- `create_cloud_front_origin_access_identity()`
- `create_distribution()`
- `create_invalidation()`
- `create_streaming_distribution()`
- `delete_cloud_front_origin_access_identity()`
- `delete_distribution()`
- `delete_streaming_distribution()`
- `generate_presigned_url()`
- `get_cloud_front_origin_access_identity()`
- `get_cloud_front_origin_access_identity_config()`
- `get_distribution()`
- `get_distribution_config()`
- `get_invalidation()`
- `get_paginaton()`
- `get_streaming_distribution()`
- `get_streaming_distribution_config()`
- `get_waiter()`
- `list_cloud_front_origin_access_identities()`
- `list_distributions()`
- `list_invalidation()`
- `list_streaming_distributions()`
- `update_cloud_front_origin_access_identity()`
- `update_distribution()`
- `update_streaming_distribution()`

`can_paginate(operation_name)`

Check if an operation can be paginated.

Parameters:
- `operation_name (string)`: The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you'd normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginaton("create_foo")`.

Returns:
- `True` if the operation can be paginated, `False` otherwise.
create_cloud_front_origin_access_identity(**kwargs)
Create a new origin access identity.

Request Syntax

```python
response = client.create_cloud_front_origin_access_identity(
    CloudFrontOriginAccessIdentityConfig={
        'CallerReference': 'string',
        'Comment': 'string'
    }
)
```

Parameters

**CloudFrontOriginAccessIdentityConfig** *(dict) – [REQUIRED]* The origin access identity’s configuration information.

- **CallerReference** *(string) – [REQUIRED]* A unique number that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the CloudFrontOriginAccessIdentityConfig object), a new origin access identity is created. If the CallerReference is a value you already sent in a previous request to create an identity, and the content of the CloudFrontOriginAccessIdentityConfig is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create an identity but the content of the CloudFrontOriginAccessIdentityConfig is different from the original request, CloudFront returns a CloudFrontOriginAccessIdentityAlreadyExists error.

- **Comment** *(string) – [REQUIRED]* Any comments you want to include about the origin access identity.

Return type  

dict

Returns

Response Syntax

```python
{
    'CloudFrontOriginAccessIdentity': {
        'Id': 'string',
        'S3CanonicalUserId': 'string',
        'CloudFrontOriginAccessIdentityConfig': {
            'CallerReference': 'string',
            'Comment': 'string'
        }
    },
    'Location': 'string',
    'ETag': 'string'
}
```

Response Structure

- *(dict) – The returned result of the corresponding request.*
  - **CloudFrontOriginAccessIdentity** *(dict) – The origin access identity’s information.*
    - **Id** *(string) – The ID for the origin access identity. For example: E74FTE3AJFJ256A.*
    - **S3CanonicalUserId** *(string) – The Amazon S3 canonical user ID for the origin access identity, which you use when giving the origin access identity read permission to an object in Amazon S3.*
    - **CloudFrontOriginAccessIdentityConfig** *(dict) – The current configuration information for the identity.*
· **CallerReference** *(string)* – A unique number that ensures the request can't be replayed. If the CallerReference is new (no matter the content of the CloudFrontOriginAccessIdentityConfig object), a new origin access identity is created. If the CallerReference is a value you already sent in a previous request to create an identity, and the content of the CloudFrontOriginAccessIdentityConfig is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create an identity but the content of the CloudFrontOriginAccessIdentityConfig is different from the original request, CloudFront returns a CloudFrontOriginAccessIdentityAlreadyExists error.

· **Comment** *(string)* – Any comments you want to include about the origin access identity.

· **Location** *(string)* – The fully qualified URI of the new origin access identity just created. For example: https://cloudfront.amazonaws.com/2010-11-01/origin-access-identity/cloudfront/E74FTE3AJFJ256A.

· **ETag** *(string)* – The current version of the origin access identity created.

```python
create_distribution(**kwargs)
```
Create a new distribution.

**Request Syntax**

```python
response = client.create_distribution(
    DistributionConfig={
        'CallerReference': 'string',
        'Aliases': {
            'Quantity': 123,
            'Items': [
                'string',
            ],
        },
        'DefaultRootObject': 'string',
        'Origins': {
            'Quantity': 123,
            'Items': [
                {
                    'Id': 'string',
                    'DomainName': 'string',
                    'OriginPath': 'string',
                    'S3OriginConfig': {
                        'OriginAccessIdentity': 'string',
                    },
                    'CustomOriginConfig': {
                        'HTTPPort': 123,
                        'HTTPSPort': 123,
                        'OriginProtocolPolicy': 'http-only'|'match-viewer',
                    },
                },
            ],
        },
        'DefaultCacheBehavior': {
            'TargetOriginId': 'string',
            'ForwardedValues': {
            },
        },
    },
)
```
'QueryString': True|False,
'Cookies': {

      'string',
    ]
  }
}
}

Parameters

**DistributionConfig (dict) – [REQUIRED]** The distribution’s configuration information.

- **CallerReference (string) – [REQUIRED]** A unique number that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the DistributionConfig object), a new distribution is created. If the CallerReference is a value you already sent in a previous request to create a distribution, and the content of the DistributionConfig is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create a distribution but the content of the DistributionConfig is different from the original request, CloudFront returns a DistributionAlreadyExists error.

- **Aliases (dict) –** A complex type that contains information about CNAMEs (alternate domain names), if any, for this distribution.
  - **Quantity (integer) – [REQUIRED]** The number of CNAMEs, if any, for this distribution.
  - **Items (list) –** Optional: A complex type that contains CNAME elements, if any, for this distribution. If Quantity is 0, you can omit Items.
    - *(string)*

- **DefaultRootObject (string) –** The object that you want CloudFront to return (for example, index.html) when an end user requests the root URL for your distribution (http://www.example.com) instead of an object in your distribution (http://www.example.com/index.html). Specifying a default root object avoids exposing the contents of your distribution. If you don’t want to specify a default root object when you create a distribution, include an empty DefaultRootObject element. To delete the default root object from an existing distribution, update the distribution configuration and include an empty DefaultRootObject element. To replace the default root object, update the distribution configuration and specify the new object.

- **Origins (dict) – [REQUIRED]** A complex type that contains information about origins for this distribution.
  - **Quantity (integer) – [REQUIRED]** The number of origins for this distribution.
  - **Items (list) –** A complex type that contains origins for this distribution.
    - *(dict)* – A complex type that describes the Amazon S3 bucket or the HTTP server (for example, a web server) from which CloudFront gets your files. You must create at least one origin.
      - **Id (string) – [REQUIRED]** A unique identifier for the origin. The value of Id must be unique within the distribution. You use the value of Id when you create a cache behavior. The Id identifies the origin that CloudFront routes a request to when...
the request matches the path pattern for that cache behavior.

- **DomainName** (string) – [REQUIRED] Amazon S3 origins: The DNS name of the Amazon S3 bucket from which you want CloudFront to get objects for this origin, for example, myawsbucket.s3.amazonaws.com. Custom origins: The DNS domain name for the HTTP server from which you want CloudFront to get objects for this origin, for example, www.example.com.

- **OriginPath** (string) – An optional element that causes CloudFront to request your content from a directory in your Amazon S3 bucket or your custom origin. When you include the OriginPath element, specify the directory name, beginning with a /. CloudFront appends the directory name to the value of DomainName.

- **S3OriginConfig** (dict) – A complex type that contains information about the Amazon S3 origin. If the origin is a custom origin, use the CustomOriginConfig element instead.

- **OriginAccessIdentity** (string) – [REQUIRED] The CloudFront origin access identity to associate with the origin. Use an origin access identity to configure the origin so that end users can only access objects in an Amazon S3 bucket through CloudFront. If you want end users to be able to access objects using either the CloudFront URL or the Amazon S3 URL, specify an empty OriginAccessIdentity element. To delete the origin access identity from an existing distribution, update the distribution configuration and include an empty OriginAccessIdentity element. To replace the origin access identity, update the distribution configuration and specify the new origin access identity. Use the format origin-access-identity/cloudfront/Id where Id is the value that CloudFront returned in the Id element when you created the origin access identity.

- **CustomOriginConfig** (dict) – A complex type that contains information about a custom origin. If the origin is an Amazon S3 bucket, use the S3OriginConfig element instead.

- **HTTPPort** (integer) – [REQUIRED] The HTTP port the custom origin listens on.

- **HTTPSPort** (integer) – [REQUIRED] The HTTPS port the custom origin listens on.

- **OriginProtocolPolicy** (string) – [REQUIRED] The origin protocol policy to apply to your origin.

- **DefaultCacheBehavior** (dict) – [REQUIRED] A complex type that describes the default cache behavior if you do not specify a CacheBehavior element or if files don’t match any of the values of PathPattern in CacheBehavior elements. You must create exactly one default cache behavior.

  - **TargetOriginId** (string) – [REQUIRED] The value of ID for the origin that you want CloudFront to route requests to when a request matches the path pattern either for a cache behavior or for the default cache behavior.

  - **ForwardedValues** (dict) – [REQUIRED] A complex type that specifies how CloudFront handles query strings, cookies and headers.

    * **QueryString** (boolean) – [REQUIRED] Indicates whether you want CloudFront to forward query strings to the origin that is associated with this cache behavior. If so, specify true; if not, specify false.
Cookies (dict) – [REQUIRED] A complex type that specifies how CloudFront handles cookies.

* Forward (string) – [REQUIRED] Use this element to specify whether you want CloudFront to forward cookies to the origin that is associated with this cache behavior. You can specify all, none or whitelist. If you choose All, CloudFront forwards all cookies regardless of how many your application uses.
* WhitelistedNames (dict) – A complex type that specifies the whitelisted cookies, if any, that you want CloudFront to forward to your origin that is associated with this cache behavior.
* Quantity (integer) – [REQUIRED] The number of whitelisted cookies for this cache behavior.
* Items (list) – Optional: A complex type that contains whitelisted cookies for this cache behavior. If Quantity is 0, you can omit Items.

Headers (dict) – A complex type that specifies the Headers, if any, that you want CloudFront to vary upon for this cache behavior.

* Quantity (integer) – [REQUIRED] The number of different headers that you want CloudFront to forward to the origin and to vary on for this cache behavior. The maximum number of headers that you can specify by name is 10. If you want CloudFront to forward all headers to the origin and vary on all of them, specify 1 for Quantity and * for Name. If you don’t want CloudFront to forward any additional headers to the origin or to vary on any headers, specify 0 for Quantity and omit Items.
* Items (list) – Optional: A complex type that contains a Name element for each header that you want CloudFront to forward to the origin and to vary on for this cache behavior. If Quantity is 0, omit Items.

TrustedSigners (dict) – [REQUIRED] A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.

* Enabled (boolean) – [REQUIRED] Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.
* Quantity (integer) – [REQUIRED] The number of trusted signers for this cache behavior.
* Items (list) – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.

ViewerProtocolPolicy (string) – [REQUIRED] Use this element to spec-
ify the protocol that users can use to access the files in the origin specified by TargetOriginId when a request matches the path pattern in PathPattern. If you want CloudFront to allow end users to use any available protocol, specify allow-all. If you want CloudFront to require HTTPS, specify https. If you want CloudFront to respond to an HTTP request with an HTTP status code of 301 (Moved Permanently) and the HTTPS URL, specify redirect-to-https. The viewer then resubmits the request using the HTTPS URL.

- **MinTTL** *(integer)* – [REQUIRED] The minimum amount of time that you want objects to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **AllowedMethods** *(dict)* – A complex type that controls which HTTP methods CloudFront processes and forwards to your Amazon S3 bucket or your custom origin. There are three choices: - CloudFront forwards only GET and HEAD requests. - CloudFront forwards only GET, HEAD and OPTIONS requests. - CloudFront forwards GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests. If you pick the third choice, you may need to restrict access to your Amazon S3 bucket or to your custom origin so users can't perform operations that you don’t want them to. For example, you may not want users to have permission to delete objects from your origin.

  * **Quantity** *(integer)* – [REQUIRED] The number of HTTP methods that you want CloudFront to forward to your origin. Valid values are 2 (for GET and HEAD requests), 3 (for GET, HEAD and OPTIONS requests) and 7 (for GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests).

  * **Items** *(list)* – [REQUIRED] A complex type that contains the HTTP methods that you want CloudFront to process and forward to your origin.

  - *(string)* –

- **CachedMethods** *(dict)* – A complex type that controls whether CloudFront caches the response to requests using the specified HTTP methods. There are two choices: - CloudFront caches responses to GET and HEAD requests. - CloudFront caches responses to GET, HEAD, and OPTIONS requests. If you pick the second choice for your S3 Origin, you may need to forward Access-Control-Request-Method, Access-Control-Request-Headers and Origin headers for the responses to be cached correctly.

  * **Quantity** *(integer)* – [REQUIRED] The number of HTTP methods for which you want CloudFront to cache responses. Valid values are 2 (for caching responses to GET and HEAD requests) and 3 (for caching responses to GET, HEAD, and OPTIONS requests).

  * **Items** *(list)* – [REQUIRED] A complex type that contains the HTTP methods that you want CloudFront to cache responses to.

  - *(string)* –

- **SmoothStreaming** *(boolean)* – Indicates whether you want to distribute media files in Microsoft Smooth Streaming format using the origin that is associated with this cache behavior. If so, specify true; if not, specify false.

- **DefaultTTL** *(integer)* – If you don’t configure your origin to add a Cache-Control max-age directive or an Expires header, DefaultTTL is the default
amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin does not add HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **MaxTTL (integer)** – The maximum amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin adds HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **CacheBehaviors (dict)** – A complex type that contains zero or more CacheBehavior elements.
  - **Quantity (integer)** – [REQUIRED] The number of cache behaviors for this distribution.
  - **Items (list)** – Optional: A complex type that contains cache behaviors for this distribution. If Quantity is 0, you can omit Items.
    * (dict) – A complex type that describes how CloudFront processes requests. You can create up to 10 cache behaviors. You must create at least as many cache behaviors (including the default cache behavior) as you have origins if you want CloudFront to distribute objects from all of the origins. Each cache behavior specifies the one origin from which you want CloudFront to get objects. If you have two origins and only the default cache behavior, the default cache behavior will cause CloudFront to get objects from one of the origins, but the other origin will never be used. If you don’t want to specify any cache behaviors, include only an empty CacheBehaviors element. Don’t include an empty CacheBehavior element, or CloudFront returns a MalformedXML error. To delete all cache behaviors in an existing distribution, update the distribution configuration and include only an empty CacheBehaviors element. To add, change, or remove one or more cache behaviors, update the distribution configuration and specify all of the cache behaviors that you want to include in the updated distribution.
    - **PathPattern (string)** – [REQUIRED] The pattern (for example, images/*.jpg) that specifies which requests you want this cache behavior to apply to. When CloudFront receives an end-user request, the requested path is compared with path patterns in the order in which cache behaviors are listed in the distribution. The path pattern for the default cache behavior is * and cannot be changed. If the request for an object does not match the path pattern for any cache behaviors, CloudFront applies the behavior in the default cache behavior.
    - **TargetOriginId (string)** – [REQUIRED] The value of ID for the origin that you want CloudFront to route requests to when a request matches the path pattern either for a cache behavior or for the default cache behavior.
    - **ForwardedValues (dict)** – [REQUIRED] A complex type that specifies how CloudFront handles query strings, cookies and headers.
    - **QueryString (boolean)** – [REQUIRED] Indicates whether you want CloudFront to forward query strings to the origin
that is associated with this cache behavior. If so, specify true; if not, specify false.

- **Cookies (dict)** – [REQUIRED] A complex type that specifies how CloudFront handles cookies.
- **Forward (string)** – [REQUIRED] Use this element to specify whether you want CloudFront to forward cookies to the origin that is associated with this cache behavior. You can specify all, none or whitelist. If you choose All, CloudFront forwards all cookies regardless of how many your application uses.
- **WhitelistedNames (dict)** – A complex type that specifies the whitelisted cookies, if any, that you want CloudFront to forward to your origin that is associated with this cache behavior.
- **Quantity (integer)** – [REQUIRED] The number of whitelisted cookies for this cache behavior.
- **Items (list)** – Optional: A complex type that contains whitelisted cookies for this cache behavior. If Quantity is 0, you can omit Items.
- **Headers (dict)** – A complex type that specifies the Headers, if any, that you want CloudFront to vary upon for this cache behavior.
- **Quantity (integer)** – [REQUIRED] The number of different headers that you want CloudFront to forward to the origin and to vary on for this cache behavior. The maximum number of headers that you can specify by name is 10. If you want CloudFront to forward all headers to the origin and vary on all of them, specify 1 for Quantity and * for Name. If you don’t want CloudFront to forward any additional headers to the origin or to vary on any headers, specify 0 for Quantity and omit Items.
- **Items (list)** – Optional: A complex type that contains a Name element for each header that you want CloudFront to forward to the origin and to vary on for this cache behavior. If Quantity is 0, omit Items.
- **TrustedSigners (dict)** – [REQUIRED] A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.
- **Enabled (boolean)** – [REQUIRED] Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.
- **Quantity (integer)** – [REQUIRED] The number of trusted signers for this cache behavior.
- **Items (list)** – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.
- **(string)** – 
- **ViewerProtocolPolicy (string)** – [REQUIRED] Use this element to specify the protocol that users can use to access the files in the origin specified by TargetOriginId when a request matches the path pattern in PathPattern. If you want CloudFront to allow end users to use any available protocol, specify allow-all. If you want CloudFront to require HTTPS, specify https. If you want CloudFront to respond to an HTTP request with an HTTP status code of 301 (Moved Permanently) and the HTTPS URL, specify redirect-to-https. The viewer then resubmits the request using the HTTPS URL.
- **MinTTL (integer)** – [REQUIRED] The minimum amount of time that you want objects to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 3,153,600,000 seconds (100 years).
- **AllowedMethods (dict)** – A complex type that controls which HTTP methods CloudFront processes and forwards to your Amazon S3 bucket or your custom origin. There are three choices: - CloudFront forwards only GET and HEAD requests. - CloudFront forwards only GET, HEAD and OPTIONS requests. - CloudFront forwards GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests. If you pick the third choice, you may need to restrict access to your Amazon S3 bucket or to your custom origin so users can’t perform operations that you don’t want them to. For example, you may not want users to have permission to delete objects from your origin.
- **Quantity (integer)** – [REQUIRED] The number of HTTP methods that you want CloudFront to forward to your origin. Valid values are 2 (for GET and HEAD requests), 3 (for GET, HEAD and OPTIONS requests) and 7 (for GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests).
- **Items (list)** – [REQUIRED] A complex type that contains the HTTP methods that you want CloudFront to process and forward to your origin.
- **(string)** – 
- **CachedMethods (dict)** – A complex type that controls whether CloudFront caches the response to requests using the specified HTTP methods. There are two choices: - CloudFront caches responses to GET and HEAD requests. - CloudFront caches responses to GET, HEAD, and OPTIONS requests. If you pick the second choice for your S3 Origin, you may need to forward Access-Control-Request-Method, Access-Control-Request-Headers and Origin headers for the responses to be cached correctly.
- **Quantity (integer)** – [REQUIRED] The number of HTTP methods for which you want CloudFront to cache responses. Valid values are 2 (for caching responses to GET and HEAD
A complex type that contains the HTTP methods that you want CloudFront to cache responses to.

- **SmoothStreaming** *(boolean)* – Indicates whether you want to distribute media files in Microsoft Smooth Streaming format using the origin that is associated with this cache behavior. If so, specify true; if not, specify false.

- **DefaultTTL** *(integer)* – If you don’t configure your origin to add a Cache-Control max-age directive or an Expires header, DefaultTTL is the default amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin does not add HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **MaxTTL** *(integer)* – The maximum amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin adds HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **CustomErrorResponses** *(dict)* – A complex type that contains zero or more CustomErrorResponse elements.
  - **Quantity** *(integer)* – [REQUIRED] The number of custom error responses for this distribution.
  - **Items** *(list)* – Optional: A complex type that contains custom error responses for this distribution. If Quantity is 0, you can omit Items.
    * *(dict)* – A complex type that describes how you’d prefer CloudFront to respond to requests that result in either a 4xx or 5xx response. You can control whether a custom error page should be displayed, what the desired response code should be for this error page and how long should the error response be cached by CloudFront. If you don’t want to specify any custom error responses, include only an empty CustomErrorResponses element. To delete all custom error responses in an existing distribution, update the distribution configuration and include only an empty CustomErrorResponses element. To add, change, or remove one or more custom error responses, update the distribution configuration and specify all of the custom error responses that you want to include in the updated distribution.
      - **ErrorCode** *(integer)* – [REQUIRED] The 4xx or 5xx HTTP status code that you want to customize. For a list of HTTP status codes that you can customize, see CloudFront documentation.
      - **ResponsePagePath** *(string)* – The path of the custom error page (for example, /custom_404.html). The path is relative to the distribution and must begin with a slash (/). If the path includes any non-ASCII characters or unsafe characters as de-
fined in RFC 1783 (http://www.ietf.org/rfc/rfc1738.txt), URL encode those characters. Do not URL encode any other characters in the path, or CloudFront will not return the custom error page to the viewer.

- **ResponseCode** *(string)* – The HTTP status code that you want CloudFront to return with the custom error page to the viewer. For a list of HTTP status codes that you can replace, see CloudFront Documentation.

- **ErrorCachingMinTTL** *(integer)* – The minimum amount of time you want HTTP error codes to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 31,536,000.

- **Comment** *(string)* – [REQUIRED] Any comments you want to include about the distribution.

- **Logging** *(dict)* – A complex type that controls whether access logs are written for the distribution.

  - **Enabled** *(boolean)* – [REQUIRED] Specifies whether you want CloudFront to save access logs to an Amazon S3 bucket. If you do not want to enable logging when you create a distribution or if you want to disable logging for an existing distribution, specify false for Enabled, and specify empty Bucket and Prefix elements. If you specify false for Enabled but you specify values for Bucket, prefix and IncludeCookies, the values are automatically deleted.

  - **IncludeCookies** *(boolean)* – [REQUIRED] Specifies whether you want CloudFront to include cookies in access logs, specify true for IncludeCookies. If you choose to include cookies in logs, CloudFront logs all cookies regardless of how you configure the cache behaviors for this distribution. If you do not want to include cookies when you create a distribution or if you want to disable include cookies for an existing distribution, specify false for IncludeCookies.

  - **Bucket** *(string)* – [REQUIRED] The Amazon S3 bucket to store the access logs in, for example, myawslogbucket.s3.amazonaws.com.

  - **Prefix** *(string)* – [REQUIRED] An optional string that you want CloudFront to prefix to the access log filenames for this distribution, for example, myprefix/. If you want to enable logging, but you do not want to specify a prefix, you still must include an empty Prefix element in the Logging element.

- **PriceClass** *(string)* – A complex type that contains information about price class for this distribution.

- **Enabled** *(boolean)* – [REQUIRED] Whether the distribution is enabled to accept end user requests for content.

- **ViewerCertificate** *(dict)* – A complex type that contains information about viewer certificates for this distribution.

  - **IAMCertificateId** *(string)* – If you want viewers to use HTTPS to request your objects and you’re using an alternate domain name in your object URLs (for example, https://example.com/logo.jpg), specify the IAM certificate identifier of the custom viewer certificate for this distribution. Specify either this value or CloudFrontDefaultCertificate.

  - **CloudFrontDefaultCertificate** *(boolean)* – If you want viewers to use HTTPS to request your objects and you’re using the CloudFront domain name of your distribution in your object URLs (for example, https://d111111abcdef8.cloudfront.net/logo.jpg), set to true. Omit this value if you are setting an IAMCertificateId.
- **SSLSupportMethod** *(string)* – If you specify a value for IAMCertificateId, you must also specify how you want CloudFront to serve HTTPS requests. Valid values are vip and sni-only. If you specify vip, CloudFront uses dedicated IP addresses for your content and can respond to HTTPS requests from any viewer. However, you must request permission to use this feature, and you incur additional monthly charges. If you specify sni-only, CloudFront can only respond to HTTPS requests from viewers that support Server Name Indication (SNI). All modern browsers support SNI, but some browsers still in use don’t support SNI. Do not specify a value for SSLSupportMethod if you specified true for CloudFrontDefaultCertificate.

- **MinimumProtocolVersion** *(string)* – Specify the minimum version of the SSL protocol that you want CloudFront to use, SSLv3 or TLSv1, for HTTPS connections. CloudFront will serve your objects only to browsers or devices that support at least the SSL version that you specify. The TLSv1 protocol is more secure, so we recommend that you specify SSLv3 only if your users are using browsers or devices that don’t support TLSv1. If you’re using a custom certificate (if you specify a value for IAMCertificateId) and if you’re using dedicated IP (if you specify vip for SSLSupportMethod), you can choose SSLv3 or TLSv1 as the MinimumProtocolVersion. If you’re using a custom certificate (if you specify a value for IAMCertificateId) and if you’re using SNI (if you specify sni-only for SSLSupportMethod), you must specify TLSv1 for MinimumProtocolVersion.

**Restrictions** *(dict)* – A complex type that identifies ways in which you want to restrict distribution of your content.

- **GeoRestriction** *(dict)* – [REQUIRED] A complex type that controls the countries in which your content is distributed. For more information about geo restriction, go to Customizing Error Responses in the Amazon CloudFront Developer Guide. CloudFront determines the location of your users using MaxMind GeoIP databases. For information about the accuracy of these databases, see How accurate are your GeoIP databases? on the MaxMind website.

  - **RestrictionType** *(string)* – [REQUIRED] The method that you want to use to restrict distribution of your content by country: - none: No geo restriction is enabled, meaning access to content is not restricted by client geo location. - blacklist: The Location elements specify the countries in which you do not want CloudFront to distribute your content. - whitelist: The Location elements specify the countries in which you want CloudFront to distribute your content.

  - **Quantity** *(integer)* – [REQUIRED] When geo restriction is enabled, this is the number of countries in your whitelist or blacklist. Otherwise, when it is not enabled, Quantity is 0, and you can omit Items.

  - **Items** *(list)* – A complex type that contains a Location element for each country in which you want CloudFront either to distribute your content (whitelist) or not distribute your content (blacklist). The Location element is a two-letter, uppercase country code for a country that you want to include in your blacklist or whitelist. Include one Location element for each country. CloudFront and MaxMind both use ISO 3166 country codes. For the current list of countries and the corresponding codes, see ISO 3166-1-alpha-2 code on the International Organization for Standardization website. You can also refer
to the country list in the CloudFront console, which includes both country names and codes.

Return type  dict

Returns

Response Syntax

```python
{
    'Distribution': {
        'Id': 'string',

Response Structure

• (dict) – The returned result of the corresponding request.
  – Distribution (dict) – The distribution’s information.
    • Id (string) – The identifier for the distribution. For example: EDFD-VBD632BHDS5.
    • Status (string) – This response element indicates the current status of the distribution. When the status is Deployed, the distribution’s information is fully propagated throughout the Amazon CloudFront system.
    • LastModifiedTime (datetime) – The date and time the distribution was last modified.
    • InProgressInvalidationBatches (integer) – The number of invalidation batches currently in progress.
    • DomainName (string) – The domain name corresponding to the distribution. For example: d604721fxaayq9.cloudfront.net.
    • ActiveTrustedSigners (dict) – CloudFront automatically adds this element to the response only if you’ve set up the distribution to serve private content with signed URLs. The element lists the key pair IDs that CloudFront is aware of for each trusted signer. The Signer child element lists the AWS account number of the trusted signer (or an empty Self element if the signer is you). The Signer element also includes the IDs of any active key pairs associated with the trusted signer’s AWS account. If no KeyPairId element appears for a Signer, that signer can’t create working signed URLs.
      • Enabled (boolean) – Each active trusted signer.
      • Quantity (integer) – The number of unique trusted signers included in all cache behaviors. For example, if three cache behaviors all list the same three AWS accounts, the value of Quantity for ActiveTrustedSigners will be 3.
      • Items (list) – A complex type that contains one Signer complex type for each unique trusted signer that is specified in the TrustedSigners complex type, including trusted signers in the default cache behavior and in all of the other cache behaviors.
  • (dict) – A complex type that lists the AWS accounts that were included in the TrustedSigners complex type, as well as their
· **AwsAccountNumber (string)** – Specifies an AWS account that can create signed URLs. Values: self, which indicates that the AWS account that was used to create the distribution can created signed URLs, or an AWS account number. Omit the dashes in the account number.

· **KeyPairIds (dict)** – A complex type that lists the active CloudFront key pairs, if any, that are associated with AwsAccountNumber.

· **Quantity (integer)** – The number of active CloudFront key pairs for AwsAccountNumber.

· **Items (list)** – A complex type that lists the active CloudFront key pairs, if any, that are associated with AwsAccountNumber.

· **CallerReference (string)** – A unique number that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the DistributionConfig object), a new distribution is created. If the CallerReference is a value you already sent in a previous request to create a distribution, and the content of the DistributionConfig is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create a distribution but the content of the DistributionConfig is different from the original request, CloudFront returns a DistributionAlreadyExists error.

· **Aliases (dict)** – A complex type that contains information about CNAMEs (alternate domain names), if any, for this distribution.

· **Quantity (integer)** – The number of CNAMEs, if any, for this distribution.

· **Items (list)** – Optional: A complex type that contains CNAME elements, if any, for this distribution. If Quantity is 0, you can omit Items.

· **DefaultRootObject (string)** – The object that you want CloudFront to return (for example, index.html) when an end user requests the root URL for your distribution (http://www.example.com) instead of an object in your distribution (http://www.example.com/index.html). Specifying a default root object avoids exposing the contents of your distribution. If you don’t want to specify a default root object when you create a distribution, include an empty DefaultRootObject element. To delete the default root object from an existing distribution, update the distribution configuration and include an empty DefaultRootObject element. To replace the default root object, update the distribution configuration and specify the new object.

· **Origins (dict)** – A complex type that contains information about origins for this distribution.

· **Quantity (integer)** – The number of origins for this distribution.
tion.

- **Items (list)** – A complex type that contains origins for this distribution.

- **(dict)** – A complex type that describes the Amazon S3 bucket or the HTTP server (for example, a web server) from which CloudFront gets your files. You must create at least one origin.

- **Id (string)** – A unique identifier for the origin. The value of Id must be unique within the distribution. You use the value of Id when you create a cache behavior. The Id identifies the origin that CloudFront routes a request to when the request matches the path pattern for that cache behavior.

- **DomainName (string)** – Amazon S3 origins: The DNS name of the Amazon S3 bucket from which you want CloudFront to get objects for this origin, for example, myawsbucket.s3.amazonaws.com. Custom origins: The DNS domain name for the HTTP server from which you want CloudFront to get objects for this origin, for example, www.example.com.

- **OriginPath (string)** – An optional element that causes CloudFront to request your content from a directory in your Amazon S3 bucket or your custom origin. When you include the OriginPath element, specify the directory name, beginning with a /. CloudFront appends the directory name to the value of DomainName.

- **S3OriginConfig (dict)** – A complex type that contains information about the Amazon S3 origin. If the origin is a custom origin, use the CustomOriginConfig element instead.

- **OriginAccessIdentity (string)** – The CloudFront origin access identity to associate with the origin. Use an origin access identity to configure the origin so that end users can only access objects in an Amazon S3 bucket through CloudFront. If you want end users to be able to access objects using either the CloudFront URL or the Amazon S3 URL, specify an empty OriginAccessIdentity element. To delete the origin access identity from an existing distribution, update the distribution configuration and include an empty OriginAccessIdentity element. To replace the origin access identity, update the distribution configuration and specify the new origin access identity. Use the format origin-access-identity/cloudfront/Id where Id is the value that CloudFront returned in the Id element when you created the origin access identity.

- **CustomOriginConfig (dict)** – A complex type that contains information about a custom origin. If the origin is an Amazon S3 bucket, use the S3OriginConfig element instead.

- **HTTPPort (integer)** – The HTTP port the custom origin listens on.

- **HTTPSPort (integer)** – The HTTPS port the custom origin listens on.

- **OriginProtocolPolicy (string)** – The origin protocol policy to apply to your origin.

- **DefaultCacheBehavior (dict)** – A complex type that describes the default cache behavior if you do not specify a CacheBehavior element or if files don’t match any of the values of PathPattern in CacheBehavior elements. You must cre-
ate exactly one default cache behavior.

- **TargetOriginId** (**string**) – The value of ID for the origin that you want CloudFront to route requests to when a request matches the path pattern either for a cache behavior or for the default cache behavior.

- **ForwardedValues** (**dict**) – A complex type that specifies how CloudFront handles query strings, cookies and headers.
  - **QueryString** (**boolean**) – Indicates whether you want CloudFront to forward query strings to the origin that is associated with this cache behavior. If so, specify true; if not, specify false.
  - **Cookies** (**dict**) – A complex type that specifies how CloudFront handles cookies.
    - **Forward** (**string**) – Use this element to specify whether you want CloudFront to forward cookies to the origin that is associated with this cache behavior. You can specify all, none or whitelist. If you choose All, CloudFront forwards all cookies regardless of how many your application uses.
    - **WhitelistedNames** (**dict**) – A complex type that specifies the whitelisted cookies, if any, that you want CloudFront to forward to your origin that is associated with this cache behavior.
    - **Quantity** (**integer**) – The number of whitelisted cookies for this cache behavior.
    - **Items** (**list**) – Optional: A complex type that contains whitelisted cookies for this cache behavior. If Quantity is 0, you can omit Items.
  - **Headers** (**dict**) – A complex type that specifies the Headers, if any, that you want CloudFront to vary upon for this cache behavior.
    - **Quantity** (**integer**) – The number of different headers that you want CloudFront to forward to the origin and to vary on for this cache behavior. The maximum number of headers that you can specify by name is 10. If you want CloudFront to forward all headers to the origin and vary on all of them, specify 1 for Quantity and * for Name. If you don’t want CloudFront to forward any additional headers to the origin or to vary on any headers, specify 0 for Quantity and omit Items.
    - **Items** (**list**) – Optional: A complex type that contains a Name element for each header that you want CloudFront to forward to the origin and to vary on for this cache behavior. If Quantity is 0, omit Items.
  - **TrustedSigners** (**dict**) – A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more
trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.

- **Enabled (boolean)** – Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.
- **Quantity (integer)** – The number of trusted signers for this cache behavior.
- **Items (list)** – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.
- **(string)** –
- **ViewerProtocolPolicy (string)** – Use this element to specify the protocol that users can use to access the files in the origin specified by TargetOriginId when a request matches the path pattern in PathPattern. If you want CloudFront to allow end users to use any available protocol, specify allow-all. If you want CloudFront to require HTTPS, specify https. If you want CloudFront to respond to an HTTP request with an HTTP status code of 301 (Moved Permanently) and the HTTPS URL, specify redirect-to-https. The viewer then resubmits the request using the HTTPS URL.
- **MinTTL (integer)** – The minimum amount of time that you want objects to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 3,153,600,000 seconds (100 years).
- **AllowedMethods (dict)** – A complex type that controls which HTTP methods CloudFront processes and forwards to your Amazon S3 bucket or your custom origin. There are three choices: - CloudFront forwards only GET and HEAD requests. - CloudFront forwards only GET, HEAD and OPTIONS requests. - CloudFront forwards GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests. If you pick the third choice, you may need to restrict access to your Amazon S3 bucket or to your custom origin so users can’t perform operations that you don’t want them to. For example, you may not want users to have permission to delete objects from your origin.
- **Quantity (integer)** – The number of HTTP methods that you want CloudFront to forward to your origin. Valid values are 2 (for GET and HEAD requests), 3 (for GET, HEAD and OPTIONS requests) and 7 (for GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests).
- **Items (list)** – A complex type that contains the HTTP methods that you want CloudFront to process and forward to your origin.
- **(string)** –
- **CachedMethods (dict)** – A complex type that controls whether CloudFront caches the response to requests using the specified HTTP methods. There are two choices: - CloudFront caches responses to GET and HEAD requests. - CloudFront caches responses to GET, HEAD, and OPTIONS requests. If you pick the second choice for your S3 Origin,
you may need to forward Access-Control-Request-Method, Access-Control-Request-Headers and Origin headers for the responses to be cached correctly.

- **Quantity (integer)** – The number of HTTP methods for which you want CloudFront to cache responses. Valid values are 2 (for caching responses to GET and HEAD requests) and 3 (for caching responses to GET, HEAD, and OPTIONS requests).
- **Items (list)** – A complex type that contains the HTTP methods that you want CloudFront to cache responses to.
- **SmoothStreaming (boolean)** – Indicates whether you want to distribute media files in Microsoft Smooth Streaming format using the origin that is associated with this cache behavior. If so, specify true; if not, specify false.
- **DefaultTTL (integer)** – If you don’t configure your origin to add a Cache-Control max-age directive or an Expires header, DefaultTTL is the default amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin does not add HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).
- **MaxTTL (integer)** – The maximum amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin adds HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).
- **CacheBehaviors (dict)** – A complex type that contains zero or more CacheBehavior elements.
- **Quantity (integer)** – The number of cache behaviors for this distribution.
- **Items (list)** – Optional: A complex type that contains cache behaviors for this distribution. If Quantity is 0, you can omit Items.
- **(dict)** – A complex type that describes how CloudFront processes requests. You can create up to 10 cache behaviors. You must create at least as many cache behaviors (including the default cache behavior) as you have origins if you want CloudFront to distribute objects from all of the origins. Each cache behavior specifies the one origin from which you want CloudFront to get objects. If you have two origins and only the default cache behavior, the default cache behavior will cause CloudFront to get objects from one of the origins, but the other origin will never be used. If you don’t want to specify any cache behaviors, include only an empty CacheBehaviors element. Don’t include an empty CacheBehavior element, or CloudFront returns a MalformedXML error. To delete all cache behaviors in an existing distribution, update the distribution configuration and include only an
empty CacheBehaviors element. To add, change, or remove one or more cache behaviors, update the distribution configuration and specify all of the cache behaviors that you want to include in the updated distribution.

- **PathPattern (string)** – The pattern (for example, images/*, .jpg) that specifies which requests you want this cache behavior to apply to. When CloudFront receives an end-user request, the requested path is compared with path patterns in the order in which cache behaviors are listed in the distribution. The path pattern for the default cache behavior is * and cannot be changed. If the request for an object does not match the path pattern for any cache behaviors, CloudFront applies the behavior in the default cache behavior.

- **TargetOriginId (string)** – The value of ID for the origin that you want CloudFront to route requests to when a request matches the path pattern either for a cache behavior or for the default cache behavior.

- **ForwardedValues (dict)** – A complex type that specifies how CloudFront handles query strings, cookies and headers.

- **QueryString (boolean)** – Indicates whether you want CloudFront to forward query strings to the origin that is associated with this cache behavior. If so, specify true; if not, specify false.

- **Cookies (dict)** – A complex type that specifies how CloudFront handles cookies.

- **Forward (string)** – Use this element to specify whether you want CloudFront to forward cookies to the origin that is associated with this cache behavior. You can specify all, none or whitelist. If you choose All, CloudFront forwards all cookies regardless of how many your application uses.

- **WhitelistedNames (dict)** – A complex type that specifies the whitelisted cookies, if any, that you want CloudFront to forward to your origin that is associated with this cache behavior.

- **Quantity (integer)** – The number of whitelisted cookies for this cache behavior.

- **Items (list)** – Optional: A complex type that contains whitelisted cookies for this cache behavior. If Quantity is 0, you can omit Items.

- **(string)** –

- **Headers (dict)** – A complex type that specifies the Headers, if any, that you want CloudFront to vary upon for this cache behavior.

- **Quantity (integer)** – The number of different headers that you want CloudFront to forward to the origin and to vary on for this cache behavior. The maximum number of headers that you can specify by name is 10. If you want CloudFront to forward all headers to the origin and vary on all of them, specify 1 for Quantity and * for Name. If you don’t want CloudFront to forward any additional headers to the origin or to vary on any headers, specify 0 for Quantity and omit Items.

- **Items (list)** – Optional: A complex type that contains a Name element for each header that you want CloudFront to forward to the origin and to vary on for this cache behavior. If Quantity is 0, omit Items.
· (string) –
· TrustedSigners (dict) – A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.
· Enabled (boolean) – Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.
· Quantity (integer) – The number of trusted signers for this cache behavior.
· Items (list) – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.
· (string) –
· ViewerProtocolPolicy (string) – Use this element to specify the protocol that users can use to access the files in the origin specified by TargetOriginId when a request matches the path pattern in PathPattern. If you want CloudFront to allow end users to use any available protocol, specify allow-all. If you want CloudFront to require HTTPS, specify https. If you want CloudFront to respond to an HTTP request with an HTTP status code of 301 (Moved Permanently) and the HTTPS URL, specify redirect-to-https. The viewer then resubmits the request using the HTTPS URL.
· MinTTL (integer) – The minimum amount of time that you want objects to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 3,153,600,000 seconds (100 years).
· AllowedMethods (dict) – A complex type that controls which HTTP methods CloudFront processes and forwards to your Amazon S3 bucket or your custom origin. There are three choices: - CloudFront forwards only GET and HEAD requests. - CloudFront forwards only GET, HEAD and OPTIONS requests. - CloudFront forwards GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests. If you pick the third choice, you may need to restrict access to your Amazon S3 bucket or to your custom origin so users can’t perform operations that you don’t want them to. For example, you may not want users to have permission to delete objects from your origin.
· Quantity (integer) – The number of HTTP methods that you want CloudFront to forward to your origin. Valid values are 2 (for GET and HEAD requests), 3 (for GET, HEAD and OP-
TIONS requests) and 7 (for GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests).

- **Items (list)** – A complex type that contains the HTTP methods that you want CloudFront to process and forward to your origin.

- **(string)** –

- **CachedMethods (dict)** – A complex type that controls whether CloudFront caches the response to requests using the specified HTTP methods. There are two choices: - CloudFront caches responses to GET and HEAD requests. - CloudFront caches responses to GET, HEAD, and OPTIONS requests. If you pick the second choice for your S3 Origin, you may need to forward Access-Control-Request-Method, Access-Control-Request-Headers and Origin headers for the responses to be cached correctly.

- **Quantity (integer)** – The number of HTTP methods for which you want CloudFront to cache responses. Valid values are 2 (for caching responses to GET and HEAD requests) and 3 (for caching responses to GET, HEAD, and OPTIONS requests).

- **Items (list)** – A complex type that contains the HTTP methods that you want CloudFront to cache responses to.

- **(string)** –

- **SmoothStreaming (boolean)** – Indicates whether you want to distribute media files in Microsoft Smooth Streaming format using the origin that is associated with this cache behavior. If so, specify true; if not, specify false.

- **DefaultTTL (integer)** – If you don’t configure your origin to add a Cache-Control max-age directive or an Expires header, DefaultTTL is the default amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin does not add HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **MaxTTL (integer)** – The maximum amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin adds HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **CustomErrorResponses (dict)** – A complex type that contains zero or more CustomErrorResponse elements.

- **Quantity (integer)** – The number of custom error responses for this distribution.

- **Items (list)** – Optional: A complex type that contains custom error responses for this distribution. If Quantity is 0, you can omit Items.

- **(dict)** – A complex type that describes how you’d prefer CloudFront to respond to requests that result in either a 4xx or 5xx response. You can control whether a custom error page
should be displayed, what the desired response code should be for this error page and how long should the error response be cached by CloudFront. If you don’t want to specify any custom error responses, include only an empty CustomErrorResponses element. To delete all custom error responses in an existing distribution, update the distribution configuration and include only an empty CustomErrorResponses element. To add, change, or remove one or more custom error responses, update the distribution configuration and specify all of the custom error responses that you want to include in the updated distribution.

- **ErrorCode (integer)** – The 4xx or 5xx HTTP status code that you want to customize. For a list of HTTP status codes that you can customize, see CloudFront documentation.
- **ResponsePagePath (string)** – The path of the custom error page (for example, /custom_404.html). The path is relative to the distribution and must begin with a slash (/). If the path includes any non-ASCII characters or unsafe characters as defined in RFC 1783 (http://www.ietf.org/rfc/rfc1738.txt), URL encode those characters. Do not URL encode any other characters in the path, or CloudFront will not return the custom error page to the viewer.
- **ResponseCode (string)** – The HTTP status code that you want CloudFront to return with the custom error page to the viewer. For a list of HTTP status codes that you can replace, see CloudFront Documentation.
- **ErrorCachingMinTTL (integer)** – The minimum amount of time you want HTTP error codes to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 31,536,000.
- **Comment (string)** – Any comments you want to include about the distribution.
- **Logging (dict)** – A complex type that controls whether access logs are written for the distribution.
- **Enabled (boolean)** – Specifies whether you want CloudFront to save access logs to an Amazon S3 bucket. If you do not want to enable logging when you create a distribution or if you want to disable logging for an existing distribution, specify false for Enabled, and specify empty Bucket and Prefix elements. If you specify false for Enabled but you specify values for Bucket, prefix and IncludeCookies, the values are automatically deleted.
- **IncludeCookies (boolean)** – Specifies whether you want CloudFront to include cookies in access logs, specify true for IncludeCookies. If you choose to include cookies in logs, CloudFront logs all cookies regardless of how you configure the cache behaviors for this distribution. If you do not want to include cookies when you create a distribution or if you want to disable include cookies for an existing distribution, specify false for IncludeCookies.
- **Bucket (string)** – The Amazon S3 bucket to store the access logs in, for example, myawslogbucket.s3.amazonaws.com.
- **Prefix (string)** – An optional string that you want CloudFront
to prefix to the access log filenames for this distribution, for example, myprefix/. If you want to enable logging, but you do not want to specify a prefix, you still must include an empty Prefix element in the Logging element.

- **PriceClass (string)** – A complex type that contains information about price class for this distribution.
- **Enabled (boolean)** – Whether the distribution is enabled to accept end user requests for content.
- **ViewerCertificate (dict)** – A complex type that contains information about viewer certificates for this distribution.
- **IAMCertificateId (string)** – If you want viewers to use HTTPS to request your objects and you’re using an alternate domain name in your object URLs (for example, https://example.com/logo.jpg), specify the IAM certificate identifier of the custom viewer certificate for this distribution. Specify either this value or CloudFrontDefaultCertificate.
- **CloudFrontDefaultCertificate (boolean)** – If you want viewers to use HTTPS to request your objects and you’re using the CloudFront domain name of your distribution in your object URLs (for example, https://d1111111abcdef8.cloudfront.net/logo.jpg), set to true. Omit this value if you are setting an IAMCertificateId.
- **SSLSupportMethod (string)** – If you specify a value for IAMCertificateId, you must also specify how you want CloudFront to serve HTTPS requests. Valid values are vip and sni-only. If you specify vip, CloudFront uses dedicated IP addresses for your content and can respond to HTTPS requests from any viewer. However, you must request permission to use this feature, and you incur additional monthly charges. If you specify sni-only, CloudFront can only respond to HTTPS requests from viewers that support Server Name Indication (SNI). All modern browsers support SNI, but some browsers still in use don’t support SNI. Do not specify a value for SSLSupportMethod if you specified true for CloudFrontDefaultCertificate.
- **MinimumProtocolVersion (string)** – Specify the minimum version of the SSL protocol that you want CloudFront to use, SSLv3 or TLSv1, for HTTPS connections. CloudFront will serve your objects only to browsers or devices that support at least the SSL version that you specify. The TLSv1 protocol is more secure, so we recommend that you specify SSLv3 only if your users are using browsers or devices that don’t support TLSv1. If you’re using a custom certificate (if you specify a value for IAMCertificateId) and if you’re using dedicated IP (if you specify vip for SSLSupportMethod), you can choose SSLv3 or TLSv1 as the MinimumProtocolVersion. If you’re using a custom certificate (if you specify a value for IAMCertificateId) and if you’re using SNI (if you specify sni-only for SSLSupportMethod), you must specify TLSv1 for MinimumProtocolVersion.
- **Restrictions (dict)** – A complex type that identifies ways in which you want to restrict distribution of your content.
- **GeoRestriction (dict)** – A complex type that controls the countries in which your content is distributed. For more in-
information about geo restriction, go to Customizing Error Responses in the Amazon CloudFront Developer Guide. CloudFront determines the location of your users using MaxMind GeoIP databases. For information about the accuracy of these databases, see How accurate are your GeoIP databases? on the MaxMind website.

- **RestrictionType (string)** – The method that you want to use to restrict distribution of your content by country: - none: No geo restriction is enabled, meaning access to content is not restricted by client geo location. - blacklist: The Location elements specify the countries in which you do not want CloudFront to distribute your content. - whitelist: The Location elements specify the countries in which you want CloudFront to distribute your content.

- **Quantity (integer)** – When geo restriction is enabled, this is the number of countries in your whitelist or blacklist. Otherwise, when it is not enabled, Quantity is 0, and you can omit Items.

- **Items (list)** – A complex type that contains a Location element for each country in which you want CloudFront either to distribute your content (whitelist) or not distribute your content (blacklist). The Location element is a two-letter, uppercase country code for a country that you want to include in your blacklist or whitelist. Include one Location element for each country. CloudFront and MaxMind both use ISO 3166 country codes. For the current list of countries and the corresponding codes, see ISO 3166-1-alpha-2 code on the International Organization for Standardization website. You can also refer to the country list in the CloudFront console, which includes both country names and codes.

- **(string)** –
  - **Location (string)** – The fully qualified URI of the new distribution resource just created. For example: https://cloudfront.amazonaws.com/2010-11-01/distribution/EDFDVBD632BHDS5.
  - **ETag (string)** – The current version of the distribution created.

**create_invalidation(****kwargs**

Create a new invalidation.

**Request Syntax**

```python
response = client.create_invalidation(
    DistributionId='string',
    InvalidationBatch={
        'Paths': {
            'Quantity': 123,
            'Items': [
                'string',
            ]
        },
        'CallerReference': 'string'
    }
)
```

**Parameters**
• **DistributionId** *(string)* – [REQUIRED] The distribution’s id.
• **InvalidationBatch** *(dict)* – [REQUIRED] The batch information for the invalidation.
  - **Paths** *(dict)* – [REQUIRED] The path of the object to invalidate. The path is relative to the distribution and must begin with a slash (/). You must enclose each invalidation object with the Path element tags. If the path includes non-ASCII characters or unsafe characters as defined in RFC 1783 (http://www.ietf.org/rfc/rfc1738.txt), URL encode those characters. Do not URL encode any other characters in the path, or CloudFront will not invalidate the old version of the updated object.
    * **Quantity** *(integer)* – [REQUIRED] The number of objects that you want to invalidate.
    * **Items** *(list)* – A complex type that contains a list of the objects that you want to invalidate.
    · *(string)* –
  - **CallerReference** *(string)* – [REQUIRED] A unique name that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the Path object), a new distribution is created. If the CallerReference is a value you already sent in a previous request to create an invalidation batch, and the content of each Path element is identical to the original request, the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create a distribution but the content of any Path is different from the original request, CloudFront returns an Invalidation-BatchAlreadyExists error.

Return type  dict

Returns

Response Syntax

{  
    'Location': 'string',  
    'Invalidation': {  
        'Id': 'string',  
        'Status': 'string',  
        'CreateTime': datetime(2015, 1, 1),  
        'InvalidationBatch': {  
            'Paths': {  
                'Quantity': 123,  
                'Items': [  
                    'string',  
                ]  
            },  
            'CallerReference': 'string'  
        }  
    }  
}

Response Structure

• *(dict)* – The returned result of the corresponding request.
  - **Location** *(string)* – The fully qualified URI of the distribution and invalidation batch request, including the Invalidation ID.
  - **Invalidation** *(dict)* – The invalidation’s information.
    * **Id** *(string)* – The identifier for the invalidation request. For example: IDFDVBD632BHDS5.
**Status (string)** – The status of the invalidation request. When the invalidation batch is finished, the status is Completed.

**CreateTime (datetime)** – The date and time the invalidation request was first made.

**InvalidationBatch (dict)** – The current invalidation information for the batch request.

- **Paths (dict)** – The path of the object to invalidate. The path is relative to the distribution and must begin with a slash (/). You must enclose each invalidation object with the Path element tags. If the path includes non-ASCII characters or unsafe characters as defined in RFC 1783 (http://www.ietf.org/rfc/rfc1738.txt), URL encode those characters. Do not URL encode any other characters in the path, or CloudFront will not invalidate the old version of the updated object.

- **Quantity (integer)** – The number of objects that you want to invalidate.

- **Items (list)** – A complex type that contains a list of the objects that you want to invalidate.

- **CallerReference (string)** – A unique name that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the Path object), a new distribution is created. If the CallerReference is a value you already sent in a previous request to create an invalidation batch, and the content of each Path element is identical to the original request, the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create a distribution but the content of any Path is different from the original request, CloudFront returns an InvalidationBatchAlreadyExists error.

```python
create_streaming_distribution(**kwargs)

Create a new streaming distribution.

Request Syntax

response = client.create_streaming_distribution(
    StreamingDistributionConfig={
        'CallerReference': 'string',
        'S3Origin': {
            'DomainName': 'string',
            'OriginAccessIdentity': 'string'
        },
        'Aliases': {
            'Quantity': 123,
            'Items': [
                'string'
            ]
        },
        'Comment': 'string',
        'Logging': {
            'Enabled': True|False,
            'Bucket': 'string',
            'Prefix': 'string'
        }
    )
```

200 Chapter 3. API Reference
'TrustedSigners': {
    'Enabled': True|False,
    'Quantity': 123,
    'Items': [
        'string',
    ],
},
'PriceClass': 'PriceClass_100'|'PriceClass_200'|'PriceClass_All',
'Enabled': True|False
}

Parameters

- CallerReference (string) – [REQUIRED] A unique number that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the StreamingDistributionConfig object), a new streaming distribution is created. If the CallerReference is a value you already sent in a previous request to create a streaming distribution, and the content of the StreamingDistributionConfig is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create a streaming distribution but the content of the StreamingDistributionConfig is different from the original request, CloudFront returns a DistributionAlreadyExists error.

- S3Origin (dict) – [REQUIRED] A complex type that contains information about the Amazon S3 bucket from which you want CloudFront to get your media files for distribution.
  - DomainName (string) – [REQUIRED] The DNS name of the S3 origin.

- Aliases (dict) – A complex type that contains information about CNAMEs (alternate domain names), if any, for this streaming distribution.
  - Quantity (integer) – [REQUIRED] The number of CNAMEs, if any, for this distribution.
  - Items (list) – Optional: A complex type that contains CNAME elements, if any, for this distribution. If Quantity is 0, you can omit Items.

- Comment (string) – [REQUIRED] Any comments you want to include about the streaming distribution.

- Logging (dict) – A complex type that controls whether access logs are written for the streaming distribution.
  - Enabled (boolean) – [REQUIRED] Specifies whether you want CloudFront to save access logs to an Amazon S3 bucket. If you do not want to enable logging when you create a streaming distribution or if you want to disable logging for an existing streaming distribution, specify false for Enabled, and specify empty Bucket and Prefix elements. If you specify false for Enabled but you specify values for Bucket and Prefix, the values are automatically deleted.
  - Bucket (string) – [REQUIRED] The Amazon S3 bucket to store the access logs in, for example, myawslogbucket.s3.amazonaws.com.
  - Prefix (string) – [REQUIRED] An optional string that you want CloudFront to prefix to the access log filenames for this streaming distribution, for example, myprefix/. If you want to enable logging, but you do not want to specify a prefix, you still must include an empty Prefix element in the Logging element.
• **TrustedSigners** (*dict*) – [REQUIRED] A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.

  – **Enabled** (*boolean*) – [REQUIRED] Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.

  – **Quantity** (*integer*) – [REQUIRED] The number of trusted signers for this cache behavior.

  – **Items** (*list*) – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.

• **PriceClass** (*string*) – A complex type that contains information about price class for this streaming distribution.

• **Enabled** (*boolean*) – [REQUIRED] Whether the streaming distribution is enabled to accept end user requests for content.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
  'StreamingDistribution': {
    'Id': 'string',
    'Status': 'string',
    'LastModifiedTime': datetime(2015, 1, 1),
    'DomainName': 'string',
    'ActiveTrustedSigners': {
      'Enabled': True|False,
      'Quantity': 123,
      'Items': [
        {
          'AwsAccountNumber': 'string',
          'KeyPairIds': {
            'Quantity': 123,
            'Items': [
              'string',
            ]
          }
        }
      ],
    },
    'StreamingDistributionConfig': {
      'CallerReference': 'string',
      'S3Origin': {
        'DomainName': 'string',
        'OriginAccessIdentity': 'string'
      },
      'Aliases': {
      }
    }
  }
}
```
'Quantity': 123,
'Items': [
    'string',
]
},
'Comment': 'string',
'Logging': {
    'Enabled': True|False,
    'Bucket': 'string',
    'Prefix': 'string'
},
'TrustedSigners': {
    'Enabled': True|False,
    'Quantity': 123,
    'Items': [
        'string',
    ]
},
'PriceClass': 'PriceClass_100'|'PriceClass_200'|'PriceClass_All',
'Enabled': True|False
},
'Location': 'string',
'ETag': 'string'

**Response Structure**

- *(dict)* – The returned result of the corresponding request.
  - **StreamingDistribution**(dict) – The streaming distribution’s information.
    - **Id**(string) – The identifier for the streaming distribution. For example: EGTXBD79H29TRA8.
    - **Status**(string) – The current status of the streaming distribution. When the status is Deployed, the distribution’s information is fully propagated throughout the Amazon CloudFront system.
    - **LastModifiedTime**(datetime) – The date and time the distribution was last modified.
    - **DomainName**(string) – The domain name corresponding to the streaming distribution. For example: s5c39gqb8ow64r.cloudfront.net.
    - **ActiveTrustedSigners**(dict) – CloudFront automatically adds this element to the response only if you’ve set up the distribution to serve private content with signed URLs. The element lists the key pair IDs that CloudFront is aware of for each trusted signer. The Signer child element lists the AWS account number of the trusted signer (or an empty Self element if the signer is you). The Signer element also includes the IDs of any active key pairs associated with the trusted signer’s AWS account. If no KeyPairId element appears for a Signer, that signer can’t create working signed URLs.
      - **Enabled**(boolean) – Each active trusted signer.
      - **Quantity**(integer) – The number of unique trusted signers included in all cache behaviors. For example, if three cache behaviors all list the same three AWS accounts, the value of Quantity for ActiveTrustedSigners will be 3.
      - **Items**(list) – A complex type that contains one Signer complex type for each unique trusted signer that is specified in the TrustedSigners complex type, including trusted signers in the
default cache behavior and in all of the other cache behaviors.

- (dict) – A complex type that lists the AWS accounts that were included in the TrustedSigners complex type, as well as their active CloudFront key pair IDs, if any.
- **AwsAccountNumber** *(string)* – Specifies an AWS account that can create signed URLs. Values: self, which indicates that the AWS account that was used to create the distribution can created signed URLs, or an AWS account number. Omit the dashes in the account number.
- **KeyIdPairIds** *(dict)* – A complex type that lists the active CloudFront key pairs, if any, that are associated with AwsAccountNumber.
- **Quantity** *(integer)* – The number of active CloudFront key pairs for AwsAccountNumber.
- **Items** *(list)* – A complex type that lists the active CloudFront key pairs, if any, that are associated with AwsAccountNumber.
- *(string)* –

**StreamingDistributionConfig** *(dict)* – The current configuration information for the streaming distribution.

- **CallerReference** *(string)* – A unique number that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the StreamingDistributionConfig object), a new streaming distribution is created. If the CallerReference is a value you already sent in a previous request to create a streaming distribution, and the content of the StreamingDistributionConfig is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create a streaming distribution but the content of the StreamingDistributionConfig is different from the original request, CloudFront returns a DistributionAlreadyExists error.
- **S3Origin** *(dict)* – A complex type that contains information about the Amazon S3 bucket from which you want CloudFront to get your media files for distribution.
- **DomainName** *(string)* – The DNS name of the S3 origin.
- **OriginAccessIdentity** *(string)* – Your S3 origin’s origin access identity.
- **Aliases** *(dict)* – A complex type that contains information about CNAMEs (alternate domain names), if any, for this streaming distribution.
- **Quantity** *(integer)* – The number of CNAMEs, if any, for this distribution.
- **Items** *(list)* – Optional: A complex type that contains CNAME elements, if any, for this distribution. If Quantity is 0, you can omit Items.
- *(string)* –
- **Comment** *(string)* – Any comments you want to include about the streaming distribution.
- **Logging** *(dict)* – A complex type that controls whether access logs are written for the streaming distribution.
- **Enabled** *(boolean)* – Specifies whether you want CloudFront to save access logs to an Amazon S3 bucket. If you do not
want to enable logging when you create a streaming distribution or if you want to disable logging for an existing streaming distribution, specify false for Enabled, and specify empty Bucket and Prefix elements. If you specify false for Enabled but you specify values for Bucket and Prefix, the values are automatically deleted.

- **Bucket** *(string)* – The Amazon S3 bucket to store the access logs in, for example, myawslogbucket.s3.amazonaws.com.
- **Prefix** *(string)* – An optional string that you want CloudFront to prefix to the access log filenames for this streaming distribution, for example, myprefix/. If you want to enable logging, but you do not want to specify a prefix, you still must include an empty Prefix element in the Logging element.
- **TrustedSigners** *(dict)* – A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.
- **Enabled** *(boolean)* – Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.
- **Quantity** *(integer)* – The number of trusted signers for this cache behavior.
- **Items** *(list)* – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.
- **PriceClass** *(string)* – A complex type that contains information about price class for this streaming distribution.
- **Enabled** *(boolean)* – Whether the streaming distribution is enabled to accept end user requests for content.

- **ETag** *(string)* – The current version of the streaming distribution created.

```python
delete_cloud_front_origin_access_identity(**kwargs)
```

Delete an origin access identity.

**Request Syntax**

```python
response = client.delete_cloud_front_origin_access_identity(
    Id='string',
    IfMatch='string'
)
```
Parameters
• **Id** *(string)* – [REQUIRED] The origin access identity’s id.
• **IfMatch** *(string)* – The value of the ETag header you received from a previous
  GET or PUT request. For example: E2QWRUHAPOMQZL.

Returns None

data-testid="Boto3DocumentationRelease1.1.4"
data-testid="Boto3DocumentationRelease1.1.4"
data-testid="Boto3DocumentationRelease1.1.4"
data-testid="Boto3DocumentationRelease1.1.4"
data-testid="Boto3DocumentationRelease1.1.4"
data-testid="Boto3DocumentationRelease1.1.4"
data-testid="Boto3DocumentationRelease1.1.4"
data-testid="Boto3DocumentationRelease1.1.4"

delete_distribution (**kwargs)**
Delete a distribution.

Request Syntax

```python
response = client.delete_distribution(
    Id='string',
    IfMatch='string'
)
```

Parameters
• **Id** *(string)* – [REQUIRED] The distribution id.
• **IfMatch** *(string)* – The value of the ETag header you received when you disabled
  the distribution. For example: E2QWRUHAPOMQZL.

Returns None

data-testid="Boto3DocumentationRelease1.1.4"

data-testid="Boto3DocumentationRelease1.1.4"

delete_streaming_distribution (**kwargs)**
Delete a streaming distribution.

Request Syntax

```python
response = client.delete_streaming_distribution(
    Id='string',
    IfMatch='string'
)
```

Parameters
• **Id** *(string)* – [REQUIRED] The distribution id.
• **IfMatch** *(string)* – The value of the ETag header you received when you disabled
  the streaming distribution. For example: E2QWRUHAPOMQZL.

Returns None

generate_presigned_url *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*
Generate a presigned url given a client, its method, and arguments

Parameters
• **ClientMethod** *(string)* – The client method to presign for
• **Params** *(dict)* – The parameters normally passed to ClientMethod.
• **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By
  default it expires in an hour (3600 seconds)
• **HttpMethod** *(string)* – The http method to use on the generated url. By default,
  the http method is whatever is used in the method’s model.

Returns The presigned url

generate_signing_url *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*
Generate a signing url given a client, its method, and arguments

Parameters
• **ClientMethod** *(string)* – The client method to presign for
• **Params** *(dict)* – The parameters normally passed to ClientMethod.
• **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By
  default it expires in an hour (3600 seconds)
• **HttpMethod** *(string)* – The http method to use on the generated url. By default,
  the http method is whatever is used in the method’s model.

Returns The presigned url

generate_presigned_url_for_object *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*
Generate a presigned url for an object in the S3 bucket.

Parameters
• **ClientMethod** *(string)* – The client method to presign for
• **Params** *(dict)* – The parameters normally passed to ClientMethod.
• **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By
  default it expires in an hour (3600 seconds)
• **HttpMethod** *(string)* – The http method to use on the generated url. By default,
  the http method is whatever is used in the method’s model.

Returns The presigned url

generate_presigned_post_url *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*
Generate a presigned url for a post request.

Parameters
• **ClientMethod** *(string)* – The client method to presign for
• **Params** *(dict)* – The parameters normally passed to ClientMethod.
• **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By
  default it expires in an hour (3600 seconds)
• **HttpMethod** *(string)* – The http method to use on the generated url. By default,
  the http method is whatever is used in the method’s model.

Returns The presigned url

generate_presigned_url_for_object_(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*
Generate a presigned url for an object in the S3 bucket.

Parameters
• **ClientMethod** *(string)* – The client method to presign for
• **Params** *(dict)* – The parameters normally passed to ClientMethod.
• **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By
  default it expires in an hour (3600 seconds)
• **HttpMethod** *(string)* – The http method to use on the generated url. By default,
  the http method is whatever is used in the method’s model.

Returns The presigned url

generate_presigned_post_url_(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*
Generate a presigned url for a post request.

Parameters
• **ClientMethod** *(string)* – The client method to presign for
• **Params** *(dict)* – The parameters normally passed to ClientMethod.
• **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By
  default it expires in an hour (3600 seconds)
• **HttpMethod** *(string)* – The http method to use on the generated url. By default,
  the http method is whatever is used in the method’s model.

Returns The presigned url

data-testid="Boto3DocumentationRelease1.1.4"

data-testid="Boto3DocumentationRelease1.1.4"

data-testid="Boto3DocumentationRelease1.1.4"

data-testid="Boto3DocumentationRelease1.1.4"

data-testid="Boto3DocumentationRelease1.1.4"

data-testid="Boto3DocumentationRelease1.1.4"

data-testid="Boto3DocumentationRelease1.1.4"

data-testid="Boto3DocumentationRelease1.1.4"

get_cloud_front_origin_access_identity (**kwargs)**
Get the information about an origin access identity.

Request Syntax

```python
response = client.get_cloud_front_origin_access_identity(
    Id='string'
)
```

Parameters
• **Id** *(string)* – [REQUIRED] The identity’s id.
Return type  dict
Returns

Response Syntax

```
{
    'CloudFrontOriginAccessIdentity': {
        'Id': 'string',
        'S3CanonicalUserId': 'string',
        'CloudFrontOriginAccessIdentityConfig': {
            'CallerReference': 'string',
            'Comment': 'string'
        }
    },
    'ETag': 'string'
}
```

Response Structure

- (dict) – The returned result of the corresponding request.
  - CloudFrontOriginAccessIdentity (dict) – The origin access identity’s information.
    - **Id** (string) – The ID for the origin access identity. For example: E74FTE3AJFJ256A.
    - **S3CanonicalUserId** (string) – The Amazon S3 canonical user ID for the origin access identity, which you use when giving the origin access identity read permission to an object in Amazon S3.
    - **CloudFrontOriginAccessIdentityConfig** (dict) – The current configuration information for the identity.
      - **CallerReference** (string) – A unique number that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the CloudFrontOriginAccessIdentityConfig object), a new origin access identity is created. If the CallerReference is a value you already sent in a previous request to create an identity, and the content of the CloudFrontOriginAccessIdentityConfig is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create an identity but the content of the CloudFrontOriginAccessIdentityConfig is different from the original request, CloudFront returns a CloudFrontOriginAccessIdentityAlreadyExists error.
      - **Comment** (string) – Any comments you want to include about the origin access identity.
    - **ETag** (string) – The current version of the origin access identity’s information. For example: E2QWRUHAPOMQZL.

get_cloud_front_origin_access_identity_config(**kwargs)
Get the configuration information about an origin access identity.

Request Syntax

```python
response = client.get_cloud_front_origin_access_identity_config(
    Id='string'
)
```

Parameters  
- **Id** (string) – [REQUIRED] The identity’s id.
Return type  dict
Returns

Response Syntax

```python
{
    'CloudFrontOriginAccessIdentityConfig': {
        'CallerReference': 'string',
        'Comment': 'string'
    },
    'ETag': 'string'
}
```

Response Structure

- *(dict)* – The returned result of the corresponding request.
  - **CloudFrontOriginAccessIdentityConfig** *(dict)* – The origin access identity’s configuration information.
    - **CallerReference** *(string)* – A unique number that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the CloudFrontOriginAccessIdentityConfig object), a new origin access identity is created. If the CallerReference is a value you already sent in a previous request to create an identity, and the content of the CloudFrontOriginAccessIdentityConfig is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create an identity but the content of the CloudFrontOriginAccessIdentityConfig is different from the original request, CloudFront returns a CloudFrontOriginAccessIdentityAlreadyExists error.
    - **Comment** *(string)* – Any comments you want to include about the origin access identity.
  - **ETag** *(string)* – The current version of the configuration. For example: E2QWRUHAPOMQZL.

**get_distribution(**kwargs**)**

Get the information about a distribution.

Request Syntax

```python
response = client.get_distribution(
    Id='string'
)
```

Parameters  **Id** *(string)* – [REQUIRED] The distribution’s id.

Return type  dict
Returns

Response Syntax

```python
{
    'Distribution': {
        'Id': 'string',
        'Status': 'string',
        'LastModifiedTime': datetime(2015, 1, 1),

3.1. Services 211
Response Structure

- **(dict)** – The returned result of the corresponding request.
  - **Distribution (dict)** – The distribution’s information.
    - **Id (string)** – The identifier for the distribution. For example: EDFD-VBD632BHDS5.
    - **Status (string)** – This response element indicates the current status of the distribution. When the status is Deployed, the distribution’s information is fully propagated throughout the Amazon CloudFront system.
    - **LastModifiedTime (datetime)** – The date and time the distribution was last modified.
    - **InProgressInvalidationBatches (integer)** – The number of invalidation batches currently in progress.
    - **DomainName (string)** – The domain name corresponding to the distribution. For example: d604721fxxaqy9.cloudfront.net.
    - **ActiveTrustedSigners (dict)** – CloudFront automatically adds this element to the response only if you’ve set up the distribution to serve private content with signed URLs. The element lists the key pair IDs that CloudFront is aware of for each trusted signer. The Signer child element lists the AWS account number of the trusted signer (or an empty Self element if the signer is you). The Signer element also includes the IDs of any active key pairs associated with the trusted signer’s AWS account. If no KeyPairId element appears for a Signer, that signer can’t create working signed URLs.
      - **Enabled (boolean)** – Each active trusted signer.
      - **Quantity (integer)** – The number of unique trusted signers included in all cache behaviors. For example, if three cache behaviors all list the same three AWS accounts, the value of Quantity for ActiveTrustedSigners will be 3.
      - **Items (list)** – A complex type that contains one Signer complex type for each unique trusted signer that is specified in the TrustedSigners complex type, including trusted signers in the default cache behavior and in all of the other cache behaviors.
      - **(dict)** – A complex type that lists the AWS accounts that were included in the TrustedSigners complex type, as well as their active CloudFront key pair IDs, if any.
    - **AwsAccountNumber (string)** – Specifies an AWS account that can create signed URLs. Values: self, which indicates that the AWS account that was used to create the distribution can created signed URLs, or an AWS account number. Omit the dashes in the account number.
    - **KeyPairIds (dict)** – A complex type that lists the active CloudFront key pairs, if any, that are associated with AwsAccountNumber.
      - **Quantity (integer)** – The number of active CloudFront key pairs for AwsAccountNumber.
      - **Items (list)** – A complex type that lists the active CloudFront key pairs, if any, that are associated with AwsAccountNumber.
    - **(string)** –
      - **DistributionConfig (dict)** – The current configuration information
for the distribution.

- **CallerReference** *(string)* – A unique number that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the DistributionConfig object), a new distribution is created. If the CallerReference is a value you already sent in a previous request to create a distribution, and the content of the DistributionConfig is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create a distribution but the content of the DistributionConfig is different from the original request, CloudFront returns a DistributionAlreadyExists error.

- **Aliases** *(dict)* – A complex type that contains information about CNAMEs (alternate domain names), if any, for this distribution.

- **Quantity** *(integer)* – The number of CNAMEs, if any, for this distribution.

- **Items** *(list)* – Optional: A complex type that contains CNAME elements, if any, for this distribution. If Quantity is 0, you can omit Items.

- **DefaultRootObject** *(string)* – The object that you want CloudFront to return (for example, index.html) when an end user requests the root URL for your distribution (http://www.example.com) instead of an object in your distribution (http://www.example.com/index.html). Specifying a default root object avoids exposing the contents of your distribution. If you don’t want to specify a default root object when you create a distribution, include an empty DefaultRootObject element. To delete the default root object from an existing distribution, update the distribution configuration and include an empty DefaultRootObject element. To replace the default root object, update the distribution configuration and specify the new object.

- **Origins** *(dict)* – A complex type that contains information about origins for this distribution.

- **Quantity** *(integer)* – The number of origins for this distribution.

- **Items** *(list)* – A complex type that contains origins for this distribution.

- **(dict)** – A complex type that describes the Amazon S3 bucket or the HTTP server (for example, a web server) from which CloudFront gets your files. You must create at least one origin.

- **Id** *(string)* – A unique identifier for the origin. The value of Id must be unique within the distribution. You use the value of Id when you create a cache behavior. The Id identifies the origin that CloudFront routes a request to when the request matches the path pattern for that cache behavior.

- **DomainName** *(string)* – Amazon S3 origins: The DNS name of the Amazon S3 bucket from which you want CloudFront to get objects for this origin, for example, myaws-bucket.s3.amazonaws.com. Custom origins: The DNS domain name for the HTTP server from which you want
CloudFront to get objects for this origin, for example, www.example.com.
- **OriginPath (string)** – An optional element that causes CloudFront to request your content from a directory in your Amazon S3 bucket or your custom origin. When you include the OriginPath element, specify the directory name, beginning with a /. CloudFront appends the directory name to the value of DomainName.
- **S3OriginConfig (dict)** – A complex type that contains information about the Amazon S3 origin. If the origin is a custom origin, use the CustomOriginConfig element instead.
- **OriginAccessIdentity (string)** – The CloudFront origin access identity to associate with the origin. Use an origin access identity to configure the origin so that end users can only access objects in an Amazon S3 bucket through CloudFront. If you want end users to be able to access objects using either the CloudFront URL or the Amazon S3 URL, specify an empty OriginAccessIdentity element. To delete the origin access identity from an existing distribution, update the distribution configuration and include an empty OriginAccessIdentity element. To replace the origin access identity, update the distribution configuration and specify the new origin access identity. Use the format origin-access-identity/cloudfront/Id where Id is the value that CloudFront returned in the Id element when you created the origin access identity.
- **CustomOriginConfig (dict)** – A complex type that contains information about a custom origin. If the origin is an Amazon S3 bucket, use the S3OriginConfig element instead.
- **HTTPPort (integer)** – The HTTP port the custom origin listens on.
- **HTTPSPort (integer)** – The HTTPS port the custom origin listens on.
- **OriginProtocolPolicy (string)** – The origin protocol policy to apply to your origin.
- **DefaultCacheBehavior (dict)** – A complex type that describes the default cache behavior if you do not specify a CacheBehavior element or if files don’t match any of the values of PathPattern in CacheBehavior elements. You must create exactly one default cache behavior.
- **TargetOriginId (string)** – The value of ID for the origin that you want CloudFront to route requests to when a request matches the path pattern either for a cache behavior or for the default cache behavior.
- **ForwardedValues (dict)** – A complex type that specifies how CloudFront handles query strings, cookies and headers.
- **QueryString (boolean)** – Indicates whether you want CloudFront to forward query strings to the origin that is associated with this cache behavior. If so, specify true; if not, specify false.
- **Cookies (dict)** – A complex type that specifies how CloudFront handles cookies.
- **Forward (string)** – Use this element to specify whether you want CloudFront to forward cookies to the origin that is associated with this cache behavior. You can specify all, none or
whitelist. If you choose All, CloudFront forwards all cookies regardless of how many your application uses.

- **WhitelistedNames (dict)** – A complex type that specifies the whitelisted cookies, if any, that you want CloudFront to forward to your origin that is associated with this cache behavior.

- **Quantity (integer)** – The number of whitelisted cookies for this cache behavior.

- **Items (list)** – Optional: A complex type that contains whitelisted cookies for this cache behavior. If Quantity is 0, you can omit Items.

- **Headers (dict)** – A complex type that specifies the Headers, if any, that you want CloudFront to vary upon for this cache behavior.

- **Quantity (integer)** – The number of different headers that you want CloudFront to forward to the origin and to vary on for this cache behavior. The maximum number of headers that you can specify by name is 10. If you want CloudFront to forward all headers to the origin and vary on all of them, specify 1 for Quantity and * for Name. If you don’t want CloudFront to forward any additional headers to the origin or to vary on any headers, specify 0 for Quantity and omit Items.

- **Items (list)** – Optional: A complex type that contains a Name element for each header that you want CloudFront to forward to the origin and to vary on for this cache behavior. If Quantity is 0, omit Items.

- **TrustedSigners (dict)** – A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.

- **Enabled (boolean)** – Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.

- **Quantity (integer)** – The number of trusted signers for this cache behavior.

- **Items (list)** – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.

- **ViewerProtocolPolicy (string)** – Use this element to specify the protocol that users can use to access the files in the origin specified by TargetOriginId when a request matches the path pattern in PathPattern. If you want CloudFront to allow end
users to use any available protocol, specify allow-all. If you want CloudFront to require HTTPS, specify https. If you want CloudFront to respond to an HTTP request with an HTTP status code of 301 (Moved Permanently) and the HTTPS URL, specify redirect-to-https. The viewer then resubmits the request using the HTTPS URL.

- **MinTTL (integer)** – The minimum amount of time that you want objects to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **AllowedMethods (dict)** – A complex type that controls which HTTP methods CloudFront processes and forwards to your Amazon S3 bucket or your custom origin. There are three choices: - CloudFront forwards only GET and HEAD requests. - CloudFront forwards only GET, HEAD and OPTIONS requests. - CloudFront forwards GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests. If you pick the third choice, you may need to restrict access to your Amazon S3 bucket or to your custom origin so users can’t perform operations that you don’t want them to. For example, you may not want users to have permission to delete objects from your origin.

- **Quantity (integer)** – The number of HTTP methods that you want CloudFront to forward to your origin. Valid values are 2 (for GET and HEAD requests), 3 (for GET, HEAD and OPTIONS requests) and 7 (for GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests).

- **Items (list)** – A complex type that contains the HTTP methods that you want CloudFront to process and forward to your origin.

- **CachedMethods (dict)** – A complex type that controls whether CloudFront caches the response to requests using the specified HTTP methods. There are two choices: - CloudFront caches responses to GET and HEAD requests. - CloudFront caches responses to GET, HEAD, and OPTIONS requests. If you pick the second choice for your S3 Origin, you may need to forward Access-Control-Request-Method, Access-Control-Request-Headers and Origin headers for the responses to be cached correctly.

- **Quantity (integer)** – The number of HTTP methods for which you want CloudFront to cache responses. Valid values are 2 (for caching responses to GET and HEAD requests) and 3 (for caching responses to GET, HEAD, and OPTIONS requests).

- **Items (list)** – A complex type that contains the HTTP methods that you want CloudFront to cache responses to.

- **(string)** –

- **SmoothStreaming (boolean)** – Indicates whether you want to distribute media files in Microsoft Smooth Streaming format using the origin that is associated with this cache behavior. If so, specify true; if not, specify false.

- **DefaultTTL (integer)** – If you don’t configure your origin to add a Cache-Control max-age directive or an Expires header,
DefaultTTL is the default amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin does not add HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **MaxTTL** (integer) – The maximum amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin adds HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **CacheBehaviors** (dict) – A complex type that contains zero or more CacheBehavior elements.

- **Quantity** (integer) – The number of cache behaviors for this distribution.

- **Items** (list) – Optional: A complex type that contains cache behaviors for this distribution. If Quantity is 0, you can omit Items.

- **(dict)** – A complex type that describes how CloudFront processes requests. You can create up to 10 cache behaviors. You must create at least as many cache behaviors (including the default cache behavior) as you have origins if you want CloudFront to distribute objects from all of the origins. Each cache behavior specifies the one origin from which you want CloudFront to get objects. If you have two origins and only the default cache behavior, the default cache behavior will cause CloudFront to get objects from one of the origins, but the other origin will never be used. If you don’t want to specify any cache behaviors, include only an empty CacheBehaviors element. Don’t include an empty CacheBehavior element, or CloudFront returns a MalformedXML error. To delete all cache behaviors in an existing distribution, update the distribution configuration and include only an empty CacheBehaviors element. To add, change, or remove one or more cache behaviors, update the distribution configuration and specify all of the cache behaviors that you want to include in the updated distribution.

- **PathPattern** (string) – The pattern (for example, images/*.jpg) that specifies which requests you want this cache behavior to apply to. When CloudFront receives an end-user request, the requested path is compared with path patterns in the order in which cache behaviors are listed in the distribution. The path pattern for the default cache behavior is * and cannot be changed. If the request for an object does not match the path pattern for any cache behaviors, CloudFront applies the behavior in the default cache behavior.

- **TargetOriginId** (string) – The value of ID for the origin that you want CloudFront to route requests to when a request matches the path pattern either for a cache behavior or for...
the default cache behavior.

- **ForwardedValues** *(dict)* – A complex type that specifies how CloudFront handles query strings, cookies and headers.
- **QueryString** *(boolean)* – Indicates whether you want CloudFront to forward query strings to the origin that is associated with this cache behavior. If so, specify true; if not, specify false.
- **Cookies** *(dict)* – A complex type that specifies how CloudFront handles cookies.
- **Forward** *(string)* – Use this element to specify whether you want CloudFront to forward cookies to the origin that is associated with this cache behavior. You can specify all, none or whitelist. If you choose All, CloudFront forwards all cookies regardless of how many your application uses.
- **WhitelistedNames** *(dict)* – A complex type that specifies the whitelisted cookies, if any, that you want CloudFront to forward to your origin that is associated with this cache behavior.
- **Quantity** *(integer)* – The number of whitelisted cookies for this cache behavior.
- **Items** *(list)* – Optional: A complex type that contains whitelisted cookies for this cache behavior. If Quantity is 0, you can omit Items.
- **Headers** *(dict)* – A complex type that specifies the Headers, if any, that you want CloudFront to vary upon for this cache behavior.
- **Quantity** *(integer)* – The number of different headers that you want CloudFront to forward to the origin and to vary on for this cache behavior. The maximum number of headers that you can specify by name is 10. If you want CloudFront to forward all headers to the origin and vary on all of them, specify 1 for Quantity and * for Name. If you don’t want CloudFront to forward any additional headers to the origin or to vary on any headers, specify 0 for Quantity and omit Items.
- **Items** *(list)* – Optional: A complex type that contains a Name element for each header that you want CloudFront to forward to the origin and to vary on for this cache behavior. If Quantity is 0, omit Items.
- **TrustedSigners** *(dict)* – A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.
- **Enabled** *(boolean)* – Specifies whether you want to require
end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.

- **Quantity (integer)** – The number of trusted signers for this cache behavior.
- **Items (list)** – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.
- **(string)** –
- **ViewerProtocolPolicy (string)** – Use this element to specify the protocol that users can use to access the files in the origin specified by TargetOriginId when a request matches the path pattern in PathPattern. If you want CloudFront to allow end users to use any available protocol, specify allow-all. If you want CloudFront to require HTTPS, specify https. If you want CloudFront to respond to an HTTP request with an HTTP status code of 301 (Moved Permanently) and the HTTPS URL, specify redirect-to-https. The viewer then resubmits the request using the HTTPS URL.
- **MinTTL (integer)** – The minimum amount of time that you want objects to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 3,153,600,000 seconds (100 years).
- **AllowedMethods (dict)** – A complex type that controls which HTTP methods CloudFront processes and forwards to your Amazon S3 bucket or your custom origin. There are three choices: - CloudFront forwards only GET and HEAD requests. - CloudFront forwards only GET, HEAD and OPTIONS requests. - CloudFront forwards GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests. If you pick the third choice, you may need to restrict access to your Amazon S3 bucket or to your custom origin so users can’t perform operations that you don’t want them to. For example, you may not want users to have permission to delete objects from your origin.
- **Quantity (integer)** – The number of HTTP methods that you want CloudFront to forward to your origin. Valid values are 2 (for GET and HEAD requests), 3 (for GET, HEAD and OPTIONS requests) and 7 (for GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests).
- **Items (list)** – A complex type that contains the HTTP methods that you want CloudFront to process and forward to your origin.
- **(string)** –
- **CachedMethods (dict)** – A complex type that controls whether CloudFront caches the response to requests using the specified HTTP methods. There are two choices: - CloudFront caches responses to GET and HEAD requests. - CloudFront caches responses to GET, HEAD, and OPTIONS requests. If you pick the second choice for your S3 Origin, you may need to forward Access-Control-Request-Method, Access-Control-Request-Headers and Origin headers for the responses to be cached correctly.
- **Quantity (integer)** – The number of HTTP methods for which
you want CloudFront to cache responses. Valid values are 2 (for caching responses to GET and HEAD requests) and 3 (for caching responses to GET, HEAD, and OPTIONS requests).

- **Items** *(list)* – A complex type that contains the HTTP methods that you want CloudFront to cache responses to.

- **(string)** –

- **SmoothStreaming** *(boolean)* – Indicates whether you want to distribute media files in Microsoft Smooth Streaming format using the origin that is associated with this cache behavior. If so, specify true; if not, specify false.

- **DefaultTTL** *(integer)* – If you don’t configure your origin to add a Cache-Control max-age directive or an Expires header, DefaultTTL is the default amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin does not add HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **MaxTTL** *(integer)* – The maximum amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin adds HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **CustomErrorResponses** *(dict)* – A complex type that contains zero or more CustomErrorResponse elements.

- **Quantity** *(integer)* – The number of custom error responses for this distribution.

- **Items** *(list)* – Optional: A complex type that contains custom error responses for this distribution. If Quantity is 0, you can omit Items.

- **(dict)** – A complex type that describes how you’d prefer CloudFront to respond to requests that result in either a 4xx or 5xx response. You can control whether a custom error page should be displayed, what the desired response code should be for this error page and how long should the error response be cached by CloudFront. If you don’t want to specify any custom error responses, include only an empty CustomErrorResponse element. To delete all custom error responses in an existing distribution, update the distribution configuration and include only an empty CustomErrorResponse element. To add, change, or remove one or more custom error responses, update the distribution configuration and specify all of the custom error responses that you want to include in the updated distribution.

- **ErrorCode** *(integer)* – The 4xx or 5xx HTTP status code that you want to customize. For a list of HTTP status codes that you can customize, see CloudFront documentation.

- **ResponsePagePath** *(string)* – The path of the custom error page (for example, /custom_404.html). The path is relative...
to the distribution and must begin with a slash (/). If the path includes any non-ASCII characters or unsafe characters as defined in RFC 1783 (http://www.ietf.org/rfc/rfc1738.txt), URL encode those characters. Do not URL encode any other characters in the path, or CloudFront will not return the custom error page to the viewer.

- **ResponseCode (string)** – The HTTP status code that you want CloudFront to return with the custom error page to the viewer. For a list of HTTP status codes that you can replace, see CloudFront Documentation.

- **ErrorCachingMinTTL (integer)** – The minimum amount of time you want HTTP error codes to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 31,536,000.

- **Comment (string)** – Any comments you want to include about the distribution.

- **Logging (dict)** – A complex type that controls whether access logs are written for the distribution.

- **Enabled (boolean)** – Specifies whether you want CloudFront to save access logs to an Amazon S3 bucket. If you do not want to enable logging when you create a distribution or if you want to disable logging for an existing distribution, specify false for Enabled, and specify empty Bucket and Prefix elements. If you specify false for Enabled but you specify values for Bucket, prefix and IncludeCookies, the values are automatically deleted.

- **IncludeCookies (boolean)** – Specifies whether you want CloudFront to include cookies in access logs, specify true for IncludeCookies. If you choose to include cookies in logs, CloudFront logs all cookies regardless of how you configure the cache behaviors for this distribution. If you do not want to include cookies when you create a distribution or if you want to disable include cookies for an existing distribution, specify false for IncludeCookies.

- **Bucket (string)** – The Amazon S3 bucket to store the access logs in, for example, myawslogbucket.s3.amazonaws.com.

- **Prefix (string)** – An optional string that you want CloudFront to prefix to the access log filenames for this distribution, for example, myprefix/. If you want to enable logging, but you do not want to specify a prefix, you still must include an empty Prefix element in the Logging element.

- **PriceClass (string)** – A complex type that contains information about price class for this distribution.

- **Enabled (boolean)** – Whether the distribution is enabled to accept end user requests for content.

- **ViewerCertificate (dict)** – A complex type that contains information about viewer certificates for this distribution.

- **IAMCertificateId (string)** – If you want viewers to use HTTPS to request your objects and you're using an alternate domain name in your object URLs (for example, https://example.com/logo.jpg), specify the IAM certificate identifier of the custom viewer certificate for this distribution. Specify either this value or CloudFrontDefaultCertificate.
· **CloudFrontDefaultCertificate** *(boolean)* – If you want viewers to use HTTPS to request your objects and you’re using the CloudFront domain name of your distribution in your object URLs (for example, https://d111111abcdef8.cloudfront.net/logo.jpg), set to true. Omit this value if you are setting an IAMCertificateId.

· **SSLSupportMethod** *(string)* – If you specify a value for IAMCertificateId, you must also specify how you want CloudFront to serve HTTPS requests. Valid values are vip and sni-only. If you specify vip, CloudFront uses dedicated IP addresses for your content and can respond to HTTPS requests from any viewer. However, you must request permission to use this feature, and you incur additional monthly charges. If you specify sni-only, CloudFront can only respond to HTTPS requests from viewers that support Server Name Indication (SNI). All modern browsers support SNI, but some browsers still in use don’t support SNI. Do not specify a value for SSLSupportMethod if you specified true for CloudFrontDefaultCertificate.

· **MinimumProtocolVersion** *(string)* – Specify the minimum version of the SSL protocol that you want CloudFront to use, SSLv3 or TLSv1, for HTTPS connections. CloudFront will serve your objects only to browsers or devices that support at least the SSL version that you specify. The TLSv1 protocol is more secure, so we recommend that you specify SSLv3 only if your users are using browsers or devices that don’t support TLSv1. If you’re using a custom certificate (if you specify a value for IAMCertificateId) and you’re using dedicated IP (if you specify vip for SSLSupportMethod), you can choose SSLv3 or TLSv1 as the MinimumProtocolVersion. If you’re using a custom certificate (if you specify a value for IAMCertificateId) and if you’re using SNI (if you specify sni-only for SSLSupportMethod), you must specify TLSv1 for MinimumProtocolVersion.

· **Restrictions** *(dict)* – A complex type that identifies ways in which you want to restrict distribution of your content.

· **GeoRestriction** *(dict)* – A complex type that controls the countries in which your content is distributed. For more information about geo restriction, go to Customizing Error Responses in the Amazon CloudFront Developer Guide. CloudFront determines the location of your users using MaxMind GeoIP databases. For information about the accuracy of these databases, see How accurate are your GeoIP databases? on the MaxMind website.

· **RestrictionType** *(string)* – The method that you want to use to restrict distribution of your content by country: - none: No geo restriction is enabled, meaning access to content is not restricted by client geo location. - blacklist: The Location elements specify the countries in which you do not want CloudFront to distribute your content. - whitelist: The Location elements specify the countries in which you want CloudFront to distribute your content.

· **Quantity** *(integer)* – When geo restriction is enabled, this is the number of countries in your whitelist or blacklist. Other-
wise, when it is not enabled, Quantity is 0, and you can omit Items.

- **Items** (list) – A complex type that contains a Location element for each country in which you want CloudFront either to distribute your content (whitelist) or not distribute your content (blacklist). The Location element is a two-letter, uppercase country code for a country that you want to include in your blacklist or whitelist. Include one Location element for each country. CloudFront and MaxMind both use ISO 3166 country codes. For the current list of countries and the corresponding codes, see ISO 3166-1-alpha-2 code on the International Organization for Standardization website. You can also refer to the country list in the CloudFront console, which includes both country names and codes.

- **ETag** (string) – The current version of the distribution’s information. For example: E2QWRUHAPOMQZL.

```python
get_distribution_config(**kwargs)
Get the configuration information about a distribution.

Request Syntax
response = client.get_distribution_config(
    Id='string'
)
```

**Parameters**

- **Id** (string) – [REQUIRED] The distribution’s id.

**Return type**
dict

**Returns**

**Response Syntax**

```python
{
    'DistributionConfig': {
        'CallerReference': 'string',
        'Aliases': {
            'Quantity': 123,
            'Items': ['string'],
        },
        'DefaultRootObject': 'string',
        'Origins': {
            'Quantity': 123,
            'Items': [
                {'Id': 'string',
                 'DomainName': 'string',
                 'OriginPath': 'string',
                 'S3OriginConfig': {
                     'OriginAccessIdentity': 'string'
                 },
                 'CustomOriginConfig': {
                     'HTTPPort': 123,
                     'HTTPSPort': 123,
                     'OriginProtocolPolicy': 'http-only'|'match-viewer'
                 }
            ]
        }
    }
}
```
'DefaultCacheBehavior': {  
    'TargetOriginId': 'string',  
    'ForwardedValues': {  
        'QueryString': True|False,  
        'Cookies': {  
            'Forward': 'none'|'whitelist'|'all',  
            'WhitelistedNames': {  
            'Quantity': 123,

Response Structure

- (dict) – The returned result of the corresponding request.
  - DistributionConfig (dict) – The distribution’s configuration information.
    - CallerReference (string) – A unique number that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the DistributionConfig object), a new distribution is created. If the CallerReference is a value you already sent in a previous request to create a distribution, and the content of the DistributionConfig is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create a distribution but the content of the DistributionConfig is different from the original request, CloudFront returns a DistributionAlreadyExists error.
    -Aliases (dict) – A complex type that contains information about CNAMEs (alternate domain names), if any, for this distribution.
      - Quantity (integer) – The number of CNAMEs, if any, for this distribution.
      - Items (list) – Optional: A complex type that contains CNAME elements, if any, for this distribution. If Quantity is 0, you can omit Items.
    - (string)
    - DefaultRootObject (string) – The object that you want CloudFront to return (for example, index.html) when an end user requests the root URL for your distribution (http://www.example.com) instead of an object in your distribution (http://www.example.com/index.html). Specifying a default root object avoids exposing the contents of your distribution. If you don’t want to specify a default root object when you create a distribution, include an empty DefaultRootObject element. To delete the default root object from an existing distribution, update the distribution configuration and include an empty DefaultRootObject.
element. To replace the default root object, update the distribution configuration and specify the new object.

- **Origins** *(dict)* – A complex type that contains information about origins for this distribution.
  - **Quantity** *(integer)* – The number of origins for this distribution.
  - **Items** *(list)* – A complex type that contains origins for this distribution.
    - *(dict)* – A complex type that describes the Amazon S3 bucket or the HTTP server (for example, a web server) from which CloudFront gets your files. You must create at least one origin.
  - **Id** *(string)* – A unique identifier for the origin. The value of Id must be unique within the distribution. You use the value of Id when you create a cache behavior. The Id identifies the origin that CloudFront routes a request to when the request matches the path pattern for that cache behavior.
  - **DomainName** *(string)* – Amazon S3 origins: The DNS name of the Amazon S3 bucket from which you want CloudFront to get objects for this origin, for example, myaws-bucket.s3.amazonaws.com. Custom origins: The DNS domain name for the HTTP server from which you want CloudFront to get objects for this origin, for example, www.example.com.
  - **OriginPath** *(string)* – An optional element that causes CloudFront to request your content from a directory in your Amazon S3 bucket or your custom origin. When you include the OriginPath element, specify the directory name, beginning with a /. CloudFront appends the directory name to the value of DomainName.
  - **S3OriginConfig** *(dict)* – A complex type that contains information about the Amazon S3 origin. If the origin is a custom origin, use the CustomOriginConfig element instead.
  - **OriginAccessIdentity** *(string)* – The CloudFront origin access identity to associate with the origin. Use an origin access identity to configure the origin so that end users can only access objects in an Amazon S3 bucket through CloudFront. If you want end users to be able to access objects using either the CloudFront URL or the Amazon S3 URL, specify an empty OriginAccessIdentity element. To delete the origin access identity from an existing distribution, update the distribution configuration and include an empty OriginAccessIdentity element. To replace the origin access identity, update the distribution configuration and specify the new origin access identity. Use the format origin-access-identity/cloudfront/Id where Id is the value that CloudFront returned in the Id element when you created the origin access identity.
  - **CustomOriginConfig** *(dict)* – A complex type that contains information about a custom origin. If the origin is an Amazon S3 bucket, use the S3OriginConfig element instead.
  - **HTTPPort** *(integer)* – The HTTP port the custom origin listens on.
  - **HTTPSPort** *(integer)* – The HTTPS port the custom origin listens on.
  - **OriginProtocolPolicy** *(string)* – The origin protocol policy
to apply to your origin.

* DefaultCacheBehavior (dict) – A complex type that describes the default cache behavior if you do not specify a CacheBehavior element or if files don’t match any of the values of PathPattern in CacheBehavior elements. You must create exactly one default cache behavior.

  - TargetOriginId (string) – The value of ID for the origin that you want CloudFront to route requests to when a request matches the path pattern either for a cache behavior or for the default cache behavior.
  - ForwardedValues (dict) – A complex type that specifies how CloudFront handles query strings, cookies and headers.
  - QueryString (boolean) – Indicates whether you want CloudFront to forward query strings to the origin that is associated with this cache behavior. If so, specify true; if not, specify false.
  - Cookies (dict) – A complex type that specifies how CloudFront handles cookies.
  - Forward (string) – Use this element to specify whether you want CloudFront to forward cookies to the origin that is associated with this cache behavior. You can specify all, none or whitelist. If you choose All, CloudFront forwards all cookies regardless of how many your application uses.
  - WhitelistedNames (dict) – A complex type that specifies the whitelisted cookies, if any, that you want CloudFront to forward to your origin that is associated with this cache behavior.
  - Quantity (integer) – The number of whitelisted cookies for this cache behavior.
  - Items (list) – Optional: A complex type that contains whitelisted cookies for this cache behavior. If Quantity is 0, you can omit Items.

  - (string) –
    - Headers (dict) – A complex type that specifies the Headers, if any, that you want CloudFront to vary upon for this cache behavior.
  - Quantity (integer) – The number of different headers that you want CloudFront to forward to the origin and to vary on for this cache behavior. The maximum number of headers that you can specify by name is 10. If you want CloudFront to forward all headers to the origin and vary on all of them, specify 1 for Quantity and * for Name. If you don’t want CloudFront to forward any additional headers to the origin or to vary on any headers, specify 0 for Quantity and omit Items.
  - Items (list) – Optional: A complex type that contains a Name element for each header that you want CloudFront to forward to the origin and to vary on for this cache behavior. If Quantity is 0, omit Items.

  - (string) –
    - TrustedSigners (dict) – A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items.
more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.

- **Enabled (boolean)** – Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.
- **Quantity (integer)** – The number of trusted signers for this cache behavior.
- **Items (list)** – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.

- **ViewerProtocolPolicy (string)** – Use this element to specify the protocol that users can use to access the files in the origin specified by TargetOriginId when a request matches the path pattern in PathPattern. If you want CloudFront to allow end users to use any available protocol, specify allow-all. If you want CloudFront to require HTTPS, specify https. If you want CloudFront to respond to an HTTP request with an HTTP status code of 301 (Moved Permanently) and the HTTPS URL, specify redirect-to-https. The viewer then resubmits the request using the HTTPS URL.
- **MinTTL (integer)** – The minimum amount of time that you want objects to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 3,153,600,000 seconds (100 years).
- **AllowedMethods (dict)** – A complex type that controls which HTTP methods CloudFront processes and forwards to your Amazon S3 bucket or your custom origin. There are three choices: - CloudFront forwards only GET and HEAD requests. - CloudFront forwards only GET, HEAD and OPTIONS requests. - CloudFront forwards GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests. If you pick the third choice, you may need to restrict access to your Amazon S3 bucket or to your custom origin so users can’t perform operations that you don’t want them to. For example, you may not want users to have permission to delete objects from your origin.
- **Quantity (integer)** – The number of HTTP methods that you want CloudFront to forward to your origin. Valid values are 2 (for GET and HEAD requests), 3 (for GET, HEAD and OPTIONS requests) and 7 (for GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests).
- **Items (list)** – A complex type that contains the HTTP methods that you want CloudFront to process and forward to your origin.

- **(string)** –
- **CachedMethods (dict)** – A complex type that controls
whether CloudFront caches the response to requests using the specified HTTP methods. There are two choices: - CloudFront caches responses to GET and HEAD requests. - CloudFront caches responses to GET, HEAD, and OPTIONS requests. If you pick the second choice for your S3 Origin, you may need to forward Access-Control-Request-Method, Access-Control-Request-Headers and Origin headers for the responses to be cached correctly.

- **Quantity (integer)** – The number of HTTP methods for which you want CloudFront to cache responses. Valid values are 2 (for caching responses to GET and HEAD requests) and 3 (for caching responses to GET, HEAD, and OPTIONS requests).
- **Items (list)** – A complex type that contains the HTTP methods that you want CloudFront to cache responses to.
  - **(string)**
  - **SmoothStreaming (boolean)** – Indicates whether you want to distribute media files in Microsoft Smooth Streaming format using the origin that is associated with this cache behavior. If so, specify true; if not, specify false.
- **DefaultTTL (integer)** – If you don’t configure your origin to add a Cache-Control max-age directive or an Expires header, DefaultTTL is the default amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin does not add HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).
- **MaxTTL (integer)** – The maximum amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin adds HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **CacheBehaviors (dict)** – A complex type that contains zero or more CacheBehavior elements.
  - **Quantity (integer)** – The number of cache behaviors for this distribution.
  - **Items (list)** – Optional: A complex type that contains cache behaviors for this distribution. If Quantity is 0, you can omit Items.
  - **(dict)** – A complex type that describes how CloudFront processes requests. You can create up to 10 cache behaviors. You must create at least as many cache behaviors (including the default cache behavior) as you have origins if you want CloudFront to distribute objects from all of the origins. Each cache behavior specifies the one origin from which you want CloudFront to get objects. If you have two origins and only the default cache behavior, the default cache behavior will cause CloudFront to get objects from one of the origins, but the other origin will never be used. If you don’t
want to specify any cache behaviors, include only an empty CacheBehaviors element. Don’t include an empty CacheBehavior element, or CloudFront returns a MalformedXML error. To delete all cache behaviors in an existing distribution, update the distribution configuration and include only an empty CacheBehaviors element. To add, change, or remove one or more cache behaviors, update the distribution configuration and specify all of the cache behaviors that you want to include in the updated distribution.

- **PathPattern** *(string)* – The pattern (for example, images/*, .jpg) that specifies which requests you want this cache behavior to apply to. When CloudFront receives an end-user request, the requested path is compared with path patterns in the order in which cache behaviors are listed in the distribution. The path pattern for the default cache behavior is * and cannot be changed. If the request for an object does not match the path pattern for any cache behaviors, CloudFront applies the behavior in the default cache behavior.

- **TargetOriginId** *(string)* – The value of ID for the origin that you want CloudFront to route requests to when a request matches the path pattern either for a cache behavior or for the default cache behavior.

- **ForwardedValues** *(dict)* – A complex type that specifies how CloudFront handles query strings, cookies and headers.

  - **QueryString** *(boolean)* – Indicates whether you want CloudFront to forward query strings to the origin that is associated with this cache behavior. If so, specify true; if not, specify false.

  - **Cookies** *(dict)* – A complex type that specifies how CloudFront handles cookies.

    - **Forward** *(string)* – Use this element to specify whether you want CloudFront to forward cookies to the origin that is associated with this cache behavior. You can specify all, none or whitelist. If you choose All, CloudFront forwards all cookies regardless of how many your application uses.

    - **WhitelistedNames** *(dict)* – A complex type that specifies the whitelisted cookies, if any, that you want CloudFront to forward to your origin that is associated with this cache behavior.

      - **Quantity** *(integer)* – The number of whitelisted cookies for this cache behavior.

        - **Items** *(list)* – Optional: A complex type that contains whitelisted cookies for this cache behavior. If Quantity is 0, you can omit Items.

        - *(string)*

        - **Headers** *(dict)* – A complex type that specifies the Headers, if any, that you want CloudFront to vary upon for this cache behavior.

          - **Quantity** *(integer)* – The number of different headers that you want CloudFront to forward to the origin and to vary on for this cache behavior. The maximum number of headers that you can specify by name is 10. If you want CloudFront to forward all headers to the origin and vary on all of them, specify 1 for Quantity and * for Name. If you don’t want CloudFront to forward any additional headers to the origin or to vary on
any headers, specify 0 for Quantity and omit Items.

- **Items (list)** – Optional: A complex type that contains a Name element for each header that you want CloudFront to forward to the origin and to vary on for this cache behavior. If Quantity is 0, omit Items.

- **(string)** –

- **TrustedSigners (dict)** – A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.

- **Enabled (boolean)** – Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.

- **Quantity (integer)** – The number of trusted signers for this cache behavior.

- **Items (list)** – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.

- **(string)** –

- **ViewerProtocolPolicy (string)** – Use this element to specify the protocol that users can use to access the files in the origin specified by TargetOriginId when a request matches the path pattern in PathPattern. If you want CloudFront to allow end users to use any available protocol, specify allow-all. If you want CloudFront to require HTTPS, specify https. If you want CloudFront to respond to an HTTP request with an HTTP status code of 301 (Moved Permanently) and the HTTPS URL, specify redirect-to-https. The viewer then resubmits the request using the HTTPS URL.

- **MinTTL (integer)** – The minimum amount of time that you want objects to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **AllowedMethods (dict)** – A complex type that controls which HTTP methods CloudFront processes and forwards to your Amazon S3 bucket or your custom origin. There are three choices: - CloudFront forwards only GET and HEAD requests. - CloudFront forwards only GET, HEAD and OPTIONS requests. - CloudFront forwards GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests. If you pick the third choice, you may need to restrict access to your Amazon S3 bucket or to your custom origin so users can’t perform operations that you don’t want them to. For example,
you may not want users to have permission to delete objects from your origin.

- **Quantity** *(integer)* – The number of HTTP methods that you want CloudFront to forward to your origin. Valid values are 2 (for GET and HEAD requests), 3 (for GET, HEAD and OPTIONS requests) and 7 (for GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests).

- **Items** *(list)* – A complex type that contains the HTTP methods that you want CloudFront to process and forward to your origin.

- **CachedMethods** *(dict)* – A complex type that controls whether CloudFront caches the response to requests using the specified HTTP methods. There are two choices: - CloudFront caches responses to GET and HEAD requests. - CloudFront caches responses to GET, HEAD, and OPTIONS requests. If you pick the second choice for your S3 Origin, you may need to forward Access-Control-Request-Method, Access-Control-Request-Headers and Origin headers for the responses to be cached correctly.

- **Quantity** *(integer)* – The number of HTTP methods for which you want CloudFront to cache responses. Valid values are 2 (for caching responses to GET and HEAD requests) and 3 (for caching responses to GET, HEAD, and OPTIONS requests).

- **Items** *(list)* – A complex type that contains the HTTP methods that you want CloudFront to cache responses to.

- **SmoothStreaming** *(boolean)* – Indicates whether you want to distribute media files in Microsoft Smooth Streaming format using the origin that is associated with this cache behavior. If so, specify true; if not, specify false.

- **DefaultTTL** *(integer)* – If you don’t configure your origin to add a Cache-Control max-age directive or an Expires header, DefaultTTL is the default amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin does not add HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **MaxTTL** *(integer)* – The maximum amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin adds HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **CustomErrorResponses** *(dict)* – A complex type that contains zero or more CustomErrorResponse elements.

- **Quantity** *(integer)* – The number of custom error responses for this distribution.

- **Items** *(list)* – Optional: A complex type that contains custom
error responses for this distribution. If Quantity is 0, you can omit Items.

- *(dict)* – A complex type that describes how you’d prefer CloudFront to respond to requests that result in either a 4xx or 5xx response. You can control whether a custom error page should be displayed, what the desired response code should be for this error page and how long should the error response be cached by CloudFront. If you don’t want to specify any custom error responses, include only an empty CustomErrorResponses element. To delete all custom error responses in an existing distribution, update the distribution configuration and include only an empty CustomErrorResponses element. To add, change, or remove one or more custom error responses, update the distribution configuration and specify all of the custom error responses that you want to include in the updated distribution.

- **ErrorCode** *(integer)* – The 4xx or 5xx HTTP status code that you want to customize. For a list of HTTP status codes that you can customize, see CloudFront documentation.

- **ResponsePagePath** *(string)* – The path of the custom error page (for example, /custom_404.html). The path is relative to the distribution and must begin with a slash (/). If the path includes any non-ASCII characters or unsafe characters as defined in RFC 1783 (http://www.ietf.org/rfc/rfc1738.txt), URL encode those characters. Do not URL encode any other characters in the path, or CloudFront will not return the custom error page to the viewer.

- **ResponseCode** *(string)* – The HTTP status code that you want CloudFront to return with the custom error page to the viewer. For a list of HTTP status codes that you can replace, see CloudFront Documentation.

- **ErrorCachingMinTTL** *(integer)* – The minimum amount of time you want HTTP error codes to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 31,536,000.

- **Comment** *(string)* – Any comments you want to include about the distribution.

- **Logging** *(dict)* – A complex type that controls whether access logs are written for the distribution.

  - **Enabled** *(boolean)* – Specifies whether you want CloudFront to save access logs to an Amazon S3 bucket. If you do not want to enable logging when you create a distribution or if you want to disable logging for an existing distribution, specify false for Enabled, and specify empty Bucket and Prefix elements. If you specify false for Enabled but you specify values for Bucket, prefix and IncludeCookies, the values are automatically deleted.

  - **IncludeCookies** *(boolean)* – Specifies whether you want CloudFront to include cookies in access logs, specify true for IncludeCookies. If you choose to include cookies in logs, CloudFront logs all cookies regardless of how you configure the cache behaviors for this distribution. If you do not want to include cookies when you create a distribution or if you want
to disable include cookies for an existing distribution, specify false for IncludeCookies.

- **Bucket** *(string)* – The Amazon S3 bucket to store the access logs in, for example, myawslogbucket.s3.amazonaws.com.
- **Prefix** *(string)* – An optional string that you want CloudFront to prefix to the access log filenames for this distribution, for example, myprefix/. If you want to enable logging, but you do not want to specify a prefix, you still must include an empty Prefix element in the Logging element.

- **PriceClass** *(string)* – A complex type that contains information about price class for this distribution.
- **Enabled** *(boolean)* – Whether the distribution is enabled to accept end user requests for content.
- **ViewerCertificate** *(dict)* – A complex type that contains information about viewer certificates for this distribution.
  - **IAMCertificateId** *(string)* – If you want viewers to use HTTPS to request your objects and you’re using an alternate domain name in your object URLs (for example, https://example.com/logo.jpg), specify the IAM certificate identifier of the custom viewer certificate for this distribution. Specify either this value or CloudFrontDefaultCertificate.
  - **CloudFrontDefaultCertificate** *(boolean)* – If you want viewers to use HTTPS to request your objects and you’re using the CloudFront domain name of your distribution in your object URLs (for example, https://d111111abcdef8.cloudfront.net/logo.jpg), set to true. Omit this value if you are setting an IAMCertificateId.
  - **SSLSupportMethod** *(string)* – If you specify a value for IAMCertificateId, you must also specify how you want CloudFront to serve HTTPS requests. Valid values are vip and sni-only. If you specify vip, CloudFront uses dedicated IP addresses for your content and can respond to HTTPS requests from any viewer. However, you must request permission to use this feature, and you incur additional monthly charges. If you specify sni-only, CloudFront can only respond to HTTPS requests from viewers that support Server Name Indication (SNI). All modern browsers support SNI, but some browsers still in use don’t support SNI. Do not specify a value for SSLSupportMethod if you specified true for CloudFrontDefaultCertificate.
  - **MinimumProtocolVersion** *(string)* – Specify the minimum version of the SSL protocol that you want CloudFront to use, SSLv3 or TLSv1, for HTTPS connections. CloudFront will serve your objects only to browsers or devices that support at least the SSL version that you specify. The TLSv1 protocol is more secure, so we recommend that you specify SSLv3 only if your users are using browsers or devices that don’t support TLSv1. If you’re using a custom certificate (if you specify a value for IAMCertificateId) and if you’re using dedicated IP (if you specify vip for SSLSupportMethod), you can choose SSLv3 or TLSv1 as the MinimumProtocolVersion. If you’re using a custom certificate (if you specify a value for IAMCertificateId) and if you’re using SNI (if you specify sni-only for SSLSupportMethod), you must specify TLSv1 for Mini-
Restrictions (dict) – A complex type that identifies ways in which you want to restrict distribution of your content.

- GeoRestriction (dict) – A complex type that controls the countries in which your content is distributed. For more information about geo restriction, go to Customizing Error Responses in the Amazon CloudFront Developer Guide. CloudFront determines the location of your users using MaxMind GeoIP databases. For information about the accuracy of these databases, see How accurate are your GeoIP databases? on the MaxMind website.

- RestrictionType (string) – The method that you want to use to restrict distribution of your content by country:
  - none: No geo restriction is enabled, meaning access to content is not restricted by client geo location.
  - blacklist: The Location elements specify the countries in which you do not want CloudFront to distribute your content.
  - whitelist: The Location elements specify the countries in which you want CloudFront to distribute your content.

- Quantity (integer) – When geo restriction is enabled, this is the number of countries in your whitelist or blacklist. Otherwise, when it is not enabled, Quantity is 0, and you can omit Items.

- Items (list) – A complex type that contains a Location element for each country in which you want CloudFront either to distribute your content (whitelist) or not distribute your content (blacklist). The Location element is a two-letter, uppercase country code for a country that you want to include in your blacklist or whitelist. Include one Location element for each country. CloudFront and MaxMind both use ISO 3166 country codes. For the current list of countries and the corresponding codes, see ISO 3166-1-alpha-2 code on the International Organization for Standardization website. You can also refer to the country list in the CloudFront console, which includes both country names and codes.

- ETag (string) – The current version of the configuration. For example: E2QWRUHAPOMQZL.

get_invalidation(**kwargs)

Get the information about an invalidation.

Request Syntax

response = client.get_invalidation(
    DistributionId='string',
    Id='string'
)

Parameters

- DistributionId (string) – [REQUIRED] The distribution’s id.
- Id (string) – [REQUIRED] The invalidation’s id.

Return type  dict

Returns

Response Syntax
{  
  'Invalidation': {  
    'Id': 'string',  
    'Status': 'string',  
    'CreateTime': datetime(2015, 1, 1),  
    'InvalidationBatch': {  
      'Paths': {  
        'Quantity': 123,  
        'Items': [  
          'string',  
        ],  
      },  
      'CallerReference': 'string'  
    }  
  }  
}

Response Structure

- (dict) – The returned result of the corresponding request.
  - **Invalidation** (dict) – The invalidation’s information.
    - **Id** (string) – The identifier for the invalidation request. For example: IDFDVBD632BHDS5.
    - **Status** (string) – The status of the invalidation request. When the invalidation batch is finished, the status is Completed.
    - **CreateTime** (datetime) – The date and time the invalidation request was first made.
    - **InvalidationBatch** (dict) – The current invalidation information for the batch request.
      - **Paths** (dict) – The path of the object to invalidate. The path is relative to the distribution and must begin with a slash (/). You must enclose each invalidation object with the Path element tags. If the path includes non-ASCII characters or unsafe characters as defined in RFC 1783 (http://www.ietf.org/rfc/rfc1738.txt), URL encode those characters. Do not URL encode any other characters in the path, or CloudFront will not invalidate the old version of the updated object.
      - **Quantity** (integer) – The number of objects that you want to invalidate.
      - **Items** (list) – A complex type that contains a list of the objects that you want to invalidate.
    - **CallerReference** (string) – A unique name that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the Path object), a new distribution is created. If the CallerReference is a value you already sent in a previous request to create an invalidation batch, and the content of each Path element is identical to the original request, the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create a distribution but the content of any Path is different from the original request, CloudFront returns an InvalidationBatchAlreadyExists error.

**get_paginators ((operation_name))**
Create a paginator for an operation.

**Parameters** operation_name (string) – The operation name. This is the same name as
the method name on the client. For example, if the method name is create_foo,
and you’d normally invoke the operation as `client.create_foo(**kwargs)`.
If the `create_foo` operation can be paginated, you can use the call
`client.get_paginator("create_foo")`.

**Raises** OperationNotPageableError Raised if the operation is not pageable. You can use
the `client.can_paginate` method to check if an operation is pageable.

**Return type** L{botocore.paginate.Paginator}

**Returns** A paginator object.

**get_streaming_distribution(**kwargs)**

Get the information about a streaming distribution.

**Request Syntax**

```python
response = client.get_streaming_distribution(
    Id='string'
)
```

**Parameters** Id (string) – [REQUIRED] The streaming distribution’s id.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'StreamingDistribution': {
        'Id': 'string',
        'Status': 'string',
        'LastModifiedTime': datetime(2015, 1, 1),
        'DomainName': 'string',
        'ActiveTrustedSigners': {
            'Enabled': True|False,
            'Quantity': 123,
            'Items': [
                {'AwsAccountNumber': 'string',
                 'KeyPairIds': {
                     'Quantity': 123,
                     'Items': [
                         'string',
                     ]
                 }
            ]
        },
        'StreamingDistributionConfig': {
            'CallerReference': 'string',
            'S3Origin': {
                'DomainName': 'string',
                'OriginAccessIdentity': 'string'
            },
            'Aliases': {
                'Quantity': 123,
                'Items': [
                    'string',
                ]
            }
        }
    }
}
```
Response Structure

- **(dict)** – The returned result of the corresponding request.
  - **StreamingDistribution (dict)** – The streaming distribution’s information.
    - **Id (string)** – The identifier for the streaming distribution. For example: EGTXBD79H29TRA8.
    - **Status (string)** – The current status of the streaming distribution. When the status is Deployed, the distribution’s information is fully propagated throughout the Amazon CloudFront system.
    - **LastModifiedTime (datetime)** – The date and time the distribution was last modified.
    - **DomainName (string)** – The domain name corresponding to the streaming distribution. For example: s5c39gqb8ow64r.cloudfront.net.
    - **ActiveTrustedSigners (dict)** – CloudFront automatically adds this element to the response only if you’ve set up the distribution to serve private content with signed URLs. The element lists the key pair IDs that CloudFront is aware of for each trusted signer. The Signer child element lists the AWS account number of the trusted signer (or an empty Self element if the signer is you). The Signer element also includes the IDs of any active key pairs associated with the trusted signer’s AWS account. If no KeyPairId element appears for a Signer, that signer can’t create working signed URLs.
      - **Enabled (boolean)** – Each active trusted signer.
      - **Quantity (integer)** – The number of unique trusted signers included in all cache behaviors. For example, if three cache behaviors all list the same three AWS accounts, the value of Quantity for ActiveTrustedSigners will be 3.
      - **Items (list)** – A complex type that contains one Signer complex type for each unique trusted signer that is specified in the TrustedSigners complex type, including trusted signers in the default cache behavior and in all of the other cache behaviors.
      - **ETag (string)** – Indicates whether this information is cached.
· **AwsAccountNumber** *(string)* – Specifies an AWS account that can create signed URLs. Values: self, which indicates that the AWS account that was used to create the distribution can created signed URLs, or an AWS account number. Omit the dashes in the account number.

· **KeyPairIds** *(dict)* – A complex type that lists the active CloudFront key pairs, if any, that are associated with `AwsAccountNumber`.

· **Quantity** *(integer)* – The number of active CloudFront key pairs for `AwsAccountNumber`.

· **Items** *(list)* – A complex type that lists the active CloudFront key pairs, if any, that are associated with `AwsAccountNumber`.

· *(string)*

* **StreamingDistributionConfig** *(dict)* – The current configuration information for the streaming distribution.

  · **CallerReference** *(string)* – A unique number that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the `StreamingDistributionConfig` object), a new streaming distribution is created. If the CallerReference is a value you already sent in a previous request to create a streaming distribution, and the content of the `StreamingDistributionConfig` is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create a streaming distribution but the content of the `StreamingDistributionConfig` is different from the original request, CloudFront returns a DistributionAlreadyExists error.

· **S3Origin** *(dict)* – A complex type that contains information about the Amazon S3 bucket from which you want CloudFront to get your media files for distribution.

  · **DomainName** *(string)* – The DNS name of the S3 origin.

  · **OriginAccessIdentity** *(string)* – Your S3 origin’s origin access identity.

  · **Aliases** *(dict)* – A complex type that contains information about CNAMEs (alternate domain names), if any, for this streaming distribution.

  · **Quantity** *(integer)* – The number of CNAMEs, if any, for this distribution.

  · **Items** *(list)* – Optional: A complex type that contains CNAME elements, if any, for this distribution. If Quantity is 0, you can omit Items.

  · *(string)*

  · **Comment** *(string)* – Any comments you want to include about the streaming distribution.

· **Logging** *(dict)* – A complex type that controls whether access logs are written for the streaming distribution.

· **Enabled** *(boolean)* – Specifies whether you want CloudFront to save access logs to an Amazon S3 bucket. If you do not want to enable logging when you create a streaming distribution or if you want to disable logging for an existing streaming distribution, specify false for Enabled, and specify empty Bucket and Prefix elements. If you specify false for Enabled
but you specify values for Bucket and Prefix, the values are automatically deleted.

- **Bucket (string)** – The Amazon S3 bucket to store the access logs in, for example, myawslogbucket.s3.amazonaws.com.
- **Prefix (string)** – An optional string that you want CloudFront to prefix to the access log filenames for this streaming distribution, for example, myprefix/. If you want to enable logging, but you do not want to specify a prefix, you still must include an empty Prefix element in the Logging element.
- **TrustedSigners (dict)** – A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.
- **Enabled (boolean)** – Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.
- **Quantity (integer)** – The number of trusted signers for this cache behavior.
- **Items (list)** – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.

- **PriceClass (string)** – A complex type that contains information about price class for this streaming distribution.
- **Enabled (boolean)** – Whether the streaming distribution is enabled to accept end user requests for content.

- **ETag (string)** – The current version of the streaming distribution’s information. For example: E2QWRUHAPOMQZL.

**get_streaming_distribution_config(**kwargs**)

Get the configuration information about a streaming distribution.

**Request Syntax**

```
response = client.get_streaming_distribution_config(
    Id='string'
)
```

**Parameters**

- **Id (string)** – [REQUIRED] The streaming distribution’s id.

**Return type**

dict

**Returns**

- **Response Syntax**

```
{
    'StreamingDistributionConfig': {
```
'CallerReference': 'string',
'S3Origin': {
    'DomainName': 'string',
    'OriginAccessIdentity': 'string'
},
'Aliases': {
    'Quantity': 123,
    'Items': [
        'string',
    ]
},
'Comment': 'string',
'Logging': {
    'Enabled': True|False,
    'Bucket': 'string',
    'Prefix': 'string'
},
'TrustedSigners': {
    'Enabled': True|False,
    'Quantity': 123,
    'Items': [
        'string',
    ]
},
'PriceClass': 'PriceClass_100'|'PriceClass_200'|'PriceClass_All',
'Enabled': True|False
},
'ETag': 'string'
}

Response Structure

- (dict) – The returned result of the corresponding request.
  - StreamingDistributionConfig (dict) – The streaming distribution’s configuration information.
    - CallerReference (string) – A unique number that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the StreamingDistributionConfig object), a new streaming distribution is created. If the CallerReference is a value you already sent in a previous request to create a streaming distribution, and the content of the StreamingDistributionConfig is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create a streaming distribution but the content of the StreamingDistributionConfig is different from the original request, CloudFront returns a DistributionAlreadyExists error.
    - S3Origin (dict) – A complex type that contains information about the Amazon S3 bucket from which you want CloudFront to get your media files for distribution.
      - DomainName (string) – The DNS name of the S3 origin.
      - OriginAccessIdentity (string) – Your S3 origin’s origin access identity.
    - Aliases (dict) – A complex type that contains information about CNAMEs (alternate domain names), if any, for this streaming distribution.
      - Quantity (integer) – The number of CNAMEs, if any, for this
distribution.

- **Items (list)** – Optional: A complex type that contains CNAME elements, if any, for this distribution. If Quantity is 0, you can omit Items.
- **(string)** –
  - **Comment (string)** – Any comments you want to include about the streaming distribution.
  - **Logging (dict)** – A complex type that controls whether access logs are written for the streaming distribution.
    - **Enabled (boolean)** – Specifies whether you want CloudFront to save access logs to an Amazon S3 bucket. If you do not want to enable logging when you create a streaming distribution or if you want to disable logging for an existing streaming distribution, specify false for Enabled, and specify empty Bucket and Prefix elements. If you specify false for Enabled but you specify values for Bucket and Prefix, the values are automatically deleted.
    - **Bucket (string)** – The Amazon S3 bucket to store the access logs in, for example, myawslogbucket.s3.amazonaws.com.
    - **Prefix (string)** – An optional string that you want CloudFront to prefix to the access log filenames for this streaming distribution, for example, myprefix/. If you want to enable logging, but you do not want to specify a prefix, you still must include an empty Prefix element in the Logging element.
  - **TrustedSigners (dict)** – A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.
    - **Enabled (boolean)** – Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.
    - **Quantity (integer)** – The number of trusted signers for this cache behavior.
    - **Items (list)** – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.
    - **(string)** –
      - **PriceClass (string)** – A complex type that contains information about price class for this streaming distribution.
      - **Enabled (boolean)** – Whether the streaming distribution is enabled to accept end user requests for content.
      - **ETag (string)** – The current version of the configuration. For example: E2QWRRUHAPOMQZL.

```
get_waiter(waiter_name)
```
list_cloud_front_origin_access_identities(**kwargs)
List origin access identities.

Request Syntax

response = client.list_cloud_front_origin_access_identities(
    Marker='string',
    MaxItems='string'
)

Parameters

• **Marker (string)** – Use this when paginating results to indicate where to begin in your list of origin access identities. The results include identities in the list that occur after the marker. To get the next page of results, set the Marker to the value of the NextMarker from the current page’s response (which is also the ID of the last identity on that page).

• **MaxItems (string)** – The maximum number of origin access identities you want in the response body.

Return type  dict

Returns

Response Syntax

```python
{
    'CloudFrontOriginAccessIdentityList': {
        'Marker': 'string',
        'NextMarker': 'string',
        'MaxItems': 123,
        'IsTruncated': True|False,
        'Quantity': 123,
        'Items': [
            {
                'Id': 'string',
                'S3CanonicalUserId': 'string',
                'Comment': 'string'
            }
        ]
    }
}
```

Response Structure

• **(dict)** – The returned result of the corresponding request.

    • **Marker (string)** – The value you provided for the Marker request parameter.
    • **NextMarker (string)** – If IsTruncated is true, this element is present and contains the value you can use for the Marker request parameter to continue listing your origin access identities where they left off.
    • **MaxItems (integer)** – The value you provided for the MaxItems request parameter.
    • **IsTruncated (boolean)** – A flag that indicates whether more origin access identities remain to be listed. If your results were truncated, you can make a follow-up pagination request using the Marker request parameter to retrieve more items in the list.
    • **Quantity (integer)** – The number of CloudFront origin access identities that were created by the current AWS account.
Items (list) – A complex type that contains one CloudFrontOriginAccessIdentitySummary element for each origin access identity that was created by the current AWS account.

- (dict) – Summary of the information about a CloudFront origin access identity.
- Id (string) – The ID for the origin access identity. For example: E74FTE3AJFJ256A.
- S3CanonicalUserId (string) – The Amazon S3 canonical user ID for the origin access identity, which you use when giving the origin access identity read permission to an object in Amazon S3.
- Comment (string) – The comment for this origin access identity, as originally specified when created.

list_distributions(**kwargs)

List distributions.

Request Syntax

def list_distributions(**kwargs):
    Marker='string',
    MaxItems='string'

Parameters

- Marker (string) – Use this when paginating results to indicate where to begin in your list of distributions. The results include distributions in the list that occur after the marker. To get the next page of results, set the Marker to the value of the NextMarker from the current page’s response (which is also the ID of the last distribution on that page).
- MaxItems (string) – The maximum number of distributions you want in the response body.

Return type dict

Returns

Response Syntax

{  
    'DistributionList': {
        'Marker': 'string',
        'NextMarker': 'string',
        'MaxItems': 123,

Response Structure

- *(dict)* – The returned result of the corresponding request.
  
  - **DistributionList (dict)** – The DistributionList type.
    
    - **Marker (string)** – The value you provided for the Marker request parameter.
    
    - **NextMarker (string)** – If IsTruncated is true, this element is present and contains the value you can use for the Marker request parameter to continue listing your distributions where they left off.
    
    - **MaxItems (integer)** – The value you provided for the MaxItems request parameter.
    
    - **IsTruncated (boolean)** – A flag that indicates whether more distributions remain to be listed. If your results were truncated, you can make a follow-up pagination request using the Marker request parameter to retrieve more distributions in the list.
    
    - **Quantity (integer)** – The number of distributions that were created by the current AWS account.
    
    - **Items (list)** – A complex type that contains one DistributionSummary element for each distribution that was created by the current AWS account.
      
      - *(dict)* – A summary of the information for an Amazon CloudFront distribution.
      
      - **Id (string)** – The identifier for the distribution. For example: EDFDVBD632BHDS5.
      
      - **Status (string)** – This response element indicates the current status of the distribution. When the status is Deployed, the
distribution’s information is fully propagated throughout the Amazon CloudFront system.

- **LastModifiedTime** *(datetime)* – The date and time the distribution was last modified.
- **DomainName** *(string)* – The domain name corresponding to the distribution. For example: d604721fxaaqy9.cloudfront.net.
- **Aliases** *(dict)* – A complex type that contains information about CNAMEs (alternate domain names), if any, for this distribution.
- **Quantity** *(integer)* – The number of CNAMEs, if any, for this distribution.
- **Items** *(list)* – Optional: A complex type that contains CNAME elements, if any, for this distribution. If Quantity is 0, you can omit Items.
- **Origins** *(dict)* – A complex type that contains information about origins for this distribution.
- **Quantity** *(integer)* – The number of origins for this distribution.
- **Items** *(list)* – A complex type that contains origins for this distribution.
- **S3OriginConfig** *(dict)* – A complex type that describes the Amazon S3 bucket or the HTTP server (for example, a web server) from which CloudFront gets your files. You must create at least one origin.
- **Id** *(string)* – A unique identifier for the origin. The value of Id must be unique within the distribution. You use the value of Id when you create a cache behavior. The Id identifies the origin that CloudFront routes a request to when the request matches the path pattern for that cache behavior.
- **DomainName** *(string)* – Amazon S3 origins: The DNS name of the Amazon S3 bucket from which you want CloudFront to get objects for this origin, for example, myawsbucket.s3.amazonaws.com. Custom origins: The DNS domain name for the HTTP server from which you want CloudFront to get objects for this origin, for example, www.example.com.
- **OriginPath** *(string)* – An optional element that causes CloudFront to request your content from a directory in your Amazon S3 bucket or your custom origin. When you include the OriginPath element, specify the directory name, beginning with a /. CloudFront appends the directory name to the value of DomainName.
- **S3OriginConfig** *(dict)* – A complex type that contains information about the Amazon S3 origin. If the origin is a custom origin, use the CustomOriginConfig element instead.
- **OriginAccessIdentity** *(string)* – The CloudFront origin access identity to associate with the origin. Use an origin access identity to configure the origin so that end users can only access objects in an Amazon S3 bucket through CloudFront. If you want end users to be able to access objects using either the CloudFront URL or the Amazon S3 URL, specify an empty OriginAccessIdentity element. To delete the origin access identity from an existing distribution, update the distri-
distribution configuration and include an empty OriginAccessIdentity element. To replace the origin access identity, update the distribution configuration and specify the new origin access identity. Use the format origin-access-identity/cloudfront/Id where Id is the value that CloudFront returned in the Id element when you created the origin access identity.

- **CustomOriginConfig (dict)** – A complex type that contains information about a custom origin. If the origin is an Amazon S3 bucket, use the S3OriginConfig element instead.
- **HTTPPort (integer)** – The HTTP port the custom origin listens on.
- **HTTPSPort (integer)** – The HTTPS port the custom origin listens on.
- **OriginProtocolPolicy (string)** – The origin protocol policy to apply to your origin.
- **DefaultCacheBehavior (dict)** – A complex type that describes the default cache behavior if you do not specify a CacheBehavior element or if files don’t match any of the values of PathPattern in CacheBehavior elements. You must create exactly one default cache behavior.
- **TargetOriginId (string)** – The value of ID for the origin that you want CloudFront to route requests to when a request matches the path pattern either for a cache behavior or for the default cache behavior.
- **ForwardedValues (dict)** – A complex type that specifies how CloudFront handles query strings, cookies and headers.
- **QueryString (boolean)** – Indicates whether you want CloudFront to forward query strings to the origin that is associated with this cache behavior. If so, specify true; if not, specify false.
- **Cookies (dict)** – A complex type that specifies how CloudFront handles cookies.
- **Forward (string)** – Use this element to specify whether you want CloudFront to forward cookies to the origin that is associated with this cache behavior. You can specify all, none or whitelist. If you choose All, CloudFront forwards all cookies regardless of how many your application uses.
- **WhitelistedNames (dict)** – A complex type that specifies the whitelisted cookies, if any, that you want CloudFront to forward to your origin that is associated with this cache behavior.
- **Quantity (integer)** – The number of whitelisted cookies for this cache behavior.
- **Items (list)** – Optional: A complex type that contains whitelisted cookies for this cache behavior. If Quantity is 0, you can omit Items.
- **Headers (dict)** – A complex type that specifies the Headers, if any, that you want CloudFront to vary upon for this cache behavior.
- **Quantity (integer)** – The number of different headers that you want CloudFront to forward to the origin and to vary on for this cache behavior. The maximum number of headers that you can specify by name is 10. If you want CloudFront to forward all headers to the origin and vary on all of them, specify
1 for Quantity and * for Name. If you don’t want CloudFront
to forward any additional headers to the origin or to vary on
any headers, specify 0 for Quantity and omit Items.

- **Items** *(list)* – Optional: A complex type that contains a Name
element for each header that you want CloudFront to forward
to the origin and to vary on for this cache behavior. If Quantity
is 0, omit Items.

- *(string)* –

- **TrustedSigners** *(dict)* – A complex type that specifies the
AWS accounts, if any, that you want to allow to create signed
URLs for private content. If you want to require signed URLs
in requests for objects in the target origin that match the Path-
Pattern for this cache behavior, specify true for Enabled, and
specify the applicable values for Quantity and Items. For
more information, go to Using a Signed URL to Serve Private
Content in the Amazon CloudFront Developer Guide. If you
don’t want to require signed URLs in requests for objects that
match PathPattern, specify false for Enabled and 0 for Quan-
ty. Omit Items. To add, change, or remove one or more
trusted signers, change Enabled to true (if it’s currently false),
change Quantity as applicable, and specify all of the trusted
signers that you want to include in the updated distribution.

- **Enabled** *(boolean)* – Specifies whether you want to require
end users to use signed URLs to access the files specified by
PathPattern and TargetOriginId.

- **Quantity** *(integer)* – The number of trusted signers for this
cache behavior.

- **Items** *(list)* – Optional: A complex type that contains trusted
signers for this cache behavior. If Quantity is 0, you can omit
Items.

- *(string)* –

- **ViewerProtocolPolicy** *(string)* – Use this element to specify
the protocol that users can use to access the files in the origin
specified by TargetOriginId when a request matches the path
pattern in PathPattern. If you want CloudFront to allow end
users to use any available protocol, specify allow-all. If you
want CloudFront to require HTTPS, specify https. If you want
CloudFront to respond to an HTTP request with an HTTP sta-
tus code of 301 (Moved Permanently) and the HTTPS URL,
specify redirect-to-https. The viewer then resubmits the re-
quest using the HTTPS URL.

- **MinTTL** *(integer)* – The minimum amount of time that you
want objects to stay in CloudFront caches before CloudFront
queries your origin to see whether the object has been up-
dated. You can specify a value from 0 to 3,153,600,000 sec-
onds (100 years).

- **AllowedMethods** *(dict)* – A complex type that controls which
HTTP methods CloudFront processes and forwards to your
Amazon S3 bucket or your custom origin. There are three
choices: - CloudFront forwards only GET and HEAD re-
quests. - CloudFront forwards only GET, HEAD and OP-
TIONS requests. - CloudFront forwards GET, HEAD, OP-
TIONS, PUT, PATCH, POST, and DELETE requests. If you
pick the third choice, you may need to restrict access to your
Amazon S3 bucket or to your custom origin so users can’t perform operations that you don’t want them to. For example, you may not want users to have permission to delete objects from your origin.

- **Quantity (integer)** – The number of HTTP methods that you want CloudFront to forward to your origin. Valid values are 2 (for GET and HEAD requests), 3 (for GET, HEAD, and OPTIONS requests) and 7 (for GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests).

- **Items (list)** – A complex type that contains the HTTP methods that you want CloudFront to process and forward to your origin.

- **CachedMethods (dict)** – A complex type that controls whether CloudFront caches the response to requests using the specified HTTP methods. There are two choices: CloudFront caches responses to GET and HEAD requests. CloudFront caches responses to GET, HEAD, and OPTIONS requests. If you pick the second choice for your S3 Origin, you may need to forward Access-Control-Request-Method, Access-Control-Request-Headers and Origin headers for the responses to be cached correctly.

- **Quantity (integer)** – The number of HTTP methods for which you want CloudFront to cache responses. Valid values are 2 (for caching responses to GET and HEAD requests) and 3 (for caching responses to GET, HEAD, and OPTIONS requests).

- **Items (list)** – A complex type that contains the HTTP methods that you want CloudFront to cache responses to.

- **SmoothStreaming (boolean)** – Indicates whether you want to distribute media files in Microsoft Smooth Streaming format using the origin that is associated with this cache behavior. If so, specify true; if not, specify false.

- **DefaultTTL (integer)** – If you don’t configure your origin to add a Cache-Control max-age directive or an Expires header, DefaultTTL is the default amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin does not add HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **MaxTTL (integer)** – The maximum amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin adds HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **CacheBehaviors (dict)** – A complex type that contains zero or more CacheBehavior elements.

- **Quantity (integer)** – The number of cache behaviors for this
distribution.

- **Items** (list) – Optional: A complex type that contains cache behaviors for this distribution. If Quantity is 0, you can omit Items.

- **(dict)** – A complex type that describes how CloudFront processes requests. You can create up to 10 cache behaviors. You must create at least as many cache behaviors (including the default cache behavior) as you have origins if you want CloudFront to distribute objects from all of the origins. Each cache behavior specifies the one origin from which you want CloudFront to get objects. If you have two origins and only the default cache behavior, the default cache behavior will cause CloudFront to get objects from one of the origins, but the other origin will never be used. If you don’t want to specify any cache behaviors, include only an empty CacheBehaviors element. Don’t include an empty CacheBehavior element, or CloudFront returns a MalformedXML error. To delete all cache behaviors in an existing distribution, update the distribution configuration and include only an empty CacheBehaviors element. To add, change, or remove one or more cache behaviors, update the distribution configuration and specify all of the cache behaviors that you want to include in the updated distribution.

- **PathPattern** (string) – The pattern (for example, images/*, .jpg) that specifies which requests you want this cache behavior to apply to. When CloudFront receives an end-user request, the requested path is compared with path patterns in the order in which cache behaviors are listed in the distribution. The path pattern for the default cache behavior is * and cannot be changed. If the request for an object does not match the path pattern for any cache behaviors, CloudFront applies the behavior in the default cache behavior.

- **TargetOriginId** (string) – The value of ID for the origin that you want CloudFront to route requests to when a request matches the path pattern either for a cache behavior or for the default cache behavior.

- **ForwardedValues** (dict) – A complex type that specifies how CloudFront handles query strings, cookies and headers.

- **QueryString** (boolean) – Indicates whether you want CloudFront to forward query strings to the origin that is associated with this cache behavior. If so, specify true; if not, specify false.

- **Cookies** (dict) – A complex type that specifies how CloudFront handles cookies.

- **Forward** (string) – Use this element to specify whether you want CloudFront to forward cookies to the origin that is associated with this cache behavior. You can specify all, none or whitelist. If you choose All, CloudFront forwards all cookies regardless of how many your application uses.

- **WhitelistedNames** (dict) – A complex type that specifies the whitelisted cookies, if any, that you want CloudFront to forward to your origin that is associated with this cache behavior.

- **Quantity** (integer) – The number of whitelisted cookies for this cache behavior.
- **Items** *(list)* – Optional: A complex type that contains whitelisted cookies for this cache behavior. If Quantity is 0, you can omit Items.
- *(string)* –
- **Headers** *(dict)* – A complex type that specifies the Headers, if any, that you want CloudFront to vary upon for this cache behavior.
- **Quantity** *(integer)* – The number of different headers that you want CloudFront to forward to the origin and to vary on for this cache behavior. The maximum number of headers that you can specify by name is 10. If you want CloudFront to forward all headers to the origin and vary on all of them, specify 1 for Quantity and * for Name. If you don’t want CloudFront to forward any additional headers to the origin or to vary on any headers, specify 0 for Quantity and omit Items.
- **Items** *(list)* – Optional: A complex type that contains a Name element for each header that you want CloudFront to forward to the origin and to vary on for this cache behavior. If Quantity is 0, omit Items.
- *(string)* –
- **TrustedSigners** *(dict)* – A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.
- **Enabled** *(boolean)* – Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.
- **Quantity** *(integer)* – The number of trusted signers for this cache behavior.
- **Items** *(list)* – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.
- *(string)* –
- **ViewerProtocolPolicy** *(string)* – Use this element to specify the protocol that users can use to access the files in the origin specified by TargetOriginId when a request matches the path pattern in PathPattern. If you want CloudFront to allow end users to use any available protocol, specify allow-all. If you want CloudFront to require HTTPS, specify https. If you want CloudFront to respond to an HTTP request with an HTTP status code of 301 (Moved Permanently) and the HTTPS URL, specify redirect-to-https. The viewer then resubmits the request using the HTTPS URL.
- **MinTTL** *(integer)* – The minimum amount of time that you
want objects to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **AllowedMethods** *(dict)* – A complex type that controls which HTTP methods CloudFront processes and forwards to your Amazon S3 bucket or your custom origin. There are three choices:
  - CloudFront forwards only GET and HEAD requests.
  - CloudFront forwards only GET, HEAD and OPTIONS requests.
  - CloudFront forwards GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests. If you pick the third choice, you may need to restrict access to your Amazon S3 bucket or to your custom origin so users can’t perform operations that you don’t want them to. For example, you may not want users to have permission to delete objects from your origin.

- **Quantity** *(integer)* – The number of HTTP methods that you want CloudFront to forward to your origin. Valid values are 2 (for GET and HEAD requests), 3 (for GET, HEAD and OPTIONS requests) and 7 (for GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests).

- **Items** *(list)* – A complex type that contains the HTTP methods that you want CloudFront to process and forward to your origin.

- **CachedMethods** *(dict)* – A complex type that controls whether CloudFront caches the response to requests using the specified HTTP methods. There are two choices:
  - CloudFront caches responses to GET and HEAD requests.
  - CloudFront caches responses to GET, HEAD, and OPTIONS requests. If you pick the second choice for your S3 Origin, you may need to forward Access-Control-Request-Method, Access-Control-Request-Headers and Origin headers for the responses to be cached correctly.

- **Quantity** *(integer)* – The number of HTTP methods for which you want CloudFront to cache responses. Valid values are 2 (for caching responses to GET and HEAD requests) and 3 (for caching responses to GET, HEAD, and OPTIONS requests).

- **Items** *(list)* – A complex type that contains the HTTP methods that you want CloudFront to cache responses to.

- **SmoothStreaming** *(boolean)* – Indicates whether you want to distribute media files in Microsoft Smooth Streaming format using the origin that is associated with this cache behavior. If so, specify true; if not, specify false.

- **DefaultTTL** *(integer)* – If you don’t configure your origin to add a Cache-Control max-age directive or an Expires header, DefaultTTL is the default amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin does not add HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds.
seconds (100 years).

- **MaxTTL (integer)** – The maximum amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin adds HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **CustomErrorResponses (dict)** – A complex type that contains zero or more CustomErrorResponses elements.

- **Quantity (integer)** – The number of custom error responses for this distribution.

- **Items (list)** – Optional: A complex type that contains custom error responses for this distribution. If Quantity is 0, you can omit Items.

- **(dict)** – A complex type that describes how you’d prefer CloudFront to respond to requests that result in either a 4xx or 5xx response. You can control whether a custom error page should be displayed, what the desired response code should be for this error page and how long should the error response be cached by CloudFront. If you don’t want to specify any custom error responses, include only an empty CustomErrorResponses element. To delete all custom error responses in an existing distribution, update the distribution configuration and include only an empty CustomErrorResponses element. To add, change, or remove one or more custom error responses, update the distribution configuration and specify all of the custom error responses that you want to include in the updated distribution.

- **ErrorCode (integer)** – The 4xx or 5xx HTTP status code that you want to customize. For a list of HTTP status codes that you can customize, see CloudFront documentation.

- **ResponsePagePath (string)** – The path of the custom error page (for example, /custom_404.html). The path is relative to the distribution and must begin with a slash (/). If the path includes any non-ASCII characters or unsafe characters as defined in RFC 1783 (http://www.ietf.org/rfc/rfc1738.txt), URL encode those characters. Do not URL encode any other characters in the path, or CloudFront will not return the custom error page to the viewer.

- **ResponseCode (string)** – The HTTP status code that you want CloudFront to return with the custom error page to the viewer. For a list of HTTP status codes that you can replace, see CloudFront Documentation.

- **ErrorCachingMinTTL (integer)** – The minimum amount of time you want HTTP error codes to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 31,536,000.

- **Comment (string)** – The comment originally specified when this distribution was created.

- **PriceClass (string)** –

- **Enabled (boolean)** – Whether the distribution is enabled to
accept end user requests for content.

- **ViewerCertificate** *(dict)* – A complex type that contains information about viewer certificates for this distribution.

- **IAMCertificateId** *(string)* – If you want viewers to use HTTPS to request your objects and you’re using an alternate domain name in your object URLs (for example, `https://example.com/logo.jpg`), specify the IAM certificate identifier of the custom viewer certificate for this distribution. Specify either this value or CloudFrontDefaultCertificate.

- **CloudFrontDefaultCertificate** *(boolean)* – If you want viewers to use HTTPS to request your objects and you’re using the CloudFront domain name of your distribution in your object URLs (for example, `https://d111111abcdef8.cloudfront.net/logo.jpg`), set to true. Omit this value if you are setting an IAMCertificateId.

- **SSLSupportMethod** *(string)* – If you specify a value for IAMCertificateId, you must also specify how you want CloudFront to serve HTTPS requests. Valid values are vip and sni-only. If you specify vip, CloudFront uses dedicated IP addresses for your content and can respond to HTTPS requests from any viewer. However, you must request permission to use this feature, and you incur additional monthly charges. If you specify sni-only, CloudFront can only respond to HTTPS requests from viewers that support Server Name Indication (SNI). All modern browsers support SNI, but some browsers still in use don’t support SNI. Do not specify a value for SSLSupportMethod if you specified true for CloudFrontDefaultCertificate.

- **MinimumProtocolVersion** *(string)* – Specify the minimum version of the SSL protocol that you want CloudFront to use, SSLv3 or TLSv1, for HTTPS connections. CloudFront will serve your objects only to browsers or devices that support at least the SSL version that you specify. The TLSv1 protocol is more secure, so we recommend that you specify SSLv3 only if your users are using browsers or devices that don’t support TLSv1. If you’re using a custom certificate (if you specify a value for IAMCertificateId) and you’re using dedicated IP (if you specify vip for SSLSupportMethod), you can choose SSLv3 or TLSv1 as the MinimumProtocolVersion. If you’re using a custom certificate (if you specify a value for IAMCertificateId) and you’re using SNI (if you specify sni-only for SSLSupportMethod), you must specify TLSv1 for MinimumProtocolVersion.

- **Restrictions** *(dict)* – A complex type that identifies ways in which you want to restrict distribution of your content.

- **GeoRestriction** *(dict)* – A complex type that controls the countries in which your content is distributed. For more information about geo restriction, go to Customizing Error Responses in the Amazon CloudFront Developer Guide. CloudFront determines the location of your users using MaxMind GeoIP databases. For information about the accuracy of these databases, see How accurate are your GeoIP databases? on the MaxMind website.

- **RestrictionType** *(string)* – The method that you want to use
to restrict distribution of your content by country: - none: No
geo restriction is enabled, meaning access to content is not
restricted by client geo location. - blacklist: The Location el-
ements specify the countries in which you do not want Cloud-
Front to distribute your content. - whitelist: The Location el-
ements specify the countries in which you want CloudFront
to distribute your content.

- **Quantity (integer)** – When geo restriction is enabled, this is
the number of countries in your whitelist or blacklist. Other-
wise, when it is not enabled, Quantity is 0, and you can omit
Items.

- **Items (list)** – A complex type that contains a Location ele-
ment for each country in which you want CloudFront either to
distribute your content (whitelist) or not distribute your con-
tent (blacklist). The Location element is a two-letter, upper-
case country code for a country that you want to include in
your blacklist or whitelist. Include one Location element for
each country. CloudFront and MaxMind both use ISO 3166
country codes. For the current list of countries and the cor-
responding codes, see ISO 3166-1-alpha-2 code on the Inter-
national Organization for Standardization website. You can
also refer to the country list in the CloudFront console, which
includes both country names and codes.

- **list_invalidations(**kwargs)**

  List invalidation batches.

  **Request Syntax**

  ```
  response = client.list_invalidations(
    DistributionId='string',
    Marker='string',
    MaxItems='string',
  )
  ```

  **Parameters**

  - **DistributionId (string)** – [REQUIRED] The distribution’s id.
  - **Marker (string)** – Use this parameter when paginating results to indicate where
to begin in your list of invalidation batches. Because the results are returned in
decreasing order from most recent to oldest, the most recent results are on the
first page, the second page will contain earlier results, and so on. To get the next
page of results, set the Marker to the value of the NextMarker from the current
page’s response. This value is the same as the ID of the last invalidation batch
on that page.
  - **MaxItems (string)** – The maximum number of invalidation batches you want in
the response body.

  **Return type**  dict

  **Returns**

  **Response Syntax**

  ```
  {
    'InvalidationList': {
      'Marker': 'string',
      'NextMarker': 'string',
  ```
Response Structure

- *(dict)* – The returned result of the corresponding request.
  
  - **InvalidationList (dict)** – Information about invalidation batches.
    
      - **Marker (string)** – The value you provided for the Marker request parameter.
    
      - **NextMarker (string)** – If IsTruncated is true, this element is present and contains the value you can use for the Marker request parameter to continue listing your invalidation batches where they left off.
    
      - **MaxItems (integer)** – The value you provided for the MaxItems request parameter.
    
      - **IsTruncated (boolean)** – A flag that indicates whether more invalidation batch requests remain to be listed. If your results were truncated, you can make a follow-up pagination request using the Marker request parameter to retrieve more invalidation batches in the list.
    
      - **Quantity (integer)** – The number of invalidation batches that were created by the current AWS account.
    
      - **Items (list)** – A complex type that contains one InvalidationSummary element for each invalidation batch that was created by the current AWS account.
      
        - *(dict)* – Summary of an invalidation request.
      
        - **Id (string)** – The unique ID for an invalidation request.
      
        - **CreateTime (datetime)** –
      
        - **Status (string)** – The status of an invalidation request.

`list_streaming_distributions (**kwargs)`

List streaming distributions.

Request Syntax

```python
response = client.list_streaming_distributions(
    Marker='string',
    MaxItems='string'
)
```

Parameters

- **Marker (string)** – Use this when paginating results to indicate where to begin in your list of streaming distributions. The results include distributions in the list that occur after the marker. To get the next page of results, set the Marker to the value of the NextMarker from the current page’s response (which is also the ID of the last distribution on that page).
- **MaxItems (string)** – The maximum number of streaming distributions you want in the response body.
Return type  dict

Returns

Response Syntax

```python
{
    'StreamingDistributionList': {
        'Marker': 'string',
        'NextMarker': 'string',
        'MaxItems': 123,
        'IsTruncated': True|False,
        'Quantity': 123,
        'Items': [
            {
                'Id': 'string',
                'Status': 'string',
                'LastModifiedTime': datetime(2015, 1, 1),
                'DomainName': 'string',
                'S3Origin': {
                    'DomainName': 'string',
                    'OriginAccessIdentity': 'string'
                },
                'Aliases': {
                    'Quantity': 123,
                    'Items': [
                        'string',
                    ]
                },
                'TrustedSigners': {
                    'Enabled': True|False,
                    'Quantity': 123,
                    'Items': [
                        'string',
                    ]
                },
                'Comment': 'string',
                'PriceClass': 'PriceClass_100'|'PriceClass_200'|'PriceClass_All',
                'Enabled': True|False
            }
        ]
    }
}
```

Response Structure

- *(dict)* – The returned result of the corresponding request.
  - **StreamingDistributionList** *(dict)* – The StreamingDistributionList type.
    - **Marker** *(string)* – The value you provided for the Marker request parameter.
    - **NextMarker** *(string)* – If IsTruncated is true, this element is present and contains the value you can use for the Marker request parameter to continue listing your streaming distributions where they left off.
    - **MaxItems** *(integer)* – The value you provided for the MaxItems request parameter.
    - **IsTruncated** *(boolean)* – A flag that indicates whether more streaming distributions remain to be listed. If your results were truncated, you can make a follow-up pagination request using the Marker request parameter to retrieve more distributions in the list.
+ **Quantity** (integer) – The number of streaming distributions that were created by the current AWS account.

+ **Items** (list) – A complex type that contains one StreamingDistributionSummary element for each distribution that was created by the current AWS account.

  - *(dict)* – A summary of the information for an Amazon CloudFront streaming distribution.
  - **Id** (string) – The identifier for the distribution. For example: EDFDVBD632BHDS5.
  - **Status** (string) – Indicates the current status of the distribution. When the status is Deployed, the distribution’s information is fully propagated throughout the Amazon CloudFront system.
  - **LastModifiedTime** (datetime) – The date and time the distribution was last modified.
  - **DomainName** (string) – The domain name corresponding to the distribution. For example: d604721fxaasqy9.cloudfront.net.
  - **S3Origin** (dict) – A complex type that contains information about the Amazon S3 bucket from which you want CloudFront to get your media files for distribution.
    - **DomainName** (string) – The DNS name of the S3 origin.
    - **OriginAccessIdentity** (string) – Your S3 origin’s origin access identity.
    - **Aliases** (dict) – A complex type that contains information about CNAMEs (alternate domain names), if any, for this streaming distribution.
  - **Quantity** (integer) – The number of CNAMEs, if any, for this distribution.
  - **Items** (list) – Optional: A complex type that contains CNAME elements, if any, for this distribution. If Quantity is 0, you can omit Items.
  - *(string)* –
  - **TrustedSigners** (dict) – A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.
  - **Enabled** (boolean) – Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.
  - **Quantity** (integer) – The number of trusted signers for this cache behavior.
  - **Items** (list) – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit...
Items.

- *(string)* –
- **Comment** *(string)* – The comment originally specified when this distribution was created.
- **PriceClass** *(string)* –
- **Enabled** *(boolean)* – Whether the distribution is enabled to accept end user requests for content.

```python
update_cloud_front_origin_access_identity(**kwargs)
```
Update an origin access identity.

**Request Syntax**

```python
response = client.update_cloud_front_origin_access_identity(
    CloudFrontOriginAccessIdentityConfig={
        'CallerReference': 'string',
        'Comment': 'string'
    },
    Id='string',
    IfMatch='string'
)
```

**Parameters**

  
  - **CallerReference** *(string)* – [REQUIRED] A unique number that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the CloudFrontOriginAccessIdentityConfig object), a new origin access identity is created. If the CallerReference is a value you already sent in a previous request to create an identity, and the content of the CloudFrontOriginAccessIdentityConfig is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create an identity but the content of the CloudFrontOriginAccessIdentityConfig is different from the original request, CloudFront returns a CloudFrontOriginAccessIdentityAlreadyExists error.
  
  - **Comment** *(string)* – [REQUIRED] Any comments you want to include about the origin access identity.

- **Id** *(string)* – [REQUIRED] The identity’s id.

- **IfMatch** *(string)* – The value of the ETag header you received when retrieving the identity’s configuration. For example: E2QWRUHAPOMQZL.

**Return type** dict

**Returns**

**Response Syntax**

```python
{'CloudFrontOriginAccessIdentity': {
    'Id': 'string',
    'S3CanonicalUserId': 'string',
    'CloudFrontOriginAccessIdentityConfig': {
        'CallerReference': 'string',
        'Comment': 'string'
    }
}},
```
'ETag': 'string'
}

**Response Structure**

- **(dict)** – The returned result of the corresponding request.
  - **CloudFrontOriginAccessIdentity (dict)** – The origin access identity’s information.
    - **Id (string)** – The ID for the origin access identity. For example: E74FTE3AJFJ256A.
    - **S3CanonicalUserId (string)** – The Amazon S3 canonical user ID for the origin access identity, which you use when giving the origin access identity read permission to an object in Amazon S3.
    - **CloudFrontOriginAccessIdentityConfig (dict)** – The current configuration information for the identity.
      - **CallerReference (string)** – A unique number that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the CloudFrontOriginAccessIdentityConfig object), a new origin access identity is created. If the CallerReference is a value you already sent in a previous request to create an identity, and the content of the CloudFrontOriginAccessIdentityConfig is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create an identity but the content of the CloudFrontOriginAccessIdentityConfig is different from the original request, CloudFront returns a CloudFrontOriginAccessIdentityAlreadyExists error.
      - **Comment (string)** – Any comments you want to include about the origin access identity.
  - **ETag (string)** – The current version of the configuration. For example: E2QWRUHAPOMQZL.

**update_distribution(**kwargs**)

Update a distribution.

**Request Syntax**

```python
response = client.update_distribution(
    DistributionConfig={
        'CallerReference': 'string',
        'Aliases': {
            'Quantity': 123,
            'Items': [
                'string',
            ],
        },
        'DefaultRootObject': 'string',
        'Origins': {
            'Quantity': 123,
            'Items': [
                {'Id': 'string',
                 'DomainName': 'string',
                 'OriginPath': 'string',
                 'S3OriginConfig': {
            ...
```
'OriginAccessIdentity': 'string',

  'Items': [ {
    'ErrorCode': 123,
    'ResponsePagePath': 'string',
    'ResponseCode': 'string',
    'ErrorCachingMinTTL': 123
  } ]
}
Parameters

  - **CallerReference (string)** – [REQUIRED] A unique number that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the DistributionConfig object), a new distribution is created. If the CallerReference is a value you already sent in a previous request to create a distribution, and the content of the DistributionConfig is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create a distribution but the content of the DistributionConfig is different from the original request, CloudFront returns a DistributionAlreadyExists error.
  - **Aliases (dict)** – A complex type that contains information about CNAMEs (alternate domain names), if any, for this distribution.
    - **Quantity (integer)** – [REQUIRED] The number of CNAMEs, if any, for this distribution.
    - **Items (list)** – Optional: A complex type that contains CNAME elements, if any, for this distribution. If Quantity is 0, you can omit Items.
      - (string)
  - **DefaultRootObject (string)** – The object that you want CloudFront to return (for example, index.html) when an end user requests the root URL for your distribution (http://www.example.com) instead of an object in your distribution (http://www.example.com/index.html). Specifying a default root object avoids exposing the contents of your distribution. If you don’t
want to specify a default root object when you create a distribution, include an empty DefaultRootObject element. To delete the default root object from an existing distribution, update the distribution configuration and include an empty DefaultRootObject element. To replace the default root object, update the distribution configuration and specify the new object.

- **Origins** *(dict)* – [REQUIRED] A complex type that contains information about origins for this distribution.
  
  * **Quantity** *(integer)* – [REQUIRED] The number of origins for this distribution.
  
  * **Items** *(list)* – A complex type that contains origins for this distribution.

  - *(dict)* – A complex type that describes the Amazon S3 bucket or the HTTP server (for example, a web server) from which CloudFront gets your files. You must create at least one origin.
  
  - **Id** *(string)* – [REQUIRED] A unique identifier for the origin. The value of Id must be unique within the distribution. You use the value of Id when you create a cache behavior. The Id identifies the origin that CloudFront routes a request to when the request matches the path pattern for that cache behavior.
  
  * **DomainName** *(string)* – [REQUIRED] Amazon S3 origins: The DNS name of the Amazon S3 bucket from which you want CloudFront to get objects for this origin, for example, myawsbucket.s3.amazonaws.com. Custom origins: The DNS domain name for the HTTP server from which you want CloudFront to get objects for this origin, for example, www.example.com.
  
  * **OriginPath** *(string)* – An optional element that causes CloudFront to request your content from a directory in your Amazon S3 bucket or your custom origin. When you include the OriginPath element, specify the directory name, beginning with a / . CloudFront appends the directory name to the value of DomainName.
  
  * **S3OriginConfig** *(dict)* – A complex type that contains information about the Amazon S3 origin. If the origin is a custom origin, use the CustomOriginConfig element instead.
  
  * **OriginAccessIdentity** *(string)* – [REQUIRED] The CloudFront origin access identity to associate with the origin. Use an origin access identity to configure the origin so that end users can only access objects in an Amazon S3 bucket through CloudFront. If you want end users to be able to access objects using either the CloudFront URL or the Amazon S3 URL, specify an empty OriginAccessIdentity element. To delete the origin access identity from an existing distribution, update the distribution configuration and include an empty OriginAccessIdentity element. To replace the origin access identity, update the distribution configuration and specify the new origin access identity. Use the format origin-access-identity/cloudfront/Id where Id is the value that CloudFront returned in the Id element when you created the origin access identity.
  
  * **CustomOriginConfig** *(dict)* – A complex type that contains information about a custom origin. If the origin is an Amazon S3 bucket, use the S3OriginConfig element instead.
  
  * **HTTPPort** *(integer)* – [REQUIRED] The HTTP port the
custom origin listens on.

- **HTTPSPort** (integer) – [REQUIRED] The HTTPS port the custom origin listens on.
- **OriginProtocolPolicy** (string) – [REQUIRED] The origin protocol policy to apply to your origin.

- **DefaultCacheBehavior** (dict) – [REQUIRED] A complex type that describes the default cache behavior if you do not specify a CacheBehavior element or if files don’t match any of the values of PathPattern in CacheBehavior elements. You must create exactly one default cache behavior.
  * **TargetOriginId** (string) – [REQUIRED] The value of ID for the origin that you want CloudFront to route requests to when a request matches the path pattern either for a cache behavior or for the default cache behavior.
  * **ForwardedValues** (dict) – [REQUIRED] A complex type that specifies how CloudFront handles query strings, cookies and headers.
    * **QueryString** (boolean) – [REQUIRED] Indicates whether you want CloudFront to forward query strings to the origin that is associated with this cache behavior. If so, specify true; if not, specify false.
    * **Cookies** (dict) – [REQUIRED] A complex type that specifies how CloudFront handles cookies.
      * **Forward** (string) – [REQUIRED] Use this element to specify whether you want CloudFront to forward cookies to the origin that is associated with this cache behavior. You can specify all, none or whitelist. If you choose All, CloudFront forwards all cookies regardless of how many your application uses.
      * **WhitelistedNames** (dict) – A complex type that specifies the whitelisted cookies, if any, that you want CloudFront to forward to your origin that is associated with this cache behavior.
      * **Quantity** (integer) – [REQUIRED] The number of whitelisted cookies for this cache behavior.
      * **Items** (list) – Optional: A complex type that contains whitelisted cookies for this cache behavior. If Quantity is 0, you can omit Items.
    * **Headers** (dict) – A complex type that specifies the Headers, if any, that you want CloudFront to vary upon for this cache behavior.
      * **Quantity** (integer) – [REQUIRED] The number of different headers that you want CloudFront to forward to the origin and to vary on for this cache behavior. The maximum number of headers that you can specify by name is 10. If you want CloudFront to forward all headers to the origin and vary on all of them, specify 1 for Quantity and * for Name. If you don’t want CloudFront to forward any additional headers to the origin or to vary on any headers, specify 0 for Quantity and omit Items.
      * **Items** (list) – Optional: A complex type that contains a Name element for each header that you want CloudFront to forward to the origin and to vary on for this cache behavior. If Quantity is 0, omit Items.
* TrustedSigners (dict) – [REQUIRED] A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.

  - **Enabled (boolean) – [REQUIRED]** Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.
  - **Quantity (integer) – [REQUIRED]** The number of trusted signers for this cache behavior.
  - **Items (list) –** Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.

* ViewerProtocolPolicy (string) – [REQUIRED] Use this element to specify the protocol that users can use to access the files in the origin specified by TargetOriginId when a request matches the path pattern in PathPattern. If you want CloudFront to allow end users to use any available protocol, specify allow-all. If you want CloudFront to require HTTPS, specify https. If you want CloudFront to respond to an HTTP request with an HTTP status code of 301 (Moved Permanently) and the HTTPS URL, specify redirect-to-https. The viewer then resubmits the request using the HTTPS URL.

* MinTTL (integer) – [REQUIRED] The minimum amount of time that you want objects to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

* AllowedMethods (dict) – A complex type that controls which HTTP methods CloudFront processes and forwards to your Amazon S3 bucket or your custom origin. There are three choices: - CloudFront forwards only GET and HEAD requests. - CloudFront forwards only GET, HEAD and OPTIONS requests. - CloudFront forwards GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests. If you pick the third choice, you may need to restrict access to your Amazon S3 bucket or to your custom origin so users can’t perform operations that you don’t want them to. For example, you may not want users to have permission to delete objects from your origin.

  - **Quantity (integer) – [REQUIRED]** The number of HTTP methods that you want CloudFront to forward to your origin. Valid values are 2 (for GET and HEAD requests), 3 (for GET, HEAD and OPTIONS requests) and 7 (for GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests).
  - **Items (list) – [REQUIRED]** A complex type that contains the HTTP methods that you want CloudFront to process and
forward to your origin.

- *(string)* –
  - **CachedMethods** *(dict)* – A complex type that controls whether CloudFront caches the response to requests using the specified HTTP methods. There are two choices: - CloudFront caches responses to GET and HEAD requests. - CloudFront caches responses to GET, HEAD, and OPTIONS requests. If you pick the second choice for your S3 Origin, you may need to forward Access-Control-Request-Method, Access-Control-Request-Headers and Origin headers for the responses to be cached correctly.
  - **Quantity** *(integer)* – [REQUIRED] The number of HTTP methods for which you want CloudFront to cache responses. Valid values are 2 (for caching responses to GET and HEAD requests) and 3 (for caching responses to GET, HEAD, and OPTIONS requests).
  - **Items** *(list)* – [REQUIRED] A complex type that contains the HTTP methods that you want CloudFront to cache responses to.
    - *(string)* –
      - **SmoothStreaming** *(boolean)* – Indicates whether you want to distribute media files in Microsoft Smooth Streaming format using the origin that is associated with this cache behavior. If so, specify true; if not, specify false.
      - **DefaultTTL** *(integer)* – If you don’t configure your origin to add a Cache-Control max-age directive or an Expires header, DefaultTTL is the default amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin does not add HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).
      - **MaxTTL** *(integer)* – The maximum amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin adds HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).
  - **CacheBehaviors** *(dict)* – A complex type that contains zero or more CacheBehavior elements.
    - **Quantity** *(integer)* – [REQUIRED] The number of cache behaviors for this distribution.
    - **Items** *(list)* – Optional: A complex type that contains cache behaviors for this distribution. If Quantity is 0, you can omit Items.
      - *(dict)* – A complex type that describes how CloudFront processes requests. You can create up to 10 cache behaviors. You must create at least as many cache behaviors (including the default cache behavior) as you have origins if you want CloudFront to distribute objects from all of the origins. Each cache behavior specifies the one origin from which you want CloudFront to get objects. If you have two origins and only the default cache behavior, the default cache behavior
will cause CloudFront to get objects from one of the origins, but the other origin will never be used. If you don’t want to specify any cache behaviors, include only an empty CacheBehaviors element. Don’t include an empty CacheBehavior element, or CloudFront returns a MalformedXML error. To delete all cache behaviors in an existing distribution, update the distribution configuration and include only an empty CacheBehaviors element. To add, change, or remove one or more cache behaviors, update the distribution configuration and specify all of the cache behaviors that you want to include in the updated distribution.

- **PathPattern (string)** – [REQUIRED] The pattern (for example, images/*.jpg) that specifies which requests you want this cache behavior to apply to. When CloudFront receives an end-user request, the requested path is compared with path patterns in the order in which cache behaviors are listed in the distribution. The path pattern for the default cache behavior is * and cannot be changed. If the request for an object does not match the path pattern for any cache behaviors, CloudFront applies the behavior in the default cache behavior.

- **TargetOriginId (string)** – [REQUIRED] The value of ID for the origin that you want CloudFront to route requests to when a request matches the path pattern either for a cache behavior or for the default cache behavior.

- **ForwardedValues (dict)** – [REQUIRED] A complex type that specifies how CloudFront handles query strings, cookies and headers.

- **QueryString (boolean)** – [REQUIRED] Indicates whether you want CloudFront to forward query strings to the origin that is associated with this cache behavior. If so, specify true; if not, specify false.

- **Cookies (dict)** – [REQUIRED] A complex type that specifies how CloudFront handles cookies.

- **Forward (string)** – [REQUIRED] Use this element to specify whether you want CloudFront to forward cookies to the origin that is associated with this cache behavior. You can specify all, none or whitelist. If you choose All, CloudFront forwards all cookies regardless of how many your application uses.

- **WhitelistedNames (dict)** – A complex type that specifies the whitelisted cookies, if any, that you want CloudFront to forward to your origin that is associated with this cache behavior.

- **Quantity (integer)** – [REQUIRED] The number of whitelisted cookies for this cache behavior.

- **Items (list)** – Optional: A complex type that contains whitelisted cookies for this cache behavior. If Quantity is 0, you can omit Items.

- **Headers (dict)** – A complex type that specifies the Headers, if any, that you want CloudFront to vary upon for this cache behavior.

- **Quantity (integer)** – [REQUIRED] The number of different headers that you want CloudFront to forward to the origin and to vary on for this cache behavior. The maximum number
of headers that you can specify by name is 10. If you want CloudFront to forward all headers to the origin and vary on all of them, specify 1 for Quantity and * for Name. If you don’t want CloudFront to forward any additional headers to the origin or to vary on any headers, specify 0 for Quantity and omit Items.

- **Items** (list) – Optional: A complex type that contains a Name element for each header that you want CloudFront to forward to the origin and to vary on for this cache behavior. If Quantity is 0, omit Items.
  - 
  - **(string)** –
  - 

- **TrustedSigners** (dict) – [REQUIRED] A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.

- **Enabled** (boolean) – [REQUIRED] Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.

- **Quantity** (integer) – [REQUIRED] The number of trusted signers for this cache behavior.

- **Items** (list) – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.

- **(string)** –

- **ViewerProtocolPolicy** (string) – [REQUIRED] Use this element to specify the protocol that users can use to access the files in the origin specified by TargetOriginId when a request matches the path pattern in PathPattern. If you want CloudFront to allow end users to use any available protocol, specify allow-all. If you want CloudFront to require HTTPS, specify https. If you want CloudFront to respond to an HTTP request with an HTTP status code of 301 (Moved Permanently) and the HTTPS URL, specify redirect-to-https. The viewer then resubmits the request using the HTTPS URL.

- **MinTTL** (integer) – [REQUIRED] The minimum amount of time that you want objects to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **AllowedMethods** (dict) – A complex type that controls which HTTP methods CloudFront processes and forwards to your Amazon S3 bucket or your custom origin. There are three choices: - CloudFront forwards only GET and HEAD re-
quests. - CloudFront forwards only GET, HEAD and OPTIONS requests. - CloudFront forwards GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests. If you pick the third choice, you may need to restrict access to your Amazon S3 bucket or to your custom origin so users can’t perform operations that you don’t want them to. For example, you may not want users to have permission to delete objects from your origin.

- **Quantity (integer)** – [REQUIRED] The number of HTTP methods that you want CloudFront to forward to your origin. Valid values are 2 (for GET and HEAD requests), 3 (for GET, HEAD and OPTIONS requests) and 7 (for GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests).

- **Items (list)** – [REQUIRED] A complex type that contains the HTTP methods that you want CloudFront to process and forward to your origin.

  - **(string)** –

- **CachedMethods (dict)** – A complex type that controls whether CloudFront caches the response to requests using the specified HTTP methods. There are two choices: - CloudFront caches responses to GET and HEAD requests. - CloudFront caches responses to GET, HEAD, and OPTIONS requests. If you pick the second choice for your S3 Origin, you may need to forward Access-Control-Request-Method, Access-Control-Request-Headers and Origin headers for the responses to be cached correctly.

- **Quantity (integer)** – [REQUIRED] The number of HTTP methods for which you want CloudFront to cache responses. Valid values are 2 (for caching responses to GET and HEAD requests) and 3 (for caching responses to GET, HEAD, and OPTIONS requests).

- **Items (list)** – [REQUIRED] A complex type that contains the HTTP methods that you want CloudFront to cache responses to.

  - **(string)** –

- **SmoothStreaming (boolean)** – Indicates whether you want to distribute media files in Microsoft Smooth Streaming format using the origin that is associated with this cache behavior. If so, specify true; if not, specify false.

- **DefaultTTL (integer)** – If you don’t configure your origin to add a Cache-Control max-age directive or an Expires header, DefaultTTL is the default amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin does not add HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **MaxTTL (integer)** – The maximum amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin adds HTTP headers
such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **CustomErrorResponses** (*dict*) – A complex type that contains zero or more CustomErrorResponse elements.
  * **Quantity** (*integer*) – [REQUIRED] The number of custom error responses for this distribution.
  * **Items** (*list*) – Optional: A complex type that contains custom error responses for this distribution. If Quantity is 0, you can omit Items.
    - (**dict**) – A complex type that describes how you’d prefer CloudFront to respond to requests that result in either a 4xx or 5xx response. You can control whether a custom error page should be displayed, what the desired response code should be for this error page and how long should the error response be cached by CloudFront. If you don’t want to specify any custom error responses, include only an empty CustomErrorResponses element. To delete all custom error responses in an existing distribution, update the distribution configuration and include only an empty CustomErrorResponses element. To add, change, or remove one or more custom error responses, update the distribution configuration and specify all of the custom error responses that you want to include in the updated distribution.
    - **ErrorCode** (*integer*) – [REQUIRED] The 4xx or 5xx HTTP status code that you want to customize. For a list of HTTP status codes that you can customize, see CloudFront documentation.
    - **ResponsePagePath** (*string*) – The path of the custom error page (for example, /custom_404.html). The path is relative to the distribution and must begin with a slash (/). If the path includes any non-ASCII characters or unsafe characters as defined in RFC 1783 (http://www.ietf.org/rfc/rfc1738.txt), URL encode those characters. Do not URL encode any other characters in the path, or CloudFront will not return the custom error page to the viewer.
    - **ResponseCode** (*string*) – The HTTP status code that you want CloudFront to return with the custom error page to the viewer. For a list of HTTP status codes that you can replace, see CloudFront Documentation.
    - **ErrorCachingMinTTL** (*integer*) – The minimum amount of time you want HTTP error codes to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 31,536,000.
  - **Comment** (*string*) – [REQUIRED] Any comments you want to include about the distribution.
  - **Logging** (*dict*) – A complex type that controls whether access logs are written for the distribution.
    - **Enabled** (*boolean*) – [REQUIRED] Specifies whether you want CloudFront to save access logs to an Amazon S3 bucket. If you do not want to enable logging when you create a distribution or if you want to disable logging for an existing distribution, specify false for Enabled, and specify empty Bucket and Prefix elements. If you specify false for Enabled but you specify values for Bucket, prefix
and IncludeCookies, the values are automatically deleted.

- **IncludeCookies** *(boolean)* – [REQUIRED] Specifies whether you want CloudFront to include cookies in access logs, specify true for IncludeCookies. If you choose to include cookies in logs, CloudFront logs all cookies regardless of how you configure the cache behaviors for this distribution. If you do not want to include cookies when you create a distribution or if you want to disable include cookies for an existing distribution, specify false for IncludeCookies.

- **Bucket** *(string)* – [REQUIRED] The Amazon S3 bucket to store the access logs in, for example, myawslogbucket.s3.amazonaws.com.

- **Prefix** *(string)* – [REQUIRED] An optional string that you want CloudFront to prefix to the access log filenames for this distribution, for example, myprefix/. If you want to enable logging, but you do not want to specify a prefix, you still must include an empty Prefix element in the Logging element.

- **PriceClass** *(string)* – A complex type that contains information about price class for this distribution.

- **Enabled** *(boolean)* – [REQUIRED] Whether the distribution is enabled to accept end user requests for content.

- **ViewerCertificate** *(dict)* – A complex type that contains information about viewer certificates for this distribution.

  - **IAMCertificateId** *(string)* – If you want viewers to use HTTPS to request your objects and you’re using an alternate domain name in your object URLs (for example, https://example.com/logo.jpg), specify the IAM certificate identifier of the custom viewer certificate for this distribution. Specify either this value or CloudFrontDefaultCertificate.

  - **CloudFrontDefaultCertificate** *(boolean)* – If you want viewers to use HTTPS to request your objects and you’re using the CloudFront domain name of your distribution in your object URLs (for example, https://d111111abcdef8.cloudfront.net/logo.jpg), set to true. Omit this value if you are setting an IAMCertificateId.

  - **SSLSupportMethod** *(string)* – If you specify a value for IAMCertificateId, you must also specify how you want CloudFront to serve HTTPS requests. Valid values arevip and sni-only. If you specify vip, CloudFront uses dedicated IP addresses for your content and can respond to HTTPS requests from any viewer. However, you must request permission to use this feature, and you incur additional monthly charges. If you specify sni-only, CloudFront can only respond to HTTPS requests from viewers that support Server Name Indication (SNI). All modern browsers support SNI, but some browsers still in use don’t support SNI. Do not specify a value for SSLSupportMethod if you specified true for CloudFrontDefaultCertificate.

  - **MinimumProtocolVersion** *(string)* – Specify the minimum version of the SSL protocol that you want CloudFront to use, SSLv3 or TLSv1, for HTTPS connections. CloudFront will serve your objects only to browsers or devices that support at least the SSL version that you specify. The TLSv1 protocol is more secure, so we recommend that you specify SSLv3 only if your users are using browsers or devices that don’t support TLSv1. If you’re using a custom certificate (if you specify a value for IAMCertificateId) and if you’re
using dedicated IP (if you specify vip for SSSLsupportMethod), you can choose SSLv3 or TLSv1 as the MinimumProtocolVersion. If you’re using a custom certificate (if you specify a value for IAMCertificateId) and if you’re using SNI (if you specify sni-only for SSSLsupportMethod), you must specify TLSv1 for MinimumProtocolVersion.

- **Restrictions** *(dict)* – A complex type that identifies ways in which you want to restrict distribution of your content.
  - **GeoRestriction** *(dict)* – [REQUIRED] A complex type that controls the countries in which your content is distributed. For more information about geo restriction, go to Customizing Error Responses in the Amazon CloudFront Developer Guide. CloudFront determines the location of your users using MaxMind GeoIP databases. For information about the accuracy of these databases, see How accurate are your GeoIP databases? on the MaxMind website.
    - **RestrictionType** *(string)* – [REQUIRED] The method that you want to use to restrict distribution of your content by country: - none: No geo restriction is enabled, meaning access to content is not restricted by client geo location. - blacklist: The Location elements specify the countries in which you do not want CloudFront to distribute your content. - whitelist: The Location elements specify the countries in which you want CloudFront to distribute your content.
    - **Quantity** *(integer)* – [REQUIRED] When geo restriction is enabled, this is the number of countries in your whitelist or blacklist. Otherwise, when it is not enabled, Quantity is 0, and you can omit Items.
    - **Items** *(list)* – A complex type that contains a Location element for each country in which you want CloudFront either to distribute your content (whitelist) or not distribute your content (blacklist). The Location element is a two-letter, upper-case country code for a country that you want to include in your blacklist or whitelist. Include one Location element for each country. CloudFront and MaxMind both use ISO 3166 country codes. For the current list of countries and the corresponding codes, see ISO 3166-1-alpha-2 code on the International Organization for Standardization website. You can also refer to the country list in the CloudFront console, which includes both country names and codes.
      - **Id** *(string)* – [REQUIRED] The distribution’s id.
      - **IfMatch** *(string)* – The value of the ETag header you received when retrieving the distribution’s configuration. For example: E2QWRUHAPOMQZL.

Return type  dict

3.1. Services
Response Structure

- (dict) – The returned result of the corresponding request.
  - Distribution (dict) – The distribution’s information.
    - Id (string) – The identifier for the distribution. For example: EDFD-VBD632BHDS5.
    - Status (string) – This response element indicates the current status of the distribution. When the status is Deployed, the distribution’s information is fully propagated throughout the Amazon CloudFront system.
    - LastModifiedTime (datetime) – The date and time the distribution was last modified.
    - InProgressInvalidationBatches (integer) – The number of invalidation batches currently in progress.
    - DomainName (string) – The domain name corresponding to the distribution. For example: d604721fxaaqy9.cloudfront.net.
    - ActiveTrustedSigners (dict) – CloudFront automatically adds this element to the response only if you’ve set up the distribution to serve private content with signed URLs. The element lists the key pair IDs that CloudFront is aware of for each trusted signer. The Signer child element lists the AWS account number of the trusted signer (or an empty Self element if the signer is you). The Signer element also includes the IDs of any active key pairs associated with the trusted signer’s AWS account. If no KeyPairId element appears for a Signer, that signer can’t create working signed URLs.
      - Enabled (boolean) – Each active trusted signer.
      - Quantity (integer) – The number of unique trusted signers included in all cache behaviors. For example, if three cache behaviors all list the same three AWS accounts, the value of Quantity for ActiveTrustedSigners will be 3.
      - Items (list) – A complex type that contains one Signer complex type for each unique trusted signer that is specified in the TrustedSigners complex type, including trusted signers in the default cache behavior and in all of the other cache behaviors.
      - (dict) – A complex type that lists the AWS accounts that were included in the TrustedSigners complex type, as well as their active CloudFront key pair IDs, if any.
    - AwsAccountNumber (string) – Specifies an AWS account that can create signed URLs. Values: self, which indicates that the AWS account that was used to create the distribution can create signed URLs, or an AWS account number. Omit the dashes in the account number.
    - KeyPairIds (dict) – A complex type that lists the active CloudFront key pairs, if any, that are associated with AwsAccountNumber.
      - Quantity (integer) – The number of active CloudFront key pairs for AwsAccountNumber.
      - Items (list) – A complex type that lists the active CloudFront key pairs, if any, that are associated with AwsAccountNumber.
      - (string) –
Boto3 Documentation, Release 1.1.4

* DistributionConfig (dict) – The current configuration information for the distribution.
  - CallerReference (string) – A unique number that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the DistributionConfig object), a new distribution is created. If the CallerReference is a value you already sent in a previous request to create a distribution, and the content of the DistributionConfig is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create a distribution but the content of the DistributionConfig is different from the original request, CloudFront returns a DistributionAlreadyExists error.
  - Aliases (dict) – A complex type that contains information about CNAMEs (alternate domain names), if any, for this distribution.
  - Quantity (integer) – The number of CNAMEs, if any, for this distribution.
  - Items (list) – Optional: A complex type that contains CNAME elements, if any, for this distribution. If Quantity is 0, you can omit Items.
  - (string)
  - DefaultRootObject (string) – The object that you want CloudFront to return (for example, index.html) when an end user requests the root URL for your distribution (http://www.example.com) instead of an object in your distribution (http://www.example.com/index.html). Specifying a default root object avoids exposing the contents of your distribution. If you don’t want to specify a default root object when you create a distribution, include an empty DefaultRootObject element. To delete the default root object from an existing distribution, update the distribution configuration and include an empty DefaultRootObject element. To replace the default root object, update the distribution configuration and specify the new object.
  - Origins (dict) – A complex type that contains information about origins for this distribution.
  - Quantity (integer) – The number of origins for this distribution.
  - Items (list) – A complex type that contains origins for this distribution.
  - (dict) – A complex type that describes the Amazon S3 bucket or the HTTP server (for example, a web server) from which CloudFront gets your files. You must create at least one origin.
  - Id (string) – A unique identifier for the origin. The value of Id must be unique within the distribution. You use the value of Id when you create a cache behavior. The Id identifies the origin that CloudFront routes a request to when the request matches the path pattern for that cache behavior.
  - DomainName (string) – Amazon S3 origins: The DNS name of the Amazon S3 bucket from which you want CloudFront to get objects for this origin, for example, myaws-bucket.s3.amazonaws.com. Custom origins: The DNS do-
main name for the HTTP server from which you want CloudFront to get objects for this origin, for example, www.example.com.

- **OriginPath (string)** – An optional element that causes CloudFront to request your content from a directory in your Amazon S3 bucket or your custom origin. When you include the OriginPath element, specify the directory name, beginning with a / . CloudFront appends the directory name to the value of DomainName.

- **S3OriginConfig (dict)** – A complex type that contains information about the Amazon S3 origin. If the origin is a custom origin, use the CustomOriginConfig element instead.

- **OriginAccessIdentity (string)** – The CloudFront origin access identity to associate with the origin. Use an origin access identity to configure the origin so that end users can only access objects in an Amazon S3 bucket through CloudFront. If you want end users to be able to access objects using either the CloudFront URL or the Amazon S3 URL, specify an empty OriginAccessIdentity element. To delete the origin access identity from an existing distribution, update the distribution configuration and include an empty OriginAccessIdentity element. To replace the origin access identity, update the distribution configuration and specify the new origin access identity. Use the format origin-access-identity/cloudfront/Id where Id is the value that CloudFront returned in the Id element when you created the origin access identity.

- **CustomOriginConfig (dict)** – A complex type that contains information about a custom origin. If the origin is an Amazon S3 bucket, use the S3OriginConfig element instead.

- **HTTPPort (integer)** – The HTTP port the custom origin listens on.

- **HTTPSPort (integer)** – The HTTPS port the custom origin listens on.

- **OriginProtocolPolicy (string)** – The origin protocol policy to apply to your origin.

- **DefaultCacheBehavior (dict)** – A complex type that describes the default cache behavior if you do not specify a CacheBehavior element or if files don’t match any of the values of PathPattern in CacheBehavior elements. You must create exactly one default cache behavior.

- **TargetOriginId (string)** – The value of ID for the origin that you want CloudFront to route requests to when a request matches the path pattern either for a cache behavior or for the default cache behavior.

- **ForwardedValues (dict)** – A complex type that specifies how CloudFront handles query strings, cookies and headers.

- **QueryString (boolean)** – Indicates whether you want CloudFront to forward query strings to the origin that is associated with this cache behavior. If so, specify true; if not, specify false.

- **Cookies (dict)** – A complex type that specifies how CloudFront handles cookies.

- **Forward (string)** – Use this element to specify whether you want CloudFront to forward cookies to the origin that is asso-
associated with this cache behavior. You can specify all, none or whitelist. If you choose All, CloudFront forwards all cookies regardless of how many your application uses.

- **WhitelistedNames** *(dict)* – A complex type that specifies the whitelisted cookies, if any, that you want CloudFront to forward to your origin that is associated with this cache behavior.

- **Quantity** *(integer)* – The number of whitelisted cookies for this cache behavior.

- **Items** *(list)* – Optional: A complex type that contains whitelisted cookies for this cache behavior. If Quantity is 0, you can omit Items.

- **Headers** *(dict)* – A complex type that specifies the Headers, if any, that you want CloudFront to vary upon for this cache behavior.

- **Quantity** *(integer)* – The number of different headers that you want CloudFront to forward to the origin and to vary on for this cache behavior. The maximum number of headers that you can specify by name is 10. If you want CloudFront to forward all headers to the origin and vary on all of them, specify 1 for Quantity and * for Name. If you don’t want CloudFront to forward any additional headers to the origin or to vary on any headers, specify 0 for Quantity and omit Items.

- **Items** *(list)* – Optional: A complex type that contains a Name element for each header that you want CloudFront to forward to the origin and to vary on for this cache behavior. If Quantity is 0, omit Items.

- **TrustedSigners** *(dict)* – A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.

- **Enabled** *(boolean)* – Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.

- **Quantity** *(integer)* – The number of trusted signers for this cache behavior.

- **Items** *(list)* – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.

- **ViewerProtocolPolicy** *(string)* – Use this element to specify the protocol that users can use to access the files in the origin specified by TargetOriginId when a request matches the path.
pattern in PathPattern. If you want CloudFront to allow end users to use any available protocol, specify allow-all. If you want CloudFront to require HTTPS, specify https. If you want CloudFront to respond to an HTTP request with an HTTP status code of 301 (Moved Permanently) and the HTTPS URL, specify redirect-to-https. The viewer then resubmits the request using the HTTPS URL.

- **MinTTL (integer)** – The minimum amount of time that you want objects to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **AllowedMethods (dict)** – A complex type that controls which HTTP methods CloudFront processes and forwards to your Amazon S3 bucket or your custom origin. There are three choices: - CloudFront forwards only GET and HEAD requests. - CloudFront forwards only GET, HEAD and OPTIONS requests. - CloudFront forwards GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests. If you pick the third choice, you may need to restrict access to your Amazon S3 bucket or to your custom origin so users can’t perform operations that you don’t want them to. For example, you may not want users to have permission to delete objects from your origin.

- **Quantity (integer)** – The number of HTTP methods that you want CloudFront to forward to your origin. Valid values are 2 (for GET and HEAD requests), 3 (for GET, HEAD and OPTIONS requests) and 7 (for GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests).

- **Items (list)** – A complex type that contains the HTTP methods that you want CloudFront to process and forward to your origin.

- **CachedMethods (dict)** – A complex type that controls whether CloudFront caches the response to requests using the specified HTTP methods. There are two choices: - CloudFront caches responses to GET and HEAD requests. - CloudFront caches responses to GET, HEAD, and OPTIONS requests. If you pick the second choice for your S3 Origin, you may need to forward Access-Control-Request-Method, Access-Control-Request-Headers and Origin headers for the responses to be cached correctly.

- **Quantity (integer)** – The number of HTTP methods for which you want CloudFront to cache responses. Valid values are 2 (for caching responses to GET and HEAD requests) and 3 (for caching responses to GET, HEAD, and OPTIONS requests).

- **Items (list)** – A complex type that contains the HTTP methods that you want CloudFront to cache responses to.

- **SmoothStreaming (boolean)** – Indicates whether you want to distribute media files in Microsoft Smooth Streaming format using the origin that is associated with this cache behavior. If so, specify true; if not, specify false.

- **DefaultTTL (integer)** – If you don’t configure your origin to
add a Cache-Control max-age directive or an Expires header. DefaultTTL is the default amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin does not add HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **MaxTTL (integer)** – The maximum amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin adds HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).
- **CacheBehaviors (dict)** – A complex type that contains zero or more CacheBehavior elements.
- **Quantity (integer)** – The number of cache behaviors for this distribution.
- **Items (list)** – Optional: A complex type that contains cache behaviors for this distribution. If Quantity is 0, you can omit Items.
- **(dict)** – A complex type that describes how CloudFront processes requests. You can create up to 10 cache behaviors. You must create at least as many cache behaviors (including the default cache behavior) as you have origins if you want CloudFront to distribute objects from all of the origins. Each cache behavior specifies the one origin from which you want CloudFront to get objects. If you have two origins and only the default cache behavior, the default cache behavior will cause CloudFront to get objects from one of the origins, but the other origin will never be used. If you don’t want to specify any cache behaviors, include only an empty CacheBehaviors element. Don’t include an empty CacheBehavior element, or CloudFront returns a MalformedXML error. To delete all cache behaviors in an existing distribution, update the distribution configuration and include only an empty CacheBehaviors element. To add, change, or remove one or more cache behaviors, update the distribution configuration and specify all of the cache behaviors that you want to include in the updated distribution.
- **PathPattern (string)** – The pattern (for example, images/*.jpg) that specifies which requests you want this cache behavior to apply to. When CloudFront receives an end-user request, the requested path is compared with path patterns in the order in which cache behaviors are listed in the distribution. The path pattern for the default cache behavior is * and cannot be changed. If the request for an object does not match the path pattern for any cache behaviors, CloudFront applies the behavior in the default cache behavior.
- **TargetOriginId (string)** – The value of ID for the origin that you want CloudFront to route requests to when a request
matches the path pattern either for a cache behavior or for the default cache behavior.

- **ForwardedValues** (*dict*) – A complex type that specifies how CloudFront handles query strings, cookies and headers.
- **QueryString** (*boolean*) – Indicates whether you want CloudFront to forward query strings to the origin that is associated with this cache behavior. If so, specify true; if not, specify false.
- **Cookies** (*dict*) – A complex type that specifies how CloudFront handles cookies.
- **Forward** (*string*) – Use this element to specify whether you want CloudFront to forward cookies to the origin that is associated with this cache behavior. You can specify all, none or whitelist. If you choose All, CloudFront forwards all cookies regardless of how many your application uses.
- **WhitelistedNames** (*dict*) – A complex type that specifies the whitelisted cookies, if any, that you want CloudFront to forward to your origin that is associated with this cache behavior.
- **Quantity** (*integer*) – The number of whitelisted cookies for this cache behavior.
- **Items** (*list*) – Optional: A complex type that contains whitelisted cookies for this cache behavior. If Quantity is 0, you can omit Items.
- **Headers** (*dict*) – A complex type that specifies the Headers, if any, that you want CloudFront to vary upon for this cache behavior.
- **Quantity** (*integer*) – The number of different headers that you want CloudFront to forward to the origin and to vary on for this cache behavior. The maximum number of headers that you can specify by name is 10. If you want CloudFront to forward all headers to the origin and vary on all of them, specify 1 for Quantity and * for Name. If you don’t want CloudFront to forward any additional headers to the origin or to vary on any headers, specify 0 for Quantity and omit Items.
- **Items** (*list*) – Optional: A complex type that contains a Name element for each header that you want CloudFront to forward to the origin and to vary on for this cache behavior. If Quantity is 0, omit Items.
- **TrustedSigners** (*dict*) – A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.
- **Enabled** (boolean) – Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.
- **Quantity** (integer) – The number of trusted signers for this cache behavior.
- **Items** (list) – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.
- **ViewerProtocolPolicy** (string) – Use this element to specify the protocol that users can use to access the files in the origin specified by TargetOriginId when a request matches the path pattern in PathPattern. If you want CloudFront to allow end users to use any available protocol, specify allow-all. If you want CloudFront to require HTTPS, specify https. If you want CloudFront to respond to an HTTP request with an HTTP status code of 301 (Moved Permanently) and the HTTPS URL, specify redirect-to-https. The viewer then resubmits the request using the HTTPS URL.
- **MinTTL** (integer) – The minimum amount of time that you want objects to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 3,153,600,000 seconds (100 years).
- **AllowedMethods** (dict) – A complex type that controls which HTTP methods CloudFront processes and forwards to your Amazon S3 bucket or your custom origin. There are three choices: - CloudFront forwards only GET and HEAD requests. - CloudFront forwards only GET, HEAD and OPTIONS requests. - CloudFront forwards GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests. If you pick the third choice, you may need to restrict access to your Amazon S3 bucket or to your custom origin so users can’t perform operations that you don’t want them to. For example, you may not want users to have permission to delete objects from your origin.
- **Quantity** (integer) – The number of HTTP methods that you want CloudFront to forward to your origin. Valid values are 2 (for GET and HEAD requests), 3 (for GET, HEAD and OPTIONS requests) and 7 (for GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests).
- **Items** (list) – A complex type that contains the HTTP methods that you want CloudFront to process and forward to your origin.
- **CachedMethods** (dict) – A complex type that controls whether CloudFront caches the response to requests using the specified HTTP methods. There are two choices: - CloudFront caches responses to GET and HEAD requests. - CloudFront caches responses to GET, HEAD, and OPTIONS requests. If you pick the second choice for your S3 Origin, you may need to forward Access-Control-Request-Method, Access-Control-Request-Headers and Origin headers for the responses to be cached correctly.
- **Quantity (integer)** – The number of HTTP methods for which you want CloudFront to cache responses. Valid values are 2 (for caching responses to GET and HEAD requests) and 3 (for caching responses to GET, HEAD, and OPTIONS requests).
- **Items (list)** – A complex type that contains the HTTP methods that you want CloudFront to cache responses to.
  - **(string)** –
- **SmoothStreaming (boolean)** – Indicates whether you want to distribute media files in Microsoft Smooth Streaming format using the origin that is associated with this cache behavior. If so, specify true; if not, specify false.
- **DefaultTTL (integer)** – If you don’t configure your origin to add a Cache-Control max-age directive or an Expires header, DefaultTTL is the default amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin does not add HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).
- **MaxTTL (integer)** – The maximum amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin adds HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).
- **CustomErrorResponses (dict)** – A complex type that contains zero or more CustomErrorResponse elements.
- **Quantity (integer)** – The number of custom error responses for this distribution.
- **Items (list)** – Optional: A complex type that contains custom error responses for this distribution. If Quantity is 0, you can omit Items.
- **(dict)** – A complex type that describes how you’d prefer CloudFront to respond to requests that result in either a 4xx or 5xx response. You can control whether a custom error page should be displayed, what the desired response code should be for this error page and how long should the error response be cached by CloudFront. If you don’t want to specify any custom error responses, include only an empty CustomErrorResponse element. To delete all custom error responses in an existing distribution, update the distribution configuration and include only an empty CustomErrorResponses element. To add, change, or remove one or more custom error responses, update the distribution configuration and specify all of the custom error responses that you want to include in the updated distribution.
- **ErrorCode (integer)** – The 4xx or 5xx HTTP status code that you want to customize. For a list of HTTP status codes that you can customize, see CloudFront documentation.
- **ResponsePagePath (string)** – The path of the custom error
page (for example, /custom_404.html). The path is relative to the distribution and must begin with a slash (/). If the path includes any non-ASCII characters or unsafe characters as defined in RFC 1783 (http://www.ietf.org/rfc/rfc1738.txt), URL encode those characters. Do not URL encode any other characters in the path, or CloudFront will not return the custom error page to the viewer.

- **ResponseCode (string)** – The HTTP status code that you want CloudFront to return with the custom error page to the viewer. For a list of HTTP status codes that you can replace, see CloudFront Documentation.

- **ErrorCachingMinTTL (integer)** – The minimum amount of time you want HTTP error codes to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 31,536,000.

- **Comment (string)** – Any comments you want to include about the distribution.

- **Logging (dict)** – A complex type that controls whether access logs are written for the distribution.

- **Enabled (boolean)** – Specifies whether you want CloudFront to save access logs to an Amazon S3 bucket. If you do not want to enable logging when you create a distribution or if you want to disable logging for an existing distribution, specify false for Enabled, and specify empty Bucket and Prefix elements. If you specify false for Enabled but you specify values for Bucket, prefix and IncludeCookies, the values are automatically deleted.

- **IncludeCookies (boolean)** – Specifies whether you want CloudFront to include cookies in access logs, specify true for IncludeCookies. If you choose to include cookies in logs, CloudFront logs all cookies regardless of how you configure the cache behaviors for this distribution. If you do not want to include cookies when you create a distribution or if you want to disable include cookies for an existing distribution, specify false for IncludeCookies.

- **Bucket (string)** – The Amazon S3 bucket to store the access logs in, for example, myawslogbucket.s3.amazonaws.com.

- **Prefix (string)** – An optional string that you want CloudFront to prefix to the access log filenames for this distribution, for example, myprefix/. If you want to enable logging, but you do not want to specify a prefix, you still must include an empty Prefix element in the Logging element.

- **PriceClass (string)** – A complex type that contains information about price class for this distribution.

- **Enabled (boolean)** – Whether the distribution is enabled to accept end user requests for content.

- **ViewerCertificate (dict)** – A complex type that contains information about viewer certificates for this distribution.

- **IAMCertificateId (string)** – If you want viewers to use HTTPS to request your objects and you’re using an alternate domain name in your object URLs (for example, https://example.com/logo.jpg), specify the IAM certificate identifier of the custom viewer certificate for this distribution.
Specify either this value or CloudFrontDefaultCertificate.

- **CloudFrontDefaultCertificate** *(boolean)* – If you want viewers to use HTTPS to request your objects and you’re using the CloudFront domain name of your distribution in your object URLs (for example, https://d111111abcdef8.cloudfront.net/logo.jpg), set to true. Omit this value if you are setting an IAMCertificateId.

- **SSLSupportMethod** *(string)* – If you specify a value for IAMCertificateId, you must also specify how you want CloudFront to serve HTTPS requests. Valid values are vip and sni-only. If you specify vip, CloudFront uses dedicated IP addresses for your content and can respond to HTTPS requests from any viewer. However, you must request permission to use this feature, and you incur additional monthly charges. If you specify sni-only, CloudFront can only respond to HTTPS requests from viewers that support Server Name Indication (SNI). All modern browsers support SNI, but some browsers still in use don’t support SNI. Do not specify a value for SSLSupportMethod if you specified true for CloudFrontDefaultCertificate.

- **MinimumProtocolVersion** *(string)* – Specify the minimum version of the SSL protocol that you want CloudFront to use, SSLv3 or TLSv1, for HTTPS connections. CloudFront will serve your objects only to browsers or devices that support at least the SSL version that you specify. The TLSv1 protocol is more secure, so we recommend that you specify SSLv3 only if your users are using browsers or devices that don’t support TLSv1. If you’re using a custom certificate (if you specify a value for IAMCertificateId) and if you’re using dedicated IP (if you specify vip for SSLSupportMethod), you can choose SSLv3 or TLSv1 as the MinimumProtocolVersion. If you’re using a custom certificate (if you specify a value for IAMCertificateId) and if you’re using SNI (if you specify sni-only for SSLSupportMethod), you must specify TLSv1 for MinimumProtocolVersion.

- **Restrictions** *(dict)* – A complex type that identifies ways in which you want to restrict distribution of your content.

- **GeoRestriction** *(dict)* – A complex type that controls the countries in which your content is distributed. For more information about geo restriction, go to Customizing Error Responses in the Amazon CloudFront Developer Guide. CloudFront determines the location of your users using MaxMind GeoIP databases. For information about the accuracy of these databases, see How accurate are your GeoIP databases? on the MaxMind website.

- **RestrictionType** *(string)* – The method that you want to use to restrict distribution of your content by country: - none: No geo restriction is enabled, meaning access to content is not restricted by client geo location. - blacklist: The Location elements specify the countries in which you do not want CloudFront to distribute your content. - whitelist: The Location elements specify the countries in which you want CloudFront to distribute your content.

- **Quantity** *(integer)* – When geo restriction is enabled, this is
the number of countries in your whitelist or blacklist. Otherwise, when it is not enabled, Quantity is 0, and you can omit Items.

- **Items** *(list)* – A complex type that contains a Location element for each country in which you want CloudFront either to distribute your content (whitelist) or not distribute your content (blacklist). The Location element is a two-letter, uppercase country code for a country that you want to include in your blacklist or whitelist. Include one Location element for each country. CloudFront and MaxMind both use ISO 3166 country codes. For the current list of countries and the corresponding codes, see ISO 3166-1-alpha-2 code on the International Organization for Standardization website. You can also refer to the country list in the CloudFront console, which includes both country names and codes.

- *(string)* –

  - **ETag** *(string)* – The current version of the configuration. For example: E2QWRUHAPOMQZL.

```python
update_streaming_distribution(**kwargs)
```

Update a streaming distribution.

Request Syntax

```python
response = client.update_streaming_distribution(
    StreamingDistributionConfig={
        'CallerReference': 'string',
        'S3Origin': {
            'DomainName': 'string',
            'OriginAccessIdentity': 'string'
        },
        'Aliases': {
            'Quantity': 123,
            'Items': ['string'],
        },
        'Comment': 'string',
        'Logging': {
            'Enabled': True|False,
            'Bucket': 'string',
            'Prefix': 'string'
        },
        'TrustedSigners': {
            'Enabled': True|False,
            'Quantity': 123,
            'Items': ['string'],
        },
        'PriceClass': 'PriceClass_100'|'PriceClass_200'|'PriceClass_All',
        'Enabled': True|False
    },
    Id='string',
    IfMatch='string'
)
```

Parameters
• **StreamingDistributionConfig (dict) – [REQUIRED]** The streaming distribution’s configuration information.
  
  – **CallerReference (string) – [REQUIRED]** A unique number that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the StreamingDistributionConfig object), a new streaming distribution is created. If the CallerReference is a value you already sent in a previous request to create a streaming distribution, and the content of the StreamingDistributionConfig is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create a streaming distribution but the content of the StreamingDistributionConfig is different from the original request, CloudFront returns a DistributionAlreadyExists error.

  – **S3Origin (dict) – [REQUIRED]** A complex type that contains information about the Amazon S3 bucket from which you want CloudFront to get your media files for distribution.
    
    * **DomainName (string) – [REQUIRED]** The DNS name of the S3 origin.
    
    * **OriginAccessIdentity (string) – [REQUIRED]** Your S3 origin’s origin access identity.

  – **Aliases (dict)** – A complex type that contains information about CNAMEs (alternate domain names), if any, for this streaming distribution.
    
    * **Quantity (integer) – [REQUIRED]** The number of CNAMEs, if any, for this distribution.
    
    * **Items (list)** – Optional: A complex type that contains CNAME elements, if any, for this distribution. If Quantity is 0, you can omit Items.

    – **Comment (string)** – [REQUIRED] Any comments you want to include about the streaming distribution.

  – **Logging (dict)** – A complex type that controls whether access logs are written for the streaming distribution.
    
    * **Enabled (boolean) – [REQUIRED]** Specifies whether you want CloudFront to save access logs to an Amazon S3 bucket. If you do not want to enable logging when you create a streaming distribution or if you want to disable logging for an existing streaming distribution, specify false for Enabled, and specify empty Bucket and Prefix elements. If you specify false for Enabled but you specify values for Bucket and Prefix, the values are automatically deleted.
    
    * **Bucket (string) – [REQUIRED]** The Amazon S3 bucket to store the access logs in, for example, myawslogbucket.s3.amazonaws.com.
    
    * **Prefix (string) – [REQUIRED]** An optional string that you want CloudFront to prefix to the access log filenames for this streaming distribution, for example, myprefix/. If you want to enable logging, but you do not want to specify a prefix, you still must include an empty Prefix element in the Logging element.

  – **TrustedSigners (dict)** – [REQUIRED] A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t
want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it's currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.

* **Enabled (boolean)** – [REQUIRED] Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.
* **Quantity (integer)** – [REQUIRED] The number of trusted signers for this cache behavior.
* **Items (list)** – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.
  
  · *(string)* –
  
  – **PriceClass (string)** – A complex type that contains information about price class for this streaming distribution.
  
  – **Enabled (boolean)** – [REQUIRED] Whether the streaming distribution is enabled to accept end user requests for content.

• **Id (string)** – [REQUIRED] The streaming distribution’s id.

• **IfMatch (string)** – The value of the ETag header you received when retrieving the streaming distribution’s configuration. For example: E2QWRRUHAPOMQZL.

**Return type**  dict

**Returns**

**Response Syntax**

```
{
    'StreamingDistribution': {
        'Id': 'string',
        'Status': 'string',
        'LastModifiedTime': datetime(2015, 1, 1),
        'DomainName': 'string',
        'ActiveTrustedSigners': {
            'Enabled': True|False,
            'Quantity': 123,
            'Items': [
                {
                    'AwsAccountNumber': 'string',
                    'KeyPairIds': {
                        'Quantity': 123,
                        'Items': [
                            'string',
                        ],
                    },
                }
            ],
        },
    }
},

'StreamingDistributionConfig': {
    'CallerReference': 'string',
    'S3Origin': {
        'DomainName': 'string',
        'OriginAccessIdentity': 'string'
    },
    'Aliases': {
        'Quantity': 123,
        'Items': [
            'string',
        ],
    },
}
```
Response Structure

- *(dict)* – The returned result of the corresponding request.
  - **StreamingDistribution (dict)** – The streaming distribution’s information.
    - **Id (string)** – The identifier for the streaming distribution. For example: EGTXBD79H29TRA8.
    - **Status (string)** – The current status of the streaming distribution. When the status is Deployed, the distribution’s information is fully propagated throughout the Amazon CloudFront system.
    - **LastModifiedTime (datetime)** – The date and time the distribution was last modified.
    - **DomainName (string)** – The domain name corresponding to the streaming distribution. For example: s5c39gqb8ow64r.cloudfront.net.
    - **ActiveTrustedSigners (dict)** – CloudFront automatically adds this element to the response only if you’ve set up the distribution to serve private content with signed URLs. The element lists the key pair IDs that CloudFront is aware of for each trusted signer. The Signer child element lists the AWS account number of the trusted signer (or an empty Self element if the signer is you). The Signer element also includes the IDs of any active key pairs associated with the trusted signer’s AWS account. If no KeyPairId element appears for a Signer, that signer can’t create working signed URLs.
      - **Enabled (boolean)** – Each active trusted signer.
      - **Quantity (integer)** – The number of unique trusted signers included in all cache behaviors. For example, if three cache behaviors all list the same three AWS accounts, the value of Quantity for ActiveTrustedSigners will be 3.
      - **Items (list)** – A complex type that contains one Signer complex type for each unique trusted signer that is specified in the TrustedSigners complex type, including trusted signers in the default cache behavior and in all of the other cache behaviors.
      - *(dict)* – A complex type that lists the AWS accounts that were included in the TrustedSigners complex type, as well as their
active CloudFront key pair IDs, if any.

- **AwsAccountNumber (string)** – Specifies an AWS account that can create signed URLs. Values: self, which indicates that the AWS account that was used to create the distribution can create signed URLs, or an AWS account number. Omit the dashes in the account number.

- **KeyPairIds (dict)** – A complex type that lists the active CloudFront key pairs, if any, that are associated with AwsAccountNumber.

- **Quantity (integer)** – The number of active CloudFront key pairs for AwsAccountNumber.

- **Items (list)** – A complex type that lists the active CloudFront key pairs, if any, that are associated with AwsAccountNumber.

- **(string)** –

- **StreamingDistributionConfig (dict)** – The current configuration information for the streaming distribution.

  - **CallerReference (string)** – A unique number that ensures the request can’t be replayed. If the CallerReference is new (no matter the content of the StreamingDistributionConfig object), a new streaming distribution is created. If the CallerReference is a value you already sent in a previous request to create a streaming distribution, and the content of the StreamingDistributionConfig is identical to the original request (ignoring white space), the response includes the same information returned to the original request. If the CallerReference is a value you already sent in a previous request to create a streaming distribution but the content of the StreamingDistributionConfig is different from the original request, CloudFront returns a DistributionAlreadyExists error.

  - **S3Origin (dict)** – A complex type that contains information about the Amazon S3 bucket from which you want CloudFront to get your media files for distribution.

    - **DomainName (string)** – The DNS name of the S3 origin.

    - **OriginAccessIdentity (string)** – Your S3 origin’s origin access identity.

    - **Aliases (dict)** – A complex type that contains information about CNAMEs (alternate domain names), if any, for this streaming distribution.

    - **Quantity (integer)** – The number of CNAMEs, if any, for this distribution.

    - **Items (list)** – Optional: A complex type that contains CNAME elements, if any, for this distribution. If Quantity is 0, you can omit Items.

    - **(string)** –

    - **Comment (string)** – Any comments you want to include about the streaming distribution.

    - **Logging (dict)** – A complex type that controls whether access logs are written for the streaming distribution.

    - **Enabled (boolean)** – Specifies whether you want CloudFront to save access logs to an Amazon S3 bucket. If you do not want to enable logging when you create a streaming distribution or if you want to disable logging for an existing streaming distribution, specify false for Enabled, and specify empty
Bucket and Prefix elements. If you specify false for Enabled but you specify values for Bucket and Prefix, the values are automatically deleted.

- **Bucket (string)** – The Amazon S3 bucket to store the access logs in, for example, myawslogbucket.s3.amazonaws.com.
- **Prefix (string)** – An optional string that you want CloudFront to prefix to the access log filenames for this streaming distribution, for example, myprefix/. If you want to enable logging, but you do not want to specify a prefix, you still must include an empty Prefix element in the Logging element.
- **TrustedSigners (dict)** – A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.
- **Enabled (boolean)** – Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.
- **Quantity (integer)** – The number of trusted signers for this cache behavior.
- **Items (list)** – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.

- **PriceClass (string)** – A complex type that contains information about price class for this streaming distribution.
- **Enabled (boolean)** – Whether the streaming distribution is enabled to accept end user requests for content.

- **ETag (string)** – The current version of the configuration. For example: E2QWRUHAPOMQZL.

### Paginators

The available paginators are:

- CloudFront.Paginator.ListCloudFrontOriginAccessIdentities
- CloudFront.Paginator.ListDistributions
- CloudFront.Paginator.ListInvalidations
- CloudFront.Paginator.ListStreamingDistributions

**class** CloudFront.Paginator.ListCloudFrontOriginAccessIdentities
paginator = client.get_paginator('list_cloud_front_origin_access_identities')

paginate(**kwargs)

Creates an iterator that will paginate through responses from CloudFront.Client.list_cloud_front_origin_access_identities().

Request Syntax

response_iterator = paginator.paginate(
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters  
PaginationConfig (dict) – A dictionary that provides parameters to control pagination.

• **MaxItems** (integer) –
  The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

• **PageSize** (integer) –
  The size of each page.

• **StartingToken** (string) –
  A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict

Returns

Response Syntax

{
    'CloudFrontOriginAccessIdentityList': {
        'Marker': 'string',
        'NextMarker': 'string',
        'MaxItems': 123,
        'IsTruncated': True|False,
        'Quantity': 123,
        'Items': [
            {
                'Id': 'string',
                'S3CanonicalUserId': 'string',
                'Comment': 'string'
            }
        ],
        'NextToken': 'string'
    }
}

Response Structure

• (dict) – The returned result of the corresponding request.
* **Marker** *(string)* – The value you provided for the Marker request parameter.
* **NextMarker** *(string)* – If IsTruncated is true, this element is present and contains the value you can use for the Marker request parameter to continue listing your origin access identities where they left off.
* **MaxItems** *(integer)* – The value you provided for the MaxItems request parameter.
* **IsTruncated** *(boolean)* – A flag that indicates whether more origin access identities remain to be listed. If your results were truncated, you can make a follow-up pagination request using the Marker request parameter to retrieve more items in the list.
* **Quantity** *(integer)* – The number of CloudFront origin access identities that were created by the current AWS account.
* **Items** *(list)* – A complex type that contains one CloudFrontOriginAccessIdentitySummary element for each origin access identity that was created by the current AWS account.
  - *(dict)* – Summary of the information about a CloudFront origin access identity.
    - **Id** *(string)* – The ID for the origin access identity. For example: E74FTE3AJFJ256A.
    - **S3CanonicalUserId** *(string)* – The Amazon S3 canonical user ID for the origin access identity, which you use when giving the origin access identity read permission to an object in Amazon S3.
    - **Comment** *(string)* – The comment for this origin access identity, as originally specified when created.
  - **NextToken** *(string)* – A token to resume pagination.

```python
class CloudFront.Paginator.ListDistributions

paginator = client.get_paginator('list_distributions')
paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `CloudFront.Client.list_distributions()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

* **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* – The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
• **PageSize** *(integer)* —
  The size of each page.

• **StartingToken** *(string)* —
  A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'DistributionList': {
        'Marker': 'string',
        'NextMarker': 'string',
        'MaxItems': 123,
        'IsTruncated': True|False,
        'Quantity': 123,
        'Items': [
            {
                'Id': 'string',
                'Status': 'string',
                'LastModifiedTime': datetime(2015, 1, 1),
                'DomainName': 'string',
                'Aliases': {
                    'Quantity': 123,
                    'Items': [
                        'string',
                    ],
                },
                'Origins': {
                    'Quantity': 123,
                    'Items': [
                        {
                            'Id': 'string',
                            'DomainName': 'string',
                            'OriginPath': 'string',
                            'S3OriginConfig': {
                                'OriginAccessIdentity': 'string'
                            },
                            'CustomOriginConfig': {
                                'HTTPPort': 123,
                                'HTTPSPort': 123,
                                'OriginProtocolPolicy': 'http-only'|'match-viewer'
                            },
                        },
                    ],
                },
                'DefaultCacheBehavior': {
                    'TargetOriginId': 'string',
                    'ForwardedValues': {
                        'QueryString': True|False,
                        'Cookies': {
                            'Forward': 'none'|'whitelist'|'all',
                            'WhitelistedNames': {
                                'Quantity': 123,
                                'Items': [
                                    'string',
                                ],
                            },
                        },
                    },
                },
            },
        ]
    },
}
```
'Headers': {
    'Quantity': 123,
    'Items': [
        'string',
    ],

            ],
        },
    ],
}
Response Structure

- (dict) – The returned result of the corresponding request.
  - DistributionList (dict) – The DistributionList type.
    - Marker (string) – The value you provided for the Marker request parameter.
    - NextMarker (string) – If IsTruncated is true, this element is present and contains the value you can use for the Marker request parameter to continue listing your distributions where they left off.
    - MaxItems (integer) – The value you provided for the MaxItems request parameter.
    - IsTruncated (boolean) – A flag that indicates whether more distributions remain to be listed. If your results were truncated, you can make a follow-up pagination request using the Marker request parameter to retrieve more distributions in the list.
    - Quantity (integer) – The number of distributions that were created by the current AWS account.
    - Items (list) – A complex type that contains one DistributionSummary element for each distribution that was created by the current AWS account.
      - (dict) – A summary of the information for an Amazon CloudFront distribution.
        - Id (string) – The identifier for the distribution. For example: EDADFVD632BHDS5.
        - Status (string) – This response element indicates the current status of the distribution. When the status is Deployed, the distribution’s information is fully propagated throughout the Amazon CloudFront system.
        - LastModifiedTime (datetime) – The date and time the distribution was last modified.
        - DomainName (string) – The domain name corresponding to the distribution. For example: d604721fxaacqy9.cloudfront.net.
        - Aliases (dict) – A complex type that contains information about CNAMEs (alternate domain names), if any, for this distribution.
        - Quantity (integer) – The number of CNAMEs, if any, for this distribution.
        - Items (list) – Optional: A complex type that contains CNAME elements, if any, for this distribution. If Quantity is 0, you can omit Items.
      - (string) –
        - Origins (dict) – A complex type that contains information about origins for this distribution.
  - Quantity (integer) – The number of origins for this distribution.
  - Items (list) – A complex type that contains origins for this distribution.
  - (dict) – A complex type that describes the Amazon S3 bucket or the HTTP server (for example, a web server) from which
CloudFront gets your files. You must create at least one origin.

- **Id (string)** – A unique identifier for the origin. The value of Id must be unique within the distribution. You use the value of Id when you create a cache behavior. The Id identifies the origin that CloudFront routes a request to when the request matches the path pattern for that cache behavior.

- **DomainName (string)** – Amazon S3 origins: The DNS name of the Amazon S3 bucket from which you want CloudFront to get objects for this origin, for example, myawsbucket.s3.amazonaws.com. Custom origins: The DNS domain name for the HTTP server from which you want CloudFront to get objects for this origin, for example, www.example.com.

- **OriginPath (string)** – An optional element that causes CloudFront to request your content from a directory in your Amazon S3 bucket or your custom origin. When you include the OriginPath element, specify the directory name, beginning with a / . CloudFront appends the directory name to the value of DomainName.

- **S3OriginConfig (dict)** – A complex type that contains information about the Amazon S3 origin. If the origin is a custom origin, use the CustomOriginConfig element instead.

- **OriginAccessIdentity (string)** – The CloudFront origin access identity to associate with the origin. Use an origin access identity to configure the origin so that end users can only access objects in an Amazon S3 bucket through CloudFront. If you want end users to be able to access objects using either the CloudFront URL or the Amazon S3 URL, specify an empty OriginAccessIdentity element. To delete the origin access identity from an existing distribution, update the distribution configuration and include an empty OriginAccessIdentity element. To replace the origin access identity from an existing distribution, update the distribution configuration and specify the new origin access identity. Use the format origin-access-identity/cloudfront/Id where Id is the value that CloudFront returned in the Id element when you created the origin access identity.

- **CustomOriginConfig (dict)** – A complex type that contains information about a custom origin. If the origin is an Amazon S3 bucket, use the S3OriginConfig element instead.

- **HTTPPort (integer)** – The HTTP port the custom origin listens on.

- **HTTPSPort (integer)** – The HTTPS port the custom origin listens on.

- **OriginProtocolPolicy (string)** – The origin protocol policy to apply to your origin.

- **DefaultCacheBehavior (dict)** – A complex type that describes the default cache behavior if you do not specify a CacheBehavior element or if files don’t match any of the values of PathPattern in CacheBehavior elements. You must create exactly one default cache behavior.

- **TargetOriginId (string)** – The value of ID for the origin that you want CloudFront to route requests to when a request matches the path pattern either for a cache behavior or for the default cache behavior.
- **ForwardedValues** (*dict*) – A complex type that specifies how CloudFront handles query strings, cookies and headers.
- **QueryString** (*boolean*) – Indicates whether you want CloudFront to forward query strings to the origin that is associated with this cache behavior. If so, specify true; if not, specify false.
- **Cookies** (*dict*) – A complex type that specifies how CloudFront handles cookies.
- **Forward** (*string*) – Use this element to specify whether you want CloudFront to forward cookies to the origin that is associated with this cache behavior. You can specify all, none or whitelist. If you choose All, CloudFront forwards all cookies regardless of how many your application uses.
- **WhitelistedNames** (*dict*) – A complex type that specifies the whitelisted cookies, if any, that you want CloudFront to forward to your origin that is associated with this cache behavior.
- **Quantity** (*integer*) – The number of whitelisted cookies for this cache behavior.
- **Items** (*list*) – Optional: A complex type that contains whitelisted cookies for this cache behavior. If Quantity is 0, you can omit Items.
- **(string)** –
- **Headers** (*dict*) – A complex type that specifies the Headers, if any, that you want CloudFront to vary upon for this cache behavior.
- **Quantity** (*integer*) – The number of different headers that you want CloudFront to forward to the origin and to vary on for this cache behavior. The maximum number of headers that you can specify by name is 10. If you want CloudFront to forward all headers to the origin and vary on all of them, specify 1 for Quantity and * for Name. If you don’t want CloudFront to forward any additional headers to the origin or to vary on any headers, specify 0 for Quantity and omit Items.
- **Items** (*list*) – Optional: A complex type that contains a Name element for each header that you want CloudFront to forward to the origin and to vary on for this cache behavior. If Quantity is 0, omit Items.
- **(string)** –
- **TrustedSigners** (*dict*) – A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.
- **Enabled** (*boolean*) – Specifies whether you want to require end users to use signed URLs to access the files specified by
PathPattern and TargetOriginId.

- **Quantity** *(integer)* – The number of trusted signers for this cache behavior.

- **Items** *(list)* – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.

- **(string)** –
  - **ViewerProtocolPolicy** *(string)* – Use this element to specify the protocol that users can use to access the files in the origin specified by TargetOriginId when a request matches the path pattern in PathPattern. If you want CloudFront to allow end users to use any available protocol, specify allow-all. If you want CloudFront to require HTTPS, specify https. If you want CloudFront to respond to an HTTP request with an HTTP status code of 301 (Moved Permanently) and the HTTPS URL, specify redirect-to-https. The viewer then resubmits the request using the HTTPS URL.

- **MinTTL** *(integer)* – The minimum amount of time that you want objects to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **AllowedMethods** *(dict)* – A complex type that controls which HTTP methods CloudFront processes and forwards to your Amazon S3 bucket or your custom origin. There are three choices: - CloudFront forwards only GET and HEAD requests. - CloudFront forwards only GET, HEAD and OPTIONS requests. - CloudFront forwards GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests. If you pick the third choice, you may need to restrict access to your Amazon S3 bucket or to your custom origin so users can’t perform operations that you don’t want them to. For example, you may not want users to have permission to delete objects from your origin.

- **Quantity** *(integer)* – The number of HTTP methods that you want CloudFront to forward to your origin. Valid values are 2 (for GET and HEAD requests), 3 (for GET, HEAD and OPTIONS requests) and 7 (for GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests).

- **Items** *(list)* – A complex type that contains the HTTP methods that you want CloudFront to process and forward to your origin.

- **(string)** –
  - **CachedMethods** *(dict)* – A complex type that controls whether CloudFront caches the response to requests using the specified HTTP methods. There are two choices: - CloudFront caches responses to GET and HEAD requests. - CloudFront caches responses to GET, HEAD, and OPTIONS requests. If you pick the second choice for your S3 Origin, you may need to forward Access-Control-Request-Method, Access-Control-Request-Headers and Origin headers for the responses to be cached correctly.

- **Quantity** *(integer)* – The number of HTTP methods for which you want CloudFront to cache responses. Valid values are 2
(for caching responses to GET and HEAD requests) and 3 (for caching responses to GET, HEAD, and OPTIONS requests).

- **Items (list)** – A complex type that contains the HTTP methods that you want CloudFront to cache responses to.
- **(string)** –
  - **SmoothStreaming (boolean)** – Indicates whether you want to distribute media files in Microsoft Smooth Streaming format using the origin that is associated with this cache behavior. If so, specify true; if not, specify false.
  - **DefaultTTL (integer)** – If you don’t configure your origin to add a Cache-Control max-age directive or an Expires header, DefaultTTL is the default amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin does not add HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).
  - **MaxTTL (integer)** – The maximum amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin adds HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).
  - **CacheBehaviors (dict)** – A complex type that contains zero or more CacheBehavior elements.
  - **Quantity (integer)** – The number of cache behaviors for this distribution.
  - **Items (list)** – Optional: A complex type that contains cache behaviors for this distribution. If Quantity is 0, you can omit Items.
  - **(dict)** – A complex type that describes how CloudFront processes requests. You can create up to 10 cache behaviors. You must create at least as many cache behaviors (including the default cache behavior) as you have origins if you want CloudFront to distribute objects from all of the origins. Each cache behavior specifies the one origin from which you want CloudFront to get objects. If you have two origins and only the default cache behavior, the default cache behavior will cause CloudFront to get objects from one of the origins, but the other origin will never be used. If you don’t want to specify any cache behaviors, include only an empty CacheBehaviors element. Don’t include an empty CacheBehavior element, or CloudFront returns a MalformedXML error. To delete all cache behaviors in an existing distribution, update the distribution configuration and include only an empty CacheBehaviors element. To add, change, or remove one or more cache behaviors, update the distribution configuration and specify all of the cache behaviors that you want to include in the updated distribution.
  - **PathPattern (string)** – The pattern (for example, im-
that specifies which requests you want this cache behavior to apply to. When CloudFront receives an end-user request, the requested path is compared with path patterns in the order in which cache behaviors are listed in the distribution. The path pattern for the default cache behavior is * and cannot be changed. If the request for an object does not match the path pattern for any cache behaviors, CloudFront applies the behavior in the default cache behavior.

- **TargetOriginId (string)** – The value of ID for the origin that you want CloudFront to route requests to when a request matches the path pattern either for a cache behavior or for the default cache behavior.

- **ForwardedValues (dict)** – A complex type that specifies how CloudFront handles query strings, cookies and headers.

- **QueryString (boolean)** – Indicates whether you want CloudFront to forward query strings to the origin that is associated with this cache behavior. If so, specify true; if not, specify false.

- **Cookies (dict)** – A complex type that specifies how CloudFront handles cookies.

- **Forward (string)** – Use this element to specify whether you want CloudFront to forward cookies to the origin that is associated with this cache behavior. You can specify all, none or whitelist. If you choose All, CloudFront forwards all cookies regardless of how many your application uses.

- **WhitelistedNames (dict)** – A complex type that specifies the whitelisted cookies, if any, that you want CloudFront to forward to your origin that is associated with this cache behavior.

- **Quantity (integer)** – The number of whitelisted cookies for this cache behavior.

- **Items (list)** – Optional: A complex type that contains whitelisted cookies for this cache behavior. If Quantity is 0, you can omit Items.

- **Headers (dict)** – A complex type that specifies the Headers, if any, that you want CloudFront to vary upon for this cache behavior.

- **Quantity (integer)** – The number of different headers that you want CloudFront to forward to the origin and to vary on for this cache behavior. The maximum number of headers that you can specify by name is 10. If you want CloudFront to forward all headers to the origin and vary on all of them, specify 1 for Quantity and * for Name. If you don’t want CloudFront to forward any additional headers to the origin or to vary on any headers, specify 0 for Quantity and omit Items.

- **Items (list)** – Optional: A complex type that contains a Name element for each header that you want CloudFront to forward to the origin and to vary on for this cache behavior. If Quantity is 0, omit Items.

- **TrustedSigners (dict)** – A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the Path-
Pattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.

- **Enabled (boolean)** – Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.
- **Quantity (integer)** – The number of trusted signers for this cache behavior.
- **Items (list)** – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.
- **(string)** –
- **ViewerProtocolPolicy (string)** – Use this element to specify the protocol that users can use to access the files in the origin specified by TargetOriginId when a request matches the path pattern in PathPattern. If you want CloudFront to allow end users to use any available protocol, specify allow-all. If you want CloudFront to require HTTPS, specify https. If you want CloudFront to respond to an HTTP request with an HTTP status code of 301 (Moved Permanently) and the HTTPS URL, specify redirect-to-https. The viewer then resubmits the request using the HTTPS URL.
- **MinTTL (integer)** – The minimum amount of time that you want objects to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 3,153,600,000 seconds (100 years).
- **AllowedMethods (dict)** – A complex type that controls which HTTP methods CloudFront processes and forwards to your Amazon S3 bucket or your custom origin. There are three choices: - CloudFront forwards only GET and HEAD requests. - CloudFront forwards only GET, HEAD and OPTIONS requests. - CloudFront forwards GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests. If you pick the third choice, you may need to restrict access to your Amazon S3 bucket or to your custom origin so users can’t perform operations that you don’t want them to. For example, you may not want users to have permission to delete objects from your origin.
- **Quantity (integer)** – The number of HTTP methods that you want CloudFront to forward to your origin. Valid values are 2 (for GET and HEAD requests), 3 (for GET, HEAD and OPTIONS requests) and 7 (for GET, HEAD, OPTIONS, PUT, PATCH, POST, and DELETE requests).
- **Items (list)** – A complex type that contains the HTTP methods that you want CloudFront to process and forward to your origin.
- **(string)**

- **CachedMethods (dict)** – A complex type that controls whether CloudFront caches the response to requests using the specified HTTP methods. There are two choices: - CloudFront caches responses to GET and HEAD requests. - CloudFront caches responses to GET, HEAD, and OPTIONS requests. If you pick the second choice for your S3 Origin, you may need to forward Access-Control-Request-Method, Access-Control-Request-Headers and Origin headers for the responses to be cached correctly.

- **Quantity (integer)** – The number of HTTP methods for which you want CloudFront to cache responses. Valid values are 2 (for caching responses to GET and HEAD requests) and 3 (for caching responses to GET, HEAD, and OPTIONS requests).

- **Items (list)** – A complex type that contains the HTTP methods that you want CloudFront to cache responses to.

- **(string)**

- **SmoothStreaming (boolean)** – Indicates whether you want to distribute media files in Microsoft Smooth Streaming format using the origin that is associated with this cache behavior. If so, specify true; if not, specify false.

- **DefaultTTL (integer)** – If you don’t configure your origin to add a Cache-Control max-age directive or an Expires header, DefaultTTL is the default amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin does not add HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **MaxTTL (integer)** – The maximum amount of time (in seconds) that an object is in a CloudFront cache before CloudFront forwards another request to your origin to determine whether the object has been updated. The value that you specify applies only when your origin adds HTTP headers such as Cache-Control max-age, Cache-Control s-maxage, and Expires to objects. You can specify a value from 0 to 3,153,600,000 seconds (100 years).

- **CustomErrorResponses (dict)** – A complex type that contains zero or more CustomErrorResponses elements.

- **Quantity (integer)** – The number of custom error responses for this distribution.

- **Items (list)** – Optional: A complex type that contains custom error responses for this distribution. If Quantity is 0, you can omit Items.

- **(dict)** – A complex type that describes how you’d prefer CloudFront to respond to requests that result in either a 4xx or 5xx response. You can control whether a custom error page should be displayed, what the desired response code should be for this error page and how long should the error response be cached by CloudFront. If you don’t want to specify any custom error responses, include only an empty CustomErrorResponses element. To delete all custom error responses
in an existing distribution, update the distribution configuration and include only an empty CustomErrorResponses element. To add, change, or remove one or more custom error responses, update the distribution configuration and specify all of the custom error responses that you want to include in the updated distribution.

- **ErrorCode** (integer) – The 4xx or 5xx HTTP status code that you want to customize. For a list of HTTP status codes that you can customize, see CloudFront documentation.
- **ResponsePagePath** (string) – The path of the custom error page (for example, /custom_404.html). The path is relative to the distribution and must begin with a slash (/). If the path includes any non-ASCII characters or unsafe characters as defined in RFC 1783 (http://www.ietf.org/rfc/rfc1738.txt), URL encode those characters. Do not URL encode any other characters in the path, or CloudFront will not return the custom error page to the viewer.
- **ResponseCode** (string) – The HTTP status code that you want CloudFront to return with the custom error page to the viewer. For a list of HTTP status codes that you can replace, see CloudFront Documentation.
- **ErrorCachingMinTTL** (integer) – The minimum amount of time you want HTTP error codes to stay in CloudFront caches before CloudFront queries your origin to see whether the object has been updated. You can specify a value from 0 to 31,536,000.
- **Comment** (string) – The comment originally specified when this distribution was created.
- **PriceClass** (string) –
- **Enabled** (boolean) – Whether the distribution is enabled to accept end user requests for content.
- **ViewerCertificate** (dict) – A complex type that contains information about viewer certificates for this distribution.
- **IAMCertificateId** (string) – If you want viewers to use HTTPS to request your objects and you’re using an alternate domain name in your object URLs (for example, https://example.com/logo.jpg), specify the IAM certificate identifier of the custom viewer certificate for this distribution. Specify either this value or CloudFrontDefaultCertificate.
- **CloudFrontDefaultCertificate** (boolean) – If you want viewers to use HTTPS to request your objects and you’re using the CloudFront domain name of your distribution in your object URLs (for example, https://d111111abcdef8.cloudfront.net/logo.jpg), set to true. Omit this value if you are setting an IAMCertificateId.
- **SSLSupportMethod** (string) – If you specify a value for IAMCertificateId, you must also specify how you want CloudFront to serve HTTPS requests. Valid values are vip and sni-only. If you specify vip, CloudFront uses dedicated IP addresses for your content and can respond to HTTPS requests from any viewer. However, you must request permission to use this feature, and you incur additional monthly charges. If you specify sni-only, CloudFront can only respond to HTTPS requests from viewers that support Server Name Indication
All modern browsers support SNI, but some browsers still in use don’t support SNI. Do not specify a value for SSLSupportMethod if you specified true for CloudFrontDefaultCertificate.

**MinimumProtocolVersion (string)** – Specify the minimum version of the SSL protocol that you want CloudFront to use, SSLv3 or TLSv1, for HTTPS connections. CloudFront will serve your objects only to browsers or devices that support at least the SSL version that you specify. The TLSv1 protocol is more secure, so we recommend that you specify SSLv3 only if your users are using browsers or devices that don’t support TLSv1. If you’re using a custom certificate (if you specify a value for IAMCertificateId) and if you’re using dedicated IP (if you specify vip for SSLSupportMethod), you can choose SSLv3 or TLSv1 as the MinimumProtocolVersion. If you’re using a custom certificate (if you specify a value for IAMCertificateId) and if you’re using SNI (if you specify sni-only for SSLSupportMethod), you must specify TLSv1 for MinimumProtocolVersion.

**Restrictions (dict)** – A complex type that identifies ways in which you want to restrict distribution of your content.

**GeoRestriction (dict)** – A complex type that controls the countries in which your content is distributed. For more information about geo restriction, go to Customizing Error Responses in the Amazon CloudFront Developer Guide. CloudFront determines the location of your users using MaxMind GeoIP databases. For information about the accuracy of these databases, see How accurate are your GeoIP databases? on the MaxMind website.

**RestrictionType (string)** – The method that you want to use to restrict distribution of your content by country: - none: No geo restriction is enabled, meaning access to content is not restricted by client geo location. - blacklist: The Location elements specify the countries in which you do not want CloudFront to distribute your content. - whitelist: The Location elements specify the countries in which you want CloudFront to distribute your content.

**Quantity (integer)** – When geo restriction is enabled, this is the number of countries in your whitelist or blacklist. Otherwise, when it is not enabled, Quantity is 0, and you can omit Items.

**Items (list)** – A complex type that contains a Location element for each country in which you want CloudFront either to distribute your content (whitelist) or not distribute your content (blacklist). The Location element is a two-letter, uppercase country code for a country that you want to include in your blacklist or whitelist. Include one Location element for each country. CloudFront and MaxMind both use ISO 3166 country codes. For the current list of countries and the corresponding codes, see ISO 3166-1-alpha-2 code on the International Organization for Standardization website. You can also refer to the country list in the CloudFront console, which includes both country names and codes.

**(string)** –
class CloudFront.Paginator.ListInvalidations

paginator = client.get_paginator('list_invalidations')

paginate(**kwargs)

Creates an iterator that will paginate through responses from
CloudFront.Client.list_invalidations().

Request Syntax

response_iterator = paginator.paginate(
    DistributionId='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **DistributionId (string)** – [REQUIRED] The distribution’s id.
- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** –
    The total number of items to return. If the total number of items available
    is more than the value specified in max-items then a NextToken will be
    provided in the output that you can use to resume pagination.
  - **PageSize (integer)** –
    The size of each page.
  - **StartingToken (string)** –
    A token to specify where to start paginating. This is the NextToken
    from a previous response.

Return type  dict

Returns

Response Syntax

```json
{
    'InvalidationList': {
        'Marker': 'string',
        'NextMarker': 'string',
        'MaxItems': 123,
        'IsTruncated': True|False,
        'Quantity': 123,
        'Items': [
            {
                'Id': 'string',
                'CreateTime': datetime(2015, 1, 1),
                'Status': 'string'
            }
        ]
    }
}
```
Response Structure

- **dict** – The returned result of the corresponding request.
  - **InvalidationList** *(dict)* – Information about invalidation batches.
    - **Marker** *(string)* – The value you provided for the Marker request parameter.
    - **NextMarker** *(string)* – If IsTruncated is true, this element is present and contains the value you can use for the Marker request parameter to continue listing your invalidation batches where they left off.
    - **MaxItems** *(integer)* – The value you provided for the MaxItems request parameter.
    - **IsTruncated** *(boolean)* – A flag that indicates whether more invalidation batch requests remain to be listed. If your results were truncated, you can make a follow-up pagination request using the Marker request parameter to retrieve more invalidation batches in the list.
    - **Quantity** *(integer)* – The number of invalidation batches that were created by the current AWS account.
    - **Items** *(list)* – A complex type that contains one InvalidationSummary element for each invalidation batch that was created by the current AWS account.
      - *(dict)* – Summary of an invalidation request.
        - **Id** *(string)* – The unique ID for an invalidation request.
        - **CreateTime** *(datetime)* –
        - **Status** *(string)* – The status of an invalidation request.
  - **NextToken** *(string)* –
    A token to resume pagination.

```python
class CloudFront.Paginator.ListStreamingDistributions

paginator = client.get_paginator('list_streaming_distributions')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from CloudFront.Client.list_streaming_distributions().

Request Syntax

```python
response_iterator = paginator.paginate(
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided
in the output that you can use to resume pagination.

• **PageSize (integer)** –
  The size of each page.

• **StartingToken (string)** –
  A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type**  dict

**Returns**

**Response Syntax**

```
{
    'StreamingDistributionList': {
        'Marker': 'string',
        'NextMarker': 'string',
        'MaxItems': 123,
        'IsTruncated': True|False,
        'Quantity': 123,
        'Items': [
            {
                'Id': 'string',
                'Status': 'string',
                'LastModifiedTime': datetime(2015, 1, 1),
                'DomainName': 'string',
                'S3Origin': {
                    'DomainName': 'string',
                    'OriginAccessIdentity': 'string'
                },
                'Aliases': {
                    'Quantity': 123,
                    'Items': [
                        'string',
                    ]
                },
                'TrustedSigners': {
                    'Enabled': True|False,
                    'Quantity': 123,
                    'Items': [
                        'string',
                    ]
                },
                'Comment': 'string',
                'PriceClass': 'PriceClass_100'|'PriceClass_200'|'PriceClass_All',
                'Enabled': True|False
            },
        ],
        'NextToken': 'string'
    }
}
```

**Response Structure**

• *(dict)* – The returned result of the corresponding request.
  - **StreamingDistributionList (dict)** – The StreamingDistributionList type.
    - **Marker (string)** – The value you provided for the Marker request parameter.
    - **NextMarker (string)** – If IsTruncated is true, this element is present and contains the value you can use for the Marker request parameter.
to continue listing your streaming distributions where they left off.

* **MaxItems** *(integer)* – The value you provided for the MaxItems request parameter.

* **IsTruncated** *(boolean)* – A flag that indicates whether more streaming distributions remain to be listed. If your results were truncated, you can make a follow-up pagination request using the Marker request parameter to retrieve more distributions in the list.

* **Quantity** *(integer)* – The number of streaming distributions that were created by the current AWS account.

* **Items** *(list)* – A complex type that contains one `StreamingDistributionSummary` element for each distribution that was created by the current AWS account.
  
  · **(dict)** – A summary of the information for an Amazon CloudFront streaming distribution.
  
  · **Id** *(string)* – The identifier for the distribution. For example: `EDFDVBD632BHDS5`.
  
  · **Status** *(string)* – Indicates the current status of the distribution. When the status is Deployed, the distribution’s information is fully propagated throughout the Amazon CloudFront system.
  
  · **LastModifiedTime** *(datetime)* – The date and time the distribution was last modified.
  
  · **DomainName** *(string)* – The domain name corresponding to the distribution. For example: `d604721fxaaqy9.cloudfront.net`.
  
  · **S3Origin** *(dict)* – A complex type that contains information about the Amazon S3 bucket from which you want CloudFront to get your media files for distribution.
  
  · **DomainName** *(string)* – The DNS name of the S3 origin.
  
  · **OriginAccessIdentity** *(string)* – Your S3 origin’s origin access identity.
  
  · **Aliases** *(dict)* – A complex type that contains information about CNAMEs (alternate domain names), if any, for this streaming distribution.
  
  · **Quantity** *(integer)* – The number of CNAMEs, if any, for this distribution.
  
  · **Items** *(list)* – Optional: A complex type that contains CNAME elements, if any, for this distribution. If Quantity is 0, you can omit Items.
  
  · **(string)** –

  · **TrustedSigners** *(dict)* – A complex type that specifies the AWS accounts, if any, that you want to allow to create signed URLs for private content. If you want to require signed URLs in requests for objects in the target origin that match the PathPattern for this cache behavior, specify true for Enabled, and specify the applicable values for Quantity and Items. For more information, go to Using a Signed URL to Serve Private Content in the Amazon CloudFront Developer Guide. If you don’t want to require signed URLs in requests for objects that match PathPattern, specify false for Enabled and 0 for Quantity. Omit Items. To add, change, or remove one or more trusted signers, change Enabled to true (if it’s currently false), change Quantity as applicable, and specify all of the trusted signers that you want to include in the updated distribution.
• **Enabled** *(boolean)* – Specifies whether you want to require end users to use signed URLs to access the files specified by PathPattern and TargetOriginId.
• **Quantity** *(integer)* – The number of trusted signers for this cache behavior.
• **Items** *(list)* – Optional: A complex type that contains trusted signers for this cache behavior. If Quantity is 0, you can omit Items.
  • *(string)* –
  • **Comment** *(string)* – The comment originally specified when this distribution was created.
• **PriceClass** *(string)* –
• **Enabled** *(boolean)* – Whether the distribution is enabled to accept end user requests for content.
  • **NextToken** *(string)* – A token to resume pagination.

**Waiters**

The available waiters are:

- `CloudFront.Waiter.DistributionDeployed`
- `CloudFront.Waiter.InvalidationCompleted`
- `CloudFront.Waiter.StreamingDistributionDeployed`

```python
class CloudFront.Waiter.DistributionDeployed

waiter = client.get_waiter('distribution_deployed')

wait(**kwargs)
    Polls `CloudFront.Client.get_distribution()` every 60 seconds until a successful state is reached. An error is returned after 25 failed checks.

    Parameters
    `Id` *(string)* – [REQUIRED] The distribution’s id.

    Returns
    None

class CloudFront.Waiter.InvalidationCompleted

waiter = client.get_waiter('invalidation_completed')

wait(**kwargs)
    Polls `CloudFront.Client.get_invalidation()` every 20 seconds until a successful state is reached. An error is returned after 60 failed checks.

    Parameters
    `Id` *(string)* – [REQUIRED] The distribution’s id.

    Returns
    None
```
```python
waiter.wait(
    DistributionId='string',
    Id='string'
)
```

**Parameters**

- DistributionId *(string)* – [REQUIRED] The distribution’s id.
- Id *(string)* – [REQUIRED] The invalidation’s id.

**Returns**

None

class CloudFront.Waiter.StreamingDistributionDeployed

```python
waiter = client.get_waiter('streaming_distribution_deployed')
wait(**kwargs)
```

Polls `CloudFront.Client.get_streaming_distribution()` every 60 seconds until a successful state is reached. An error is returned after 25 failed checks.

**Request Syntax**

```python
waiter.wait(
    Id='string'
)
```

**Parameters**

- Id *(string)* – [REQUIRED] The streaming distribution’s id.

**Returns**

None

### CloudHSM

**Table of Contents**

- CloudHSM
  - Client

**Client**

class CloudHSM.Client

A low-level client representing Amazon CloudHSM:

```python
import boto3

client = boto3.client('cloudhsm')
```

These are the available methods:

- `can_paginate()`
- `create_hapg()`
- `create_hsm()`
- `create_luna_client()`
- `delete_hapg()`
- `delete_hsm()`
- `delete_luna_client()`
can_paginate(operation_name)
Check if an operation can be paginated.

Parameters operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginators("create_foo").

Returns True if the operation can be paginated, False otherwise.

create_hapg(**kwargs)
Creates a high-availability partition group. A high-availability partition group is a group of partitions that spans multiple physical HSMs.

Request Syntax

response = client.create_hapg(
    Label='string'
)

Parameters Label (string) – [REQUIRED]

The label of the new high-availability partition group.

Return type dict

Returns

Response Syntax

{
    'HapgArn': 'string'
}

Response Structure

• (dict) –

Contains the output of the CreateHAPartitionGroup action.

– HapgArn (string) –

The ARN of the high-availability partition group.

create_hsm(**kwargs)
Creates an uninitialized HSM instance. Running this command provisions an HSM appliance and will result in charges to your AWS account for the HSM.

Request Syntax
```python
response = client.create_hsm(
    SubnetId='string',
    SshKey='string',
    EniIp='string',
    IamRoleArn='string',
    ExternalId='string',
    SubscriptionType='PRODUCTION',
    ClientToken='string',
    SyslogIp='string'
)
```

**Parameters**

- **SubnetId** *(string)* – **[REQUIRED]**
  The identifier of the subnet in your VPC in which to place the HSM.

- **SshKey** *(string)* – **[REQUIRED]**
  The SSH public key to install on the HSM.

- **EniIp** *(string)* – The IP address to assign to the HSM’s ENI.

- **IamRoleArn** *(string)* – **[REQUIRED]**
  The ARN of an IAM role to enable the AWS CloudHSM service to allocate an ENI on your behalf.

- **ExternalId** *(string)* – The external ID from `IamRoleArn`, if present.

- **SubscriptionType** *(string)* – **[REQUIRED]**
  The subscription type.

- **ClientToken** *(string)* – A user-defined token to ensure idempotence. Subsequent calls to this action with the same token will be ignored.

- **SyslogIp** *(string)* – The IP address for the syslog monitoring server.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'HsmArn': 'string'
}
```

**Response Structure**

- *(dict)* –
  Contains the output of the CreateHsm action.

  - **HsmArn** *(string)* –
    The ARN of the HSM.

**create_luna_client(**kwargs)**

Creates an HSM client.

**Request Syntax**

```python
response = client.create_luna_client(
    Label='string',
    Certificate='string'
)
```

**Parameters**

- **Label** *(string)* – The label for the client.
• **Certificate** (*string*) – [REQUIRED]
  The contents of a Base64-Encoded X.509 v3 certificate to be installed on the HSMs used by this client.

  **Return type** dict
  **Returns**

  **Response Syntax**

  ```
  {'ClientArn': 'string'}
  ```

  **Response Structure**

  • (*dict*) –
    Contains the output of the CreateLunaClient action.
    – **ClientArn** (*string*) –
      The ARN of the client.

  **delete_hapg** (**kwargs**)
  Deletes a high-availability partition group.

  **Request Syntax**

  ```
  response = client.delete_hapg(
      HapgArn='string'
  )
  ```

  **Parameters**
  **HapgArn** (*string*) – [REQUIRED]
  The ARN of the high-availability partition group to delete.

  **Return type** dict
  **Returns**

  **Response Syntax**

  ```
  {'Status': 'string'}
  ```

  **Response Structure**

  • (*dict*) –
    Contains the output of the DeleteHapg action.
    – **Status** (*string*) –
      The status of the action.

  **delete_hsm** (**kwargs**)
  Deletes an HSM. Once complete, this operation cannot be undone and your key material cannot be recovered.

  **Request Syntax**

  ```
  response = client.delete_hsm(
      HsmArn='string'
  )
  ```
Parameters  **HsmArn** *(string)* – [REQUIRED]  
The ARN of the HSM to delete.

Return type  **dict**

Returns

Response Syntax

```
{
   'Status': 'string'
}
```

Response Structure

- *(dict)* –
  
  Contains the output of the DeleteHsm action.
  
  - **Status** *(string)* –
    
    The status of the action.

**delete_luna_client(**kwargs**)**

Deletes a client.

Request Syntax

```
response = client.delete_luna_client(
    ClientArn='string'
)
```

Parameters  **ClientArn** *(string)* – [REQUIRED]  
The ARN of the client to delete.

Return type  **dict**

Returns

Response Syntax

```
{
   'Status': 'string'
}
```

Response Structure

- *(dict)* –
  
  - **Status** *(string)* –
    
    The status of the action.

**describe_hapg(**kwargs**)**

Retrieves information about a high-availability partition group.

Request Syntax

```
response = client.describe_hapg(
    HapgArn='string'
)
```

Parameters  **HapgArn** *(string)* – [REQUIRED]  
The ARN of the high-availability partition group to describe.

Return type  **dict**
Returns

Response Syntax

```python
{
    'HapgArn': 'string',
    'HapgSerial': 'string',
    'HsmsLastActionFailed': [
        'string',
    ],
    'HsmsPendingDeletion': [
        'string',
    ],
    'HsmsPendingRegistration': [
        'string',
    ],
    'Label': 'string',
    'LastModifiedTimestamp': 'string',
    'PartitionSerialList': [
        'string',
    ],
    'State': 'READY'|'UPDATING'|'DEGRADED'
}
```

Response Structure

* (dict) –

Contains the output of the DescribeHapg action.

- **HapgArn (string)** –
  The ARN of the high-availability partition group.

- **HapgSerial (string)** –
  The serial number of the high-availability partition group.

- **HsmsLastActionFailed (list)** –
  Contains a list of ARNs that identify the HSMs.
  * (string) –
    An ARN that identifies an HSM.

- **HsmsPendingDeletion (list)** –
  Contains a list of ARNs that identify the HSMs.
  * (string) –
    An ARN that identifies an HSM.

- **HsmsPendingRegistration (list)** –
  Contains a list of ARNs that identify the HSMs.
  * (string) –
    An ARN that identifies an HSM.

- **Label (string)** –
  The label for the high-availability partition group.

- **LastModifiedTimestamp (string)** –
  The date and time the high-availability partition group was last modified.

- **PartitionSerialList (list)** –
  The list of partition serial numbers that belong to the high-availability partition group.
The state of the high-availability partition group.

describe_hsm(**kwargs)

Retrieves information about an HSM. You can identify the HSM by its ARN or its serial number.

Request Syntax

response = client.describe_hsm(
    HsmArn='string',
    HsmSerialNumber='string'
)

Parameters

- **HsmArn** *(string)* – The ARN of the HSM. Either the HsmArn or the SerialNumber parameter must be specified.
- **HsmSerialNumber** *(string)* – The serial number of the HSM. Either the HsmArn or the HsmSerialNumber parameter must be specified.

Return type  dict

Returns

Response Syntax

{
    'HsmArn': 'string',
    'Status': 'PENDING'|'RUNNING'|'UPDATING'|'SUSPENDED'|'TERMINATING'|'TERMINATED'|'DEGRADED',
    'StatusDetails': 'string',
    'AvailabilityZone': 'string',
    'EniId': 'string',
    'EniIp': 'string',
    'SubscriptionType': 'PRODUCTION',
    'SubscriptionStartDate': 'string',
    'SubscriptionEndDate': 'string',
    'VpcId': 'string',
    'SubnetId': 'string',
    'IamRoleArn': 'string',
    'SerialNumber': 'string',
    'VendorName': 'string',
    'HsmType': 'string',
    'SoftwareVersion': 'string',
    'SshPublicKey': 'string',
    'SshKeyLastUpdated': 'string',
    'ServerCertUri': 'string',
    'ServerCertLastUpdated': 'string',
    'Partitions': [  
                    'string',  
                ]
}

Response Structure

- *(dict)* –

  Contains the output of the DescribeHsm action.

    - **HsmArn** *(string)* –

      The ARN of the HSM.
– **Status** *(string)* –
  The status of the HSM.

– **StatusDetails** *(string)* –
  Contains additional information about the status of the HSM.

– **AvailabilityZone** *(string)* –
  The Availability Zone that the HSM is in.

– **EniId** *(string)* –
  The identifier of the elastic network interface (ENI) attached to the HSM.

– **EniIp** *(string)* –
  The IP address assigned to the HSM’s ENI.

– **SubscriptionType** *(string)* –
  The subscription type.

– **SubscriptionStartDate** *(string)* –
  The subscription start date.

– **SubscriptionEndDate** *(string)* –
  The subscription end date.

– **VpcId** *(string)* –
  The identifier of the VPC that the HSM is in.

– **SubnetId** *(string)* –
  The identifier of the subnet the HSM is in.

– **IamRoleArn** *(string)* –
  The ARN of the IAM role assigned to the HSM.

– **SerialNumber** *(string)* –
  The serial number of the HSM.

– **VendorName** *(string)* –
  The name of the HSM vendor.

– **HsmType** *(string)* –
  The HSM model type.

– **SoftwareVersion** *(string)* –
  The HSM software version.

– **SshPublicKey** *(string)* –
  The public SSH key.

– **SshKeyLastUpdated** *(string)* –
  The date and time the SSH key was last updated.

– **ServerCertUri** *(string)* –
  The URI of the certificate server.

– **ServerCertLastUpdated** *(string)* –
  The date and time the server certificate was last updated.

– **Partitions** *(list)* –
  The list of partitions on the HSM.

* (string) –

`describe_luna_client(**kwargs)`

Retrieves information about an HSM client.
Request Syntax

```python
response = client.describe_luna_client(
    ClientArn='string',
    CertificateFingerprint='string'
)
```

Parameters

- **ClientArn** *(string)* – The ARN of the client.
- **CertificateFingerprint** *(string)* – The certificate fingerprint.

Return type  `dict`

Returns

Response Syntax

```python
{
    'ClientArn': 'string',
    'Certificate': 'string',
    'CertificateFingerprint': 'string',
    'LastModifiedTimestamp': 'string',
    'Label': 'string'
}
```

Response Structure

- *(dict)* –
  - **ClientArn** *(string)* – The ARN of the client.
  - **Certificate** *(string)* – The certificate installed on the HSMs used by this client.
  - **CertificateFingerprint** *(string)* – The certificate fingerprint.
  - **LastModifiedTimestamp** *(string)* – The date and time the client was last modified.
  - **Label** *(string)* – The label of the client.

**generate_presigned_url** *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

Parameters

- **ClientMethod** *(string)* – The client method to presign for
- **Params** *(dict)* – The parameters normally passed to **ClientMethod**.
- **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns  The presigned url

**get_config** (**kwargs**)

Gets the configuration files necessary to connect to all high availability partition groups the client is associated with.

Request Syntax
response = client.get_config(
    ClientArn='string',
    ClientVersion='5.1'|'5.3',
    HapgList=[
        'string',
    ],
)

Parameters

- **ClientArn** (*string*) – [REQUIRED]
  
The ARN of the client.

- **ClientVersion** (*string*) – [REQUIRED]
  
The client version.

- **HapgList** (*list*) – [REQUIRED]
  
  A list of ARNs that identify the high-availability partition groups that are associated with the client.
  
  - *(string)* –

Return type  *dict*

Returns

Response Syntax

```
{
    'ConfigType': 'string',
    'ConfigFile': 'string',
    'ConfigCred': 'string'
}
```

Response Structure

- *(dict)* –
  
  - **ConfigType** (*string*) –
    
    The type of credentials.
  
  - **ConfigFile** (*string*) –
    
    The chrystoki.conf configuration file.
  
  - **ConfigCred** (*string*) –
    
    The certificate file containing the server.pem files of the HSMs.

get Paginator (operation_name)

Create a paginator for an operation.

Parameters

- **operation_name** (*string*) – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you'd normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get Paginator("create_foo")`.

Raises OperationNotPageableError

Raised if the operation is not pageable. You can use the `client.can Paginator` method to check if an operation is pageable.

Return type  *

Returns  *A paginator object.*

get Waiter (waiter_name)

list Available Zones()

Lists the Availability Zones that have available AWS CloudHSM capacity.
Request Syntax

```python
response = client.list_available_zones()
```

**Return type**  `dict`

**Returns**

**Response Syntax**

```python
{
    'AZList': [
        'string',
    ]
}
```

**Response Structure**

- `(dict)` –
  - `AZList` *(list)* –
    - The list of Availability Zones that have available AWS CloudHSM capacity.
    - *(string)* –

`list_hapgs(**kwargs)`

Lists the high-availability partition groups for the account.

This operation supports pagination with the use of the `NextToken` member. If more results are available, the `NextToken` member of the response contains a token that you pass in the next call to ListHapgs to retrieve the next set of items.

**Request Syntax**

```python
response = client.list_hapgs(
    NextToken='string'
)
```

**Parameters**

- `NextToken (string)` – The `NextToken` value from a previous call to ListHapgs. Pass null if this is the first call.

**Return type**  `dict`

**Returns**

**Response Syntax**

```python
{
    'HapgList': [
        'string',
    ],
    'NextToken': 'string'
}
```

**Response Structure**

- `(dict)` –
  - `HapgList` *(list)* –
    - The list of high-availability partition groups.
    - *(string)* –

3.1. Services 327
– **NextToken** (*string*) –

If not null, more results are available. Pass this value to ListHsms to retrieve the next set of items.

**list_hsms(**kwargs**)

Retrieves the identifiers of all of the HSMs provisioned for the current customer.

This operation supports pagination with the use of the **NextToken** member. If more results are available, the **NextToken** member of the response contains a token that you pass in the next call to ListHsms to retrieve the next set of items.

**Request Syntax**

```python
response = client.list_hsms(
    NextToken='string'
)
```

**Parameters**

- **NextToken** (*string*) – The **NextToken** value from a previous call to ListHsms.
  
  Pass null if this is the first call.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'HsmList': [
        'string',
    ],
    'NextToken': 'string'
}
```

**Response Structure**

- *(dict)* –

  Contains the output of the ListHsms action.

  - **HsmList** *(list)* –

    The list of ARNs that identify the HSMs.

    - *(string)* –

      An ARN that identifies an HSM.

  - **NextToken** *(string)* –

    If not null, more results are available. Pass this value to ListHsms to retrieve the next set of items.

**list_luna_clients(**kwargs**)

Lists all of the clients.

This operation supports pagination with the use of the **NextToken** member. If more results are available, the **NextToken** member of the response contains a token that you pass in the next call to ListLunaClients to retrieve the next set of items.

**Request Syntax**

```python
response = client.list_luna_clients(
    NextToken='string'
)
```
Parameters **NextToken** (*string*) – The *NextToken* value from a previous call to **ListLunaClients**. Pass null if this is the first call.

Return type **dict**

Returns

Response Syntax

```python
{
    'ClientList': [
        'string',
    ],
    'NextToken': 'string'
}
```

Response Structure

* (dict) –
  - **ClientList** (*list*) –
    The list of clients.
  * (string) –
  - **NextToken** (*string*) –
    If not null, more results are available. Pass this to **ListLunaClients** to retrieve the next set of items.

**modify_hapg**(**kwargs**)
Modifies an existing high-availability partition group.

Request Syntax

```python
response = client.modify_hapg(
    HapgArn='string',
    Label='string',
    PartitionSerialList=[
        'string',
    ]
)
```

Parameters

* **HapgArn** (*string*) – [REQUIRED]
  The ARN of the high-availability partition group to modify.
* **Label** (*string*) – The new label for the high-availability partition group.
* **PartitionSerialList** (*list*) – The list of partition serial numbers to make members of the high-availability partition group.
  * (string) –

Return type **dict**

Returns

Response Syntax

```python
{
    'HapgArn': 'string'
}
```

Response Structure

* (dict) –
modify_hsm(**kwargs)
Modifies an HSM.

Request Syntax

response = client.modify_hsm(
    HsmArn='string',
    SubnetId='string',
    EniIp='string',
    IamRoleArn='string',
    ExternalId='string',
    SyslogIp='string'
)

Parameters

- **HsmArn (string)** – [REQUIRED]
  The ARN of the HSM to modify.
- **SubnetId (string)** – The new identifier of the subnet that the HSM is in.
- **EniIp (string)** – The new IP address for the elastic network interface attached to the HSM.
- **IamRoleArn (string)** – The new IAM role ARN.
- **ExternalId (string)** – The new external ID.
- **SyslogIp (string)** – The new IP address for the syslog monitoring server.

Returns
dict

Response Syntax

```
{
    'HsmArn': 'string'
}
```

Response Structure

- *(dict)* –
  Contains the output of the ModifyHsm action.
- **HsmArn (string)** –
  The ARN of the HSM.

modify_luna_client(**kwargs)
Modifies the certificate used by the client.

This action can potentially start a workflow to install the new certificate on the client’s HSMs.

Request Syntax

response = client.modify_luna_client(
    ClientArn='string',
    Certificate='string'
)

Parameters

- **ClientArn (string)** – [REQUIRED]
  The ARN of the client.
• **Certificate** *(string)* – [REQUIRED]

    The new certificate for the client.

    **Return type**  dict
    **Returns**

    **Response Syntax**

    ```
    {
        'ClientArn': 'string'
    }
    ```

    **Response Structure**

    • *(dict)* –
      – **ClientArn** *(string)* –

        The ARN of the client.

**Table of Contents**

- CloudSearch
  - Client

---

**Client**

```python
class CloudSearch.Client
    A low-level client representing Amazon CloudSearch:

    import boto3

    client = boto3.client('cloudsearch')
```

**These are the available methods:**

- `build_suggesters()`
- `can_paginate()`
- `create_domain()`
- `define_analysis_scheme()`
- `define_expression()`
- `define_index_field()`
- `define_suggester()`
- `delete_analysis_scheme()`
- `delete_domain()`
- `delete_expression()`
- `delete_index_field()`
- `delete_suggester()`
- `describe_analysis_schemes()`
- `describe_availability_options()`
- `describe_domains()`
- `describe_expressions()`
- `describe_index_fields()`
- `describe_scaling_parameters()`

---

3.1. Services
build_suggesters(**kwargs)

Indexes the search suggestions. For more information, see Configuring Suggesters in the Amazon CloudSearch Developer Guide.

Request Syntax

```python
response = client.build_suggesters(
    DomainName='string'
)
```

Parameters

- **DomainName** (string) – [REQUIRED]

  A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

Return type

dict

Returns

Response Syntax

```json
{
    'FieldNames': [
        'string',
    ]
}
```

Response Structure

- (dict) –

  The result of a BuildSuggester request. Contains a list of the fields used for suggestions.

  - **FieldNames** (list) –

    A list of field names.

    - (string) –

      A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends with a wildcard. Any document fields that don’t map to a regular index field but do match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

      Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also...
be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name `score` is reserved and cannot be used as a field name.

To reference a document’s ID, you can use the name `_id`.

```python
can_paginate(operation_name)
```

Check if an operation can be paginated.

**Parameters**

- `operation_name` *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginated("create_foo")`.

**Returns**

- `True` if the operation can be paginated, `False` otherwise.

```python
create_domain(**kwargs)
```

Creates a new search domain. For more information, see Creating a Search Domain in the *Amazon CloudSearch Developer Guide*.

**Request Syntax**

```python
response = client.create_domain(
    DomainName='string'
)
```

**Parameters**

- `DomainName` *(string)* – [REQUIRED]

  A name for the domain you are creating. Allowed characters are a-z (lower-case letters), 0-9, and hyphen (-). Domain names must start with a letter or number and be at least 3 and no more than 28 characters long.

**Return type**

`dict`

**Returns**

**Response Syntax**

```python
{
    'DomainStatus': {
        'DomainId': 'string',
        'DomainName': 'string',
        'ARN': 'string',
        'Created': True|False,
        'Deleted': True|False,
        'DocService': {
            'Endpoint': 'string'
        },
        'SearchService': {
            'Endpoint': 'string'
        },
        'RequiresIndexDocuments': True|False,
        'Processing': True|False,
        'SearchInstanceType': 'string',
        'SearchPartitionCount': 123,
        'SearchInstanceCount': 123,
        'Limits': {
            'MaximumReplicationCount': 123,
            'MaximumPartitionCount': 123
        }
    }
}
```
Response Structure

- (dict) –
  The result of a CreateDomainRequest. Contains the status of a newly created domain.
  - **DomainStatus** (dict) –
    The current status of the search domain.
    * **DomainId** (string) –
      An internally generated unique identifier for a domain.
    * **DomainName** (string) –
      A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).
    * **ARN** (string) –
      The Amazon Resource Name (ARN) of the search domain. See Identifiers for IAM Entities in Using AWS Identity and Access Management for more information.
    * **Created** (boolean) –
      True if the search domain is created. It can take several minutes to initialize a domain when CreateDomain is called. Newly created search domains are returned from DescribeDomains with a false value for Created until domain creation is complete.
    * **Deleted** (boolean) –
      True if the search domain has been deleted. The system must clean up resources dedicated to the search domain when DeleteDomain is called. Newly deleted search domains are returned from DescribeDomains with a true value for IsDeleted for several minutes until resource cleanup is complete.
    * **DocService** (dict) –
      The service endpoint for updating documents in a search domain.
      - **Endpoint** (string) –
        The endpoint to which service requests can be submitted. For example,
    * **SearchService** (dict) –
      The service endpoint for requesting search results from a search domain.
      - **Endpoint** (string) –
        The endpoint to which service requests can be submitted. For example,
    * **RequiresIndexDocuments** (boolean) –
      True if IndexDocuments needs to be called to activate the current domain configuration.
* **Processing** *(boolean)* –
  True if processing is being done to activate the current domain configuration.

* **SearchInstanceType** *(string)* –
  The instance type that is being used to process search requests.

* **SearchPartitionCount** *(integer)* –
  The number of partitions across which the search index is spread.

* **SearchInstanceCount** *(integer)* –
  The number of search instances that are available to process search requests.

* **Limits** *(dict)* –
  - **MaximumReplicationCount** *(integer)* –
  - **MaximumPartitionCount** *(integer)* –

```
define_analysis_scheme(**kwargs)
```

Configures an analysis scheme that can be applied to a text or text-array field to define language-specific text processing options. For more information, see Configuring Analysis Schemes in the Amazon CloudSearch Developer Guide.

**Request Syntax**

```python
response = client.define_analysis_scheme(
    DomainName='string',
    AnalysisScheme={
        'AnalysisSchemeName': 'string',
        'AnalysisSchemeLanguage': 'ar'|'bg'|'ca'|'cs'|'da'|'de'|'el'|'en'|'es'|'eu'|'fa'|'fi'|'fr'|'ga'|'gl'|'he'|'hi'|'hu'|'hy'|'id'|'it'|'ja'|'ko'|'lv'|'mul'|'nl'|'no'|'pt'|'ro'|'ru'|'sv'|'th'|'tr'|'zh-Hans'|'zh-Hant',
        'AnalysisOptions': {
            'Synonyms': 'string',
            'Stopwords': 'string',
            'StemmingDictionary': 'string',
            'JapaneseTokenizationDictionary': 'string',
            'AlgorithmicStemming': 'none'|'minimal'|'light'|'full'
        }
    }
)
```

**Parameters**

- **DomainName** *(string)* – [REQUIRED]
  A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

- **AnalysisScheme** *(dict)* – [REQUIRED]
  Configuration information for an analysis scheme. Each analysis scheme has a unique name and specifies the language of the text to be processed. The following options can be configured for an analysis scheme: Synonyms, Stopwords, StemmingDictionary, JapaneseTokenizationDictionary and AlgorithmicStemming.
  - **AnalysisSchemeName** *(string)* – [REQUIRED]
    Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).
  - **AnalysisSchemeLanguage** *(string)* – [REQUIRED]
An IETF RFC 4646 language code or `mul` for multiple languages.

- **AnalysisOptions** *(dict)*

  Synonyms, stopwords, and stemming options for an analysis scheme. Includes tokenization dictionary for Japanese.

  - **Synonyms** *(string)*

    A JSON object that defines synonym groups and aliases. A synonym group is an array of arrays, where each sub-array is a group of terms where each term in the group is considered a synonym of every other term in the group. The aliases value is an object that contains a collection of string:value pairs where the string specifies a term and the array of values specifies each of the aliases for that term. An alias is considered a synonym of the specified term, but the term is not considered a synonym of the alias. For more information about specifying synonyms, see Synonyms in the Amazon CloudSearch Developer Guide.

  - **Stopwords** *(string)*

    A JSON array of terms to ignore during indexing and searching. For example, `["a", "an", "the", "of"]`. The stopwords dictionary must explicitly list each word you want to ignore. Wildcards and regular expressions are not supported.

  - **StemmingDictionary** *(string)*

    A JSON object that contains a collection of string:value pairs that each map a term to its stem. For example, `{"term1": "stem1", "term2": "stem2", "term3": "stem3"}`. The stemming dictionary is applied in addition to any algorithmic stemming. This enables you to override the results of the algorithmic stemming to correct specific cases of overstemming or understemming. The maximum size of a stemming dictionary is 500 KB.

  - **JapaneseTokenizationDictionary** *(string)*

    A JSON array that contains a collection of terms, tokens, readings and part of speech for Japanese Tokenization. The Japanese tokenization dictionary enables you to override the default tokenization for selected terms. This is only valid for Japanese language fields.

  - **AlgorithmicStemming** *(string)*

    The level of algorithmic stemming to perform: none, minimal, light, or full. The available levels vary depending on the language. For more information, see Language Specific Text Processing Settings in the Amazon CloudSearch Developer Guide.

Return type  dict

Returns

Response Syntax

```python
{
    'AnalysisScheme': {
        'Options': {
            'AnalysisSchemeName': 'string',
            'AnalysisSchemeLanguage': 'ar'|'bg'|'ca'|'cs'|'da'|'de'|'el'|'en'|'es'|'fa'|'fi'|'fr'|'ga'|'gl'|'he'|'hi'|'hu'|'hy'|'id'|'it'|'ja'|'ko'|'lv'|'mul'|'nl'|'no'|'pt'|'ro'|'ru'|'sv'|'th'|'tr'|'zh-Hans'|'zh-Hant',
            'AnalysisOptions': {
                'Synonyms': 'string',
                'Stopwords': 'string',
            ...
```
Response Structure

* (dict) –

The result of a `DefineAnalysisScheme` request. Contains the status of the newly-configured analysis scheme.

  - AnalysisScheme (dict) –

    The status and configuration of an AnalysisScheme.

      * Options (dict) –

        Configuration information for an analysis scheme. Each analysis scheme has a unique name and specifies the language of the text to be processed. The following options can be configured for an analysis scheme: Synonyms, Stopwords, StemmingDictionary, JapaneseTokenizationDictionary and AlgorithmicStemming.

          * AnalysisSchemeName (string) –

            Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).

          * AnalysisSchemeLanguage (string) –

            An IETF RFC 4646 language code or mul for multiple languages.

          * AnalysisOptions (dict) –

            Synonyms, stopwords, and stemming options for an analysis scheme. Includes tokenization dictionary for Japanese.

            * Synonyms (string) –

              A JSON object that defines synonym groups and aliases. A synonym group is an array of arrays, where each sub-array is a group of terms where each term in the group is considered a synonym of every other term in the group. The aliases value is an object that contains a collection of string: value pairs where the string specifies a term and the array of values specifies each of the aliases for that term. An alias is considered a synonym of the specified term, but the term is not considered a synonym of the alias. For more information about specifying synonyms, see Synonyms in the Amazon CloudSearch Developer Guide.

            * Stopwords (string) –
A JSON array of terms to ignore during indexing and searching. For example, ["a", "an", "the", "of"] . The stopwords dictionary must explicitly list each word you want to ignore. Wildcards and regular expressions are not supported.

- **StemmingDictionary** *(string)* –

  A JSON object that contains a collection of string:value pairs that each map a term to its stem. For example, "{"term1": "stem1", "term2": "stem2", "term3": "stem3"}" . The stemming dictionary is applied in addition to any algorithmic stemming. This enables you to override the results of the algorithmic stemming to correct specific cases of overstemming or understemming. The maximum size of a stemming dictionary is 500 KB.

- **JapaneseTokenizationDictionary** *(string)* –

  A JSON array that contains a collection of terms, tokens, readings and part of speech for Japanese Tokenization. The Japanese tokenization dictionary enables you to override the default tokenization for selected terms. This is only valid for Japanese language fields.

- **AlgorithmicStemming** *(string)* –

  The level of algorithmic stemming to perform: none, minimal, light, or full. The available levels vary depending on the language. For more information, see Language Specific Text Processing Settings in the Amazon CloudSearch Developer Guide

- **Status** *(dict)* –

  The status of domain configuration option.

  - **CreationDate** *(datetime)* –

    A timestamp for when this option was created.

  - **UpdateDate** *(datetime)* –

    A timestamp for when this option was last updated.

  - **UpdateVersion** *(integer)* –

    A unique integer that indicates when this option was last updated.

  - **State** *(string)* –

    The state of processing a change to an option. Possible values:

    - RequiresIndexDocuments: the option’s latest value will not be deployed until IndexDocuments has been called and indexing is complete.

    - Processing: the option’s latest value is in the process of being activated.

    - Active: the option’s latest value is completely deployed.

    - FailedToValidate: the option value is not compatible with the domain’s data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.

    - PendingDeletion *(boolean)* –

      Indicates that the option will be deleted once processing is
**define_expression(**kwargs)

Configures an "Expression" for the search domain. Used to create new expressions and modify existing ones. If the expression exists, the new configuration replaces the old one. For more information, see Configuring Expressions in the Amazon CloudSearch Developer Guide.

**Request Syntax**

```python
response = client.define_expression(
    DomainName='string',
    Expression={
        'ExpressionName': 'string',
        'ExpressionValue': 'string'
    }
)
```

**Parameters**

- **DomainName** *(string) – [REQUIRED]*
  A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

- **Expression** *(dict) – [REQUIRED]*
  A named expression that can be evaluated at search time. Can be used to sort the search results, define other expressions, or return computed information in the search results.
    - **ExpressionName** *(string) – [REQUIRED]*
      Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).
    - **ExpressionValue** *(string) – [REQUIRED]*
      The expression to evaluate for sorting while processing a search request. The Expression syntax is based on JavaScript expressions. For more information, see Configuring Expressions in the Amazon CloudSearch Developer Guide.

**Return type** dict

**Response Syntax**

```python
{
    'Expression': {
        'Options': {
            'ExpressionName': 'string',
            'ExpressionValue': 'string'
        },
        'Status': {
            'CreationDate': datetime(2015, 1, 1),
            'UpdateDate': datetime(2015, 1, 1),
            'UpdateVersion': 123,
            'State': 'RequiresIndexDocuments'|'Processing'|'Active'|'FailedToValidate',
            'PendingDeletion': True|False
        }
    }
}
```
Response Structure

- (dict) –
  The result of a DefineExpression request. Contains the status of the newly-configured expression.
  - **Expression** (dict) –
    The value of an Expression and its current status.
    - **Options** (dict) –
      The expression that is evaluated for sorting while processing a search request.
      - **ExpressionName** (string) –
        Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).
      - **ExpressionValue** (string) –
        The expression to evaluate for sorting while processing a search request. The Expression syntax is based on JavaScript expressions. For more information, see Configuring Expressions in the Amazon CloudSearch Developer Guide.
    - **Status** (dict) –
      The status of domain configuration option.
      - **CreationDate** (datetime) –
        A timestamp for when this option was created.
      - **UpdateDate** (datetime) –
        A timestamp for when this option was last updated.
      - **UpdateVersion** (integer) –
        A unique integer that indicates when this option was last updated.
      - **State** (string) –
        The state of processing a change to an option. Possible values:
        - RequiresIndexDocuments: the option’s latest value will not be deployed until IndexDocuments has been called and indexing is complete.
        - Processing: the option’s latest value is in the process of being activated.
        - Active: the option’s latest value is completely deployed.
        - FailedToValidate: the option value is not compatible with the domain’s data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.
      - **PendingDeletion** (boolean) –
        Indicates that the option will be deleted once processing is complete.

**define_index_field(****kwargs**)
Configures an “IndexField” for the search domain. Used to create new fields and modify existing ones. You must specify the name of the domain you are configuring and an index field configuration. The index field configuration specifies a unique name, the index field type, and the options you want to configure for the field. The options you can specify depend on the “IndexFieldType”. If the field exists, the new
configuration replaces the old one. For more information, see Configuring Index Fields in the Amazon CloudSearch Developer Guide.

Request Syntax

```python
response = client.define_index_field(
    DomainName='string',
    IndexField={
        'IndexFieldName': 'string',
        'IndexFieldType': 'int'|'double'|'literal'|'text'|'date'|'latlon'|'int-array'|'double-array'|'literal-array'|'text-array'|'date-array',
        'IntOptions': {
            'DefaultValue': 123,
            'SourceField': 'string',
            'FacetEnabled': True|False,
            'SearchEnabled': True|False,
            'ReturnEnabled': True|False,
            'SortEnabled': True|False
        },
        'DoubleOptions': {
            'DefaultValue': 123.0,
            'SourceField': 'string',
            'FacetEnabled': True|False,
            'SearchEnabled': True|False,
            'ReturnEnabled': True|False,
            'SortEnabled': True|False
        },
        'LiteralOptions': {
            'DefaultValue': 'string',
            'SourceField': 'string',
            'FacetEnabled': True|False,
            'SearchEnabled': True|False,
            'ReturnEnabled': True|False,
            'SortEnabled': True|False
        },
        'TextOptions': {
            'DefaultValue': 'string',
            'SourceField': 'string',
            'ReturnEnabled': True|False,
            'SortEnabled': True|False,
            'HighlightEnabled': True|False,
            'AnalysisScheme': 'string'
        },
        'DateOptions': {
            'DefaultValue': 'string',
            'SourceField': 'string',
            'ReturnEnabled': True|False,
            'SortEnabled': True|False
        },
        'LatLonOptions': {
            'DefaultValue': 'string',
            'SourceField': 'string',
            'FacetEnabled': True|False,
            'SearchEnabled': True|False,
            'ReturnEnabled': True|False,
            'SortEnabled': True|False
        },
        'IntArrayOptions': {
```

Parameters

- **DomainName** *(string)* – [REQUIRED]

  A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

- **IndexField** *(dict)* – [REQUIRED]

  The index field and field options you want to configure.

  - **IndexFieldName** *(string)* – [REQUIRED]

    A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends with a wildcard. Any document fields that don’t map to a regular index field but do match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

    Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards em-
bedded within a string are not supported.

The name `score` is reserved and cannot be used as a field name. To reference a document’s ID, you can use the name `_id`.

- **IndexFieldType** *(string)* – [REQUIRED]
  
The type of field. The valid options for a field depend on the field type. For more information about the supported field types, see Configuring Index Fields in the Amazon CloudSearch Developer Guide.

- **IntOptions** *(dict)* –
  
  Options for a 64-bit signed integer field. Present if `IndexFieldType` specifies the field is of type `int`. All options are enabled by default.
  
  * **DefaultValue** *(integer)* – A value to use for the field if the field isn’t specified for a document. This can be important if you are using the field in an expression and that field is not present in every document.
  
  * **SourceField** *(string)* –

    The name of the source field to map to the field.

  * **FacetEnabled** *(boolean)* –

    Whether facet information can be returned for the field.

  * **SearchEnabled** *(boolean)* –

    Whether the contents of the field are searchable.

  * **ReturnEnabled** *(boolean)* –

    Whether the contents of the field can be returned in the search results.

  * **SortEnabled** *(boolean)* –

    Whether the field can be used to sort the search results.

- **DoubleOptions** *(dict)* –
  
  Options for a double-precision 64-bit floating point field. Present if `IndexFieldType` specifies the field is of type `double`. All options are enabled by default.

  * **DefaultValue** *(float)* –

    A value to use for the field if the field isn’t specified for a document. This can be important if you are using the field in an expression and that field is not present in every document.

  * **SourceField** *(string)* –

    The name of the source field to map to the field.

  * **FacetEnabled** *(boolean)* –

    Whether facet information can be returned for the field.

  * **SearchEnabled** *(boolean)* –

    Whether the contents of the field are searchable.

  * **ReturnEnabled** *(boolean)* –

    Whether the contents of the field can be returned in the search results.

  * **SortEnabled** *(boolean)* –

    Whether the field can be used to sort the search results.

- **LiteralOptions** *(dict)* –
  
  Options for literal field. Present if `IndexFieldType` specifies the field is of type `literal`. All options are enabled by default.
* **DefaultValue** *(string)* — A value to use for the field if the field isn’t specified for a document.
* **SourceField** *(string)* –

A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends with a wildcard. Any document fields that don’t map to a regular index field but do match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name **score** is reserved and cannot be used as a field name. To reference a document’s ID, you can use the name **_id**.
* **FacetEnabled** *(boolean)* –

Whether facet information can be returned for the field.
* **SearchEnabled** *(boolean)* –

Whether the contents of the field are searchable.
* **ReturnEnabled** *(boolean)* –

Whether the contents of the field can be returned in the search results.
* **SortEnabled** *(boolean)* –

Whether the field can be used to sort the search results.

– **TextOptions** *(dict)* –

Options for text field. Present if **IndexFieldType** specifies the field is of type **text**. A text field is always searchable. All options are enabled by default.

* **DefaultValue** *(string)* — A value to use for the field if the field isn’t specified for a document.
* **SourceField** *(string)* –

A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends with a wildcard. Any document fields that don’t map to a regular index field but do match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name **score** is reserved and cannot be used as a field name. To reference a document’s ID, you can use the name **_id**.
* **ReturnEnabled** *(boolean)* –

Whether the contents of the field can be returned in the search results.
SortEnabled (boolean) –
Whether the field can be used to sort the search results.

HighlightEnabled (boolean) –
Whether highlights can be returned for the field.

AnalysisScheme (string) –
The name of an analysis scheme for a text field.

DateOptions (dict) –
Options for a date field. Dates and times are specified in UTC (Coordinated Universal Time) according to IETF RFC3339: yyyy-mm-ddT00:00:00Z. Present if IndexFieldType specifies the field is of type date. All options are enabled by default.

DefaultValue (string) – A value to use for the field if the field isn’t specified for a document.

SourceField (string) –
A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends with a wildcard. Any document fields that don’t map to a regular index field but do match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name score is reserved and cannot be used as a field name. To reference a document’s ID, you can use the name _id.

FacetEnabled (boolean) –
Whether facet information can be returned for the field.

SearchEnabled (boolean) –
Whether the contents of the field are searchable.

ReturnEnabled (boolean) –
Whether the contents of the field can be returned in the search results.

SortEnabled (boolean) –
Whether the field can be used to sort the search results.

LatLonOptions (dict) –
Options for a latlon field. A latlon field contains a location stored as a latitude and longitude value pair. Present if IndexFieldType specifies the field is of type latlon. All options are enabled by default.

DefaultValue (string) – A value to use for the field if the field isn’t specified for a document.

SourceField (string) –
A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends with a wildcard. Any document fields that don’t map to a regular index field but do
match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name `score` is reserved and cannot be used as a field name. To reference a document’s ID, you can use the name `_id`.

- **FacetEnabled (boolean)** – Whether facet information can be returned for the field.
- **SearchEnabled (boolean)** – Whether the contents of the field are searchable.
- **ReturnEnabled (boolean)** – Whether the contents of the field can be returned in the search results.
- **SortEnabled (boolean)** – Whether the field can be used to sort the search results.

- **IntArrayOptions (dict)** – Options for a field that contains an array of 64-bit signed integers. Present if `IndexFieldType` specifies the field is of type `int-array`. All options are enabled by default.
  - **DefaultValue (integer)** – A value to use for the field if the field isn’t specified for a document.
  - **SourceFields (string)** – A list of source fields to map to the field.
  - **FacetEnabled (boolean)** – Whether facet information can be returned for the field.
  - **SearchEnabled (boolean)** – Whether the contents of the field are searchable.
  - **ReturnEnabled (boolean)** – Whether the contents of the field can be returned in the search results.

- **DoubleArrayOptions (dict)** – Options for a field that contains an array of double-precision 64-bit floating point values. Present if `IndexFieldType` specifies the field is of type `double-array`. All options are enabled by default.
  - **DefaultValue (float)** – A value to use for the field if the field isn’t specified for a document.
  - **SourceFields (string)** – A list of source fields to map to the field.
  - **FacetEnabled (boolean)** – Whether facet information can be returned for the field.
  - **SearchEnabled (boolean)** – Whether the contents of the field are searchable.
* **ReturnEnabled** *(boolean)* –
  Whether the contents of the field can be returned in the search results.

- **LiteralArrayOptions** *(dict)* –
  Options for a field that contains an array of literal strings. Present if `IndexFieldType` specifies the field is of type `literal-array`. All options are enabled by default.
  * **DefaultValue** *(string)* – A value to use for the field if the field isn’t specified for a document.
  * **SourceFields** *(string)* –
    A list of source fields to map to the field.
  * **FacetEnabled** *(boolean)* –
    Whether facet information can be returned for the field.
  * **SearchEnabled** *(boolean)* –
    Whether the contents of the field are searchable.
  * **ReturnEnabled** *(boolean)* –
    Whether the contents of the field can be returned in the search results.

- **TextArrayOptions** *(dict)* –
  Options for a field that contains an array of text strings. Present if `IndexFieldType` specifies the field is of type `text-array`. A `text-array` field is always searchable. All options are enabled by default.
  * **DefaultValue** *(string)* – A value to use for the field if the field isn’t specified for a document.
  * **SourceFields** *(string)* –
    A list of source fields to map to the field.
  * **ReturnEnabled** *(boolean)* –
    Whether the contents of the field can be returned in the search results.
  * **HighlightEnabled** *(boolean)* –
    Whether highlights can be returned for the field.
  * **AnalysisScheme** *(string)* –
    The name of an analysis scheme for a `text-array` field.

- **DateArrayOptions** *(dict)* –
  Options for a field that contains an array of dates. Present if `IndexFieldType` specifies the field is of type `date-array`. All options are enabled by default.
  * **DefaultValue** *(string)* – A value to use for the field if the field isn’t specified for a document.
  * **SourceFields** *(string)* –
    A list of source fields to map to the field.
  * **FacetEnabled** *(boolean)* –
    Whether facet information can be returned for the field.
  * **SearchEnabled** *(boolean)* –
    Whether the contents of the field are searchable.
* **ReturnEnabled (boolean)** –

Whether the contents of the field can be returned in the search results.

**Return type**  dict

**Returns**

**Response Structure**

* (dict) –

The result of a ‘DefineIndexField’ request. Contains the status of the newly-configured index field.

- IndexField (dict) –

  The value of an IndexField and its current status.

  * Options (dict) –
Configuration information for a field in the index, including its name, type, and options. The supported options depend on the `IndexFieldType`.

- **IndexFieldName** *(string)* —
  
  A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends with a wildcard. Any document fields that don’t map to a regular index field but do match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

  Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

  The name `score` is reserved and cannot be used as a field name. To reference a document’s ID, you can use the name `_id`.

- **IndexFieldType** *(string)* —
  
  The type of field. The valid options for a field depend on the field type. For more information about the supported field types, see Configuring Index Fields in the Amazon CloudSearch Developer Guide.

- **IntOptions** *(dict)* —
  
  Options for a 64-bit signed integer field. Present if `IndexFieldType` specifies the field is of type `int`. All options are enabled by default.

- **DefaultValue** *(integer)* — A value to use for the field if the field isn’t specified for a document. This can be important if you are using the field in an expression and that field is not present in every document.

- **SourceField** *(string)* —
  
  The name of the source field to map to the field.

- **FacetEnabled** *(boolean)* —
  
  Whether facet information can be returned for the field.

- **SearchEnabled** *(boolean)* —
  
  Whether the contents of the field are searchable.

- **ReturnEnabled** *(boolean)* —
  
  Whether the contents of the field can be returned in the search results.

- **SortEnabled** *(boolean)* —
  
  Whether the field can be used to sort the search results.

- **DoubleOptions** *(dict)* —
  
  Options for a double-precision 64-bit floating point field. Present if `IndexFieldType` specifies the field is of type `double`. All options are enabled by default.

- **DefaultValue** *(float)* —
A value to use for the field if the field isn’t specified for a
document. This can be important if you are using the field in
an expression and that field is not present in every document.

- **SourceField** *(string)* –
  The name of the source field to map to the field.

- **FacetEnabled** *(boolean)* –
  Whether facet information can be returned for the field.

- **SearchEnabled** *(boolean)* –
  Whether the contents of the field are searchable.

- **ReturnEnabled** *(boolean)* –
  Whether the contents of the field can be returned in the search
  results.

- **SortEnabled** *(boolean)* –
  Whether the field can be used to sort the search results.

- **LiteralOptions** *(dict)* –
  Options for literal field. Present if IndexFieldType spec-
  ifies the field is of type literal. All options are enabled
  by default.

- **DefaultValue** *(string)* – A value to use for the field if the field
  isn’t specified for a document.

- **SourceField** *(string)* –
  A string that represents the name of an index field. Cloud-
  Search supports regular index fields as well as dynamic fields.
  A dynamic field’s name defines a pattern that begins or ends
  with a wildcard. Any document fields that don’t map to a
  regular index field but do match a dynamic field’s pattern are
  configured with the dynamic field’s indexing options.

  Regular field names begin with a letter and can contain the
  following characters: a-z (lowercase), 0-9, and _ (under-
  score). Dynamic field names must begin or end with a wild-
  card (*). The wildcard can also be the only character in a
  dynamic field name. Multiple wildcards, and wildcards em-
  bedded within a string are not supported.

  The name score is reserved and cannot be used as a field
  name. To reference a document’s ID, you can use the name
  _id.

- **FacetEnabled** *(boolean)* –
  Whether facet information can be returned for the field.

- **SearchEnabled** *(boolean)* –
  Whether the contents of the field are searchable.

- **ReturnEnabled** *(boolean)* –
  Whether the contents of the field can be returned in the search
  results.

- **SortEnabled** *(boolean)* –
  Whether the field can be used to sort the search results.

- **TextOptions** *(dict)* –
Options for text field. Present if `IndexFieldType` specifies the field is of type `text`. A `text` field is always searchable. All options are enabled by default.

- **DefaultValue (string)** – A value to use for the field if the field isn’t specified for a document.
- **SourceField (string)** – A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends with a wildcard. Any document fields that don’t map to a regular index field but do match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name `score` is reserved and cannot be used as a field name. To reference a document’s ID, you can use the name `_id`.

- **ReturnEnabled (boolean)** – Whether the contents of the field can be returned in the search results.
- **SortEnabled (boolean)** – Whether the field can be used to sort the search results.
- **HighlightEnabled (boolean)** – Whether highlights can be returned for the field.
- **AnalysisScheme (string)** – The name of an analysis scheme for a `text` field.
- **DateOptions (dict)** – Options for a date field. Dates and times are specified in UTC (Coordinated Universal Time) according to IETF RFC3339: `yyyy-mm-ddT00:00:00Z`. Present if `IndexFieldType` specifies the field is of type `date`. All options are enabled by default.

- **DefaultValue (string)** – A value to use for the field if the field isn’t specified for a document.
- **SourceField (string)** – A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends with a wildcard. Any document fields that don’t map to a regular index field but do match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a
dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name score is reserved and cannot be used as a field name. To reference a document’s ID, you can use the name _id.

- FacetEnabled (boolean) –
  Whether facet information can be returned for the field.

- SearchEnabled (boolean) –
  Whether the contents of the field are searchable.

- ReturnEnabled (boolean) –
  Whether the contents of the field can be returned in the search results.

- SortEnabled (boolean) –
  Whether the field can be used to sort the search results.

- LatLonOptions (dict) –
  Options for a latlon field. A latlon field contains a location stored as a latitude and longitude value pair. Present if IndexFieldType specifies the field is of type latlon. All options are enabled by default.

- DefaultValue (string) – A value to use for the field if the field isn’t specified for a document.

- SourceField (string) –
  A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends with a wildcard. Any document fields that don’t map to a regular index field but do match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name score is reserved and cannot be used as a field name. To reference a document’s ID, you can use the name _id.

- FacetEnabled (boolean) –
  Whether facet information can be returned for the field.

- SearchEnabled (boolean) –
  Whether the contents of the field are searchable.

- ReturnEnabled (boolean) –
  Whether the contents of the field can be returned in the search results.

- SortEnabled (boolean) –
  Whether the field can be used to sort the search results.

- IntArrayOptions (dict) –
Options for a field that contains an array of 64-bit signed integers. Present if `IndexFieldType` specifies the field is of type `int-array`. All options are enabled by default.

- **DefaultValue** *(integer)* – A value to use for the field if the field isn’t specified for a document.
- **SourceFields** *(string)* –
  A list of source fields to map to the field.
- **FacetEnabled** *(boolean)* –
  Whether facet information can be returned for the field.
- **SearchEnabled** *(boolean)* –
  Whether the contents of the field are searchable.
- **ReturnEnabled** *(boolean)* –
  Whether the contents of the field can be returned in the search results.

- **DoubleArrayOptions** *(dict)* –
  Options for a field that contains an array of double-precision 64-bit floating point values. Present if `IndexFieldType` specifies the field is of type `double-array`. All options are enabled by default.
- **DefaultValue** *(float)* – A value to use for the field if the field isn’t specified for a document.
- **SourceFields** *(string)* –
  A list of source fields to map to the field.
- **FacetEnabled** *(boolean)* –
  Whether facet information can be returned for the field.
- **SearchEnabled** *(boolean)* –
  Whether the contents of the field are searchable.
- **ReturnEnabled** *(boolean)* –
  Whether the contents of the field can be returned in the search results.

- **LiteralArrayOptions** *(dict)* –
  Options for a field that contains an array of literal strings. Present if `IndexFieldType` specifies the field is of type `literal-array`. All options are enabled by default.
- **DefaultValue** *(string)* – A value to use for the field if the field isn’t specified for a document.
- **SourceFields** *(string)* –
  A list of source fields to map to the field.
- **FacetEnabled** *(boolean)* –
  Whether facet information can be returned for the field.
- **SearchEnabled** *(boolean)* –
  Whether the contents of the field are searchable.
- **ReturnEnabled** *(boolean)* –
  Whether the contents of the field can be returned in the search results.

- **TextArrayOptions** *(dict)* –
Options for a field that contains an array of text strings. Present if `IndexFieldType` specifies the field is of type `text-array`. A `text-array` field is always searchable. All options are enabled by default.

- **DefaultValue (string)** – A value to use for the field if the field isn’t specified for a document.
- **SourceFields (string)** – A list of source fields to map to the field.
- **ReturnEnabled (boolean)** – Whether the contents of the field can be returned in the search results.
- **HighlightEnabled (boolean)** – Whether highlights can be returned for the field.
- **AnalysisScheme (string)** – The name of an analysis scheme for a `text-array` field.
- **DateArrayOptions (dict)** – Options for a field that contains an array of dates. Present if `IndexFieldType` specifies the field is of type `date-array`. All options are enabled by default.
- **DefaultValue (string)** – A value to use for the field if the field isn’t specified for a document.
- **SourceFields (string)** – A list of source fields to map to the field.
- **FacetEnabled (boolean)** – Whether facet information can be returned for the field.
- **SearchEnabled (boolean)** – Whether the contents of the field are searchable.
- **ReturnEnabled (boolean)** – Whether the contents of the field can be returned in the search results.

- **Status (dict)** – The status of domain configuration option.
  - **CreationDate (datetime)** – A timestamp for when this option was created.
  - **UpdateDate (datetime)** – A timestamp for when this option was last updated.
  - **UpdateVersion (integer)** – A unique integer that indicates when this option was last updated.
  - **State (string)** – The state of processing a change to an option. Possible values:
    - **RequiresIndexDocuments**: the option’s latest value will not be deployed until IndexDocuments has been called and indexing is complete.
    - **Processing**: the option’s latest value is in the process of being activated.
    - **Active**: the option’s latest value is completely deployed.
define_suggester(**kwargs)

Configures a suggester for a domain. A suggester enables you to display possible matches before users finish typing their queries. When you configure a suggester, you must specify the name of the text field you want to search for possible matches and a unique name for the suggester. For more information, see Getting Search Suggestions in the Amazon CloudSearch Developer Guide.

Request Syntax

```python
response = client.define_suggester(
    DomainName='string',
    Suggester={
        'SuggesterName': 'string',
        'DocumentSuggesterOptions': {
            'SourceField': 'string',
            'FuzzyMatching': 'none'|'low'|'high',
            'SortExpression': 'string'
        }
    }
)
```

Parameters

- **DomainName (string)** – [REQUIRED]
  
  A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

- **Suggester (dict)** – [REQUIRED]
  
  Configuration information for a search suggester. Each suggester has a unique name and specifies the text field you want to use for suggestions. The following options can be configured for a suggester: FuzzyMatching, SortExpression.
  
  - **SuggesterName (string)** – [REQUIRED]
    
    Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).
  
  - **DocumentSuggesterOptions (dict)** – [REQUIRED]
    
    Options for a search suggester.
    
    - **SourceField (string)** – [REQUIRED]
      
      The name of the index field you want to use for suggestions.
    
    - **FuzzyMatching (string)** –
      
      The level of fuzziness allowed when suggesting matches for a string: none, low, or high. With none, the specified string is treated as an exact prefix. With low, suggestions must differ from the specified string by no more than one character. With high, suggestions can differ by up to two characters. The default is none.
SortExpression (string) –
An expression that computes a score for each suggestion to control how they are sorted. The scores are rounded to the nearest integer, with a floor of 0 and a ceiling of 2^31-1. A document’s relevance score is not computed for suggestions, so sort expressions cannot reference the _score value. To sort suggestions using a numeric field or existing expression, simply specify the name of the field or expression. If no expression is configured for the suggester, the suggestions are sorted with the closest matches listed first.

Return type  dict
Returns

Response Syntax

```json
{
    'Suggester': {
        'Options': {
            'SuggesterName': 'string',
            'DocumentSuggesterOptions': {
                'SourceField': 'string',
                'FuzzyMatching': 'none'|'low'|'high',
                'SortExpression': 'string'
            }
        },
    'Status': {
        'CreationDate': datetime(2015, 1, 1),
        'UpdateDate': datetime(2015, 1, 1),
        'UpdateVersion': 123,
        'State': 'RequiresIndexDocuments'|'Processing'|'Active'|'FailedToValidate',
        'PendingDeletion': True|False
    }
}
```

Response Structure

• (dict) –

The result of a DefineSuggester request. Contains the status of the newly-configured suggester.

– Suggester (dict) –

The value of a Suggester and its current status.

• Options (dict) –

Configuration information for a search suggester. Each suggester has a unique name and specifies the text field you want to use for suggestions. The following options can be configured for a suggester: FuzzyMatching, SortExpression.

  • SuggesterName (string) –

Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).

  • DocumentSuggesterOptions (dict) –

Options for a search suggester.

  • SourceField (string) –

The name of the index field you want to use for suggestions.
· **FuzzyMatching** *(string)* –

   The level of fuzziness allowed when suggesting matches for a string: *none*, *low*, or *high*. With *none*, the specified string is treated as an exact prefix. With *low*, suggestions must differ from the specified string by no more than one character. With *high*, suggestions can differ by up to two characters. The default is *none*.

· **SortExpression** *(string)* –

   An expression that computes a score for each suggestion to control how they are sorted. The scores are rounded to the nearest integer, with a floor of 0 and a ceiling of $2^{31}$-1. A document’s relevance score is not computed for suggestions, so sort expressions cannot reference the `_score` value. To sort suggestions using a numeric field or existing expression, simply specify the name of the field or expression. If no expression is configured for the suggester, the suggestions are sorted with the closest matches listed first.

* **Status** *(dict)* –

   The status of domain configuration option.

   · **CreationDate** *(datetime)* –

     A timestamp for when this option was created.

   · **UpdateDate** *(datetime)* –

     A timestamp for when this option was last updated.

   · **UpdateVersion** *(integer)* –

     A unique integer that indicates when this option was last updated.

   · **State** *(string)* –

     The state of processing a change to an option. Possible values:

     · **RequiresIndexDocuments**: the option’s latest value will not be deployed until IndexDocuments has been called and indexing is complete.
     · **Processing**: the option’s latest value is in the process of being activated.
     · **Active**: the option’s latest value is completely deployed.
     · **FailedToValidate**: the option value is not compatible with the domain’s data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.

   · **PendingDeletion** *(boolean)* –

     Indicates that the option will be deleted once processing is complete.

delete_analysis_scheme(**kwargs)**

   Deletes an analysis scheme. For more information, see Configuring Analysis Schemes in the Amazon CloudSearch Developer Guide.

   **Request Syntax**

   ```python
   response = client.delete_analysis_scheme(
     DomainName='string',
   )
   ```
Parameters

- **DomainName** *(string)* – [REQUIRED]
  A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

- **AnalysisSchemeName** *(string)* – [REQUIRED]
  The name of the analysis scheme you want to delete.

Return type  *dict*

Returns

Response Syntax

```json
{
    'AnalysisScheme': {
        'Options': {
            'AnalysisSchemeName': 'string',
            'AnalysisSchemeLanguage': 'ar'|'bg'|'ca'|'cs'|'da'|'de'|'el'|'en'|'es'|'eu'|'fa'|'fi'|'fr'|'ga'|'gl'|'he'|'hi'|'hu'|'hy'|'id'|'it'|'ja'|'ko'|'lv'|'mul'|'nl'|'no'|'pt'|'ro'|'ru'|'sv'|'th'|'tr'|'zh-Hans'|'zh-Hant',
            'AnalysisOptions': {
                'Synonyms': 'string',
                'Stopwords': 'string',
                'StemmingDictionary': 'string',
                'JapaneseTokenizationDictionary': 'string',
                'AlgorithmicStemming': 'none'|'minimal'|'light'|'full'
            }
        },
        'Status': {
            'CreationDate': datetime(2015, 1, 1),
            'UpdateDate': datetime(2015, 1, 1),
            'UpdateVersion': 123,
            'State': 'RequiresIndexDocuments'|'Processing'|'Active'|'FailedToValidate',
            'PendingDeletion': True|False
        }
    }
}
```

Response Structure

- *(dict)* – The result of a **DeleteAnalysisScheme** request. Contains the status of the deleted analysis scheme.
  - **AnalysisScheme** *(dict)* – The status of the analysis scheme being deleted.
    - **Options** *(dict)* – Configuration information for an analysis scheme. Each analysis scheme has a unique name and specifies the language of the text to be processed. The following options can be configured for an analysis scheme: **Synonyms**, **Stopwords**, **StemmingDictionary**, **JapaneseTokenizationDictionary** and **AlgorithmicStemming**.
· **AnalysisSchemeName** *(string)* –
  Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).

· **AnalysisSchemeLanguage** *(string)* –
  An IETF RFC 4646 language code or mul for multiple languages.

· **AnalysisOptions** *(dict)* –
  Synonyms, stopwords, and stemming options for an analysis scheme. Includes tokenization dictionary for Japanese.

· **Synonyms** *(string)* –
  A JSON object that defines synonym groups and aliases. A synonym group is an array of arrays, where each sub-array is a group of terms where each term in the group is considered a synonym of every other term in the group. The aliases value is an object that contains a collection of string:value pairs where the string specifies a term and the array of values specifies each of the aliases for that term. An alias is considered a synonym of the specified term, but the term is not considered a synonym of the alias. For more information about specifying synonyms, see Synonyms in the Amazon CloudSearch Developer Guide.

· **Stopwords** *(string)* –
  A JSON array of terms to ignore during indexing and searching. For example, ["a", "an", "the", "of"] . The stopwords dictionary must explicitly list each word you want to ignore. Wildcards and regular expressions are not supported.

· **StemmingDictionary** *(string)* –
  A JSON object that contains a collection of string:value pairs that each map a term to its stem. For example, {"term1": "stem1", "term2": "stem2", "term3": "stem3"} . The stemming dictionary is applied in addition to any algorithmic stemming. This enables you to override the results of the algorithmic stemming to correct specific cases of overstemming or understemming. The maximum size of a stemming dictionary is 500 KB.

· **JapaneseTokenizationDictionary** *(string)* –
  A JSON array that contains a collection of terms, tokens, readings and part of speech for Japanese Tokenization. The Japanese tokenization dictionary enables you to override the default tokenization for selected terms. This is only valid for Japanese language fields.

· **AlgorithmicStemming** *(string)* –
  The level of algorithmic stemming to perform: none, minimal, light, or full. The available levels vary depending on the language. For more information, see Language Specific Text Processing Settings in the Amazon CloudSearch Developer Guide.

· **Status** *(dict)* –
The status of domain configuration option:

- **CreationDate** *(datetime)* –
  A timestamp for when this option was created.

- **UpdateDate** *(datetime)* –
  A timestamp for when this option was last updated.

- **UpdateVersion** *(integer)* –
  A unique integer that indicates when this option was last updated.

- **State** *(string)* –
  The state of processing a change to an option. Possible values:
  - **RequiresIndexDocuments**: the option’s latest value will not be deployed until IndexDocuments has been called and indexing is complete.
  - **Processing**: the option’s latest value is in the process of being activated.
  - **Active**: the option’s latest value is completely deployed.
  - **FailedToValidate**: the option value is not compatible with the domain’s data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.

- **PendingDeletion** *(boolean)* –
  Indicates that the option will be deleted once processing is complete.

```python
def delete_domain(**kwargs)
    # Permanently deletes a search domain and all of its data. Once a domain has been deleted, it cannot be
    # recovered. For more information, see Deleting a Search Domain in the Amazon CloudSearch Developer
    # Guide.

    request_syntax =
        response = client.delete_domain(
            DomainName='string'
        )

    parameters =
        Parameters DomainName *(string)* – [REQUIRED]

        The name of the domain you want to permanently delete.

    returns =
        Return type  dict
        Returns

    response_syntax =
        {  
            'DomainStatus': {  
                'DomainId': 'string',  
                'DomainName': 'string',  
                'ARN': 'string',  
                'Created': True|False,  
                'Deleted': True|False,  
                'DocService': {  
                    'Endpoint': 'string'  
                },  
                'SearchService': {  
                }  
        }  
```

3.1. Services
Response Structure

• (dict) –

The result of a `DeleteDomain` request. Contains the status of a newly deleted domain, or no status if the domain has already been completely deleted.

– DomainStatus (dict) –

The current status of the search domain.

* DomainId (string) –

An internally generated unique identifier for a domain.

* DomainName (string) –

A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

* ARN (string) –

The Amazon Resource Name (ARN) of the search domain. See Identifiers for IAM Entities in Using AWS Identity and Access Management for more information.

* Created (boolean) –

True if the search domain is created. It can take several minutes to initialize a domain when `CreateDomain` is called. Newly created search domains are returned from `DescribeDomains` with a false value for Created until domain creation is complete.

* Deleted (boolean) –

True if the search domain has been deleted. The system must clean up resources dedicated to the search domain when `DeleteDomain` is called. Newly deleted search domains are returned from `DescribeDomains` with a true value for `IsDeleted` for several minutes until resource cleanup is complete.

* DocService (dict) –

The service endpoint for updating documents in a search domain.

  · Endpoint (string) –

The endpoint to which service requests can be submitted. For example, `search-imdb-movies-oopcnjfn6ugofer3zx5iadxxca.eu-west-1.cloudsearch.amazonaws.com` or `doc-imdb-movies-oopcnjfn6ugofer3zx5iadxxca.eu-west-1.cloudsearch.amazonaws.com`.
* **SearchService (dict)** –

  The service endpoint for requesting search results from a search domain.

  - **Endpoint (string)** –
    
    The endpoint to which service requests can be submitted. For example,
    
    search-imdb-movies-oopcnjfn6ugofer3zx5iadxxca.eu-west-1.cloudsearch.amazonaws.com
    
    or
    
    doc-imdb-movies-oopcnjfn6ugofer3zx5iadxxca.eu-west-1.cloudsearch.amazonaws.com
    
* **RequiresIndexDocuments (boolean)** –

  True if IndexDocuments needs to be called to activate the current domain configuration.

* **Processing (boolean)** –

  True if processing is being done to activate the current domain configuration.

* **SearchInstanceType (string)** –

  The instance type that is being used to process search requests.

* **SearchPartitionCount (integer)** –

  The number of partitions across which the search index is spread.

* **SearchInstanceCount (integer)** –

  The number of search instances that are available to process search requests.

* **Limits (dict)** –

  - **MaximumReplicationCount (integer)** –
  
  - **MaximumPartitionCount (integer)** –

```
delete_expression(**kwargs)
```

Removes an “Expression” from the search domain. For more information, see Configuring Expressions in the Amazon CloudSearch Developer Guide.

**Request Syntax**

```python
response = client.delete_expression(
    DomainName='string',
    ExpressionName='string'
)
```

**Parameters**

- **DomainName (string)** – [REQUIRED]

  A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

- **ExpressionName (string)** – [REQUIRED]

  The name of the “Expression” to delete.

**Return type** dict

**Returns**

**Response Syntax**
Response Structure

- (dict) –

The result of a "DeleteExpression" request. Specifies the expression being deleted.

- **Expression** (dict) –

The status of the expression being deleted.

  * **Options** (dict) –

    The expression that is evaluated for sorting while processing a search request.

      - **ExpressionName** (string) –

        Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).

      - **ExpressionValue** (string) –

        The expression to evaluate for sorting while processing a search request. The Expression syntax is based on JavaScript expressions. For more information, see Configuring Expressions in the Amazon CloudSearch Developer Guide.

  * **Status** (dict) –

    The status of domain configuration option.

      - **CreationDate** (datetime) –

        A timestamp for when this option was created.

      - **UpdateDate** (datetime) –

        A timestamp for when this option was last updated.

      - **UpdateVersion** (integer) –

        A unique integer that indicates when this option was last updated.

      - **State** (string) –

        The state of processing a change to an option. Possible values:

        - RequiresIndexDocuments: the option’s latest value will not be deployed until IndexDocuments has been called and indexing is complete.
Processing: the option’s latest value is in the process of being activated.
Active: the option’s latest value is completely deployed.
FailedToValidate: the option value is not compatible with the domain’s data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.
PendingDeletion (boolean) – Indicates that the option will be deleted once processing is complete.

**delete_index_field(**kwargs)**
Removes an “IndexField” from the search domain. For more information, see Configuring Index Fields in the *Amazon CloudSearch Developer Guide*.

**Request Syntax**
```
response = client.delete_index_field(
    DomainName='string',
    IndexFieldName='string'
)
```

**Parameters**

- **DomainName (string)** – [REQUIRED]
  A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

- **IndexFieldName (string)** – [REQUIRED]
  The name of the index field your want to remove from the domain’s indexing options.

**Return type** dict
**Returns**

**Response Syntax**
```
{
    'IndexField': {
        'Options': {
            'IndexFieldName': 'string',
            'IndexFieldType': 'int'|'double'|'literal'|'text'|'date'|'latlon'|'int-array'|'double-array'|'literal-array'|'text-array'|'date-array',
            'IntOptions': {
                'DefaultValue': 123,
                'SourceField': 'string',
                'FacetEnabled': True|False,
                'SearchEnabled': True|False,
                'ReturnEnabled': True|False,
                'SortEnabled': True|False
            },
            'DoubleOptions': {
                'DefaultValue': 123.0,
                'SourceField': 'string',

  'pending_deletion': True|False
}
}
}

Response Structure

• (dict) – The result of a "DeleteIndexField" request.

  – IndexField (dict) – The status of the index field being deleted.

    • Options (dict) – Configuration information for a field in the index, including its
      name, type, and options. The supported options depend on the "IndexFieldType".

      • IndexFieldName (string) – A string that represents the name of an index field. Cloud-
        Search supports regular index fields as well as dynamic fields. A dynamic field’s
        name defines a pattern that begins or ends with a wildcard. Any document fields that
don’t map to a regular index field but do match a dynamic field’s pattern are
        configured with the dynamic field’s indexing options.

        Regular field names begin with a letter and can contain the
        following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field
        names must begin or end with a wildcard (*). The wildcard can also be the only
        character in a dynamic field name. Multiple wildcards, and wildcards
        embedded within a string are not supported.

        The name score is reserved and cannot be used as a field
        name. To reference a document’s ID, you can use the name
        _id.

      • IndexFieldType (string) – The type of field. The valid options for a field depend on the
        field type. For more information about the supported field
types, see Configuring Index Fields in the Amazon Cloud-
        Search Developer Guide.

      • IntOptions (dict) –
Options for a 64-bit signed integer field. Present if `IndexFieldType` specifies the field is of type `int`. All options are enabled by default.

- **DefaultValue (integer)** – A value to use for the field if the field isn’t specified for a document. This can be important if you are using the field in an expression and that field is not present in every document.
- **SourceField (string)** – The name of the source field to map to the field.
- **FacetEnabled (boolean)** – Whether facet information can be returned for the field.
- **SearchEnabled (boolean)** – Whether the contents of the field are searchable.
- **ReturnEnabled (boolean)** – Whether the contents of the field can be returned in the search results.
- **SortEnabled (boolean)** – Whether the field can be used to sort the search results.
- **DoubleOptions (dict)** – Options for a double-precision 64-bit floating point field. Present if `IndexFieldType` specifies the field is of type `double`. All options are enabled by default.
- **DefaultValue (float)** – A value to use for the field if the field isn’t specified for a document. This can be important if you are using the field in an expression and that field is not present in every document.
- **SourceField (string)** – The name of the source field to map to the field.
- **FacetEnabled (boolean)** – Whether facet information can be returned for the field.
- **SearchEnabled (boolean)** – Whether the contents of the field are searchable.
- **ReturnEnabled (boolean)** – Whether the contents of the field can be returned in the search results.
- **SortEnabled (boolean)** – Whether the field can be used to sort the search results.
- **LiteralOptions (dict)** – Options for literal field. Present if `IndexFieldType` specifies the field is of type `literal`. All options are enabled by default.
- **DefaultValue (string)** – A value to use for the field if the field isn’t specified for a document.
- **SourceField (string)** – A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends
with a wildcard. Any document fields that don’t map to a
regular index field but do match a dynamic field’s pattern are
configured with the dynamic field’s indexing options.

Regular field names begin with a letter and can contain the
following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wild-
card (*). The wildcard can also be the only character in a
dynamic field name. Multiple wildcards, and wildcards em-
bedded within a string are not supported.

The name score is reserved and cannot be used as a field
name. To reference a document’s ID, you can use the name
_id.

- **FacetEnabled (boolean)** –
  Whether facet information can be returned for the field.
- **SearchEnabled (boolean)** –
  Whether the contents of the field are searchable.
- **ReturnEnabled (boolean)** –
  Whether the contents of the field can be returned in the search
  results.
- **SortEnabled (boolean)** –
  Whether the field can be used to sort the search results.
- **TextOptions (dict)** –
  Options for text field. Present if IndexFieldType speci-
  fies the field is of type text. A text field is always search-
  able. All options are enabled by default.
- **DefaultValue (string)** – A value to use for the field if the field
  isn’t specified for a document.
- **SourceField (string)** –
  A string that represents the name of an index field. Cloud-
  Search supports regular index fields as well as dynamic fields.
  A dynamic field’s name defines a pattern that begins or ends
  with a wildcard. Any document fields that don’t map to a
  regular index field but do match a dynamic field’s pattern are
  configured with the dynamic field’s indexing options.

Regular field names begin with a letter and can contain the
following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wild-
card (*). The wildcard can also be the only character in a
dynamic field name. Multiple wildcards, and wildcards em-
bedded within a string are not supported.

The name score is reserved and cannot be used as a field
name. To reference a document’s ID, you can use the name
_id.

- **ReturnEnabled (boolean)** –
  Whether the contents of the field can be returned in the search
  results.
- **SortEnabled (boolean)** –
  Whether the field can be used to sort the search results.
- **HighlightEnabled** *(boolean)* –
  Whether highlights can be returned for the field.
- **AnalysisScheme** *(string)* –
  The name of an analysis scheme for a text field.
- **DateOptions** *(dict)* –
  Options for a date field. Dates and times are specified in UTC (Coordinated Universal Time) according to IETF RFC3339: yyyy-mm-ddT00:00:00Z. Present if `IndexFieldType` specifies the field is of type date. All options are enabled by default.
- **DefaultValue** *(string)* – A value to use for the field if the field isn’t specified for a document.
- **SourceField** *(string)* –
  A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends with a wildcard. Any document fields that don’t map to a regular index field but do match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

  Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

  The name `score` is reserved and cannot be used as a field name. To reference a document’s ID, you can use the name `_id`.
- **FacetEnabled** *(boolean)* –
  Whether facet information can be returned for the field.
- **SearchEnabled** *(boolean)* –
  Whether the contents of the field are searchable.
- **ReturnEnabled** *(boolean)* –
  Whether the contents of the field can be returned in the search results.
- **SortEnabled** *(boolean)* –
  Whether the field can be used to sort the search results.
- **LatLonOptions** *(dict)* –
  Options for a latlon field. A latlon field contains a location stored as a latitude and longitude value pair. Present if `IndexFieldType` specifies the field is of type latlon. All options are enabled by default.
- **DefaultValue** *(string)* – A value to use for the field if the field isn’t specified for a document.
- **SourceField** *(string)* –
  A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends
with a wildcard. Any document fields that don’t map to a regular index field but do match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name score is reserved and cannot be used as a field name. To reference a document’s ID, you can use the name _id.

- **FacetEnabled (boolean)** – Whether facet information can be returned for the field.
- **SearchEnabled (boolean)** – Whether the contents of the field are searchable.
- **ReturnEnabled (boolean)** – Whether the contents of the field can be returned in the search results.
- **SortEnabled (boolean)** – Whether the field can be used to sort the search results.
- **IntArrayOptions (dict)** – Options for a field that contains an array of 64-bit signed integers. Present if IndexFieldType specifies the field is of type int-array. All options are enabled by default.
- **DefaultValue (integer)** – A value to use for the field if the field isn’t specified for a document.
- **SourceFields (string)** – A list of source fields to map to the field.
- **FacetEnabled (boolean)** – Whether facet information can be returned for the field.
- **SearchEnabled (boolean)** – Whether the contents of the field are searchable.
- **ReturnEnabled (boolean)** – Whether the contents of the field can be returned in the search results.
- **DoubleArrayOptions (dict)** – Options for a field that contains an array of double-precision 64-bit floating point values. Present if IndexFieldType specifies the field is of type double-array. All options are enabled by default.
- **DefaultValue (float)** – A value to use for the field if the field isn’t specified for a document.
- **SourceFields (string)** – A list of source fields to map to the field.
- **FacetEnabled (boolean)** – Whether facet information can be returned for the field.
- **SearchEnabled** *(boolean)* –
  Whether the contents of the field are searchable.
- **ReturnEnabled** *(boolean)* –
  Whether the contents of the field can be returned in the search results.
- **LiteralArrayOptions** *(dict)* –
  Options for a field that contains an array of literal strings. Present if `IndexFieldType` specifies the field is of type `literal-array`. All options are enabled by default.
- **DefaultValue** *(string)* – A value to use for the field if the field isn’t specified for a document.
- **SourceFields** *(string)* –
  A list of source fields to map to the field.
- **FacetEnabled** *(boolean)* –
  Whether facet information can be returned for the field.
- **TextArrayOptions** *(dict)* –
  Options for a field that contains an array of text strings. Present if `IndexFieldType` specifies the field is of type `text-array`. A `text-array` field is always searchable. All options are enabled by default.
- **DefaultValue** *(string)* – A value to use for the field if the field isn’t specified for a document.
- **SourceFields** *(string)* –
  A list of source fields to map to the field.
- **ReturnEnabled** *(boolean)* –
  Whether the contents of the field can be returned in the search results.
- **HighlightEnabled** *(boolean)* –
  Whether highlights can be returned for the field.
- **AnalysisScheme** *(string)* –
  The name of an analysis scheme for a `text-array` field.
- **DateArrayOptions** *(dict)* –
  Options for a field that contains an array of dates. Present if `IndexFieldType` specifies the field is of type `date-array`. All options are enabled by default.
- **DefaultValue** *(string)* – A value to use for the field if the field isn’t specified for a document.
- **SourceFields** *(string)* –
  A list of source fields to map to the field.
- **FacetEnabled** *(boolean)* –
  Whether facet information can be returned for the field.
SearchEnabled (boolean) –
Whether the contents of the field are searchable.

ReturnEnabled (boolean) –
Whether the contents of the field can be returned in the search results.

* Status (dict) –
The status of domain configuration option.

  - CreationDate (datetime) –
    A timestamp for when this option was created.
  - UpdateDate (datetime) –
    A timestamp for when this option was last updated.
  - UpdateVersion (integer) –
    A unique integer that indicates when this option was last updated.
  - State (string) –
    The state of processing a change to an option. Possible values:
    - RequiresIndexDocuments: the option’s latest value will not be deployed until IndexDocuments has been called and indexing is complete.
    - Processing: the option’s latest value is in the process of being activated.
    - Active: the option’s latest value is completely deployed.
    - FailedToValidate: the option value is not compatible with the domain’s data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.

PendingDeletion (boolean) –
Indicates that the option will be deleted once processing is complete.

**delete_suggester(**kwargs**)

Deletes a suggester. For more information, see Getting Search Suggestions in the Amazon CloudSearch Developer Guide.

**Request Syntax**

```python
response = client.delete_suggester(
    DomainName='string',
    SuggesterName='string'
)
```

**Parameters**

- **DomainName (string)** – [REQUIRED]
  A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

- **SuggesterName (string)** – [REQUIRED]
  Specifies the name of the suggester you want to delete.
Returns

Response Syntax

```json
{
  'Suggester': {
    'Options': {
      'SuggesterName': 'string',
      'DocumentSuggesterOptions': {
        'SourceField': 'string',
        'FuzzyMatching': 'none'|'low'|'high',
        'SortExpression': 'string'
      }
    },
    'Status': {
      'CreationDate': datetime(2015, 1, 1),
      'UpdateDate': datetime(2015, 1, 1),
      'UpdateVersion': 123,
      'State': 'RequiresIndexDocuments'|'Processing'|'Active'|'FailedToValidate',
      'PendingDeletion': True|False
    }
  }
}
```

Response Structure

• *(dict)* – The result of a `DeleteSuggester` request. Contains the status of the deleted suggester.
  – **Suggester (dict)** – The status of the suggester being deleted.
    • **Options (dict)** – Configuration information for a search suggester. Each suggester has a unique name and specifies the text field you want to use for suggestions. The following options can be configured for a suggester: `FuzzyMatching`, `SortExpression`.
      • **SuggesterName (string)** – Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).
      • **DocumentSuggesterOptions (dict)** – Options for a search suggester.
        • **SourceField (string)** – The name of the index field you want to use for suggestions.
        • **FuzzyMatching (string)** – The level of fuzziness allowed when suggesting matches for a string: none, low, or high. With none, the specified string is treated as an exact prefix. With low, suggestions must differ from the specified string by no more than one character. With high, suggestions can differ by up to two characters. The default is none.
        • **SortExpression (string)** – An expression that computes a score for each suggestion to control how they are sorted. The scores are rounded to the
nearest integer, with a floor of 0 and a ceiling of $2^{31}-1$. A document’s relevance score is not computed for suggestions, so sort expressions cannot reference the `_score` value. To sort suggestions using a numeric field or existing expression, simply specify the name of the field or expression. If no expression is configured for the suggester, the suggestions are sorted with the closest matches listed first.

* Status (*dict*) –

The status of domain configuration option.

- **CreationDate** (*datetime*) –
  A timestamp for when this option was created.

- **UpdateDate** (*datetime*) –
  A timestamp for when this option was last updated.

- **UpdateVersion** (*integer*) –
  A unique integer that indicates when this option was last updated.

- **State** (*string*) –
  The state of processing a change to an option. Possible values:
  - **RequiresIndexDocuments**: the option’s latest value will not be deployed until `IndexDocuments` has been called and indexing is complete.
  - **Processing**: the option’s latest value is in the process of being activated.
  - **Active**: the option’s latest value is completely deployed.
  - **FailedToValidate**: the option value is not compatible with the domain’s data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.

- **PendingDeletion** (*boolean*) –
  Indicates that the option will be deleted once processing is complete.

**describe_analysis_schemes(**kwargs)**

Gets the analysis schemes configured for a domain. An analysis scheme defines language-specific text processing options for a `text` field. Can be limited to specific analysis schemes by name. By default, shows all analysis schemes and includes any pending changes to the configuration. Set the `Deployed` option to `true` to show the active configuration and exclude pending changes. For more information, see Configuring Analysis Schemes in the Amazon CloudSearch Developer Guide.

**Request Syntax**

```python
response = client.describe_analysis_schemes(
    DomainName='string',
    AnalysisSchemeNames=['string'],
    Deployed=True|False
)
```

**Parameters**

- **DomainName** (*string*) – [REQUIRED]
  The name of the domain you want to describe.
• **AnalysisSchemeNames** *(list)* – The analysis schemes you want to describe.
  - *(string)* –
    
    Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).

• **Deployed** *(boolean)* – Whether to display the deployed configuration *(true)* or include any pending changes *(false)*. Defaults to false.

Return type  *dict*

Returns

Response Syntax

```
{
    'AnalysisSchemes': [
        {
            'Options': {
                'AnalysisSchemeName': 'string',
                'AnalysisSchemeLanguage': 'ar'|'bg'|'ca'|'cs'|'da'|'de'|'el'|'en'|'es'|'eu'|'fa'|'fi'|'fr'|'ga'|'gl'|'he'|'hi'|'hu'|'hy'|'id'|'it'|'ja'|'ko'|'lv'|'mul'|'nl'|'no'|'pt'|'ro'|'ru'|'sv'|'th'|'tr'|'zh-Hans'|'zh-Hant',
                'AnalysisOptions': {
                    'Synonyms': 'string',
                    'Stopwords': 'string',
                    'StemmingDictionary': 'string',
                    'JapaneseTokenizationDictionary': 'string',
                    'AlgorithmicStemming': 'none'|'minimal'|'light'|'full'
                }
            },
            'Status': {
                'CreationDate': datetime(2015, 1, 1),
                'UpdateDate': datetime(2015, 1, 1),
                'UpdateVersion': 123,
                'State': 'RequiresIndexDocuments'|'Processing'|'Active'|'FailedToValidate',
                'PendingDeletion': True|False
            }
        },
    ],
}
```

Response Structure

• *(dict)* –
  
  The result of a DescribeAnalysisSchemes request. Contains the analysis schemes configured for the domain specified in the request.

  – **AnalysisSchemes** *(list)* –
  
    The analysis scheme descriptions.

  * *(dict)* –
    
    The status and configuration of an AnalysisScheme.

    • **Options** *(dict)* –
      
      Configuration information for an analysis scheme. Each analysis scheme has a unique name and specifies the language of the text to be processed. The following options can be configured for an analysis scheme: Synonyms, Stopwords, StemmingDictionary, JapaneseTokenizationDictionary and AlgorithmicStemming.

    • **AnalysisSchemeName** *(string)* –
Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).

- **AnalysisSchemeLanguage (string)** –
  
  An IETF RFC 4646 language code or mul for multiple languages.

- **AnalysisOptions (dict)** –
  
  Synonyms, stopwords, and stemming options for an analysis scheme. Includes tokenization dictionary for Japanese.

- **Synonyms (string)** –
  
  A JSON object that defines synonym groups and aliases. A synonym group is an array of arrays, where each sub-array is a group of terms where each term in the group is considered a synonym of every other term in the group. The aliases value is an object that contains a collection of string:value pairs where the string specifies a term and the array of values specifies each of the aliases for that term. An alias is considered a synonym of the specified term, but the term is not considered a synonym of the alias. For more information about specifying synonyms, see Synonyms in the Amazon CloudSearch Developer Guide.

- **Stopwords (string)** –
  
  A JSON array of terms to ignore during indexing and searching. For example, ["a", "an", "the", "of"]. The stopwords dictionary must explicitly list each word you want to ignore. Wildcards and regular expressions are not supported.

- **StemmingDictionary (string)** –
  
  A JSON object that contains a collection of string:value pairs that each map a term to its stem. For example, 
  
  ```json
  { "term1": "stem1", "term2": "stem2", "term3": "stem3" }
  ```
  
  The stemming dictionary is applied in addition to any algorithmic stemming. This enables you to override the results of the algorithmic stemming to correct specific cases of overstemming or understemming. The maximum size of a stemming dictionary is 500 KB.

- **JapaneseTokenizationDictionary (string)** –
  
  A JSON array that contains a collection of terms, tokens, readings and part of speech for Japanese Tokenization. The Japanese tokenization dictionary enables you to override the default tokenization for selected terms. This is only valid for Japanese language fields.

- **AlgorithmicStemming (string)** –
  
  The level of algorithmic stemming to perform: none, minimal, light, or full. The available levels vary depending on the language. For more information, see Language Specific Text Processing Settings in the Amazon CloudSearch Developer Guide.

- **Status (dict)** –
  
  The status of domain configuration option.

- **CreationDate (datetime)** –
A timestamp for when this option was created.
- **UpdateDate** *(datetime)* –
A timestamp for when this option was last updated.
- **UpdateVersion** *(integer)* –
A unique integer that indicates when this option was last updated.
- **State** *(string)* –
The state of processing a change to an option. Possible values:
- **RequiresIndexDocuments** : the option’s latest value will not be deployed until IndexDocuments has been called and indexing is complete.
- **Processing** : the option’s latest value is in the process of being activated.
- **Active** : the option’s latest value is completely deployed.
- **FailedToValidate** : the option value is not compatible with the domain’s data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.
- **PendingDeletion** *(boolean)* –
Indicates that the option will be deleted once processing is complete.

describe_availability_options(**kwargs)**

Gets the availability options configured for a domain. By default, shows the configuration with any pending changes. Set the **Deployed** option to **true** to show the active configuration and exclude pending changes. For more information, see Configuring Availability Options in the Amazon CloudSearch Developer Guide.

**Request Syntax**

```python
response = client.describe_availability_options(
    DomainName='string',
    Deployed=True|False
)
```

**Parameters**
- **DomainName** *(string)* – [REQUIRED]
  The name of the domain you want to describe.
- **Deployed** *(boolean)* – Whether to display the deployed configuration (**true**) or include any pending changes (**false**). Defaults to **false**.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'AvailabilityOptions': {
        'Options': True|False,
        'Status': {
            'CreationDate': datetime(2015, 1, 1),
            'UpdateDate': datetime(2015, 1, 1),
            'UpdateVersion': 123,
            'State': 'RequiresIndexDocuments'|'Processing'|'Active'|'FailedToValidate',
            'PendingDeletion': True|False
        }
    }
}
```
Response Structure

- (dict) –
  The result of a DescribeAvailabilityOptions request. Indicates whether or not the Multi-AZ option is enabled for the domain specified in the request.

- AvailabilityOptions (dict) –
  The availability options configured for the domain. Indicates whether Multi-AZ is enabled for the domain.

  - Options (boolean) –
    The availability options configured for the domain.
  
  - Status (dict) –
    The status of domain configuration option.

    - CreationDate (datetime) –
      A timestamp for when this option was created.
    
    - UpdateDate (datetime) –
      A timestamp for when this option was last updated.
    
    - UpdateVersion (integer) –
      A unique integer that indicates when this option was last updated.
    
    - State (string) –
      The state of processing a change to an option. Possible values:

      - RequiresIndexDocuments: the option’s latest value will not be deployed until IndexDocuments has been called and indexing is complete.
      
      - Processing: the option’s latest value is in the process of being activated.
      
      - Active: the option’s latest value is completely deployed.
      
      - FailedToValidate: the option value is not compatible with the domain’s data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.

    - PendingDeletion (boolean) –
      Indicates that the option will be deleted once processing is complete.

**describe_domains(**kwargs)**

Gets information about the search domains owned by this account. Can be limited to specific domains. Shows all domains by default. To get the number of searchable documents in a domain, use the console or submit a matchall request to your domain’s search endpoint:

```
q=matchallamp;q.parser=structuredamp;size=0
```

For more information, see Getting Information about a Search Domain in the Amazon CloudSearch Developer Guide.

Request Syntax

```python
response = client.describe_domains(
    DomainNames=[
```

3.1. Services
Parameters  **DomainNames**  *(list)* – The names of the domains you want to include in the response.

  * *(string)* –

  A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

**Return type**  **dict**

**Returns**

**Response Syntax**

```python
{
  'DomainStatusList': [
    {
      'DomainId': 'string',
      'DomainName': 'string',
      'ARN': 'string',
      'Created': True|False,
      'Deleted': True|False,
      'DocService': {
        'Endpoint': 'string'
      },
      'SearchService': {
        'Endpoint': 'string'
      },
      'RequiresIndexDocuments': True|False,
      'Processing': True|False,
      'SearchInstanceType': 'string',
      'SearchPartitionCount': 123,
      'SearchInstanceCount': 123,
      'Limits': {
        'MaximumReplicationCount': 123,
        'MaximumPartitionCount': 123
      }
    },
    ...
  ]
}
```

**Response Structure**

  * *(dict)* –

  The result of a `DescribeDomains` request. Contains the status of the domains specified in the request or all domains owned by the account.

  - **DomainStatusList** *(list)* –

    A list that contains the status of each requested domain.

    1. *(dict)* –

       The current status of the search domain.

      1. **DomainId** *(string)* –

         An internally generated unique identifier for a domain.

      1. **DomainName** *(string)* –
A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

- **ARN (string)** –

  The Amazon Resource Name (ARN) of the search domain. See Identifiers for IAM Entities in Using AWS Identity and Access Management for more information.

- **Created (boolean)** –

  True if the search domain is created. It can take several minutes to initialize a domain when CreateDomain is called. Newly created search domains are returned from DescribeDomains with a false value for Created until domain creation is complete.

- **Deleted (boolean)** –

  True if the search domain has been deleted. The system must clean up resources dedicated to the search domain when DeleteDomain is called. Newly deleted search domains are returned from DescribeDomains with a true value for IsDeleted for several minutes until resource cleanup is complete.

- **DocService (dict)** –

  The service endpoint for updating documents in a search domain.

- **Endpoint (string)** –

  The endpoint to which service requests can be submitted. For example, search-imdb-movies-oopcnjfn6ugofer3zx5iadxxca.eu-west-1.cloudsearch.amazonaws.com or doc-imdb-movies-oopcnjfn6ugofer3zx5iadxxca.eu-west-1.cloudsearch.amazonaws.com.

- **SearchService (dict)** –

  The service endpoint for requesting search results from a search domain.

- **Endpoint (string)** –

  The endpoint to which service requests can be submitted. For example, search-imdb-movies-oopcnjfn6ugofer3zx5iadxxca.eu-west-1.cloudsearch.amazonaws.com or doc-imdb-movies-oopcnjfn6ugofer3zx5iadxxca.eu-west-1.cloudsearch.amazonaws.com.

- **RequiresIndexDocuments (boolean)** –

  True if IndexDocuments needs to be called to activate the current domain configuration.

- **Processing (boolean)** –

  True if processing is being done to activate the current domain configuration.

- **SearchInstanceType (string)** –

  The instance type that is being used to process search requests.
• **SearchPartitionCount** *(integer)* –
  The number of partitions across which the search index is spread.

• **SearchInstanceCount** *(integer)* –
  The number of search instances that are available to process search requests.

• **Limits** *(dict)* –

  • **MaximumReplicationCount** *(integer)* –
  • **MaximumPartitionCount** *(integer)* –

**describe_expressions** (**kwargs**)

Gets the expressions configured for the search domain. Can be limited to specific expressions by name. By default, shows all expressions and includes any pending changes to the configuration. Set the `Deployed` option to `true` to show the active configuration and exclude pending changes. For more information, see Configuring Expressions in the Amazon CloudSearch Developer Guide.

**Request Syntax**

```python
response = client.describe_expressions(
    DomainName='string',
    ExpressionNames=[
        'string',
    ],
    Deployed=True|False
)
```

**Parameters**

• **DomainName** *(string)* – [REQUIRED]
  The name of the domain you want to describe.

• **ExpressionNames** *(list)* – Limits the ‘DescribeExpressions’ response to the specified expressions. If not specified, all expressions are shown.
  - *(string)* –
    Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).

• **Deployed** *(boolean)* – Whether to display the deployed configuration (`true`) or include any pending changes (`false`). Defaults to `false`.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'Expressions': [
        {
            'Options': {
                'ExpressionName': 'string',
                'ExpressionValue': 'string'
            },
            'Status': {
                'CreationDate': datetime(2015, 1, 1),
                'UpdateDate': datetime(2015, 1, 1),
                'UpdateVersion': 123,
                'State': 'RequiresIndexDocuments'|'Processing'|'Active'|'FailedToValidate',
                'PendingDeletion': True|False
            }
        }
    ]
}
```
Response Structure
- **(dict)** –
  The result of a `DescribeExpressions` request. Contains the expressions configured for the domain specified in the request.
  - **Expressions (list)** –
    The expressions configured for the domain.
    - **(dict)** –
      The value of an `Expression` and its current status.
      - **Options (dict)** –
        The expression that is evaluated for sorting while processing a search request.
      - **ExpressionName (string)** –
        Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).
      - **ExpressionValue (string)** –
        The expression to evaluate for sorting while processing a search request. The `Expression` syntax is based on JavaScript expressions. For more information, see Configuring Expressions in the `Amazon CloudSearch Developer Guide`.
      - **Status (dict)** –
        The status of domain configuration option.
      - **CreationDate (datetime)** –
        A timestamp for when this option was created.
      - **UpdateDate (datetime)** –
        A timestamp for when this option was last updated.
      - **UpdateVersion (integer)** –
        A unique integer that indicates when this option was last updated.
      - **State (string)** –
        The state of processing a change to an option. Possible values:
        - **RequiresIndexDocuments**: the option’s latest value will not be deployed until `IndexDocuments` has been called and indexing is complete.
        - **Processing**: the option’s latest value is in the process of being activated.
        - **Active**: the option’s latest value is completely deployed.
        - **FailedToValidate**: the option value is not compatible with the domain’s data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.
      - **PendingDeletion (boolean)** –
        Indicates that the option will be deleted once processing is complete.
**describe_index_fields**(**kwargs)

Gets information about the index fields configured for the search domain. Can be limited to specific fields by name. By default, shows all fields and includes any pending changes to the configuration. Set the Deployed option to true to show the active configuration and exclude pending changes. For more information, see Getting Domain Information in the Amazon CloudSearch Developer Guide.

**Request Syntax**

```python
response = client.describe_index_fields(
    DomainName='string',
    FieldNames=[
        'string',
    ],
    Deployed=True|False
)
```

**Parameters**

- **DomainName (string)** – [REQUIRED]
  
  The name of the domain you want to describe.

- **FieldNames (list)** – A list of the index fields you want to describe. If not specified, information is returned for all configured index fields.
  
  - (string)

- **Deployed (boolean)** – Whether to display the deployed configuration (true) or include any pending changes (false). Defaults to false.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'IndexFields': [
        {
            'Options': {
                'IndexFieldName': 'string',
                'IndexFieldType': 'int'|'double'|'literal'|'text'|'date'|'latlon',
                'IntOptions': {
                    'DefaultValue': 123,
                    'SourceField': 'string',
                    'FacetEnabled': True|False,
                    'SearchEnabled': True|False,
                    'ReturnEnabled': True|False,
                    'SortEnabled': True|False
                },
                'DoubleOptions': {
                    'DefaultValue': 123.0,
                    'SourceField': 'string',

}

**Response Structure**

- (dict) – The result of a DescribeIndexFields request. Contains the index fields configured for the domain specified in the request.

  - **IndexFields** (list) – The index fields configured for the domain.

    - (dict) – The value of an IndexField and its current status.

      - **Options** (dict) – Configuration information for a field in the index, including its name, type, and options. The supported options depend on the ‘IndexFieldType’.

      - **IndexFieldName** (string) – A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends with a wildcard. Any document fields that don’t map to a regular index field but do match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

        Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

        The name score is reserved and cannot be used as a field name. To reference a document’s ID, you can use the name _id.

      - **IndexFieldType** (string) – The type of field. The valid options for a field depend on the field type. For more information about the supported field types, see Configuring Index Fields in the Amazon CloudSearch Developer Guide.

      - **IntOptions** (dict) – Options for a 64-bit signed integer field. Present if
IndexFieldType specifies the field is of type int. All options are enabled by default.

- **DefaultValue** (integer) – A value to use for the field if the field isn’t specified for a document. This can be important if you are using the field in an expression and that field is not present in every document.
  - **SourceField** (string) –
    The name of the source field to map to the field.
- **FacetEnabled** (boolean) –
  Whether facet information can be returned for the field.
- **SearchEnabled** (boolean) –
  Whether the contents of the field are searchable.
- **ReturnEnabled** (boolean) –
  Whether the contents of the field can be returned in the search results.
- **SortEnabled** (boolean) –
  Whether the field can be used to sort the search results.
- **DoubleOptions** (dict) –
  Options for a double-precision 64-bit floating point field. Present if IndexFieldType specifies the field is of type double. All options are enabled by default.
  - **DefaultValue** (float) –
    A value to use for the field if the field isn’t specified for a document. This can be important if you are using the field in an expression and that field is not present in every document.
  - **SourceField** (string) –
    The name of the source field to map to the field.
- **FacetEnabled** (boolean) –
  Whether facet information can be returned for the field.
- **SearchEnabled** (boolean) –
  Whether the contents of the field are searchable.
- **ReturnEnabled** (boolean) –
  Whether the contents of the field can be returned in the search results.
- **SortEnabled** (boolean) –
  Whether the field can be used to sort the search results.
- **LiteralOptions** (dict) –
  Options for literal field. Present if IndexFieldType specifies the field is of type literal. All options are enabled by default.
  - **DefaultValue** (string) – A value to use for the field if the field isn’t specified for a document.
  - **SourceField** (string) –
    A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends with a wildcard. Any document fields that don’t map to a
regular index field but do match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name score is reserved and cannot be used as a field name. To reference a document’s ID, you can use the name _id.

- **FacetEnabled (boolean)** –
  Whether facet information can be returned for the field.

- **SearchEnabled (boolean)** –
  Whether the contents of the field are searchable.

- **ReturnEnabled (boolean)** –
  Whether the contents of the field can be returned in the search results.

- **SortEnabled (boolean)** –
  Whether the field can be used to sort the search results.

- **TextOptions (dict)** –
  Options for text field. Present if IndexFieldType specifies the field is of type text. A text field is always searchable. All options are enabled by default.

- **DefaultValue (string)** – A value to use for the field if the field isn’t specified for a document.

- **SourceField (string)** –
  A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends with a wildcard. Any document fields that don’t map to a regular index field but do match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name score is reserved and cannot be used as a field name. To reference a document’s ID, you can use the name _id.

- **ReturnEnabled (boolean)** –
  Whether the contents of the field can be returned in the search results.

- **SortEnabled (boolean)** –
  Whether the field can be used to sort the search results.
- **HighlightEnabled** *(boolean)* –
  Whether highlights can be returned for the field.
- **AnalysisScheme** *(string)* –
  The name of an analysis scheme for a text field.
- **DateOptions** *(dict)* –
  Options for a date field. Dates and times are specified in UTC (Coordinated Universal Time) according to IETF RFC3339: `yyyy-mm-ddT00:00:00Z`. Present if `IndexFieldType` specifies the field is of type `date`. All options are enabled by default.
- **DefaultValue** *(string)* – A value to use for the field if the field isn’t specified for a document.
- **SourceField** *(string)* –
  A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends with a wildcard. Any document fields that don’t map to a regular index field but do match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name `score` is reserved and cannot be used as a field name. To reference a document’s ID, you can use the name `_id`.
- **FacetEnabled** *(boolean)* –
  Whether facet information can be returned for the field.
- **SearchEnabled** *(boolean)* –
  Whether the contents of the field are searchable.
- **ReturnEnabled** *(boolean)* –
  Whether the contents of the field can be returned in the search results.
- **SortEnabled** *(boolean)* –
  Whether the field can be used to sort the search results.
- **LatLonOptions** *(dict)* –
  Options for a latlon field. A latlon field contains a location stored as a latitude and longitude value pair. Present if `IndexFieldType` specifies the field is of type `latlon`. All options are enabled by default.
- **DefaultValue** *(string)* – A value to use for the field if the field isn’t specified for a document.
- **SourceField** *(string)* –
  A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends...
with a wildcard. Any document fields that don’t map to a regular index field but do match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name score is reserved and cannot be used as a field name. To reference a document’s ID, you can use the name _id.

- **FacetEnabled** (boolean) – Whether facet information can be returned for the field.
- **SearchEnabled** (boolean) – Whether the contents of the field are searchable.
- **ReturnEnabled** (boolean) – Whether the contents of the field can be returned in the search results.
- **SortEnabled** (boolean) – Whether the field can be used to sort the search results.
- **IntArrayOptions** (dict) – Options for a field that contains an array of 64-bit signed integers. Present if **IndexFieldType** specifies the field is of type int-array. All options are enabled by default.
  - **DefaultValue** (integer) – A value to use for the field if the field isn’t specified for a document.
  - **SourceFields** (string) – A list of source fields to map to the field.
  - **FacetEnabled** (boolean) – Whether facet information can be returned for the field.
  - **SearchEnabled** (boolean) – Whether the contents of the field are searchable.
  - **ReturnEnabled** (boolean) – Whether the contents of the field can be returned in the search results.
  - **DoubleArrayOptions** (dict) – Options for a field that contains an array of double-precision 64-bit floating point values. Present if **IndexFieldType** specifies the field is of type double-array. All options are enabled by default.
    - **DefaultValue** (float) – A value to use for the field if the field isn’t specified for a document.
    - **SourceFields** (string) – A list of source fields to map to the field.
    - **FacetEnabled** (boolean) – Whether facet information can be returned for the field.
· **SearchEnabled** *(boolean)* –
  Whether the contents of the field are searchable.

· **ReturnEnabled** *(boolean)* –
  Whether the contents of the field can be returned in the search results.

· **LiteralArrayOptions** *(dict)* –
  Options for a field that contains an array of literal strings. Present if the `IndexFieldType` specifies the field is of type `literal-array`. All options are enabled by default.

· **DefaultValue** *(string)* – A value to use for the field if the field isn’t specified for a document.

· **SourceFields** *(string)* –
  A list of source fields to map to the field.

· **FacetEnabled** *(boolean)* –
  Whether facet information can be returned for the field.

· **SearchEnabled** *(boolean)* –
  Whether the contents of the field are searchable.

· **ReturnEnabled** *(boolean)* –
  Whether the contents of the field can be returned in the search results.

· **TextArrayOptions** *(dict)* –
  Options for a field that contains an array of text strings. Present if the `IndexFieldType` specifies the field is of type `text-array`. A `text-array` field is always searchable. All options are enabled by default.

· **DefaultValue** *(string)* – A value to use for the field if the field isn’t specified for a document.

· **SourceFields** *(string)* –
  A list of source fields to map to the field.

· **ReturnEnabled** *(boolean)* –
  Whether the contents of the field can be returned in the search results.

· **HighlightEnabled** *(boolean)* –
  Whether highlights can be returned for the field.

· **AnalysisScheme** *(string)* –
  The name of an analysis scheme for a `text-array` field.

· **DateArrayOptions** *(dict)* –
  Options for a field that contains an array of dates. Present if the `IndexFieldType` specifies the field is of type `date-array`. All options are enabled by default.

· **DefaultValue** *(string)* – A value to use for the field if the field isn’t specified for a document.

· **SourceFields** *(string)* –
  A list of source fields to map to the field.

· **FacetEnabled** *(boolean)* –
  Whether facet information can be returned for the field.
· **SearchEnabled** *(boolean)* –
  Whether the contents of the field are searchable.

· **ReturnEnabled** *(boolean)* –
  Whether the contents of the field can be returned in the search results.

· **Status** *(dict)* –
  The status of domain configuration option.

· **CreationDate** *(datetime)* –
  A timestamp for when this option was created.

· **UpdateDate** *(datetime)* –
  A timestamp for when this option was last updated.

· **UpdateVersion** *(integer)* –
  A unique integer that indicates when this option was last updated.

· **State** *(string)* –
  The state of processing a change to an option. Possible values:
  · **RequiresIndexDocuments** : the option’s latest value will not be deployed until IndexDocuments has been called and indexing is complete.
  · **Processing** : the option’s latest value is in the process of being activated.
  · **Active** : the option’s latest value is completely deployed.
  · **FailedToValidate** : the option value is not compatible with the domain’s data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.

· **PendingDeletion** *(boolean)* –
  Indicates that the option will be deleted once processing is complete.

### describe_scaling_parameters(**kwargs)**

Gets the scaling parameters configured for a domain. A domain’s scaling parameters specify the desired search instance type and replication count. For more information, see Configuring Scaling Options in the Amazon CloudSearch Developer Guide.

**Request Syntax**

```python
response = client.describe_scaling_parameters(
    DomainName='string'
)
```

**Parameters**

- **DomainName** *(string)* – [REQUIRED]
  A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

**Return type**

```
dict
```

**Returns**

**Response Syntax**
```json
{
'ScalingParameters': {
 'Options': {
 'DesiredInstanceType': 'search.m1.small'|'search.m1.large'|'search.m2.xlarge'|'search.m2.2xlarge'|'search.m3.medium'|'search.m3.large'|'search.m3.xlarge'|'search.m3.2xlarge',
 'DesiredReplicationCount': 123,
 'DesiredPartitionCount': 123
 },
 'Status': {
 'CreationDate': datetime(2015, 1, 1),
 'UpdateDate': datetime(2015, 1, 1),
 'UpdateVersion': 123,
 'State': 'RequiresIndexDocuments'|'Processing'|'Active'|'FailedToValidate',
 'PendingDeletion': True|False
}
}
}
```

**Response Structure**

- *(dict)* --

The result of a `DescribeScalingParameters` request. Contains the scaling parameters configured for the domain specified in the request.

- **ScalingParameters** *(dict)* --

The status and configuration of a search domain’s scaling parameters.

  - **Options** *(dict)* --

    The desired instance type and desired number of replicas of each index partition.

    - **DesiredInstanceType** *(string)* --

      The instance type that you want to preconfigure for your domain. For example, `search.m1.small`.

    - **DesiredReplicationCount** *(integer)* --

      The number of replicas you want to preconfigure for each index partition.

    - **DesiredPartitionCount** *(integer)* --

      The number of partitions you want to preconfigure for your domain. Only valid when you select `m2.2xlarge` as the desired instance type.

  - **Status** *(dict)* --

    The status of domain configuration option.

    - **CreationDate** *(datetime)* --

      A timestamp for when this option was created.

    - **UpdateDate** *(datetime)* --

      A timestamp for when this option was last updated.

    - **UpdateVersion** *(integer)* --

      A unique integer that indicates when this option was last updated.

    - **State** *(string)* --

      The state of processing a change to an option. Possible values:
· RequiresIndexDocuments: the option’s latest value will not be deployed until IndexDocuments has been called and indexing is complete.
· Processing: the option’s latest value is in the process of being activated.
· Active: the option’s latest value is completely deployed.
· FailedToValidate: the option value is not compatible with the domain’s data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.
· PendingDeletion (boolean) – Indicates that the option will be deleted once processing is complete.

describe_service_access_policies(**kwargs)

Gets information about the access policies that control access to the domain’s document and search endpoints. By default, shows the configuration with any pending changes. Set the Deployed option to true to show the active configuration and exclude pending changes. For more information, see Configuring Access for a Search Domain in the Amazon CloudSearch Developer Guide.

Request Syntax

response = client.describe_service_access_policies(
    DomainName='string',
    Deployed=True|False
)

Parameters

- **DomainName (string)** – [REQUIRED]
  
  The name of the domain you want to describe.
- **Deployed (boolean)** – Whether to display the deployed configuration (true) or include any pending changes (false). Defaults to false.

Return type **dict**

Returns

Response Syntax

```python
{
    'AccessPolicies': {
        'Options': 'string',
        'Status': {
            'CreationDate': datetime(2015, 1, 1),
            'UpdateDate': datetime(2015, 1, 1),
            'UpdateVersion': 123,
            'State': 'RequiresIndexDocuments'|'Processing'|'Active'|'FailedToValidate',
            'PendingDeletion': True|False
        }
    }
}
```

Response Structure

- **(dict)** – The result of a DescribeServiceAccessPolicies request.
  - **AccessPolicies (dict)** – The access rules configured for the domain specified in the request.
**Options (string)** –

Access rules for a domain’s document or search service endpoints. For more information, see Configuring Access for a Search Domain in the Amazon CloudSearch Developer Guide. The maximum size of a policy document is 100 KB.

**Status (dict)** –

The status of domain configuration option.

- **CreationDate (datetime)** –
  A timestamp for when this option was created.

- **UpdateDate (datetime)** –
  A timestamp for when this option was last updated.

- **UpdateVersion (integer)** –
  A unique integer that indicates when this option was last updated.

- **State (string)** –
  The state of processing a change to an option. Possible values:
  - **RequiresIndexDocuments**: the option’s latest value will not be deployed until IndexDocuments has been called and indexing is complete.
  - **Processing**: the option’s latest value is in the process of being activated.
  - **Active**: the option’s latest value is completely deployed.
  - **FailedToValidate**: the option value is not compatible with the domain’s data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.

- **PendingDeletion (boolean)** –
  Indicates that the option will be deleted once processing is complete.

---

**describe_suggesters (**kwargs)**

Gets the suggesters configured for a domain. A suggester enables you to display possible matches before users finish typing their queries. Can be limited to specific suggesters by name. By default, shows all suggesters and includes any pending changes to the configuration. Set the Deployed option to true to show the active configuration and exclude pending changes. For more information, see Getting Search Suggestions in the Amazon CloudSearch Developer Guide.

**Request Syntax**

```python
response = client.describe_suggesters(
    DomainName='string',
    SuggesterNames=['string',
                    ],
    Deployed=True|False
)
```

**Parameters**

- **DomainName (string)** – [REQUIRED]
  The name of the domain you want to describe.

- **SuggesterNames (list)** – The suggesters you want to describe.
- (string) –
  Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).
- **Deployed** (boolean) – Whether to display the deployed configuration (true) or include any pending changes (false). Defaults to false.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Suggesters': [
        {
            'Options': {
                'SuggesterName': 'string',
                'DocumentSuggesterOptions': {
                    'SourceField': 'string',
                    'FuzzyMatching': 'none' | 'low' | 'high',
                    'SortExpression': 'string'
                }
            },
            'Status': {
                'CreationDate': datetime(2015, 1, 1),
                'UpdateDate': datetime(2015, 1, 1),
                'UpdateVersion': 123,
                'State': 'RequiresIndexDocuments' | 'Processing' | 'Active' | 'FailedToValidate',
                'PendingDeletion': True | False
            }
        }
    ],
}
```

**Response Structure**

- **(dict)** –
  The result of a DescribeSuggesters request.
  - **Suggesters** (list) –
    The suggesters configured for the domain specified in the request.
  - **(dict)** –
    The value of a Suggester and its current status.
    - **Options** (dict) –
      Configuration information for a search suggester. Each suggester has a unique name and specifies the text field you want to use for suggestions. The following options can be configured for a suggester: FuzzyMatching, SortExpression.
    - **SuggesterName** (string) –
      Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).
    - **DocumentSuggesterOptions** (dict) –
      Options for a search suggester.
    - **SourceField** (string) –
      The name of the index field you want to use for suggestions.
- **FuzzyMatching** (*string*) –
  The level of fuzziness allowed when suggesting matches for a string: `none`, `low`, or `high`. With `none`, the specified string is treated as an exact prefix. With `low`, suggestions must differ from the specified string by no more than one character. With `high`, suggestions can differ by up to two characters. The default is `none`.

- **SortExpression** (*string*) –
  An expression that computes a score for each suggestion to control how they are sorted. The scores are rounded to the nearest integer, with a floor of 0 and a ceiling of $2^{31}-1$. A document’s relevance score is not computed for suggestions, so sort expressions cannot reference the `_score` value. To sort suggestions using a numeric field or existing expression, simply specify the name of the field or expression. If no expression is configured for the suggester, the suggestions are sorted with the closest matches listed first.

- **Status** (*dict*) –
  The status of domain configuration option.

- **CreationDate** (*datetime*) –
  A timestamp for when this option was created.

- **UpdateDate** (*datetime*) –
  A timestamp for when this option was last updated.

- **UpdateVersion** (*integer*) –
  A unique integer that indicates when this option was last updated.

- **State** (*string*) –
  The state of processing a change to an option. Possible values:
  - `RequiresIndexDocuments`: the option’s latest value will not be deployed until `IndexDocuments` has been called and indexing is complete.
  - `Processing`: the option’s latest value is in the process of being activated.
  - `Active`: the option’s latest value is completely deployed.
  - `FailedToValidate`: the option value is not compatible with the domain’s data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.

- **PendingDeletion** (*boolean*) –
  Indicates that the option will be deleted once processing is complete.

---

```python
generate_presigned_url (ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)
```

Generate a presigned url given a client, its method, and arguments

**Parameters**

- **ClientMethod** (*string*) – The client method to presign for
- **Params** (*dict*) – The parameters normally passed to `ClientMethod`.
- **ExpiresIn** (*int*) – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
HttpMethod (string) – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns The presigned url

get_paginator (operation_name)
Create a paginator for an operation.

Parameters operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

Raises OperationNotPageableError Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

Return type L{botocore.paginate.Paginator}

Returns A paginator object.

get_waiter (waiter_name)

index_documents (**kwargs)
Tells the search domain to start indexing its documents using the latest indexing options. This operation must be invoked to activate options whose OptionStatus is RequiresIndexDocuments.

Request Syntax

response = client.index_documents(
    DomainName='string'
)

Parameters DomainName (string) – [REQUIRED]

A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

Return type dict

Returns

Response Syntax

{
    'FieldNames': [
        'string',
    ]
}

Response Structure

* (dict) –

The result of an IndexDocuments request. Contains the status of the indexing operation, including the fields being indexed.

  FieldNames (list) –

The names of the fields that are currently being indexed.

    * (string) –

A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field’s name defines a pattern that begins or ends with a wildcard. Any document fields that don’t map to a regular index field but do
match a dynamic field’s pattern are configured with the dynamic field’s indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name score is reserved and cannot be used as a field name. To reference a document’s ID, you can use the name _id.

**list_domain_names()**

Lists all search domains owned by an account.

**Request Syntax**

```python
response = client.list_domain_names()
```

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'DomainNames': {
        'string': 'string'
    }
}
```

**Response Structure**

- **(dict)** – The result of a ListDomainNames request. Contains a list of the domains owned by an account.
  - **DomainNames (dict)** – The names of the search domains owned by an account.
    - **(string)** – A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

**update_availability_options(**

Configures the availability options for a domain. Enabling the Multi-AZ option expands an Amazon CloudSearch domain to an additional Availability Zone in the same Region to increase fault tolerance in the event of a service disruption. Changes to the Multi-AZ option can take about half an hour to become active. For more information, see Configuring Availability Options in the Amazon CloudSearch Developer Guide.

**Request Syntax**
response = client.update_availability_options(
    DomainName='string',
    MultiAZ=True|False
)

Parameters

- **DomainName** *(string)* – [REQUIRED]
  
  A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

- **MultiAZ** *(boolean)* – [REQUIRED]
  
  You expand an existing search domain to a second Availability Zone by setting the Multi-AZ option to true. Similarly, you can turn off the Multi-AZ option to downgrade the domain to a single Availability Zone by setting the Multi-AZ option to false.

Return type: dict

Returns

Response Syntax

```python
{
    'AvailabilityOptions': {
        'Options': True|False,
        'Status': {
            'CreationDate': datetime(2015, 1, 1),
            'UpdateDate': datetime(2015, 1, 1),
            'UpdateVersion': 123,
            'State': 'RequiresIndexDocuments'|'Processing'|'Active'|'FailedToValidate',
            'PendingDeletion': True|False
        }
    }
}
```

Response Structure

- *(dict)* –
  
  The result of a `UpdateAvailabilityOptions` request. Contains the status of the domain’s availability options.

  - **AvailabilityOptions** *(dict)* –
    
    The newly-configured availability options. Indicates whether Multi-AZ is enabled for the domain.

    - **Options** *(boolean)* –
      
      The availability options configured for the domain.

    - **Status** *(dict)* –
      
      The status of domain configuration option.

      - **CreationDate** *(datetime)* –
        
        A timestamp for when this option was created.

      - **UpdateDate** *(datetime)* –
        
        A timestamp for when this option was last updated.

      - **UpdateVersion** *(integer)* –
A unique integer that indicates when this option was last updated.

- **State (string)** –

  The state of processing a change to an option. Possible values:
  - RequiresIndexDocuments: the option’s latest value will not be deployed until IndexDocuments has been called and indexing is complete.
  - Processing: the option’s latest value is in the process of being activated.
  - Active: the option’s latest value is completely deployed.
  - FailedToValidate: the option value is not compatible with the domain’s data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.
  - PendingDeletion (boolean) –

    Indicates that the option will be deleted once processing is complete.

**update_scaling_parameters(**kwargs)**

Configures scaling parameters for a domain. A domain’s scaling parameters specify the desired search instance type and replication count. Amazon CloudSearch will still automatically scale your domain based on the volume of data and traffic, but not below the desired instance type and replication count. If the Multi-AZ option is enabled, these values control the resources used per Availability Zone. For more information, see Configuring Scaling Options in the *Amazon CloudSearch Developer Guide*.

**Request Syntax**

```python
response = client.update_scaling_parameters(
    DomainName='string',
    ScalingParameters={
        'DesiredInstanceType': 'search.m1.small'|'search.m1.large'|'search.m2.xlarge'|'search.m2.2xlarge'|'search.m3.medium'|'search.m3.large'|'search.m3.xlarge'|'search.m3.2xlarge',
        'DesiredReplicationCount': 123,
        'DesiredPartitionCount': 123
    }
)
```

**Parameters**

- **DomainName (string)** – [REQUIRED]

  A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

- **ScalingParameters (dict)** – [REQUIRED]

  The desired instance type and desired number of replicas of each index partition.

  - **DesiredInstanceType (string)** –

    The instance type that you want to preconfigure for your domain. For example, search.m1.small.

  - **DesiredReplicationCount (integer)** –

    The number of replicas you want to preconfigure for each index partition.

  - **DesiredPartitionCount (integer)** –

    The number of partitions you want to preconfigure for your domain. Only valid when you select m2.2xlarge as the desired instance type.
Return type  dict

Returns

Response Syntax

```python
{
    'ScalingParameters': {
        'Options': {
            'DesiredInstanceType': 'search.m1.small'|'search.m1.large'|'search.m2.xlarge'|'search.m2.2xlarge'|'search.m3.medium'|'search.m3.large'|'search.m3.xlarge'|'search.m3.2xlarge',
            'DesiredReplicationCount': 123,
            'DesiredPartitionCount': 123
        },
        'Status': {
            'CreationDate': datetime(2015, 1, 1),
            'UpdateDate': datetime(2015, 1, 1),
            'UpdateVersion': 123,
            'State': 'RequiresIndexDocuments'|'Processing'|'Active'|'FailedToValidate',
            'PendingDeletion': True|False
        }
    }
}
```

Response Structure

* (dict) –

The result of a `UpdateScalingParameters` request. Contains the status of the newly-configured scaling parameters.

  – **ScalingParameters** (dict) –

    The status and configuration of a search domain’s scaling parameters.

      * Options (dict) –

        The desired instance type and desired number of replicas of each index partition.

          - **DesiredInstanceType** (string) –

            The instance type that you want to preconfigure for your domain. For example, `search.m1.small`.

          - **DesiredReplicationCount** (integer) –

            The number of replicas you want to preconfigure for each index partition.

          - **DesiredPartitionCount** (integer) –

            The number of partitions you want to preconfigure for your domain. Only valid when you select `m2.2xlarge` as the desired instance type.

      * Status (dict) –

        The status of domain configuration option.

          - **CreationDate** (datetime) –

            A timestamp for when this option was created.

          - **UpdateDate** (datetime) –

            A timestamp for when this option was last updated.

          - **UpdateVersion** (integer) –

            A unique integer that indicates when this option was last updated.
- **State** (*string*) –
  The state of processing a change to an option. Possible values:
  - **RequiresIndexDocuments**: the option’s latest value will not be deployed until IndexDocuments has been called and indexing is complete.
  - **Processing**: the option’s latest value is in the process of being activated.
  - **Active**: the option’s latest value is completely deployed.
  - **FailedToValidate**: the option value is not compatible with the domain’s data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.
- **PendingDeletion** (*boolean*) –
  Indicates that the option will be deleted once processing is complete.

`update_service_access_policies(**kwargs)`

Configures the access rules that control access to the domain’s document and search endpoints. For more information, see Configuring Access for an Amazon CloudSearch Domain.

**Request Syntax**

```python
response = client.update_service_access_policies(
    DomainName='string',
    AccessPolicies='string'
)
```

**Parameters**

- **DomainName** (*string*) – [REQUIRED]
  A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).
- **AccessPolicies** (*string*) – [REQUIRED]
  The access rules you want to configure. These rules replace any existing rules.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'AccessPolicies': {
        'Options': 'string',
        'Status': {
            'CreationDate': datetime(2015, 1, 1),
            'UpdateDate': datetime(2015, 1, 1),
            'UpdateVersion': 123,
            'State': 'RequiresIndexDocuments'|'Processing'|'Active'|'FailedToValidate',
            'PendingDeletion': True|False
        }
    }
}
```

**Response Structure**
The result of an `UpdateServiceAccessPolicies` request. Contains the new access policies.

- **AccessPolicies** (`dict`) —

  The access rules configured for the domain.

  - **Options** (`string`) —

    Access rules for a domain’s document or search service endpoints. For more information, see Configuring Access for a Search Domain in the Amazon CloudSearch Developer Guide. The maximum size of a policy document is 100 KB.

- **Status** (`dict`) —

  The status of domain configuration option.

  - **CreationDate** (`datetime`) —

    A timestamp for when this option was created.

  - **UpdateDate** (`datetime`) —

    A timestamp for when this option was last updated.

  - **UpdateVersion** (`integer`) —

    A unique integer that indicates when this option was last updated.

  - **State** (`string`) —

    The state of processing a change to an option. Possible values:

    - **RequiresIndexDocuments**: the option’s latest value will not be deployed until `IndexDocuments` has been called and indexing is complete.

    - **Processing**: the option’s latest value is in the process of being activated.

    - **Active**: the option’s latest value is completely deployed.

    - **FailedToValidate**: the option value is not compatible with the domain’s data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.

    - **PendingDeletion** (`boolean`) —

      Indicates that the option will be deleted once processing is complete.

---

**CloudSearchDomain**

```python
class CloudSearchDomain.Client

A low-level client representing Amazon CloudSearch Domain:
```
import boto3

client = boto3.client('cloudsearchdomain')

These are the available methods:
• can_paginate()
• generate_presigned_url()
• get_paginator()
• get_waiter()
• search()
• suggest()
• upload_documents()

can_paginate(operation_name)
Check if an operation can be paginated.
Parameters operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").
Returns True if the operation can be paginated, False otherwise.

generate_presigned_url(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)
Generate a presigned url given a client, its method, and arguments
Parameters
• ClientMethod (string) – The client method to presign for
• Params (dict) – The parameters normally passed to ClientMethod.
• ExpiresIn (int) – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
• HttpMethod (string) – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns The presigned url

get_paginator(operation_name)
Create a paginator for an operation.
Parameters operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

Raises OperationNotPageableError Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.
Return type L{botocore.paginate.Paginator}

Returns A paginator object.

get_waiter(waiter_name)

search(**kwargs)
Retrieves a list of documents that match the specified search criteria. How you specify the search criteria depends on which query parser you use. Amazon CloudSearch supports four query parsers:
• simple: search all text and text-array fields for the specified string. Search for phrases, individual terms, and prefixes.
• structured: search specific fields, construct compound queries using Boolean operators, and use advanced features such as term boosting and proximity searching.
• lucene: specify search criteria using the Apache Lucene query parser syntax.
• dismax: specify search criteria using the simplified subset of the Apache Lucene query parser
syntax defined by the DisMax query parser. For more information, see Searching Your Data in the Amazon CloudSearch Developer Guide.

The endpoint for submitting Search requests is domain-specific. You submit search requests to a domain’s search endpoint. To get the search endpoint for your domain, use the Amazon CloudSearch configuration service DescribeDomains action. A domain’s endpoints are also displayed on the domain dashboard in the Amazon CloudSearch console.

Request Syntax

```python
response = client.search(
    cursor='string',
    expr='string',
    facet='string',
    filterQuery='string',
    highlight='string',
    partial=True|False,
    query='string',
    queryOptions='string',
    queryParser='simple'|'structured'|'lucene'|'dismax',
    return='string',
    size=123,
    sort='string',
    start=123
)
```

Parameters

- **cursor (string)** – Retrieves a cursor value you can use to page through large result sets. Use the size parameter to control the number of hits to include in each response. You can specify either the cursor or start parameter in a request; they are mutually exclusive. To get the first cursor, set the cursor value to initial. In subsequent requests, specify the cursor value returned in the hits section of the response. For more information, see Paginating Results in the Amazon CloudSearch Developer Guide.

- **expr (string)** – Defines one or more numeric expressions that can be used to sort results or specify search or filter criteria. You can also specify expressions as return fields.

You specify the expressions in JSON using the form "{"EXPRESSIONNAME":"EXPRESSION"}". You can define and use multiple expressions in a search request. For example:

```json
{"expression1":"_score*rating", "expression2":"(1/rank)*year"}
```

For information about the variables, operators, and functions you can use in expressions, see Writing Expressions in the Amazon CloudSearch Developer Guide.

- **facet (string)** – Specifies one or more fields for which to get facet information, and options that control how the facet information is returned. Each specified field must be facet-enabled in the domain configuration. The fields and options are specified in JSON using the form 

```json
{"FIELD":{"OPTION":VALUE,"OPTION":"STRING"},"FIELD":{"OPTION":VALUE,"OPTION":"STRING"}}
```

You can specify the following faceting options:

- **buckets** specifies an array of the facet values or ranges to count. Ranges are specified using the same syntax that you use to search for a range of
values. For more information, see Searching for a Range of Values in the Amazon CloudSearch Developer Guide. Buckets are returned in the order they are specified in the request. The sort and size options are not valid if you specify buckets.

- size specifies the maximum number of facets to include in the results. By default, Amazon CloudSearch returns counts for the top 10. The size parameter is only valid when you specify the sort option; it cannot be used in conjunction with buckets.

- sort specifies how you want to sort the facets in the results: bucket or count. Specify bucket to sort alphabetically or numerically by facet value (in ascending order). Specify count to sort by the facet counts computed for each facet value (in descending order). To retrieve facet counts for particular values or ranges of values, use the buckets option instead of sort.

If no facet options are specified, facet counts are computed for all field values, the facets are sorted by facet count, and the top 10 facets are returned in the results.

To count particular buckets of values, use the buckets option. For example, the following request uses the buckets option to calculate and return facet counts by decade.

To sort facets by facet count, use the count option. For example, the following request sets the sort option to count to sort the facet values by facet count, with the facet values that have the most matching documents listed first. Setting the size option to 3 returns only the top three facet values.

{"year":{"sort":"count","size":3}}

To sort the facets by value, use the bucket option. For example, the following request sets the sort option to bucket to sort the facet values numerically by year, with earliest year listed first.

{"year":{"sort":"bucket"}}

For more information, see Getting and Using Facet Information in the Amazon CloudSearch Developer Guide.

- filterQuery (string) - Specifies a structured query that filters the results of a search without affecting how the results are scored and sorted. You use filterQuery in conjunction with the query parameter to filter the documents that match the constraints specified in the query parameter. Specifying a filter controls only which matching documents are included in the results, it has no effect on how they are scored and sorted. The filterQuery parameter supports the full structured query syntax.

For more information about using filters, see Filtering Matching Documents in the Amazon CloudSearch Developer Guide.

- highlight (string) - Retrieves highlights for matches in the specified text or text-array fields. Each specified field must be highlight enabled in the domain configuration. The fields and options are specified in JSON using the form

{"FIELD":{"OPTION":VALUE,"OPTION":"STRING"},"FIELD":{"OPTION":VALUE,"OPTION":VALUE,"OPTION":VALUE}}.

You can specify the following highlight options:

- format: specifies the format of the data in the text field: text or html. When data is returned as HTML, all non-alphanumeric characters are
encoded. The default is html.

- max_phrases: specifies the maximum number of occurrences of the search term(s) you want to highlight. By default, the first occurrence is highlighted.
- pre_tag: specifies the string to prepend to an occurrence of a search term. The default for HTML highlights is \lt;emgt; . The default for text highlights is * .
- post_tag: specifies the string to append to an occurrence of a search term. The default for HTML highlights is \lt;/emgt; . The default for text highlights is * .

If no highlight options are specified for a field, the returned field text is treated as HTML and the first match is highlighted with emphasis tags: \lt;emsearch-term\lt;/emgt; .

For example, the following request retrieves highlights for the actors and title fields.

```json
{ "actors": {}, "title": { "format": "text","max_phrases": 2,"pre_tag": "**","post_tag": " ** "} }
```

- **partial** (boolean) – Enables partial results to be returned if one or more index partitions are unavailable. When your search index is partitioned across multiple search instances, by default Amazon CloudSearch only returns results if every partition can be queried. This means that the failure of a single search instance can result in 5xx (internal server) errors. When you enable partial results, Amazon CloudSearch returns whatever results are available and includes the percentage of documents searched in the search results (percent-searched). This enables you to more gracefully degrade your users’ search experience. For example, rather than displaying no results, you could display the partial results and a message indicating that the results might be incomplete due to a temporary system outage.

- **query** (string) – [REQUIRED]

Specifies the search criteria for the request. How you specify the search criteria depends on the query parser used for the request and the parser options specified in the queryOptions parameter. By default, the simple query parser is used to process requests. To use the structured, lucene, or dismax query parser, you must also specify the queryParser parameter.

For more information about specifying search criteria, see Searching Your Data in the Amazon CloudSearch Developer Guide .

- **queryOptions** (string) – Configures options for the query parser specified in the queryParser parameter. You specify the options in JSON using the following form

```
{"OPTION1":"VALUE1","OPTION2":VALUE2"..."OPTIONN":"VALUEN"}
```

The options you can configure vary according to which parser you use:

- defaultOperator: The default operator used to combine individual terms in the search string. For example: defaultOperator: 'or' . For the dismax parser, you specify a percentage that represents the percentage of terms in the search string (rounded down) that must match, rather than a default operator. A value of 0% is the equivalent to OR, and a value of 100% is equivalent to AND. The percentage must be specified as a value in the range 0-100 followed by the percent (%) symbol. For example, defaultOperator: 50%. Valid values: and, or, a percentage in the range 0%-100% (dismax). Default: and (simple, structured, lucene) or 100 (dismax). Valid for: simple,
structured, lucene, and dismax.

- **fields**: An array of the fields to search when no fields are specified in a search. If no fields are specified in a search and this option is not specified, all text and text-array fields are searched. You can specify a weight for each field to control the relative importance of each field when Amazon CloudSearch calculates relevance scores. To specify a field weight, append a caret (^) symbol and the weight to the field name. For example, to boost the importance of the title field over the description field you could specify: "fields": ["title^5", "description"]. Valid values: The name of any configured field and an optional numeric value greater than zero. Default: All text and text-array fields. Valid for: simple, structured, lucene, and dismax.

- **operators**: An array of the operators or special characters you want to disable for the simple query parser. If you disable the and, or, or not operators, the corresponding operators (+, |, -) have no special meaning and are dropped from the search string. Similarly, disabling prefix disables the wildcard operator(*) and disabling phrase disables the ability to search for phrases by enclosing phrases in double quotes. Disabling precedence disables the ability to control order of precedence using parentheses. Disabling near disables the ability to use the ~ operator to perform a sloppy phrase search. Disabling the fuzzy operator disables the ability to use the ~ operator to perform a fuzzy search. escape disabling the ability to use a backslash (\) to escape special characters within the search string. Disabling whitespace is an advanced option that prevents the parser from tokenizing on whitespace, which can be useful for Vietnamese. (It prevents Vietnamese words from being split incorrectly.) For example, you could disable all operators other than the phrase operator to support just simple term and phrase queries: "operators": ["and", "not", "or", "prefix"]. Valid values: and, escape, fuzzy, near, not, or, phrase, precedence, prefix, whitespace. Default: All operators and special characters are enabled. Valid for: simple.

- **phraseFields**: An array of the text or text-array fields you want to use for phrase searches. When the terms in the search string appear in close proximity within a field, the field scores higher. You can specify a weight for each field to boost that score. The phraseSlop option controls how much the matches can deviate from the search string and still be boosted. To specify a field weight, append a caret (^) symbol and the weight to the field name. For example, to boost phrase matches in the title field over the abstract field, you could specify: "phraseFields": ["title^3", "plot"] Valid values: The name of any text or text-array field and an optional numeric value greater than zero. Default: No fields. If you don’t specify any fields with phraseFields, proximity scoring is disabled even if phraseSlop is specified. Valid for: dismax.

- **phraseSlop**: An integer value that specifies how much matches can deviate from the search phrase and still be boosted according to the weights specified in the phraseFields option; for example, phraseSlop: 2. You must also specify phraseFields to enable proximity scoring. Valid values: positive integers. Default: 0. Valid for: dismax.

- **explicitPhraseSlop**: An integer value that specifies how much a match can deviate from the search phrase when the phrase is enclosed in double quotes in the search string. (Phrases that exceed this proximity distance are not considered a match.) For example, to
specify a slop of three for dismax phrase queries, you would specify "explicitPhraseSlop":3. Valid values: positive integers. Default: 0. Valid for: dismax.

- **tieBreaker**: When a term in the search string is found in a document’s field, a score is calculated for that field based on how common the word is in that field compared to other documents. If the term occurs in multiple fields within a document, by default only the highest scoring field contributes to the document’s overall score. You can specify a tieBreaker value to enable the matches in lower-scoring fields to contribute to the document’s score. That way, if two documents have the same max field score for a particular term, the score for the document that has matches in more fields will be higher. The formula for calculating the score with a tieBreaker is (max field score) + (tieBreaker) * (sum of the scores for the rest of the matching fields). Set tieBreaker to 0 to disregard all but the highest scoring field (pure max): "tieBreaker":0. Set to 1 to sum the scores from all fields (pure sum): "tieBreaker":1. Valid values: 0.0 to 1.0. Default: 0.0. Valid for: dismax.

- **queryParser** *(string)* – Specifies which query parser to use to process the request. If queryParser is not specified, Amazon CloudSearch uses the simple query parser.

Amazon CloudSearch supports four query parsers:

- **simple**: perform simple searches of text and text-array fields. By default, the simple query parser searches all text and text-array fields. You can specify which fields to search by with the queryOptions parameter. If you prefix a search term with a plus sign (+) documents must contain the term to be considered a match. (This is the default, unless you configure the default operator with the queryOptions parameter.) You can use the – (NOT), | (OR), and * (wildcard) operators to exclude particular terms, find results that match any of the specified terms, or search for a prefix. To search for a phrase rather than individual terms, enclose the phrase in double quotes. For more information, see Searching for Text in the Amazon CloudSearch Developer Guide.

- **structured**: perform advanced searches by combining multiple expressions to define the search criteria. You can also search within particular fields, search for values and ranges of values, and use advanced options such as term boosting, matchall, and near. For more information, see Constructing Compound Queries in the Amazon CloudSearch Developer Guide.

- **lucene**: search using the Apache Lucene query parser syntax. For more information, see Apache Lucene Query Parser Syntax.

- **dismax**: search using the simplified subset of the Apache Lucene query parser syntax defined by the DisMax query parser. For more information, see DisMax Query Parser Syntax.

- **return** *(string)* – Specifies the field and expression values to include in the response. Multiple fields or expressions are specified as a comma-separated list. By default, a search response includes all return enabled fields(_all_fields). To return only the document IDs for the matching documents, specify _no_fields. To retrieve the relevance score calculated for each document, specify _score.

- **size** *(integer)* – Specifies the maximum number of search hits to include in the response.
• **sort** (*string*) – Specifies the fields or custom expressions to use to sort the search results. Multiple fields or expressions are specified as a comma-separated list. You must specify the sort direction (*asc* or *desc*) for each field; for example, *year desc*, *title asc*. To use a field to sort results, the field must be sort-enabled in the domain configuration. Array type fields cannot be used for sorting. If no `sort` parameter is specified, results are sorted by their default relevance scores in descending order: `score desc`. You can also sort by document ID (_id *asc*) and version (_version *desc*).

For more information, see *Sorting Results* in the [Amazon CloudSearch Developer Guide](https://docs.aws.amazon.com/cloudsearch/).

• **start** (*integer*) – Specifies the offset of the first search hit you want to return. Note that the result set is zero-based; the first result is at index 0. You can specify either the `start` or `cursor` parameter in a request, they are mutually exclusive.

For more information, see *Paginating Results* in the [Amazon CloudSearch Developer Guide](https://docs.aws.amazon.com/cloudsearch/).

**Return type**  dict

**Returns**

**Response Syntax**

```json
{
  'status': {
    'timems': 123,
    'rid': 'string'
  },
  'hits': {
    'found': 123,
    'start': 123,
    'cursor': 'string',
    'hit': [
      {
        'id': 'string',
        'fields': {
          'string': [
            'string',
          ],
        },
        'exprs': {
          'string': 'string'
        },
        'highlights': {
          'string': 'string'
        }
      }
    ],
  },
  'facets': {
    'string': {
      'buckets': [
        {
          'value': 'string',
          'count': 123
        }
      ]
    }
  }
}
```
Response Structure

- (dict) –
  The result of a Search request. Contains the documents that match the specified search criteria and any requested fields, highlights, and facet information.
  
  - status (dict) –
    The status information returned for the search request.
    * timems (integer) –
      How long it took to process the request, in milliseconds.
    * rid (string) –
      The encrypted resource ID for the request.
  
  - hits (dict) –
    The documents that match the search criteria.
    * found (integer) –
      The total number of documents that match the search request.
    * start (integer) –
      The index of the first matching document.
    * cursor (string) –
      A cursor that can be used to retrieve the next set of matching documents when you want to page through a large result set.
    * hit (list) –
      A document that matches the search request.
      · (dict) –
        Information about a document that matches the search request.
      · id (string) –
        The document ID of a document that matches the search request.
      · fields (dict) –
        The fields returned from a document that matches the search request.
      · (string) –
      · (list) –
      · (string) –
      · exprs (dict) –
        The expressions returned from a document that matches the search request.
      · (string) –
      · (string) –
      · highlights (dict) –
        The highlights returned from a document that matches the search request.
      · (string) –
      · (string) –
– facets (dict) –

The requested facet information.

* (string) –
  · (dict) –
    A container for the calculated facet values and counts.
  · buckets (list) –
    A list of the calculated facet values and counts.
  · (dict) –
    A container for facet information.
  · value (string) –
    The facet value being counted.
  · count (integer) –
    The number of hits that contain the facet value in the specified facet field.

suggest (**kwargs)

Retrieves autocomplete suggestions for a partial query string. You can use suggestions enable you to display likely matches before users finish typing. In Amazon CloudSearch, suggestions are based on the contents of a particular text field. When you request suggestions, Amazon CloudSearch finds all of the documents whose values in the suggester field start with the specified query string. The beginning of the field must match the query string to be considered a match.

For more information about configuring suggesters and retrieving suggestions, see Getting Suggestions in the Amazon CloudSearch Developer Guide.

The endpoint for submitting Suggest requests is domain-specific. You submit suggest requests to a domain’s search endpoint. To get the search endpoint for your domain, use the Amazon CloudSearch configuration service DescribeDomains action. A domain’s endpoints are also displayed on the domain dashboard in the Amazon CloudSearch console.

Request Syntax

```python
response = client.suggest(
    query='string',
    suggester='string',
    size=123
)
```

Parameters

- query (string) – [REQUIRED]
  Specifies the string for which you want to get suggestions.
- suggester (string) – [REQUIRED]
  Specifies the name of the suggester to use to find suggested matches.
- size (integer) – Specifies the maximum number of suggestions to return.

Return type  dict

Returns

Response Syntax

```python
{
    'status': {
        'timems': 123,
        'rid': 'string'
    }
}
```
Boto3 Documentation, Release 1.1.4

```
{
  'suggest': {
    'query': 'string',
    'found': 123,
    'suggestions': [
      {
        'suggestion': 'string',
        'score': 123,
        'id': 'string'
      }
    ]
  }
}
```

**Response Structure**

- (dict) –
  Contains the response to a `Suggest` request.
  
  - status (dict) –
    The status of a `SuggestRequest`. Contains the resource ID (`rid`) and how long it took to process the request (`timems`).
    
    - timems (integer) –
      How long it took to process the request, in milliseconds.
    
    - rid (string) –
      The encrypted resource ID for the request.
  
  - suggest (dict) –
    Container for the matching search suggestion information.
    
    - query (string) –
      The query string specified in the suggest request.
    
    - found (integer) –
      The number of documents that were found to match the query string.
    
    - suggestions (list) –
      The documents that match the query string.
        
        - (dict) –
          An autocomplete suggestion that matches the query string specified in a `SuggestRequest`.
            
            - suggestion (string) –
              The string that matches the query string specified in the `SuggestRequest`.
            
            - score (integer) –
              The relevance score of a suggested match.
            
            - id (string) –
              The document ID of the suggested document.

**upload_documents(**kwargs)**

Posts a batch of documents to a search domain for indexing. A document batch is a collection of add and delete operations that represent the documents you want to add, update, or delete from your domain. Batches can be described in either JSON or XML. Each item that you want Amazon CloudSearch to return as a search result (such as a product) is represented as a document. Every document has a unique ID and one or more fields that contain the data that you want to search and return in results. Individual
documents cannot contain more than 1 MB of data. The entire batch cannot exceed 5 MB. To get the best possible upload performance, group add and delete operations in batches that are close the 5 MB limit. Submitting a large volume of single-document batches can overload a domain’s document service.

The endpoint for submitting UploadDocuments requests is domain-specific. To get the document endpoint for your domain, use the Amazon CloudSearch configuration service DescribeDomains action. A domain’s endpoints are also displayed on the domain dashboard in the Amazon CloudSearch console.

For more information about formatting your data for Amazon CloudSearch, see Preparing Your Data in the Amazon CloudSearch Developer Guide. For more information about uploading data for indexing, see Uploading Data in the Amazon CloudSearch Developer Guide.

Request Syntax

```python
response = client.upload_documents(
    documents=b'bytes',
    contentType='application/json'|'application/xml'
)
```

Parameters

- **documents (bytes)** – [REQUIRED]
  A batch of documents formatted in JSON or HTML.

- **contentType (string)** – [REQUIRED]
  The format of the batch you are uploading. Amazon CloudSearch supports two document batch formats:
  - application/json
  - application/xml

Return type  dict

Returns

**Response Syntax**

```json
{
    'status': 'string',
    'adds': 123,
    'deletes': 123,
    'warnings': [
        {
            'message': 'string'
        },
    ]
}
```

**Response Structure**

- **(dict)** –
  Contains the response to an UploadDocuments request.
  - **status (string)** –
    The status of an UploadDocumentsRequest.
  - **adds (integer)** –
    The number of documents that were added to the search domain.
  - **deletes (integer)** –
    The number of documents that were deleted from the search domain.
– **warnings** *(list)* –

Any warnings returned by the document service about the documents being uploaded.

* *(dict)* –

A warning returned by the document service when an issue is discovered while processing an upload request.

· **message** *(string)* –

The description for a warning returned by the document service.

### CloudTrail

```python
import boto3

client = boto3.client('cloudtrail')
```

These are the available methods:

· `can_paginate()`  
· `create_trail()`  
· `delete_trail()`  
· `describe_trails()`  
· `generate_presigned_url()`  
· `getaginator()`  
· `get_trail_status()`  
· `get_waiter()`  
· `lookup_events()`  
· `start_logging()`  
· `stop_logging()`  
· `update_trail()`

**can_paginate** *(operation_name)*

Check if an operation can be paginated.

**Parameters**

*operation_name* *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginater("create_foo")`.

**Returns**

True if the operation can be paginated, False otherwise.

**create_trail** *(**kwargs)*

From the command line, use `create-subscription`. ```
Creates a trail that specifies the settings for delivery of log data to an Amazon S3 bucket.

**Request Syntax**

```python
response = client.create_trail(
    Name='string',
    S3BucketName='string',
    S3KeyPrefix='string',
    SnsTopicName='string',
    IncludeGlobalServiceEvents=True|False,
    CloudWatchLogsLogGroupArn='string',
    CloudWatchLogsRoleArn='string'
)
```

**Parameters**

- **Name** (*string*) – [REQUIRED]
  
  Specifies the name of the trail.

- **S3BucketName** (*string*) – [REQUIRED]
  
  Specifies the name of the Amazon S3 bucket designated for publishing log files.

- **S3KeyPrefix** (*string*) – Specifies the Amazon S3 key prefix that precedes the name of the bucket you have designated for log file delivery.

- **SnsTopicName** (*string*) – Specifies the name of the Amazon SNS topic defined for notification of log file delivery.

- **IncludeGlobalServiceEvents** (*boolean*) – Specifies whether the trail is publishing events from global services such as IAM to the log files.

- **CloudWatchLogsLogGroupArn** (*string*) – Specifies a log group name using an Amazon Resource Name (ARN), a unique identifier that represents the log group to which CloudTrail logs will be delivered. Not required unless you specify CloudWatchLogsRoleArn.

- **CloudWatchLogsRoleArn** (*string*) – Specifies the role for the CloudWatch Logs endpoint to assume to write to a user's log group.

**Return type**  dict

**Returns**

**Response Syntax**

```json
{
    'Name': 'string',
    'S3BucketName': 'string',
    'S3KeyPrefix': 'string',
    'SnsTopicName': 'string',
    'IncludeGlobalServiceEvents': True|False,
    'CloudWatchLogsLogGroupArn': 'string',
    'CloudWatchLogsRoleArn': 'string'
}
```

**Response Structure**

- *(dict)* – Returns the objects or data listed below if successful. Otherwise, returns an error.
  
  - **Name** (*string*) –
    
    Specifies the name of the trail.

  - **S3BucketName** (*string*) –
    
    Specifies the name of the Amazon S3 bucket designated for publishing log files.
- **S3KeyPrefix** *(string)* –
  Specifies the Amazon S3 key prefix that precedes the name of the bucket you have designated for log file delivery.

- **SnsTopicName** *(string)* –
  Specifies the name of the Amazon SNS topic defined for notification of log file delivery.

- **IncludeGlobalServiceEvents** *(boolean)* –
  Specifies whether the trail is publishing events from global services such as IAM to the log files.

- **CloudWatchLogsLogGroupArn** *(string)* –
  Specifies the Amazon Resource Name (ARN) of the log group to which CloudTrail logs will be delivered.

- **CloudWatchLogsRoleArn** *(string)* –
  Specifies the role for the CloudWatch Logs endpoint to assume to write to a user’s log group.

### delete_trail(**kwargs**)
Deletes a trail.

**Request Syntax**

```python
response = client.delete_trail(
    Name='string'
)
```

**Parameters**

- **Name** *(string)* – [REQUIRED]
  The name of a trail to be deleted.

**Return type**

- **dict**

**Returns**

**Response Syntax**

```json
{}
```

**Response Structure**

- *(dict)* –
  Returns the objects or data listed below if successful. Otherwise, returns an error.

### describe_trails(**kwargs**)
Retrieves settings for the trail associated with the current region for your account.

**Request Syntax**

```python
response = client.describe_trails(
    trailNameList=[
        'string',
    ]
)
```

**Parameters**

- **trailNameList** *(list)* – The trail returned.
  - *(string)* –

**Return type**

- **dict**
Returns

Response Syntax

```
{
    'trailList': [
        {
            'Name': 'string',
            'S3BucketName': 'string',
            'S3KeyPrefix': 'string',
            'SnsTopicName': 'string',
            'IncludeGlobalServiceEvents': True|False,
            'CloudWatchLogsLogGroupArn': 'string',
            'CloudWatchLogsRoleArn': 'string'
        },
    ],
}
```

Response Structure

- (dict) –
  Returns the objects or data listed below if successful. Otherwise, returns an error.
  - trailList (list) –
    The list of trails.
    - (dict) –
      The settings for a trail.
      - Name (string) –
        Name of the trail set by calling CreateTrail.
      - S3BucketName (string) –
        Name of the Amazon S3 bucket into which CloudTrail delivers your trail files.
      - S3KeyPrefix (string) –
        Value of the Amazon S3 prefix.
      - SnsTopicName (string) –
        Name of the existing Amazon SNS topic that CloudTrail uses to notify the account owner when new CloudTrail log files have been delivered.
      - IncludeGlobalServiceEvents (boolean) –
        Set to True to include AWS API calls from AWS global services such as IAM. Otherwise, False.
      - CloudWatchLogsLogGroupArn (string) –
        Specifies an Amazon Resource Name (ARN), a unique identifier that represents the log group to which CloudTrail logs will be delivered.
      - CloudWatchLogsRoleArn (string) –
        Specifies the role for the CloudWatch Logs endpoint to assume to write to a user’s log group.

`generate_presigned_url` (ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)

Generate a presigned url given a client, its method, and arguments

Parameters

- ClientMethod (string) – The client method to presign for
• **Params** *(dict)* – The parameters normally passed to ClientMethod.
• **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
• **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns** The presigned url

### get_paginator *(operation_name)*

Create a paginator for an operation.

**Parameters** *operation_name* *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you'd normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

**Raises** OperationNotPageableError Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

**Return type** L{botocore.paginate.Paginator}

**Returns** A paginator object.

### get_trail_status **kwargs**

Returns a JSON-formatted list of information about the specified trail. Fields include information on delivery errors, Amazon SNS and Amazon S3 errors, and start and stop logging times for each trail.

**Request Syntax**

```python
response = client.get_trail_status(
    Name='string'
)
```

**Parameters** *Name* *(string)* – [REQUIRED]

The name of the trail for which you are requesting the current status.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'IsLogging': True|False,
    'LatestDeliveryError': 'string',
    'LatestNotificationError': 'string',
    'LatestDeliveryTime': datetime(2015, 1, 1),
    'LatestNotificationTime': datetime(2015, 1, 1),
    'StartLoggingTime': datetime(2015, 1, 1),
    'StopLoggingTime': datetime(2015, 1, 1),
    'LatestCloudWatchLogsDeliveryError': 'string',
    'LatestCloudWatchLogsDeliveryTime': datetime(2015, 1, 1)
}
```

**Response Structure**

• *(dict)* –

  Returns the objects or data listed below if successful. Otherwise, returns an error.
  
  – **IsLogging** *(boolean)* –

    Whether the CloudTrail is currently logging AWS API calls.
  
  – **LatestDeliveryError** *(string)* –
Displays any Amazon S3 error that CloudTrail encountered when attempting to deliver log files to the designated bucket. For more information see the topic Error Responses in the Amazon S3 API Reference.

- **LatestNotificationError** *(string)* –
  Displays any Amazon SNS error that CloudTrail encountered when attempting to send a notification. For more information about Amazon SNS errors, see the Amazon SNS Developer Guide.

- **LatestDeliveryTime** *(datetime)* –
  Specifies the date and time that CloudTrail last delivered log files to an account’s Amazon S3 bucket.

- **LatestNotificationTime** *(datetime)* –
  Specifies the date and time of the most recent Amazon SNS notification that CloudTrail has written a new log file to an account’s Amazon S3 bucket.

- **StartLoggingTime** *(datetime)* –
  Specifies the most recent date and time when CloudTrail started recording API calls for an AWS account.

- **StopLoggingTime** *(datetime)* –
  Specifies the most recent date and time when CloudTrail stopped recording API calls for an AWS account.

- **LatestCloudWatchLogsDeliveryError** *(string)* –
  Displays any CloudWatch Logs error that CloudTrail encountered when attempting to deliver logs to CloudWatch Logs.

- **LatestCloudWatchLogsDeliveryTime** *(datetime)* –
  Displays the most recent date and time when CloudTrail delivered logs to CloudWatch Logs.

### `get_waiter(waiter_name)`

### `lookup_events(**kwargs)`

Looks up API activity events captured by CloudTrail that create, update, or delete resources in your account. Events for a region can be looked up for the times in which you had CloudTrail turned on in that region during the last seven days. Lookup supports five different attributes: time range (defined by a start time and end time), user name, event name, resource type, and resource name. All attributes are optional. The maximum number of attributes that can be specified in any one lookup request are time range and one other attribute. The default number of results returned is 10, with a maximum of 50 possible. The response includes a token that you can use to get the next page of results. The rate of lookup requests is limited to one per second per account.

**Warning:** Events that occurred during the selected time range will not be available for lookup if CloudTrail logging was not enabled when the events occurred.

### Request Syntax

```python
text1
def get_waiter(waiter_name):

def lookup_events(**kwargs):
    response = client.lookup_events(
        LookupAttributes=[
            
            
            
            
            ],
```
Parameters

- **LookupAttributes** *(list)* – Contains a list of lookup attributes. Currently the list can contain only one item.
  - *(dict)* –

  Specifies an attribute and value that filter the events returned.
  - **AttributeKey** *(string)* – [REQUIRED]
    Specifies an attribute on which to filter the events returned.
  - **AttributeValue** *(string)* – [REQUIRED]
    Specifies a value for the specified AttributeKey.

- **StartTime** *(datetime)* – Specifies that only events that occur after or at the specified time are returned. If the specified start time is after the specified end time, an error is returned.

- **EndTime** *(datetime)* – Specifies that only events that occur before or at the specified time are returned. If the specified end time is before the specified start time, an error is returned.

- **MaxResults** *(integer)* – The number of events to return. Possible values are 1 through 50. The default is 10.

- **NextToken** *(string)* – The token to use to get the next page of results after a previous API call. This token must be passed in with the same parameters that were specified in the the original call. For example, if the original call specified an AttributeKey of 'Username' with a value of 'root', the call with NextToken should include those same parameters.

Return type  dict

Returns

Response Syntax

```python
{
'Events': [
{
'EventId': 'string',
'EventName': 'string',
'EventTime': datetime(2015, 1, 1),
'Username': 'string',
'Resources': [
{
'ResourceType': 'string',
'ResourceName': 'string'
}],
'CloudTrailEvent': 'string'
},
'NextToken': 'string'
}
```

Response Structure

- *(dict)* –
Contains a response to a LookupEvents action.

- **Events (list)** –
  A list of events returned based on the lookup attributes specified and the CloudTrail event. The events list is sorted by time. The most recent event is listed first.

  - *(dict)* –
    Contains information about an event that was returned by a lookup request. The result includes a representation of a CloudTrail event.
    - **EventId (string)** –
      The CloudTrail ID of the event returned.
    - **EventName (string)** –
      The name of the event returned.
    - **EventTime (datetime)** –
      The date and time of the event returned.
    - **Username (string)** –
      A user name or role name of the requester that called the API in the event returned.
    - **Resources (list)** –
      A list of resources referenced by the event returned.
        - *(dict)* –
          Specifies the type and name of a resource referenced by an event.
        - **ResourceType (string)** –
          The type of a resource referenced by the event returned. When the resource type cannot be determined, null is returned. Some examples of resource types are: `Instance` for EC2, `Trail` for CloudTrail, `DBInstance` for RDS, and `AccessKey` for IAM. For a list of resource types supported for event lookup, see Resource Types Supported for Event Lookup.
        - **ResourceName (string)** –
          The name of the resource referenced by the event returned. These are user-created names whose values will depend on the environment. For example, the resource name might be “auto-scaling-test-group” for an Auto Scaling Group or “i-1234567” for an EC2 Instance.
    - **CloudTrailEvent (string)** –
      A JSON string that contains a representation of the event returned.

- **NextToken (string)** –
  The token to use to get the next page of results after a previous API call. If the token does not appear, there are no more results to return. The token must be passed in with the same parameters as the previous call. For example, if the original call specified an AttributeKey of ‘Username’ with a value of ‘root’, the call with NextToken should include those same parameters.
**start_logging(**kwargs **)**

Starts the recording of AWS API calls and log file delivery for a trail.

**Request Syntax**

```python
response = client.start_logging(
    Name='string'
)
```

**Parameters** **Name** *(string)* − [REQUIRED]

The name of the trail for which CloudTrail logs AWS API calls.

**Return type** dict

**Returns**

**Response Syntax**

```python
{}
```

**Response Structure**

• *(dict)* −

Returns the objects or data listed below if successful. Otherwise, returns an error.

**stop_logging(**kwargs **)**

Suspends the recording of AWS API calls and log file delivery for the specified trail. Under most circumstances, there is no need to use this action. You can update a trail without stopping it first. This action is the only way to stop recording.

**Request Syntax**

```python
response = client.stop_logging(
    Name='string'
)
```

**Parameters** **Name** *(string)* − [REQUIRED]

Communicates to CloudTrail the name of the trail for which to stop logging AWS API calls.

**Return type** dict

**Returns**

**Response Syntax**

```python
{}
```

**Response Structure**

• *(dict)* −

Returns the objects or data listed below if successful. Otherwise, returns an error.

**update_trail(**kwargs **)**

From the command line, use `update-subscription`.

Updates the settings that specify delivery of log files. Changes to a trail do not require stopping the CloudTrail service. Use this action to designate an existing bucket for log delivery. If the existing bucket has previously been a target for CloudTrail log files, an IAM policy exists for the bucket.

**Request Syntax**
response = client.update_trail(
    Name='string',
    S3BucketName='string',
    S3KeyPrefix='string',
    SnsTopicName='string',
    IncludeGlobalServiceEvents=True|False,
    CloudWatchLogsLogGroupArn='string',
    CloudWatchLogsRoleArn='string'
)

Parameters

- **Name (string)** – [REQUIRED]
  Specifies the name of the trail.
- **S3BucketName (string)** – Specifies the name of the Amazon S3 bucket designated for publishing log files.
- **S3KeyPrefix (string)** – Specifies the Amazon S3 key prefix that precedes the name of the bucket you have designated for log file delivery.
- **SnsTopicName (string)** – Specifies the name of the Amazon SNS topic defined for notification of log file delivery.
- **IncludeGlobalServiceEvents (boolean)** – Specifies whether the trail is publishing events from global services such as IAM to the log files.
- **CloudWatchLogsLogGroupArn (string)** – Specifies a log group name using an Amazon Resource Name (ARN), a unique identifier that represents the log group to which CloudTrail logs will be delivered. Not required unless you specify CloudWatchLogsRoleArn.
- **CloudWatchLogsRoleArn (string)** – Specifies the role for the CloudWatch Logs endpoint to assume to write to a user’s log group.

Return type  dict

Returns

Response Syntax

```python
{
    'Name': 'string',
    'S3BucketName': 'string',
    'S3KeyPrefix': 'string',
    'SnsTopicName': 'string',
    'IncludeGlobalServiceEvents': True|False,
    'CloudWatchLogsLogGroupArn': 'string',
    'CloudWatchLogsRoleArn': 'string'
}
```

Response Structure

- **(dict)** – Returns the objects or data listed below if successful. Otherwise, returns an error.
  - **Name (string)** –
    Specifies the name of the trail.
  - **S3BucketName (string)** –
    Specifies the name of the Amazon S3 bucket designated for publishing log files.
  - **S3KeyPrefix (string)** –
    Specifies the Amazon S3 key prefix that precedes the name of the bucket you have designated for log file delivery.
– **SnsTopicName** *(string)* –

  Specifies the name of the Amazon SNS topic defined for notification of log file delivery.

– **IncludeGlobalServiceEvents** *(boolean)* –

  Specifies whether the trail is publishing events from global services such as IAM to the log files.

– **CloudWatchLogsLogGroupArn** *(string)* –

  Specifies the Amazon Resource Name (ARN) of the log group to which CloudTrail logs will be delivered.

– **CloudWatchLogsRoleArn** *(string)* –

  Specifies the role for the CloudWatch Logs endpoint to assume to write to a user’s log group.

### CloudWatch

#### Table of Contents

- CloudWatch
  - Client
  - Paginators

### Client

**class** `CloudWatch.Client`

A low-level client representing Amazon CloudWatch:

```python
import boto3
client = boto3.client('cloudwatch')
```

These are the available methods:

- `can_paginate()`  
- `delete_alarms()`  
- `describe_alarm_history()`  
- `describe_alarms()`  
- `describe_alarms_for_metric()`  
- `disable_alarm_actions()`  
- `enable_alarm_actions()`  
- `generate_presigned_url()`  
- `get_metric_statistics()`  
- `get_paginator()`  
- `get_waiter()`  
- `list_metrics()`  
- `put_metric_alarm()`  
- `put_metric_data()`  
- `set_alarm_state()`

**can_paginate**(operation_name)

Check if an operation can be paginated.
Parameters `operation_name (string)` – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)` if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

Returns `True` if the operation can be paginated, `False` otherwise.

delete_alarms (**kwargs)**

Deletes all specified alarms. In the event of an error, no alarms are deleted.

Request Syntax

```python
response = client.delete_alarms(
    AlarmNames=['string'],
)
```

Parameters `AlarmNames (list)` – [REQUIRED]

A list of alarms to be deleted.

- (string) –

Returns `None`

describe_alarm_history (**kwargs)**

Retrieves history for the specified alarm. Filter alarms by date range or item type. If an alarm name is not specified, Amazon CloudWatch returns histories for all of the owner’s alarms.

Request Syntax

```python
response = client.describe_alarm_history(
    AlarmName='string',
    HistoryItemType='ConfigurationUpdate'|'StateUpdate'|'Action',
    StartDate=datetime(2015, 1, 1),
    EndDate=datetime(2015, 1, 1),
    MaxRecords=123,
    NextToken='string'
)
```

Parameters

- `AlarmName (string)` – The name of the alarm.
- `HistoryItemType (string)` – The type of alarm histories to retrieve.
- `StartDate (datetime)` – The starting date to retrieve alarm history.
- `EndDate (datetime)` – The ending date to retrieve alarm history.
- `MaxRecords (integer)` – The maximum number of alarm history records to retrieve.
- `NextToken (string)` – The token returned by a previous call to indicate that there is more data available.

Returns `dict`

Response Syntax

```python
{
    'AlarmHistoryItems': [
        {
            'AlarmName': 'string',
            'Timestamp': datetime(2015, 1, 1),
        },
    ]
}
```
Response Structure

- (dict) –
  The output for the DescribeAlarmHistory action.
  - AlarmHistoryItems (list) –
    A list of alarm histories in JSON format.
      * (dict) –
        The AlarmHistoryItem data type contains descriptive information about the history of a specific alarm. If you call DescribeAlarmHistory, Amazon CloudWatch returns this data type as part of the DescribeAlarmHistoryResult data type.
          - AlarmName (string) –
            The descriptive name for the alarm.
          - Timestamp (datetime) –
            The time stamp for the alarm history item. Amazon CloudWatch uses Coordinated Universal Time (UTC) when returning time stamps, which do not accommodate seasonal adjustments such as daylight savings time. For more information, see Time stamps in the Amazon CloudWatch Developer Guide.
          - HistoryItemType (string) –
            The type of alarm history item.
          - HistorySummary (string) –
            A human-readable summary of the alarm history.
          - HistoryData (string) –
            Machine-readable data about the alarm in JSON format.
      - NextToken (string) –
        A string that marks the start of the next batch of returned results.

**describe_alarms(**kwargs**)

Retrieves alarms with the specified names. If no name is specified, all alarms for the user are returned. Alarms can be retrieved by using only a prefix for the alarm name, the alarm state, or a prefix for any action.

**Request Syntax**

```
response = client.describe_alarms(
    AlarmNames=[
        'string',
    ],
    AlarmNamePrefix='string',
    StateValue='OK'|'ALARM'|'INSUFFICIENT_DATA',
    ActionPrefix='string',
    MaxRecords=123,
)```
Parameters

- **AlarmNames** *(list)* – A list of alarm names to retrieve information for.
  - *(string)*
- **AlarmNamePrefix** *(string)* – The alarm name prefix. *AlarmNames* cannot be specified if this parameter is specified.
- **StateValue** *(string)* – The state value to be used in matching alarms.
- **ActionPrefix** *(string)* – The action name prefix.
- **MaxRecords** *(integer)* – The maximum number of alarm descriptions to retrieve.
- **NextToken** *(string)* – The token returned by a previous call to indicate that there is more data available.

Return type: dict

Returns

Response Syntax

```python
{
    'MetricAlarms': [
        {
            'AlarmName': 'string',
            'AlarmArn': 'string',
            'AlarmDescription': 'string',
            'AlarmConfigurationUpdatedTimestamp': datetime(2015, 1, 1),
            'ActionsEnabled': True|False,
            'OKActions': [
                'string',
            ],
            'AlarmActions': [
                'string',
            ],
            'InsufficientDataActions': [
                'string',
            ],
            'StateValue': 'OK'|'ALARM'|'INSUFFICIENT_DATA',
            'StateReason': 'string',
            'StateReasonData': 'string',
            'StateUpdatedTimestamp': datetime(2015, 1, 1),
            'MetricName': 'string',
            'Namespace': 'string',
            'Statistic': 'SampleCount'|'Average'|'Sum'|'Minimum'|'Maximum',
            'Dimensions': [
                {
                    'Name': 'string',
                    'Value': 'string'
                },
            ],
            'Period': 123,
            'Unit': 'Seconds'|'Microseconds'|'Milliseconds'|'Bytes'|'Kilobytes'|'Megabytes'|'Gigabytes'|'Terabytes'|'Counts'|'None',
            'EvaluationPeriods': 123,
            'Threshold': 123.0,
            'ComparisonOperator': 'GreaterThanOrEqualToThreshold'|'GreaterThanThreshold'|'LessThanThreshold'|'LessThanOrEqualToThreshold'
        },
    ],
    'NextToken': 'string'
}
```
Response Structure

- (dict) –

  The output for the DescribeAlarms action.

  - MetricAlarms (list) –

    A list of information for the specified alarms.

    * (dict) –

      The MetricAlarm data type represents an alarm. You can use Put-MetricAlarm to create or update an alarm.

      - AlarmName (string) –

        The name of the alarm.

      - AlarmArn (string) –

        The Amazon Resource Name (ARN) of the alarm.

      - AlarmDescription (string) –

        The description for the alarm.

      - AlarmConfigurationUpdatedTimestamp (datetime) –

        The time stamp of the last update to the alarm configuration. Amazon CloudWatch uses Coordinated Universal Time (UTC) when returning time stamps, which do not accommodate seasonal adjustments such as daylight savings time. For more information, see Time stamps in the Amazon CloudWatch Developer Guide.

      - ActionsEnabled (boolean) –

        Indicates whether actions should be executed during any changes to the alarm’s state.

      - OKActions (list) –

        The list of actions to execute when this alarm transitions into an OK state from any other state. Each action is specified as an Amazon Resource Number (ARN). Currently the only actions supported are publishing to an Amazon SNS topic and triggering an Auto Scaling policy.

      - (string) –

      - AlarmActions (list) –

        The list of actions to execute when this alarm transitions into an ALARM state from any other state. Each action is specified as an Amazon Resource Number (ARN). Currently the only actions supported are publishing to an Amazon SNS topic and triggering an Auto Scaling policy.

      - (string) –

      - InsufficientDataActions (list) –

        The list of actions to execute when this alarm transitions into an INSUFFICIENT_DATA state from any other state. Each action is specified as an Amazon Resource Number (ARN). Currently the only actions supported are publishing to an Amazon SNS topic or triggering an Auto Scaling policy.

      - (string) –

      Warning: The current WSDL lists this attribute as UnknownActions.
· **StateValue** *(string)* —
  The state value for the alarm.

· **StateReason** *(string)* —
  A human-readable explanation for the alarm’s state.

· **StateReasonData** *(string)* —
  An explanation for the alarm’s state in machine-readable JSON format

· **StateUpdatedTimestamp** *(datetime)* —
  The time stamp of the last update to the alarm’s state. Amazon CloudWatch uses Coordinated Universal Time (UTC) when returning time stamps, which do not accommodate seasonal adjustments such as daylight savings time. For more information, see Time stamps in the Amazon CloudWatch Developer Guide.

· **MetricName** *(string)* —
  The name of the alarm’s metric.

· **Namespace** *(string)* —
  The namespace of alarm’s associated metric.

· **Statistic** *(string)* —
  The statistic to apply to the alarm’s associated metric.

· **Dimensions** *(list)* —
  The list of dimensions associated with the alarm’s associated metric.

  · *(dict)* —
    The Dimension data type further expands on the identity of a metric using a Name, Value pair.

    For examples that use one or more dimensions, see PutMetricData.

· **Name** *(string)* —
  The name of the dimension.

· **Value** *(string)* —
  The value representing the dimension measurement.

· **Period** *(integer)* —
  The period in seconds over which the statistic is applied.

· **Unit** *(string)* —
  The unit of the alarm’s associated metric.

· **EvaluationPeriods** *(integer)* —
  The number of periods over which data is compared to the specified threshold.

· **Threshold** *(float)* —
  The value against which the specified statistic is compared.

· **ComparisonOperator** *(string)* —
  The arithmetic operation to use when comparing the specified Statistic and Threshold. The specified Statistic value is used as the first operand.
– **NextToken** (*string*) –

A string that marks the start of the next batch of returned results.

describe_alarms_for_metric(**kwargs)

Retrieves all alarms for a single metric. Specify a statistic, period, or unit to filter the set of alarms further.

**Request Syntax**

```python
response = client.describe_alarms_for_metric(
    MetricName='string',
    Namespace='string',
    Statistic='SampleCount'|'Average'|'Sum'|'Minimum'|'Maximum',
    Dimensions=[
        {
            'Name': 'string',
            'Value': 'string'
        },
    ],
    Period=123,
    Unit='Seconds'|'Microseconds'|'Milliseconds'|'Bytes'|'Kilobytes'|'Megabytes'|'Gigabytes'|'Terabytes'|'Bits'|'Kilobits'|'Megabits'|'Gigabits'|'Terabits'|'Count/Second'|'None'
)
```

**Parameters**

- **MetricName** (*string*) – [REQUIRED]
  
The name of the metric.

- **Namespace** (*string*) – [REQUIRED]
  
The namespace of the metric.

- **Statistic** (*string*) – The statistic for the metric.

- **Dimensions** (*list*) – The list of dimensions associated with the metric.
  
  - (*dict*) –

  The Dimension data type further expands on the identity of a metric using a Name, Value pair.

  For examples that use one or more dimensions, see PutMetricData .

  - **Name** (*string*) – [REQUIRED]
    
The name of the dimension.

  - **Value** (*string*) – [REQUIRED]
    
The value representing the dimension measurement

- **Period** (*integer*) – The period in seconds over which the statistic is applied.

- **Unit** (*string*) – The unit for the metric.

**Return type**  dict

**Returns**

**Response Syntax**

```python
{
    'MetricAlarms': [
        {
            'AlarmName': 'string',
            'AlarmArn': 'string',
            'AlarmDescription': 'string',
            'AlarmConfigurationUpdatedTimestamp': datetime(2015, 1, 1),
            'ActionsEnabled': True|False,
            'OKActions': [
```
Response Structure

* `(dict)` –

The output for the `DescribeAlarmsForMetric` action.

- **MetricAlarms** *(list)* –

  A list of information for each alarm with the specified metric.

  * `(dict)` –

  The MetricAlarm data type represents an alarm. You can use `PutMetricAlarm` to create or update an alarm.

  - **AlarmName** *(string)* –

    The name of the alarm.

  - **AlarmArn** *(string)* –

    The Amazon Resource Name (ARN) of the alarm.

  - **AlarmDescription** *(string)* –

    The description for the alarm.

  - **AlarmConfigurationUpdatedTimestamp** *(datetime)* –

    The time stamp of the last update to the alarm configuration. Amazon CloudWatch uses Coordinated Universal Time (UTC) when returning time stamps, which do not accommodate seasonal adjustments such as daylight savings time. For more information, see Time stamps in the Amazon CloudWatch Developer Guide.

  - **ActionsEnabled** *(boolean)* –
Indicates whether actions should be executed during any changes to the alarm’s state.

- **OKActions** *(list)* –
  The list of actions to execute when this alarm transitions into an **OK** state from any other state. Each action is specified as an Amazon Resource Number (ARN). Currently the only actions supported are publishing to an Amazon SNS topic and triggering an Auto Scaling policy.

- **AlarmActions** *(list)* –
  The list of actions to execute when this alarm transitions into an **ALARM** state from any other state. Each action is specified as an Amazon Resource Number (ARN). Currently the only actions supported are publishing to an Amazon SNS topic and triggering an Auto Scaling policy.

- **InsufficientDataActions** *(list)* –
  The list of actions to execute when this alarm transitions into an **INSUFFICIENT_DATA** state from any other state. Each action is specified as an Amazon Resource Number (ARN). Currently the only actions supported are publishing to an Amazon SNS topic or triggering an Auto Scaling policy.

**Warning:** The current WSDL lists this attribute as **UnknownActions**.

- **STATE** *(string)* –
  The state value for the alarm.

- **StateReason** *(string)* –
  A human-readable explanation for the alarm’s state.

- **StateReasonData** *(string)* –
  An explanation for the alarm’s state in machine-readable JSON format

- **StateUpdatedTimestamp** *(datetime)* –
  The time stamp of the last update to the alarm’s state. Amazon CloudWatch uses Coordinated Universal Time (UTC) when returning time stamps, which do not accommodate seasonal adjustments such as daylight savings time. For more information, see Time stamps in the Amazon CloudWatch Developer Guide.

- **MetricName** *(string)* –
  The name of the alarm’s metric.

- **Namespace** *(string)* –
  The namespace of alarm’s associated metric.

- **Statistic** *(string)* –
  The statistic to apply to the alarm’s associated metric.

- **Dimensions** *(list)* –
The list of dimensions associated with the alarm’s associated metric.

- (dict) –
  The Dimension data type further expands on the identity of a metric using a Name, Value pair.

For examples that use one or more dimensions, see PutMetricData.

- Name (string) –
  The name of the dimension.

- Value (string) –
  The value representing the dimension measurement

- Period (integer) –
  The period in seconds over which the statistic is applied.

- Unit (string) –
  The unit of the alarm’s associated metric.

- EvaluationPeriods (integer) –
  The number of periods over which data is compared to the specified threshold.

- Threshold (float) –
  The value against which the specified statistic is compared.

- ComparisonOperator (string) –
  The arithmetic operation to use when comparing the specified Statistic and Threshold. The specified Statistic value is used as the first operand.

**disable_alarm_actions(**kwargs)**
Disables actions for the specified alarms. When an alarm’s actions are disabled the alarm’s state may change, but none of the alarm’s actions will execute.

**Request Syntax**

```python
response = client.disable_alarm_actions(
    AlarmNames=[
        'string',
    ]
)
```

**Parameters**

- **AlarmNames (list)** – [REQUIRED]
  The names of the alarms to disable actions for.
  - (string) –

**Returns**

None

**enable_alarm_actions(**kwargs)**
Enables actions for the specified alarms.

**Request Syntax**

```python
response = client.enable_alarm_actions(
    AlarmNames=[
        'string',
    ]
)
```
Parameters  

**AlarmNames** (list) – [REQUIRED]

The names of the alarms to enable actions for.

- (string)

Returns  
None

**generate_presigned_url** *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

Parameters

- **ClientMethod** (string) – The client method to presign for
- **Params** (dict) – The parameters normally passed to **ClientMethod**.
- **ExpiresIn** (int) – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** (string) – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns  
The presigned url

**get_metric_statistics** (**kwargs**)

Gets statistics for the specified metric.

The maximum number of data points returned from a single **GetMetricStatistics** request is 1,440, whereas the maximum number of data points that can be queried is 50,850. If you make a request that generates more than 1,440 data points, Amazon CloudWatch returns an error. In such a case, you can alter the request by narrowing the specified time range or increasing the specified period. Alternatively, you can make multiple requests across adjacent time ranges.

Amazon CloudWatch aggregates data points based on the length of the **period** that you specify. For example, if you request statistics with a one-minute granularity, Amazon CloudWatch aggregates data points with time stamps that fall within the same one-minute period. In such a case, the data points queried can greatly outnumber the data points returned.

The following examples show various statistics allowed by the data point query maximum of 50,850 when you call **GetMetricStatistics** on Amazon EC2 instances with detailed (one-minute) monitoring enabled:

- Statistics for up to 400 instances for a span of one hour
- Statistics for up to 35 instances over a span of 24 hours
- Statistics for up to 2 instances over a span of 2 weeks

For information about the namespace, metric names, and dimensions that other Amazon Web Services products use to send metrics to Cloudwatch, go to Amazon CloudWatch Metrics, Namespaces, and Dimensions Reference in the Amazon CloudWatch Developer Guide.

Request Syntax

```python
response = client.get_metric_statistics(
    Namespace='string',
    MetricName='string',
    Dimensions=[],
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    Period=123,
)```

Statistics=[
    'SampleCount'|'Average'|'Sum'|'Minimum'|'Maximum',
],
Unit='Seconds'|'Microseconds'|'Milliseconds'|'Bytes'|'Kilobytes'|'Megabytes'|'Gigabytes'|'Terabytes'|'Bits'|'Kilobits'|'Megabits'|'Gigabits'|'Terabits'|'Count/Second'|'None'

Parameters

• **Namespace (string)** – [REQUIRED]
  The namespace of the metric, with or without spaces.

• **MetricName (string)** – [REQUIRED]
  The name of the metric, with or without spaces.

• **Dimensions (list)** – A list of dimensions describing qualities of the metric.
  - (dict) –
    The Dimension data type further expands on the identity of a metric using a Name, Value pair.
    
    For examples that use one or more dimensions, see PutMetricData.
    
    * **Name (string)** – [REQUIRED]
      The name of the dimension.
    
    * **Value (string)** – [REQUIRED]
      The value representing the dimension measurement

• **StartTime (datetime)** – [REQUIRED]
  The time stamp to use for determining the first datapoint to return. The value specified is inclusive; results include datapoints with the time stamp specified.

• **EndTime (datetime)** – [REQUIRED]
  The time stamp to use for determining the last datapoint to return. The value specified is exclusive; results will include datapoints up to the time stamp specified.

• **Period (integer)** – [REQUIRED]
  The granularity, in seconds, of the returned datapoints. Period must be at least 60 seconds and must be a multiple of 60. The default value is 60.

• **Statistics (list)** – [REQUIRED]
  The metric statistics to return. For information about specific statistics returned by GetMetricStatistics, go to Statistics in the Amazon CloudWatch Developer Guide.

Valid Values: Average | Sum | SampleCount | Maximum | Minimum
  - (string) –

• **Unit (string)** – The unit for the metric.

Return type  dict

Returns

Response Syntax

```json
{
    'Label': 'string',
    'Datapoints': [
        {
            'Timestamp': datetime(2015, 1, 1),
            'SampleCount': 123.0,
        }
    ]
}
```
Response Structure

- (dict) –
  The output for the GetMetricStatistics action.
  - Label (string) –
    A label describing the specified metric.
  - Datapoints (list) –
    The datapoints for the specified metric.
    - (dict) –
      The Datapoint data type encapsulates the statistical data that Amazon CloudWatch computes from metric data.
      - Timestamp (datetime) –
        The time stamp used for the datapoint. Amazon CloudWatch uses Coordinated Universal Time (UTC) when returning time stamps, which do not accommodate seasonal adjustments such as daylight savings time. For more information, see Time stamps in the Amazon CloudWatch Developer Guide.
      - SampleCount (float) –
        The number of metric values that contributed to the aggregate value of this datapoint.
      - Average (float) –
        The average of metric values that correspond to the datapoint.
      - Sum (float) –
        The sum of metric values used for the datapoint.
      - Minimum (float) –
        The minimum metric value used for the datapoint.
      - Maximum (float) –
        The maximum of the metric value used for the datapoint.
      - Unit (string) –
        The standard unit used for the datapoint.

get_paginator (operation_name)

Create a paginator for an operation.

Parameters operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

Raises OperationNotPageableError Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.
**get_waiter**(*waiter_name*)

**list_metrics**(**kwargs**)

Returns a list of valid metrics stored for the AWS account owner. Returned metrics can be used with GetMetricStatisticsto obtain statistical data for a given metric.

**Request Syntax**

```python
response = client.list_metrics(
    Namespace='string',
    MetricName='string',
    Dimensions=[
        {'Name': 'string',
         'Value': 'string'},
    ],
    NextToken='string'
)
```

**Parameters**

- **Namespace** (*string*) – The namespace to filter against.
- **MetricName** (*string*) – The name of the metric to filter against.
- **Dimensions** (*list*) – A list of dimensions to filter against.
  - *(dict)* – 

  The `DimensionFilter` data type is used to filter `ListMetrics` results.

    * **Name** (*string*) – [REQUIRED]
      
      The dimension name to be matched.
    
    * **Value** (*string*) –
      
      The value of the dimension to be matched.

- **NextToken** (*string*) – The token returned by a previous call to indicate that there is more data available.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Metrics': [
        {'Namespace': 'string',
         'MetricName': 'string',
         'Dimensions': [
             {'Name': 'string',
              'Value': 'string'},
           ],
        'NextToken': 'string'
    ]
}
```

**Response Structure**
• (dict) –
   The output for the ListMetrics action.
   – **Metrics** (list) –
     A list of metrics used to generate statistics for an AWS account.
      * (dict) –
       The Metric data type contains information about a specific metric.
       If you call ListMetrics, Amazon CloudWatch returns information contained by this data type.
       The example in the Examples section publishes two metrics named buffers and latency. Both metrics are in the examples namespace. Both metrics have two dimensions, InstanceID and InstanceType.
        · **Namespace** (string) –
          The namespace of the metric.
        · **MetricName** (string) –
          The name of the metric.
        · **Dimensions** (list) –
          A list of dimensions associated with the metric.
        · (dict) –
          The Dimension data type further expands on the identity of a metric using a Name, Value pair.
          For examples that use one or more dimensions, see PutMetricData.
        · **Name** (string) –
          The name of the dimension.
        · **Value** (string) –
          The value representing the dimension measurement
   – **NextToken** (string) –
     A string that marks the start of the next batch of returned results.

**put_metric_alarm(**kwargs)**

Creates or updates an alarm and associates it with the specified Amazon CloudWatch metric. Optionally, this operation can associate one or more Amazon Simple Notification Service resources with the alarm.

When this operation creates an alarm, the alarm state is immediately set to INSUFFICIENT_DATA. The alarm is evaluated and its StateValue is set appropriately. Any actions associated with the StateValue is then executed.

**Request Syntax**

```python
response = client.put_metric_alarm(
    AlarmName='string',
    AlarmDescription='string',
    ActionsEnabled=True|False,
    OKActions=[
        'string',
    ],
    AlarmActions=[
        'string',
    ],
    InsufficientDataActions=[
```

Boto3 Documentation, Release 1.1.4
Parameters

- **AlarmName** *(string)* – [REQUIRED]
  
  The descriptive name for the alarm. This name must be unique within the user’s AWS account.

- **AlarmDescription** *(string)* – The description for the alarm.

- **ActionsEnabled** *(boolean)* – Indicates whether or not actions should be executed during any changes to the alarm’s state.

- **OKActions** *(list)* – The list of actions to execute when this alarm transitions into an OK state from any other state. Each action is specified as an Amazon Resource Number (ARN). Currently the only action supported is publishing to an Amazon SNS topic or an Amazon Auto Scaling policy.
  
  - *(string)* –

- **AlarmActions** *(list)* – The list of actions to execute when this alarm transitions into an ALARM state from any other state. Each action is specified as an Amazon Resource Number (ARN). Currently the only action supported is publishing to an Amazon SNS topic or an Amazon Auto Scaling policy.
  
  - *(string)* –

- **InsufficientDataActions** *(list)* – The list of actions to execute when this alarm transitions into an INSUFFICIENT_DATA state from any other state. Each action is specified as an Amazon Resource Number (ARN). Currently the only action supported is publishing to an Amazon SNS topic or an Amazon Auto Scaling policy.
  
  - *(string)* –

- **MetricName** *(string)* – [REQUIRED]
  
  The name for the alarm’s associated metric.

- **Namespace** *(string)* – [REQUIRED]
  
  The namespace for the alarm’s associated metric.

- **Statistic** *(string)* – [REQUIRED]
  
  The statistic to apply to the alarm’s associated metric.

- **Dimensions** *(list)* – The dimensions for the alarm’s associated metric.
  
  - *(dict)* –
    
    The Dimension data type further expands on the identity of a metric using a Name, Value pair.
    
    For examples that use one or more dimensions, see PutMetricData.
put_metric_data(**kwargs)

Publishes metric data points to Amazon CloudWatch. Amazon CloudWatch associates the data points with the specified metric. If the specified metric does not exist, Amazon CloudWatch creates the metric. It can take up to fifteen minutes for a new metric to appear in calls to the ListMetrics action.

The size of a PutMetricData request is limited to 8 KB for HTTP GET requests and 40 KB for HTTP POST requests.

Warning: Although the Value parameter accepts numbers of type Double, Amazon CloudWatch truncates values with very large exponents. Values with base-10 exponents greater than 126 (1 x 10^126) are truncated. Likewise, values with base-10 exponents less than -130 (1 x 10^-130) are also truncated.

Data that is timestamped 24 hours or more in the past may take in excess of 48 hours to become available from submission time using GetMetricStatistics.

Request Syntax

```python
response = client.put_metric_data(
    Namespace='string',
    MetricData=[
        {
            'MetricName': 'string',
            'Dimensions': [
                {
                    'Name': 'string',
                    'Value': 'string'
                },
            ],
            'Timestamp': datetime(2015, 1, 1),
            'Value': 123.0,
            'StatisticValues': {
                'SampleCount': 123.0,
                'Sum': 123.0,
                'Minimum': 123.0,
                'Maximum': 123.0
            },
            'Unit': 'Seconds'|'Microseconds'|'Milliseconds'|'Bytes'|'Kilobytes'|'Megabytes'
        }
    ]
)
```
Parameters

- **Namespace** *(string)* – [REQUIRED]
  The namespace for the metric data.

- **MetricData** *(list)* – [REQUIRED]
  A list of data describing the metric.
  
  - *(dict)* –
    The **MetricDatum** data type encapsulates the information sent with PutMetricData to either create a new metric or add new values to be aggregated into an existing metric.
    
    - **MetricName** *(string)* – [REQUIRED]
      The name of the metric.
    
    - **Dimensions** *(list)* –
      A list of dimensions associated with the metric. Note, when using the Dimensions value in a query, you need to append .member.N to it (e.g., Dimensions.member.N).
      
      - *(dict)* –
        The **Dimension** data type further expands on the identity of a metric using a Name, Value pair.
        
        For examples that use one or more dimensions, see PutMetricData.
        
        - **Name** *(string)* – [REQUIRED]
          The name of the dimension.
        
        - **Value** *(string)* – [REQUIRED]
          The value representing the dimension measurement

    - **Timestamp** *(datetime)* –
      The time stamp used for the metric. If not specified, the default value is set to the time the metric data was received. Amazon CloudWatch uses Coordinated Universal Time (UTC) when returning time stamps, which do not accommodate seasonal adjustments such as daylight savings time. For more information, see Time stamps in the Amazon CloudWatch Developer Guide.
    
    - **Value** *(float)* –
      The value for the metric.

    **Warning:** Although the **Value** parameter accepts numbers of type **Double**, Amazon CloudWatch truncates values with very large exponents. Values with base-10 exponents greater than 126 (1 x 10^126) are truncated. Likewise, values with base-10 exponents less than -130 (1 x 10^-130) are also truncated.

    - **StatisticValues** *(dict)* –
      A set of statistical values describing the metric.
      
      - **SampleCount** *(float)* – [REQUIRED]
        The number of samples used for the statistic.
Returns None

set_alarm_state(**kwargs)
Temporarily sets the state of an alarm. When the updated StateValue differs from the previous value, the action configured for the appropriate state is invoked. This is not a permanent change. The next periodic alarm check (in about a minute) will set the alarm to its actual state.

Request Syntax

response = client.set_alarm_state(
    AlarmName='string',
    StateValue='OK'|'ALARM'|'INSUFFICIENT_DATA',
    StateReason='string',
    StateReasonData='string'
)

Parameters

• **AlarmName (string)** – [REQUIRED]
  The descriptive name for the alarm. This name must be unique within the user’s AWS account. The maximum length is 255 characters.

• **StateValue (string)** – [REQUIRED]
  The value of the state.

• **StateReason (string)** – [REQUIRED]
  The reason that this alarm is set to this specific state (in human-readable text format)

• **StateReasonData (string)** – The reason that this alarm is set to this specific state (in machine-readable JSON format)

Returns None

Paginators

The available paginators are:

• CloudWatch.Paginator.DescribeAlarmHistory
• CloudWatch.Paginator.DescribeAlarms
• CloudWatch.Paginator.ListMetrics

class CloudWatch.Paginator.DescribeAlarmHistory

    paginator = client.get_paginator('describe_alarm_history')
paginate(**kwargs)

Creates an iterator that will paginate through responses from
CloudWatch.Client.describe_alarm_history().

Request Syntax

```python
response_iterator = paginator.paginate(
    AlarmName='string',
    HistoryItemType='ConfigurationUpdate'|'StateUpdate'|'Action',
    StartDate=datetime(2015, 1, 1),
    EndDate=datetime(2015, 1, 1),
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **AlarmName**(string) – The name of the alarm.
- **HistoryItemType**(string) – The type of alarm histories to retrieve.
- **StartDate**(datetime) – The starting date to retrieve alarm history.
- **EndDate**(datetime) – The ending date to retrieve alarm history.
- **PaginationConfig**(dict) – A dictionary that provides parameters to control pagination.
  - **MaxItems**(integer) – The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize**(integer) – The size of each page.
  - **StartingToken**(string) – A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict  

Returns  

Response Syntax

```python
{}

  'AlarmHistoryItems': [  
    {  
      'AlarmName': 'string',
      'Timestamp': datetime(2015, 1, 1),
      'HistoryItemType': 'ConfigurationUpdate'|'StateUpdate'|'Action',
      'HistorySummary': 'string',
      'HistoryData': 'string'
    },
    ],
  }
```

Response Structure

- **(dict)** – The output for the DescribeAlarmHistory action.
– **AlarmHistoryItems (list)** –

A list of alarm histories in JSON format.

* (dict) –

The `AlarmHistoryItem` data type contains descriptive information about the history of a specific alarm. If you call DescribeAlarmHistory, Amazon CloudWatch returns this data type as part of the DescribeAlarmHistoryResult data type.

- **AlarmName (string)** –
  
The descriptive name for the alarm.

- **Timestamp (datetime)** –
  
The time stamp for the alarm history item. Amazon CloudWatch uses Coordinated Universal Time (UTC) when returning time stamps, which do not accommodate seasonal adjustments such as daylight savings time. For more information, see Time stamps in the Amazon CloudWatch Developer Guide.

- **HistoryItemType (string)** –
  
The type of alarm history item.

- **HistorySummary (string)** –
  
A human-readable summary of the alarm history.

- **HistoryData (string)** –
  
Machine-readable data about the alarm in JSON format.

```python
class CloudWatch.Paginator.DescribeAlarms

paginator = client.get_paginator('describe_alarms')

paginate(**kwargs)

Creates an iterator that will paginate through responses from CloudWatch.Client.describe_alarms().

Request Syntax

response_iterator = paginator.paginate(
    AlarmNames=[
        'string',
    ],
    AlarmNamePrefix='string',
    StateValue='OK'|'ALARM'|'INSUFFICIENT_DATA',
    ActionPrefix='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **AlarmNames (list)** – A list of alarm names to retrieve information for.
  
  - (string) –

- **AlarmNamePrefix (string)** – The alarm name prefix. `AlarmNames` cannot be specified if this parameter is specified.
• **StateValue** *(string)* – The state value to be used in matching alarms.
• **ActionPrefix** *(string)* – The action name prefix.
• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  - **MaxItems** *(integer)* – The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  
  - **PageSize** *(integer)* – The size of each page.
  
  - **StartingToken** *(string)* – A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'MetricAlarms': [
        {
            'AlarmName': 'string',
            'AlarmArn': 'string',
            'AlarmDescription': 'string',
            'AlarmConfigurationUpdatedTimestamp': datetime(2015, 1, 1),
            'ActionsEnabled': True|False,
            'OKActions': [
                'string',
            ],
            'AlarmActions': [
                'string',
            ],
            'InsufficientDataActions': [
                'string',
            ],
            'StateValue': 'OK'|'ALARM'|'INSUFFICIENT_DATA',
            'StateReason': 'string',
            'StateReasonData': 'string',
            'StateUpdatedTimestamp': datetime(2015, 1, 1),
            'MetricName': 'string',
            'Namespace': 'string',
            'Statistic': 'SampleCount'|'Average'|'Sum'|'Minimum'|'Maximum',
            'Dimensions': [
                {
                    'Name': 'string',
                    'Value': 'string',
                },
            ],
            'Period': 123,
            'Unit': 'Seconds'|'Microseconds'|'Milliseconds'|'Bytes'|'Kilobytes'|'Megabytes'|'Gigabytes'|'Terabytes'|'Count/Second'|'None',
            'EvaluationPeriods': 123,
            'Threshold': 123.0,
            'ComparisonOperator': 'GreaterThanThreshold'|'GreaterThanOrEqualToThreshold'|'LessThanThreshold'|'LessThanOrEqualToThreshold'
        },
    ],
}
```

3.1. Services 447
Response Structure

- *(dict)* –
  
  The output for the DescribeAlarms action.

  - **MetricAlarms** *(list)* –
    
    A list of information for the specified alarms.
    
    - *(dict)* –
      
      The MetricAlarm data type represents an alarm. You can use PutMetricAlarm to create or update an alarm.
      
      - **AlarmName** *(string)* –
        
        The name of the alarm.
      
      - **AlarmArn** *(string)* –
        
        The Amazon Resource Name (ARN) of the alarm.
      
      - **AlarmDescription** *(string)* –
        
        The description for the alarm.
      
      - **AlarmConfigurationUpdatedTimestamp** *(datetime)* –
        
        The time stamp of the last update to the alarm configuration. Amazon CloudWatch uses Coordinated Universal Time (UTC) when returning time stamps, which do not accommodate seasonal adjustments such as daylight savings time. For more information, see Time stamps in the Amazon CloudWatch Developer Guide .
      
      - **ActionsEnabled** *(boolean)* –
        
        Indicates whether actions should be executed during any changes to the alarm’s state.
      
      - **OKActions** *(list)* –
        
        The list of actions to execute when this alarm transitions into an OK state from any other state. Each action is specified as an Amazon Resource Number (ARN). Currently the only actions supported are publishing to an Amazon SNS topic and triggering an Auto Scaling policy.
      
      - *(string)* –
      
      - **AlarmActions** *(list)* –
        
        The list of actions to execute when this alarm transitions into an ALARM state from any other state. Each action is specified as an Amazon Resource Number (ARN). Currently the only actions supported are publishing to an Amazon SNS topic and triggering an Auto Scaling policy.
      
      - *(string)* –
      
      - **InsufficientDataActions** *(list)* –
        
        The list of actions to execute when this alarm transitions into an INSUFFICIENT_DATA state from any other state. Each action is specified as an Amazon Resource Number (ARN). Currently the only actions supported are publishing to an Amazon SNS topic or triggering an Auto Scaling policy.
Warning: The current WSDL lists this attribute as UnknownActions.

- **(string)** –
- **StateValue (string)** –
  The state value for the alarm.
- **StateReason (string)** –
  A human-readable explanation for the alarm’s state.
- **StateReasonData (string)** –
  An explanation for the alarm’s state in machine-readable JSON format
- **StateUpdatedTimestamp (datetime)** –
  The time stamp of the last update to the alarm’s state. Amazon CloudWatch uses Coordinated Universal Time (UTC) when returning time stamps, which do not accommodate seasonal adjustments such as daylight savings time. For more information, see Time stamps in the Amazon CloudWatch Developer Guide.
- **MetricName (string)** –
  The name of the alarm’s metric.
- **Namespace (string)** –
  The namespace of alarm’s associated metric.
- **Statistic (string)** –
  The statistic to apply to the alarm’s associated metric.
- **Dimensions (list)** –
  The list of dimensions associated with the alarm’s associated metric.
- **(dict)** –
  The Dimension data type further expands on the identity of a metric using a Name, Value pair.
  For examples that use one or more dimensions, see PutMetricData.
- **Name (string)** –
  The name of the dimension.
- **Value (string)** –
  The value representing the dimension measurement
- **Period (integer)** –
  The period in seconds over which the statistic is applied.
- **Unit (string)** –
  The unit of the alarm’s associated metric.
- **EvaluationPeriods (integer)** –
  The number of periods over which data is compared to the specified threshold.
- **Threshold (float)** –
  The value against which the specified statistic is compared.
ComparisonOperator (string) –

The arithmetic operation to use when comparing the specified Statistic and Threshold. The specified Statistic value is used as the first operand.

class CloudWatch.Paginator.ListMetrics

paginator = client.get_paginator('list_metrics')

paginate(**kwargs)

Creates an iterator that will paginate through responses from CloudWatch.Client.list_metrics().

Request Syntax

response_iterator = paginator.paginate(
    Namespace='string',
    MetricName='string',
    Dimensions=[
        {'Name': 'string',
        'Value': 'string'}
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- Namespace (string) – The namespace to filter against.
- MetricName (string) – The name of the metric to filter against.
- Dimensions (list) – A list of dimensions to filter against.
  - (dict) –
    The DimensionFilter data type is used to filter ListMetrics results.
    - Name (string) – [REQUIRED]
      The dimension name to be matched.
    - Value (string) –
      The value of the dimension to be matched.
- PaginationConfig (dict) – A dictionary that provides parameters to control pagination.
  - MaxItems (integer) –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - PageSize (integer) –
    The size of each page.
  - StartingToken (string) –
    A token to specify where to start paginating. This is the NextToken from a previous response.
Return type  dict

Returns

Response Syntax

```python
{
  'Metrics': [
    {
      'Namespace': 'string',
      'MetricName': 'string',
      'Dimensions': [
        {
          'Name': 'string',
          'Value': 'string'
        }
      ]
    },
    ...
  ]
}
```

Response Structure

- *(dict)* –
  The output for the ListMetrics action.
  - **Metrics** *(list)* –
    A list of metrics used to generate statistics for an AWS account.
    - *(dict)* –
      The `Metric` data type contains information about a specific metric.
      If you call `ListMetrics`, Amazon CloudWatch returns information contained by this data type.
      
      The example in the Examples section publishes two metrics named buffers and latency. Both metrics are in the examples namespace. Both metrics have two dimensions, InstanceID and InstanceType.
      - **Namespace** *(string)* –
        The namespace of the metric.
      - **MetricName** *(string)* –
        The name of the metric.
      - **Dimensions** *(list)* –
        A list of dimensions associated with the metric.
      - *(dict)* –
        The `Dimension` data type further expands on the identity of a metric using a Name, Value pair.

      For examples that use one or more dimensions, see `PutMetricData`.
      - **Name** *(string)* –
        The name of the dimension.
      - **Value** *(string)* –
        The value representing the dimension measurement
Client

class CodeCommit.Client
    A low-level client representing AWS CodeCommit:

        import boto3

        client = boto3.client('codecommit')

    These are the available methods:
        • batch_get_repositories()
        • can_paginate()
        • create_branch()
        • create_repository()
        • delete_repository()
        • generate_presigned_url()
        • get_branch()
        • get_paginators()
        • get_repository()
        • get_waiter()
        • list_branches()
        • list.repositories()
        • update_default_branch()
        • update_repository_description()
        • update_repository_name()

    batch_get_repositories(**kwargs)
        Gets information about one or more repositories.

        Note: The description field for a repository accepts all HTML characters and all valid Unicode characters. Applications that do not HTML-encode the description and display it in a web page could expose users to potentially malicious code. Make sure that you HTML-encode the description field in any application that uses this API to display the repository description on a web page.

        Request Syntax

            response = client.batch_get_repositories(
                repositoryNames=[
                    'string',
                ]
            )

        Parameters  repositoryNames (list) – [REQUIRED]
            The names of the repositories to get information about.
• (string) – Repository name is restricted to alphanumeric characters (a-z, A-Z, 0-9), ".", "_", and "-". Additionally, the suffix ".git" is prohibited in a repository name.

Return type  dict

Returns

Response Syntax

```
{
    'repositories': [
        {
            'accountId': 'string',
            'repositoryId': 'string',
            'repositoryName': 'string',
            'repositoryDescription': 'string',
            'defaultBranch': 'string',
            'lastModifiedDate': datetime(2015, 1, 1),
            'creationDate': datetime(2015, 1, 1),
            'cloneUrlHttp': 'string',
            'cloneUrlSsh': 'string',
            'Arn': 'string'
        },
    ],
    'repositoriesNotFound': [
        'string',
    ]
}
```

Response Structure

* (dict) –

Represents the output of a batch get repositories operation.

- repositories (list) –

A list of repositories returned by the batch get repositories operation.

* (dict) –

Information about a repository.

- accountId (string) –

The ID of the AWS account associated with the repository.

- repositoryId (string) –

The ID of the repository.

- repositoryName (string) –

The repository’s name.

- repositoryDescription (string) –

A comment or description about the repository.

- defaultBranch (string) –

The repository’s default branch name.

- lastModifiedDate (datetime) –

The date and time the repository was last modified, in timestamp format.

- creationDate (datetime) –

The date and time the repository was created, in timestamp format.
The URL to use for cloning the repository over HTTPS.
- **cloneUrlSsh** *(string)*
  The URL to use for cloning the repository over SSH.
- **Arn** *(string)*
  The Amazon Resource Name (ARN) of the repository.

- **repositoriesNotFound** *(list)*
  Returns a list of repository names for which information could not be found.
  *
  *(string)* – Repository name is restricted to alphanumeric characters *(a-z, A-Z, 0-9), ".", ".", and "."*. Additionally, the suffix ".git" is prohibited in a repository name.

### can_paginate *(operation_name)*
Check if an operation can be paginated.

**Parameters**
- **operation_name** *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you'd normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

**Returns**
- True if the operation can be paginated, False otherwise.

### create_branch (**kwargs**)
Creates a new branch in a repository and points the branch to a commit.

**Note:** Calling the create branch operation does not set a repository’s default branch. To do this, call the update default branch operation.

**Request Syntax**

```python
response = client.create_branch(
    repositoryName='string',
    branchName='string',
    commitId='string'
)
```

**Parameters**

- **repositoryName** *(string)* – [REQUIRED]
  The name of the repository in which you want to create the new branch.

- **branchName** *(string)* – [REQUIRED]
  The name of the new branch to create.

- **commitId** *(string)* – [REQUIRED]
  The ID of the commit to point the new branch to.

**Note:** If this commit ID is not specified, the new branch will point to the commit that is pointed to by the repository’s default branch.

**Returns**
- None

### create_repository (**kwargs**)
Creates a new, empty repository.

**Request Syntax**
response = client.create_repository(
    repositoryName='string',
    repositoryDescription='string'
)

Parameters
  • repositoryName (string) – [REQUIRED]
    The name of the new repository to be created.
  • repositoryDescription (string) – A comment or description about the new repository.

Return type  dict

Returns

Response Syntax

```python
{
    'repositoryMetadata': {
        'accountId': 'string',
        'repositoryId': 'string',
        'repositoryName': 'string',
        'repositoryDescription': 'string',
        'defaultBranch': 'string',
        'lastModifiedDate': datetime(2015, 1, 1),
        'creationDate': datetime(2015, 1, 1),
        'cloneUrlHttp': 'string',
        'cloneUrlSsh': 'string',
        'Arn': 'string'
    }
}
```

Response Structure

• (dict) –

  Represents the output of a create repository operation.
  – repositoryMetadata (dict) –
    Information about the newly created repository.
      • accountId (string) –
        The ID of the AWS account associated with the repository.
      • repositoryId (string) –
        The ID of the repository.
      • repositoryName (string) –
        The repository's name.
      • repositoryDescription (string) –
        A comment or description about the repository.
      • defaultBranch (string) –
        The repository’s default branch name.
      • lastModifiedDate (datetime) –

Note: The repository name must be unique across the calling AWS account. In addition, repository names are restricted to alphanumeric characters. The suffix ".git" is prohibited.
The date and time the repository was last modified, in timestamp format.
* `creationDate (datetime)` –

The date and time the repository was created, in timestamp format.
* `cloneUrlHttp (string)` –

The URL to use for cloning the repository over HTTPS.
* `cloneUrlSsh (string)` –

The URL to use for cloning the repository over SSH.
* `Arn (string)` –

The Amazon Resource Name (ARN) of the repository.

**delete_repository (**kwargs)**

Deletes a repository. If a specified repository was already deleted, a null repository ID will be returned.

**Warning:** Deleting a repository also deletes all associated objects and metadata. After a repository is deleted, all future push calls to the deleted repository will fail.

**Request Syntax**

```python
response = client.delete_repository(
    repositoryName='string'
)
```

**Parameters**

- **repositoryName (string)** – [REQUIRED]

  The name of the repository to delete.

**Return type**

dict

**Returns**

**Response Syntax**

```python
{
    'repositoryId': 'string'
}
```

**Response Structure**

- **(dict)** –

  Represents the output of a delete repository operation.

  - **repositoryId (string)** –

    The ID of the repository that was deleted.

**generate_presigned_url (ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)**

Generate a presigned url given a client, its method, and arguments

**Parameters**

- **ClientMethod (string)** – The client method to presign for
- **Params (dict)** – The parameters normally passed to `ClientMethod`.
- **ExpiresIn (int)** – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod (string)** – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns**

The presigned url
get_branch(**kwargs)
Retrieves information about a repository branch, including its name and the last commit ID.

Request Syntax

response = client.get_branch(
    repositoryName='string',
    branchName='string'
)

Parameters
- repositoryName (string) – Repository name is restricted to alphanumeric characters (a-z, A-Z, 0-9), ",", ",", and ",". Additionally, the suffix ",.git" is prohibited in a repository name.
- branchName (string) – The name of the branch for which you want to retrieve information.

Return type dict

Returns

Response Syntax

{
    'branch': {
        'branchName': 'string',
        'commitId': 'string'
    }
}

Response Structure
- (dict) – Represents the output of a get branch operation.
  - branch (dict) –
    The name of the branch.
      * branchName (string) –
        The name of the branch.
      * commitId (string) –
        The ID of the last commit made to the branch.

getPaginator(operation_name)
Create a paginator for an operation.

Parameters operation_name (string) – The operation name. This is the same name as
the method name on the client. For example, if the method name is create_foo,
you’d normally invoke the operation as client.create_foo(**kwargs),
if the create_foo operation can be paginated, you can use the call
client.get_paginate("create_foo").

Raises OperationNotPageableError Raised if the operation is not pageable. You can use
the client.can_paginate method to check if an operation is pageable.

Return type L{botocorepaginate.Paginator}

Returns A paginator object.

getRepository(**kwargs)
Gets information about a repository.

Note: The description field for a repository accepts all HTML characters and all valid Unicode characters.
Applications that do not HTML-encode the description and display it in a web page could expose users
to potentially malicious code. Make sure that you HTML-encode the description field in any application that uses this API to display the repository description on a web page.

**Request Syntax**

```python
response = client.get_repository(
    repositoryName='string'
)
```

**Parameters**  
repositoryName *(string)* – [REQUIRED]

The name of the repository to get information about.

**Return type**  
dict

**Returns**

**Response Syntax**

```json
{
    'repositoryMetadata': {
        'accountId': 'string',
        'repositoryId': 'string',
        'repositoryName': 'string',
        'repositoryDescription': 'string',
        'defaultBranch': 'string',
        'lastModifiedDate': datetime(2015, 1, 1),
        'creationDate': datetime(2015, 1, 1),
        'cloneUrlHttp': 'string',
        'cloneUrlSsh': 'string',
        'Arn': 'string'
    }
}
```

**Response Structure**

- *(dict)* –  

  Represents the output of a get repository operation.

- **repositoryMetadata**(dict) –  

  Information about the repository.

  - **accountId**(string) –  

    The ID of the AWS account associated with the repository.

  - **repositoryId**(string) –  

    The ID of the repository.

  - **repositoryName**(string) –  

    The repository’s name.

  - **repositoryDescription**(string) –  

    A comment or description about the repository.

  - **defaultBranch**(string) –  

    The repository’s default branch name.

  - **lastModifiedDate**(datetime) –  

    The date and time the repository was last modified, in timestamp format.

  - **creationDate**(datetime) –  

    The date and time the repository was created, in timestamp format.
cloneUrlHttp (string) –
The URL to use for cloning the repository over HTTPS.
cloneUrlSsh (string) –
The URL to use for cloning the repository over SSH.
Arn (string) –
The Amazon Resource Name (ARN) of the repository.

get_waiter (waiter_name)
list_branches (**kwargs)
  Gets information about one or more branches in a repository.

Request Syntax

```python
response = client.list_branches(
    repositoryName='string',
    nextToken='string'
)
```

Parameters

• repositoryName (string) – [REQUIRED]
The name of the repository that contains the branches.
• nextToken (string) – An enumeration token that allows the operation to batch the results.

Returns

Response Syntax

```json
{
    'branches': [ 'string',
    'string',
    'nextToken': 'string'
}
```

Response Structure

• (dict) –
  Represents the output of a list branches operation.
  • branches (list) –
    The list of branch names.
    • (string) –
      • nextToken (string) –
        An enumeration token that returns the batch of the results.

list_repositories (**kwargs)
  Gets information about one or more repositories.

Request Syntax

```python
response = client.list_repositories(
    nextToken='string',
    sortBy='repositoryName'|'lastModifiedDate',
```
Parameters

- **nextToken** *(string)* – An enumeration token that allows the operation to batch the results of the operation. Batch sizes are 1,000 for list repository operations. When the client sends the token back to AWS CodeCommit, another page of 1,000 records is retrieved.

- **sortBy** *(string)* – The criteria used to sort the results of a list repositories operation.

- **order** *(string)* – The order in which to sort the results of a list repositories operation.

Return type  **dict**

Returns

Response Syntax

```python
{
    'repositories': [
        {
            'repositoryName': 'string',
            'repositoryId': 'string'
        },
        
        'nextToken': 'string'
    ]
}
```

Response Structure

- *(dict)* – Represents the output of a list repositories operation.

  - **repositories** *(list)* – Lists the repositories called by the list repositories operation.

    - *(dict)* – Information about a repository name and ID.

      - **repositoryName** *(string)* – Repository name is restricted to alphanumeric characters (a-z, A-Z, 0-9), ",", ",", and ",". Additionally, the suffix ",.git" is prohibited in a repository name.

      - **repositoryId** *(string)* – The ID associated with the repository name.

    - **nextToken** *(string)* – An enumeration token that allows the operation to batch the results of the operation. Batch sizes are 1,000 for list repository operations. When the client sends the token back to AWS CodeCommit, another page of 1,000 records is retrieved.

`update_default_branch(**kwargs)`

Sets or changes the default branch name for the specified repository.

**Note:** If you use this operation to change the default branch name to the current default branch name, a success message is returned even though the default branch did not change.

Request Syntax
response = client.update_default_branch(
    repositoryName='string',
    defaultBranchName='string'
)

Parameters

- repositoryName (string) – [REQUIRED]
  The name of the repository to set or change the default branch for.
- defaultBranchName (string) – [REQUIRED]
  The name of the branch to set as the default.

Returns  None

update_repository_description(**kwargs)

Sets or changes the comment or description for a repository.

Note: The description field for a repository accepts all HTML characters and all valid Unicode characters. Applications that do not HTML-encode the description and display it in a web page could expose users to potentially malicious code. Make sure that you HTML-encode the description field in any application that uses this API to display the repository description on a web page.

Request Syntax

response = client.update_repository_description(
    repositoryName='string',
    repositoryDescription='string'
)

Parameters

- repositoryName (string) – [REQUIRED]
  The name of the repository to set or change the comment or description for.
- repositoryDescription (string) – The new comment or description for the specified repository.

Returns  None

update_repository_name(**kwargs)

 Renames a repository.

Request Syntax

response = client.update_repository_name(
    oldName='string',
    newName='string'
)

Parameters

- oldName (string) – [REQUIRED] Repository name is restricted to alphanumeric characters (a-z, A-Z, 0-9), ".", ",", and ".". Additionally, the suffix ".git" is prohibited in a repository name.
- newName (string) – [REQUIRED] Repository name is restricted to alphanumeric characters (a-z, A-Z, 0-9), ".", ",", and ".". Additionally, the suffix ".git" is prohibited in a repository name.

Returns  None
CodeDeploy

class CodeDeploy.Client

A low-level client representing AWS CodeDeploy:

```python
import boto3

client = boto3.client('codedeploy')
```

These are the available methods:

- `add_tags_to_on_premises_instances()`
- `batch_get_applications()`
- `batch_get_deployments()`
- `batch_get_on_premises_instances()`
- `can_paginate()`
- `create_application()`
- `create_deployment()`
- `create_deployment_config()`
- `create_deployment_group()`
- `delete_application()`
- `delete_deployment_config()`
- `delete_deployment_group()`
- `deregister_on_premises_instance()`
- `generate_presigned_url()`
- `get_application()`
- `get_application_revision()`
- `get_deployment()`
- `get_deployment_config()`
- `get_deployment_group()`
- `get_deployment_instance()`
- `get_on_premises_instance()`
- `getaginator()`
- `get_waiter()`
- `list_application_revisions()`
- `list_applications()`
- `list_deployment_configs()`
- `list_deployment_groups()`
- `list_deployment_instances()`
- `list_deployments()`
- `list_on_premises_instances()`
- `register_application_revision()`
- `register_on_premises_instance()`
- `remove_tags_from_on_premises_instances()`
- `stop_deployment()`
- `update_application()`
• **update_deployment_group()**
  add_tags_to_on_premises_instances (**kwargs)**
  Adds tags to on-premises instances.

**Request Syntax**

```python
response = client.add_tags_to_on_premises_instances(
    tags=[
    {'Key': 'string',
     'Value': 'string'
    },
    ],
    instanceNames=[
    'string',
    ]
)
```

**Parameters**

- **tags (list)** – [REQUIRED]
  The tag key-value pairs to add to the on-premises instances.
  Keys and values are both required. Keys cannot be nulls or empty strings. Value-only tags are not allowed.
  - (dict) –
    Information about a tag.
    * **Key (string)** –
      The tag’s key.
    * **Value (string)** –
      The tag’s value.

- **instanceNames (list)** – [REQUIRED]
  The names of the on-premises instances to add tags to.
  - (string) –

**Returns** None

**batch_get_applications (**kwargs**)**

Gets information about one or more applications.

**Request Syntax**

```python
response = client.batch_get_applications(
    applicationNames=[
    'string',
    ]
)
```

**Parameters** **applicationNames (list)** – A list of application names, with multiple application names separated by spaces.
  - (string) –

**Return type** dict

**Returns**

**Response Syntax**
Response Structure

- (dict) – Represents the output of a batch get applications operation.
  - applicationsInfo (list) – Information about the applications.
    * (dict) – Information about an application.
      - applicationId (string) – The application ID.
      - applicationName (string) – The application name.
      - createTime (datetime) – The time that the application was created.
      - linkedToGitHub (boolean) – True if the user has authenticated with GitHub for the specified application; otherwise, false.

batch_get_deployments (**kwargs)

Gets information about one or more deployments.

Request Syntax

```python
response = client.batch_get_deployments(
    deploymentIds=['string',
                   'string'],
)
```

Parameters deploymentIds (list) – A list of deployment IDs, with multiple deployment IDs separated by spaces.

Return type dict

Returns

Response Syntax

```python
{
    'deploymentsInfo': [
        {
            'applicationName': 'string',
            'deploymentGroupName': 'string',
            'deploymentConfigName': 'string',
            'deploymentId': 'string',
            'applicationId': 'string',
            'createTime': datetime(2015, 1, 1),
            'linkedToGitHub': True|False
        },
    ],
}
```
'deploymentId': 'string',
'revision': {
    'revisionType': 'S3'|'GitHub',
    's3Location': {
        'bucket': 'string',
        'key': 'string',
        'bundleType': 'tar'|'tgz'|'zip',
        'version': 'string',
        'eTag': 'string'
    },
    'gitHubLocation': {
        'repository': 'string',
        'commitId': 'string'
    }
},
'status': 'Created'|'Queued'|'InProgress'|'Succeeded'|'Failed'|'Stopped',
'errorInformation': {
    'code': 'DEPLOYMENT_GROUP_MISSING'|'APPLICATION_MISSING'|'REVISION_MISSING',
    'message': 'string'
},
'createTime': datetime(2015, 1, 1),
'startTime': datetime(2015, 1, 1),
'completeTime': datetime(2015, 1, 1),
'deploymentOverview': {
    'Pending': 123,
    'InProgress': 123,
    'Succeeded': 123,
    'Failed': 123,
    'Skipped': 123
},
'description': 'string',
'creator': 'user'|'autoscaling',
'ignoreApplicationStopFailures': True|False

Response Structure

• (dict) –

    Represents the output of a batch get deployments operation.

    – deploymentsInfo (list) –

        Information about the deployments.

        * (dict) –

            Information about a deployment.

            • applicationName (string) –

                The application name.

            • deploymentGroupName (string) –

                The deployment group name.

            • deploymentConfigName (string) –

                The deployment configuration name.

            • deploymentId (string) –

                The deployment ID.

            • revision (dict) –

3.1. Services
Information about the location of application artifacts that are stored and the service to retrieve them from.

- **revisionType** *(string)* –
  
The application revision’s type:
  
- S3: An application revision stored in Amazon S3.
- GitHub: An application revision stored in GitHub.

- **s3Location** *(dict)* –
  
Information about the location of application artifacts that are stored in Amazon S3.

- **bucket** *(string)* –
  
The name of the Amazon S3 bucket where the application revision is stored.

- **key** *(string)* –
  
The name of the Amazon S3 object that represents the bundled artifacts for the application revision.

- **bundleType** *(string)* –
  
The file type of the application revision. Must be one of the following:
  
- tar: A tar archive file.
- tgz: A compressed tar archive file.

- **version** *(string)* –
  
A specific version of the Amazon S3 object that represents the bundled artifacts for the application revision.

If the version is not specified, the system will use the most recent version by default.

- **eTag** *(string)* –
  
The ETag of the Amazon S3 object that represents the bundled artifacts for the application revision.

If the ETag is not specified as an input parameter, ETag validation of the object will be skipped.

- **githubLocation** *(dict)* –
  
Information about the location of application artifacts that are stored in GitHub.

- **repository** *(string)* –
  
The GitHub account and repository pair that stores a reference to the commit that represents the bundled artifacts for the application revision.

Specified as account/repository.

- **commitId** *(string)* –
  
The SHA1 commit ID of the GitHub commit that references the that represents the bundled artifacts for the application revision.

- **status** *(string)* –
  
The current state of the deployment as a whole.

- **errorInformation** *(dict)* –
Information about any error associated with this deployment.

- **code (string)** –
  The error code:
  - APPLICATION_MISSING: The application was missing. Note that this error code will most likely be raised if the application is deleted after the deployment is created but before it starts.
  - DEPLOYMENT_GROUP_MISSING: The deployment group was missing. Note that this error code will most likely be raised if the deployment group is deleted after the deployment is created but before it starts.
  - HEALTH_CONSTRAINTS: The deployment failed on too many instances to be able to successfully deploy within the specified instance health constraints.
  - HEALTH_CONSTRAINTS_INVALID: The revision can never successfully deploy within the instance health constraints as specified.
  - IAM_ROLE_MISSING: The service role cannot be accessed.
  - IAM_ROLE_PERMISSIONS: The service role does not have the correct permissions.
  - INTERNAL_ERROR: There was an internal error.
  - NO_EC2_SUBSCRIPTION: The calling account is not subscribed to the Amazon EC2 service.
  - NO_INSTANCES: No instances were specified, or no instances can be found.
  - OVER_MAX_INSTANCES: The maximum number of instances was exceeded.
  - THROTTLLED: The operation was throttled because the calling account exceeded the throttling limits of one or more AWS services.
  - TIMEOUT: The deployment has timed out.
  - REVISION_MISSING: The revision ID was missing. Note that this error code will most likely be raised if the revision is deleted after the deployment is created but before it starts.

- **message (string)** –
  An accompanying error message.

- **createTime (datetime)** –
  A timestamp indicating when the deployment was created.

- **startTime (datetime)** –
  A timestamp indicating when the deployment began deploying to the deployment group.

  Note that in some cases, the reported value of the start time may be later than the complete time. This is due to differences in the clock settings of various back-end servers that participate in the overall deployment process.

- **completeTime (datetime)** –
  A timestamp indicating when the deployment was completed.

- **deploymentOverview (dict)** –
  A summary of the deployment status of the instances in the deployment.
- **Pending (integer)** – The number of instances that are pending in the deployment.
- **InProgress (integer)** – The number of instances that are in progress in the deployment.
- **Succeeded (integer)** – The number of instances that have succeeded in the deployment.
- **Failed (integer)** – The number of instances that have failed in the deployment.
- **Skipped (integer)** – The number of instances that have been skipped in the deployment.
- **description (string)** – A comment about the deployment.
- **creator (string)** – How the deployment was created:
  - user: A user created the deployment.
  - autoscaling: Auto Scaling created the deployment.
- **ignoreApplicationStopFailures (boolean)** – If true, then if the deployment causes the ApplicationStop deployment lifecycle event to fail to a specific instance, the deployment will not be considered to have failed to that instance at that point and will continue on to the BeforeInstall deployment lifecycle event.

If false or not specified, then if the deployment causes the ApplicationStop deployment lifecycle event to fail to a specific instance, the deployment will stop to that instance, and the deployment to that instance will be considered to have failed.

### batch_get_on_premises_instances (**kwargs)**

Gets information about one or more on-premises instances.

**Request Syntax**

```python
response = client.batch_get_on_premises_instances(
    instanceNames=[
        'string',
    ]
)
```

**Parameters**  
**instanceNames (list)** – The names of the on-premises instances to get information about.
- **(string)** –

**Return type**  
**dict**

**Returns**

**Response Syntax**

```python
{
    'instanceInfos': [
```
Response Structure

- *(dict)* – Represents the output of a batch get on-premises instances operation.
  - **instanceInfos** *(list)* – Information about the on-premises instances.
    - *(dict)* – Information about an on-premises instance.
      - **instanceName** *(string)* – The name of the on-premises instance.
      - **iamUserArn** *(string)* – The IAM user ARN associated with the on-premises instance.
      - **instanceArn** *(string)* – The ARN of the on-premises instance.
      - **registerTime** *(datetime)* – The time that the on-premises instance was registered.
      - **deregisterTime** *(datetime)* – If the on-premises instance was deregistered, the time that the on-premises instance was deregistered.
      - **tags** *(list)* – The tags that are currently associated with the on-premises instance.
        - *(dict)* – Information about a tag.
          - **Key** *(string)* – The tag’s key.
          - **Value** *(string)* – The tag’s value.

**can_paginate** *(operation_name)*

Check if an operation can be paginated.

**Parameters**

- **operation_name** *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs),`
if the `create_foo` operation can be paginated, you can use the call
client.get_paginator("create_foo").

Returns True if the operation can be paginated, False otherwise.

`create_application(**kwargs)`
Creates a new application.

Request Syntax

```python
response = client.create_application(
    applicationName='string'
)
```

Parameters

- `applicationName (string)` – [REQUIRED]
  The name of the application. This name must be unique with the applicable IAM user or AWS account.

Return type
dict

Returns

Response Syntax

```json
{
    'applicationId': 'string'
}
```

Response Structure

- (dict) – Represents the output of a create application operation.
  - `applicationId (string)` – A unique application ID.

`create_deployment(**kwargs)`
Deploys an application revision through the specified deployment group.

Request Syntax

```python
response = client.create_deployment(
    applicationName='string',
    deploymentGroupName='string',
    revision={
        'revisionType': 'S3'|'GitHub',
        's3Location': {
            'bucket': 'string',
            'key': 'string',
            'bundleType': 'tar'|'tgz'|'zip',
            'version': 'string',
            'eTag': 'string'
        },
        'gitHubLocation': {
            'repository': 'string',
            'commitId': 'string'
        }
    },
    deploymentConfigName='string',
    description='string',
    ignoreApplicationStopFailures=True|False
)
```
Parameters

- **applicationName** *(string)* – [REQUIRED]
  
  The name of an existing AWS CodeDeploy application associated with the applicable IAM user or AWS account.

- **deploymentGroupName** *(string)* – The deployment group’s name.

- **revision** *(dict)* – The type of revision to deploy, along with information about the revision’s location.
  
  - **revisionType** *(string)* –
    
    The application revision’s type:
    
    * S3: An application revision stored in Amazon S3.
    * GitHub: An application revision stored in GitHub.

  - **s3Location** *(dict)* –
    
    Information about the location of application artifacts that are stored in Amazon S3.
    
    * **bucket** *(string)* –
      
      The name of the Amazon S3 bucket where the application revision is stored.
    
    * **key** *(string)* –
      
      The name of the Amazon S3 object that represents the bundled artifacts for the application revision.
    
    * **bundleType** *(string)* –
      
      The file type of the application revision. Must be one of the following:
      
      - tar: A tar archive file.
      - tgz: A compressed tar archive file.
    
    * **version** *(string)* –
      
      A specific version of the Amazon S3 object that represents the bundled artifacts for the application revision.
      
      If the version is not specified, the system will use the most recent version by default.
    
    * **eTag** *(string)* –
      
      The ETag of the Amazon S3 object that represents the bundled artifacts for the application revision.
      
      If the ETag is not specified as an input parameter, ETag validation of the object will be skipped.

  - **gitHubLocation** *(dict)* –
    
    Information about the location of application artifacts that are stored in GitHub.
    
    * **repository** *(string)* –
      
      The GitHub account and repository pair that stores a reference to the commit that represents the bundled artifacts for the application revision.
      
      Specified as account/repository.
    
    * **commitId** *(string)* –
      
      The SHA1 commit ID of the GitHub commit that references the that represents the bundled artifacts for the application revision.
• **deploymentConfigName** (*string*) – The name of an existing deployment configuration associated with the applicable IAM user or AWS account.

If not specified, the value configured in the deployment group will be used as the default. If the deployment group does not have a deployment configuration associated with it, then CodeDeployDefault.OneAtATime will be used by default.

• **description** (*string*) – A comment about the deployment.

• **ignoreApplicationStopFailures** (*boolean*) – If set to true, then if the deployment causes the ApplicationStop deployment lifecycle event to fail to a specific instance, the deployment will not be considered to have failed to that instance at that point and will continue on to the BeforeInstall deployment lifecycle event.

If set to false or not specified, then if the deployment causes the ApplicationStop deployment lifecycle event to fail to a specific instance, the deployment will stop to that instance, and the deployment to that instance will be considered to have failed.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'deploymentId': 'string'
}
```

**Response Structure**

• (`dict`) –

  Represents the output of a create deployment operation.

  – **deploymentId** (*string*) –

    A unique deployment ID.

**create_deployment_config** (**kwargs**)

Creates a new deployment configuration.

**Request Syntax**

```python
response = client.create_deployment_config(
    deploymentConfigName='string',
    minimumHealthyHosts={
        'value': 123,
        'type': 'HOST_COUNT'|'FLEET_PERCENT'
    }
)
```

**Parameters**

• **deploymentConfigName** (*string*) – [REQUIRED]

  The name of the deployment configuration to create.

• **minimumHealthyHosts** (*dict*) – The minimum number of healthy instances that should be available at any time during the deployment. There are two parameters expected in the input: type and value.

  The type parameter takes either of the following values:

  – **HOST_COUNT**: The value parameter represents the minimum number of healthy instances, as an absolute value.

  – **FLEET_PERCENT**: The value parameter represents the minimum number of healthy instances, as a percentage of the total number of instances in
the deployment. If you specify FLEET_PERCENT, then at the start of the
deployment AWS CodeDeploy converts the percentage to the equivalent
number of instances and rounds fractional instances up.

The value parameter takes an integer.

For example, to set a minimum of 95% healthy instances, specify a type of
FLEET_PERCENT and a value of 95.

- value (integer) –
  The minimum healthy instances value.

- type (string) –
  The minimum healthy instances type:
  * HOST_COUNT: The minimum number of healthy instances, as an
    absolute value.
  * FLEET_PERCENT: The minimum number of healthy instances, as
    a percentage of the total number of instances in the deployment.

For example, for 9 instances, if a HOST_COUNT of 6 is specified, deploy
to up to 3 instances at a time. The deployment succeeds if 6 or more
instances are successfully deployed to; otherwise, the deployment fails.
If a FLEET_PERCENT of 40 is specified, deploy to up to 5 instances at
a time. The deployment succeeds if 4 or more instances are successfully
deployed to; otherwise, the deployment fails.

Note: In a call to the get deployment configuration operation,
CodeDeployDefault.OneAtATime will return a minimum healthy in-
stances type of MOST_CONCURRENCY and a value of 1. This
means a deployment to only one instances at a time. (You cannot
set the type to MOST_CONCURRENCY, only to HOST_COUNT or
FLEET_PERCENT.)

**Return type** dict

**Returns**

**Response Syntax**

```python
{
  'deploymentConfigId': 'string'
}
```

**Response Structure**

- (dict) –

  Represents the output of a create deployment configuration operation.

  - deploymentConfigId (string) –

    A unique deployment configuration ID.

**create_deployment_group(**kwargs)**

Creates a new deployment group for application revisions to be deployed to.

**Request Syntax**

```python
response = client.create_deployment_group(
    applicationName='string',
    deploymentGroupName='string',
    deploymentConfigName='string',
    ec2TagFilters=[
    {
```
Parameters

- **applicationName (string)** – [REQUIRED]

  The name of an existing AWS CodeDeploy application associated with the applicable IAM user or AWS account.

- **deploymentGroupName (string)** – [REQUIRED]

  The name of an existing deployment group for the specified application.

- **deploymentConfigName (string)** – If specified, the deployment configuration name must be one of the predefined values, or it can be a custom deployment configuration:

  - **CodeDeployDefault.AllAtOnce** deploys an application revision to up to all of the instances at once. The overall deployment succeeds if the application revision deploys to at least one of the instances. The overall deployment fails after the application revision fails to deploy to all of the instances. For example, for 9 instances, deploy to up to all 9 instances at once. The overall deployment succeeds if any of the 9 instances is successfully deployed to, and it fails if all 9 instances fail to be deployed to.

  - **CodeDeployDefault.HalfAtATime** deploys to up to half of the instances at a time (with fractions rounded down). The overall deployment succeeds if the application revision deploys to at least half of the instances (with fractions rounded up); otherwise, the deployment fails. For example, for 9 instances, deploy to up to 4 instances at a time. The overall deployment succeeds if 5 or more instances are successfully deployed to; otherwise, the deployment fails. Note that the deployment may successfully deploy to some instances, even if the overall deployment fails.

  - **CodeDeployDefault.OneAtATime** deploys the application revision to only one of the instances at a time. The overall deployment succeeds if the application revision deploys to all of the instances. The overall deployment fails after the application revision first fails to deploy to any one instances. For example, for 9 instances, deploy to one instance at a time. The overall deployment succeeds if all 9 instances are successfully deployed to, and it fails if any of one of the 9 instances fail to be deployed to. Note that the deployment may successfully deploy to some instances, even if the overall deployment fails. This is the default deployment configuration if a configuration isn’t specified for either the deployment or the deployment group.

To create a custom deployment configuration, call the create deployment config-
ura tion operation.

- **ec2TagFilters** (list) – The Amazon EC2 tags to filter on.
  - (dict) –
    Information about a tag filter.
    * **Key** (string) –
      The tag filter key.
    * **Value** (string) –
      The tag filter value.
    * **Type** (string) –
      The tag filter type:
      - **KEY_ONLY**: Key only.
      - **VALUE_ONLY**: Value only.
      - **KEY_AND_VALUE**: Key and value.

- **onPremisesInstanceTagFilters** (list) – The on-premises instance tags to filter on.
  - (dict) –
    Information about an on-premises instance tag filter.
    * **Key** (string) –
      The on-premises instance tag filter key.
    * **Value** (string) –
      The on-premises instance tag filter value.
    * **Type** (string) –
      The on-premises instance tag filter type:
      - **KEY_ONLY**: Key only.
      - **VALUE_ONLY**: Value only.
      - **KEY_AND_VALUE**: Key and value.

- **autoScalingGroups** (list) – A list of associated Auto Scaling groups.
  - (string) –

- **serviceRoleArn** (string) – [REQUIRED]
  
  A service role ARN that allows AWS CodeDeploy to act on the user’s behalf when interacting with AWS services.

Return type: dict

Returns

Response Syntax

```python
{
    'deploymentGroupId': 'string'
}
```

Response Structure

- (dict) –

  Represents the output of a create deployment group operation.
  - **deploymentGroupId** (string) –

    A unique deployment group ID.

``delete_application(**kwargs)``

Deletes an application.

Request Syntax
Response Syntax

```python
response = client.delete_application(
    applicationName='string'
)
```

**Parameters**

- **applicationName** *(string)* – [REQUIRED]
  
The name of an existing AWS CodeDeploy application associated with the applicable IAM user or AWS account.

**Returns**

None

### delete_deployment_config(**kwargs)**

Deletes a deployment configuration.

**Note:** A deployment configuration cannot be deleted if it is currently in use. Also, predefined configurations cannot be deleted.

**Request Syntax**

```python
response = client.delete_deployment_config(
    deploymentConfigName='string'
)
```

**Parameters**

- **deploymentConfigName** *(string)* – [REQUIRED]
  
The name of an existing deployment configuration associated with the applicable IAM user or AWS account.

**Returns**

None

### delete_deployment_group(**kwargs)**

Deletes a deployment group.

**Request Syntax**

```python
response = client.delete_deployment_group(
    applicationName='string',
    deploymentGroupName='string'
)
```

**Parameters**

- **applicationName** *(string)* – [REQUIRED]
  
The name of an existing AWS CodeDeploy application associated with the applicable IAM user or AWS account.
- **deploymentGroupName** *(string)* – [REQUIRED]
  
The name of an existing deployment group for the specified application.

**Return type**

**dict**

**Returns**

Response Syntax

```python
{  
    'hooksNotCleanedUp': [  
        {  
            'name': 'string',  
            'hook': 'string'  
        },  
    ],
```

Response Structure
- (dict) –
  Represents the output of a delete deployment group operation.
  - hooksNotCleanedUp (list) –
    If the output contains no data, and the corresponding deployment group contained at least one Auto Scaling group, AWS CodeDeploy successfully removed all corresponding Auto Scaling lifecycle event hooks from the Amazon EC2 instances in the Auto Scaling. If the output does contain data, AWS CodeDeploy could not remove some Auto Scaling lifecycle event hooks from the Amazon EC2 instances in the Auto Scaling group.
  - (dict) –
    Information about an Auto Scaling group.
      - name (string) –
        The Auto Scaling group name.
      - hook (string) –
        An Auto Scaling lifecycle event hook name.

deregister_on_premises_instance(**kwargs)
Deregisters an on-premises instance.

Request Syntax

```python
response = client.deregister_on_premises_instance(
    instanceName='string'
)
```

Parameters
- instanceName (string) – [REQUIRED]
  The name of the on-premises instance to deregister.

Returns
None

generate_presigned_url (ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)
Generate a presigned url given a client, its method, and arguments

Parameters
- ClientMethod (string) – The client method to presign for
- Params (dict) – The parameters normally passed to ClientMethod.
- ExpiresIn (int) – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- HttpMethod (string) – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns
The presigned url

get_application(**kwargs)
Gets information about an application.

Request Syntax

```python
response = client.get_application(
    applicationName='string'
)
```
Parameters  

**applicationName** *(string)* – [REQUIRED]  
The name of an existing AWS CodeDeploy application associated with the applicable IAM user or AWS account.  

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'application': {
        'applicationId': 'string',
        'applicationName': 'string',
        'createTime': datetime(2015, 1, 1),
        'linkedToGitHub': True|False
    }
}
```

**Response Structure**

- *(dict)* –  
  Represents the output of a get application operation.  
  - **application** *(dict)* –  
    Information about the application.
    - **applicationId** *(string)* –  
      The application ID.
    - **applicationName** *(string)* –  
      The application name.
    - **createTime** *(datetime)* –  
      The time that the application was created.
    - **linkedToGitHub** *(boolean)* –  
      True if the user has authenticated with GitHub for the specified application; otherwise, false.

**get_application_revision**(**kwargs**)  

Gets information about an application revision.  

**Request Syntax**

```python
response = client.get_application_revision(
    applicationName='string',
    revision={
        'revisionType': 'S3'|'GitHub',
        's3Location': {
            'bucket': 'string',
            'key': 'string',
            'bundleType': 'tar'|'tgz'|'zip',
            'version': 'string',
            'eTag': 'string'
        },
        'gitHubLocation': {
            'repository': 'string',
            'commitId': 'string'
        }
    }
)
```
Parameters

- **applicationName** *(string)* – [REQUIRED]
  The name of the application that corresponds to the revision.

- **revision** *(dict)* – [REQUIRED]
  Information about the application revision to get, including the revision’s type and its location.

  - **revisionType** *(string)* –
    The application revision’s type:
    * S3: An application revision stored in Amazon S3.
    * GitHub: An application revision stored in GitHub.

  - **s3Location** *(dict)* –
    Information about the location of application artifacts that are stored in Amazon S3.
    * **bucket** *(string)* –
      The name of the Amazon S3 bucket where the application revision is stored.
    * **key** *(string)* –
      The name of the Amazon S3 object that represents the bundled artifacts for the application revision.
    * **bundleType** *(string)* –
      The file type of the application revision. Must be one of the following:
      · tar: A tar archive file.
      · tgz: A compressed tar archive file.
      · zip: A zip archive file.
    * **version** *(string)* –
      A specific version of the Amazon S3 object that represents the bundled artifacts for the application revision.
      If the version is not specified, the system will use the most recent version by default.
    * **eTag** *(string)* –
      The ETag of the Amazon S3 object that represents the bundled artifacts for the application revision.
      If the ETag is not specified as an input parameter, ETag validation of the object will be skipped.

  - **gitHubLocation** *(dict)* –
    Information about the location of application artifacts that are stored in GitHub.
    * **repository** *(string)* –
      The GitHub account and repository pair that stores a reference to the commit that represents the bundled artifacts for the application revision.
      Specified as account/repository.
    * **commitId** *(string)* –
      The SHA1 commit ID of the GitHub commit that references the that represents the bundled artifacts for the application revision.
Return type  dict

Returns

Response Syntax

```py
{
    'applicationName': 'string',
    'revision': {
        'revisionType': 'S3'|'GitHub',
        's3Location': {
            'bucket': 'string',
            'key': 'string',
            'bundleType': 'tar'|'tgz'|'zip',
            'version': 'string',
            'eTag': 'string'
        },
        'gitHubLocation': {
            'repository': 'string',
            'commitId': 'string'
        }
    },
    'revisionInfo': {
        'description': 'string',
        'deploymentGroups': ['string'],
        'firstUsedTime': datetime(2015, 1, 1),
        'lastUsedTime': datetime(2015, 1, 1),
        'registerTime': datetime(2015, 1, 1)
    }
}
```

Response Structure

• *(dict)* –

  Represents the output of a get application revision operation.

  – **applicationName** *(string)* –

    The name of the application that corresponds to the revision.

  – **revision** *(dict)* –

    Additional information about the revision, including the revision’s type and its location.

    * **revisionType** *(string)* –

      The application revision’s type:
      · S3: An application revision stored in Amazon S3.
      · GitHub: An application revision stored in GitHub.

    * **s3Location** *(dict)* –

      Information about the location of application artifacts that are stored in Amazon S3.

      · **bucket** *(string)* –

        The name of the Amazon S3 bucket where the application revision is stored.

      · **key** *(string)* –

        The name of the Amazon S3 object that represents the bundled artifacts for the application revision.
- **bundleType** *(string)* –
  The file type of the application revision. Must be one of the following:
  - tar: A tar archive file.
  - tgz: A compressed tar archive file.
- **version** *(string)* –
  A specific version of the Amazon S3 object that represents the bundled artifacts for the application revision.
  If the version is not specified, the system will use the most recent version by default.
- **eTag** *(string)* –
  The ETag of the Amazon S3 object that represents the bundled artifacts for the application revision.
  If the ETag is not specified as an input parameter, ETag validation of the object will be skipped.
- **gitHubLocation** *(dict)* –
  Information about the location of application artifacts that are stored in GitHub.
  - **repository** *(string)* –
    The GitHub account and repository pair that stores a reference to the commit that represents the bundled artifacts for the application revision.
    Specified as account/repository.
  - **commitId** *(string)* –
    The SHA1 commit ID of the GitHub commit that references the that represents the bundled artifacts for the application revision.
- **revisionInfo** *(dict)* –
  General information about the revision.
  - **description** *(string)* –
    A comment about the revision.
  - **deploymentGroups** *(list)* –
    A list of deployment groups that use this revision.
    - **firstUsedTime** *(datetime)* –
      When the revision was first used by AWS CodeDeploy.
  - **lastUsedTime** *(datetime)* –
    When the revision was last used by AWS CodeDeploy.
  - **registerTime** *(datetime)* –
    When the revision was registered with AWS CodeDeploy.

**get_deployment** (**kwargs**)
Gets information about a deployment.

Request Syntax
response = client.get_deployment(
    deploymentId='string'
)

Parameters deploymentId (string) – [REQUIRED]

An existing deployment ID associated with the applicable IAM user or AWS account.

Return type dict

Returns

Response Syntax

{  
    'deploymentInfo': {
        'applicationName': 'string',
        'deploymentGroupName': 'string',
        'deploymentConfigName': 'string',
        'deploymentId': 'string',
        'revision': {
            'revisionType': 'S3'|'GitHub',
            's3Location': {
                'bucket': 'string',
                'key': 'string',
                'bundleType': 'tar'|'tgz'|'zip',
                'version': 'string',
                'eTag': 'string'
            },
            'gitHubLocation': {
                'repository': 'string',
                'commitId': 'string'
            }
        },
        'status': 'Created'|'Queued'|'InProgress'|'Succeeded'|'Failed'|'Stopped',
        'errorInformation': {
            'code': 'DEPLOYMENT_GROUP_MISSING'|'APPLICATION_MISSING'|'REVISION_MISMATCH'|'INCONSISTENT_APPLICATION'|'BUNDLE_VALIDATION_FAILED'|'INVALID_DEPENDENCY'|'EXCESSIVE_DEPENDENCY'|'INVALID_METADATA'|'NO_DEPENDENCY'|'INCONSISTENT_DEPENDENCY'|'INCONSISTENT_METADATA'|'INTERNAL_ERROR'|'THROTTLED',
            'message': 'string'
        },
        'createTime': datetime(2015, 1, 1),
        'startTime': datetime(2015, 1, 1),
        'completeTime': datetime(2015, 1, 1),
        'deploymentOverview': {
            'Pending': 123,
            'InProgress': 123,
            'Succeeded': 123,
            'Failed': 123,
            'Skipped': 123
        },
        'description': 'string',
        'creator': 'user'|'autoscaling',
        'ignoreApplicationStopFailures': True|False
    }
}

Response Structure

- (dict) –

  Represents the output of a get deployment operation.

  - deploymentInfo (dict) –
Information about the deployment.
* **applicationName** *(string)* –
  The application name.
* **deploymentGroupName** *(string)* –
  The deployment group name.
* **deploymentConfigName** *(string)* –
  The deployment configuration name.
* **deploymentId** *(string)* –
  The deployment ID.
* **revision** *(dict)* –
  Information about the location of application artifacts that are stored and the service to retrieve them from.
  · **revisionType** *(string)* –
    The application revision’s type:
    · S3: An application revision stored in Amazon S3.
    · GitHub: An application revision stored in GitHub.
  · **s3Location** *(dict)* –
    Information about the location of application artifacts that are stored in Amazon S3.
    · **bucket** *(string)* –
      The name of the Amazon S3 bucket where the application revision is stored.
    · **key** *(string)* –
      The name of the Amazon S3 object that represents the bundled artifacts for the application revision.
    · **bundleType** *(string)* –
      The file type of the application revision. Must be one of the following:
      · tar: A tar archive file.
      · tgz: A compressed tar archive file.
      · zip: A zip archive file.
    · **version** *(string)* –
      A specific version of the Amazon S3 object that represents the bundled artifacts for the application revision.
      If the version is not specified, the system will use the most recent version by default.
  · **eTag** *(string)* –
    The ETag of the Amazon S3 object that represents the bundled artifacts for the application revision.
    If the ETag is not specified as an input parameter, ETag validation of the object will be skipped.
  · **gitHubLocation** *(dict)* –
    Information about the location of application artifacts that are stored in GitHub.
  · **repository** *(string)* –
The GitHub account and repository pair that stores a reference to the commit that represents the bundled artifacts for the application revision.

Specified as account/repository.

- **commitId** *(string)* –
  
  The SHA1 commit ID of the GitHub commit that references the that represents the bundled artifacts for the application revision.

- **status** *(string)* –
  
  The current state of the deployment as a whole.

- **errorInformation** *(dict)* –
  
  Information about any error associated with this deployment.

  - **code** *(string)* –
    
    The error code:

    - APPLICATION_MISSING: The application was missing. Note that this error code will most likely be raised if the application is deleted after the deployment is created but before it starts.
    - DEPLOYMENT_GROUP_MISSING: The deployment group was missing. Note that this error code will most likely be raised if the deployment group is deleted after the deployment is created but before it starts.
    - HEALTH_CONSTRAINTS: The deployment failed on too many instances to be able to successfully deploy within the specified instance health constraints.
    - HEALTH_CONSTRAINTS_INVALID: The revision can never successfully deploy within the instance health constraints as specified.
    - IAM_ROLE_MISSING: The service role cannot be accessed.
    - IAM_ROLE_PERMISSIONS: The service role does not have the correct permissions.
    - INTERNAL_ERROR: There was an internal error.
    - NO_EC2_SUBSCRIPTION: The calling account is not subscribed to the Amazon EC2 service.
    - NO_INSTANCES: No instances were specified, or no instances can be found.
    - OVER_MAX_INSTANCES: The maximum number of instances was exceeded.
    - THROTTLED: The operation was throttled because the calling account exceeded the throttling limits of one or more AWS services.
    - TIMEOUT: The deployment has timed out.
    - REVISION_MISSING: The revision ID was missing. Note that this error code will most likely be raised if the revision is deleted after the deployment is created but before it starts.

  - **message** *(string)* –
    
    An accompanying error message.

- **createTime** *(datetime)* –
  
  A timestamp indicating when the deployment was created.

- **startTime** *(datetime)* –
A timestamp indicating when the deployment began deploying to the deployment group.

Note that in some cases, the reported value of the start time may be later than the complete time. This is due to differences in the clock settings of various back-end servers that participate in the overall deployment process.

* **completeTime** *(datetime)* –
A timestamp indicating when the deployment was completed.

* **deploymentOverview** *(dict)* –
A summary of the deployment status of the instances in the deployment.
  - **Pending** *(integer)* –
    The number of instances that are pending in the deployment.
  - **InProgress** *(integer)* –
    The number of instances that are in progress in the deployment.
  - **Succeeded** *(integer)* –
    The number of instances that have succeeded in the deployment.
  - **Failed** *(integer)* –
    The number of instances that have failed in the deployment.
  - **Skipped** *(integer)* –
    The number of instances that have been skipped in the deployment.

* **description** *(string)* –
A comment about the deployment.

* **creator** *(string)* –
How the deployment was created:
  - user: A user created the deployment.
  - autoscaling: Auto Scaling created the deployment.

* **ignoreApplicationStopFailures** *(boolean)* –
If true, then if the deployment causes the ApplicationStop deployment lifecycle event to fail to a specific instance, the deployment will not be considered to have failed to that instance at that point and will continue on to the BeforeInstall deployment lifecycle event.

If false or not specified, then if the deployment causes the ApplicationStop deployment lifecycle event to fail to a specific instance, the deployment will stop to that instance, and the deployment to that instance will be considered to have failed.

### get_deployment_config(**kwargs)**

Gets information about a deployment configuration.

**Request Syntax**

```python
response = client.get_deployment_config(
    deploymentConfigName='string'
)
```
Parameters  deploymentConfigName *(string) – [REQUIRED]*

The name of an existing deployment configuration associated with the applicable IAM user or AWS account.

Return type  dict

Returns

Response Syntax

```
{
    'deploymentConfigInfo': {
        'deploymentConfigId': 'string',
        'deploymentConfigName': 'string',
        'minimumHealthyHosts': {
            'value': 123,
            'type': 'HOST_COUNT'|'FLEET_PERCENT',
        },
        'createTime': datetime(2015, 1, 1)
    }
}
```

Response Structure

• *(dict) –*

Represents the output of a get deployment configuration operation.

– deploymentConfigInfo *(dict) –*

Information about the deployment configuration.

* deploymentConfigId *(string) –*

The deployment configuration ID.

* deploymentConfigName *(string) –*

The deployment configuration name.

* minimumHealthyHosts *(dict) –*

Information about the number or percentage of minimum healthy instances.

• value *(integer) –*

The minimum healthy instances value.

• type *(string) –*

The minimum healthy instances type:

• HOST_COUNT: The minimum number of healthy instances, as an absolute value.

• FLEET_PERCENT: The minimum number of healthy instances, as a percentage of the total number of instances in the deployment. For example, for 9 instances, if a HOST_COUNT of 6 is specified, deploy to up to 3 instances at a time. The deployment succeeds if 6 or more instances are successfully deployed to; otherwise, the deployment fails. If a FLEET_PERCENT of 40 is specified, deploy to up to 5 instances at a time. The deployment succeeds if 4 or more instances are successfully deployed to; otherwise, the deployment fails.

Note: In a call to the get deployment configuration operation, CodeDeployDefault.OneAtATime will return a minimum healthy instances type of MOST_CONCURRENCY and a
value of 1. This means a deployment to only one instances at a time. (You cannot set the type to MOST_CONCURRENCY, only to HOST_COUNT or FLEET_PERCENT.)

* createTime (datetime) –

The time that the deployment configuration was created.

**get_deployment_group(**kwargs)**

Gets information about a deployment group.

Request Syntax

```python
response = client.get_deployment_group(
    applicationName='string',
    deploymentGroupName='string'
)
```

Parameters

- **applicationName (string)** – [REQUIRED]

  The name of an existing AWS CodeDeploy application associated with the applicable IAM user or AWS account.

- **deploymentGroupName (string)** – [REQUIRED]

  The name of an existing deployment group for the specified application.

Return type  dict

Returns

Response Syntax

```json
{
    'deploymentGroupInfo': {
        'applicationName': 'string',
        'deploymentGroupId': 'string',
        'deploymentGroupName': 'string',
        'deploymentConfigName': 'string',
        'ec2TagFilters': [
            {'Key': 'string',
             'Value': 'string',
             'Type': 'KEY_ONLY'|'VALUE_ONLY'|'KEY_AND_VALUE'},
        ],
        'onPremisesInstanceTagFilters': [
            {'Key': 'string',
             'Value': 'string',
             'Type': 'KEY_ONLY'|'VALUE_ONLY'|'KEY_AND_VALUE'},
        ],
        'autoScalingGroups': [
            {'name': 'string',
             'hook': 'string'},
        ],
        'serviceRoleArn': 'string',
        'targetRevision': {
            'revisionType': 'S3'|'GitHub',
```
's3Location': {
    'bucket': 'string',
    'key': 'string',
    'bundleType': 'tar'|'tgz'|'zip',
    'version': 'string',
    'eTag': 'string'
},
'gitHubLocation': {
    'repository': 'string',
    'commitId': 'string'
}
}

Response Structure

* (dict) –

Represents the output of a get deployment group operation.

– deploymentGroupInfo (dict) –

Information about the deployment group.

* applicationName (string) –

The application name.

* deploymentGroupId (string) –

The deployment group ID.

* deploymentGroupName (string) –

The deployment group name.

* deploymentConfigName (string) –

The deployment configuration name.

* ec2TagFilters (list) –

The Amazon EC2 tags to filter on.

  • (dict) –

    Information about a tag filter.

    • Key (string) –

    The tag filter key.

    • Value (string) –

    The tag filter value.

    • Type (string) –

    The tag filter type:

    • KEY_ONLY: Key only.

    • VALUE_ONLY: Value only.

    • KEY_AND_VALUE: Key and value.

* onPremisesInstanceTagFilters (list) –

The on-premises instance tags to filter on.

  • (dict) –

    Information about an on-premises instance tag filter.

    • Key (string) –

    The on-premises instance tag filter key.
- **Value (string)** –
  The on-premises instance tag filter value.
- **Type (string)** –
  The on-premises instance tag filter type:
  - KEY_ONLY: Key only.
  - VALUE_ONLY: Value only.
  - KEY_AND_VALUE: Key and value.

* **autoScalingGroups (list)** –
A list of associated Auto Scaling groups.
  - (dict) –
    Information about an Auto Scaling group.
    - **name (string)** –
      The Auto Scaling group name.
    - **hook (string)** –
      An Auto Scaling lifecycle event hook name.

* **serviceRoleArn (string)** –
A service role ARN.

* **targetRevision (dict)** –
Information about the deployment group’s target revision, including the revision’s type and its location.
  - **revisionType (string)** –
    The application revision’s type:
    - S3: An application revision stored in Amazon S3.
    - GitHub: An application revision stored in GitHub.
  - **s3Location (dict)** –
    Information about the location of application artifacts that are stored in Amazon S3.
    - **bucket (string)** –
      The name of the Amazon S3 bucket where the application revision is stored.
    - **key (string)** –
      The name of the Amazon S3 object that represents the bundled artifacts for the application revision.
  - **bundleType (string)** –
    The file type of the application revision. Must be one of the following:
    - tar: A tar archive file.
    - tgz: A compressed tar archive file.
    - **version (string)** –
      A specific version of the Amazon S3 object that represents the bundled artifacts for the application revision.
      
      If the version is not specified, the system will use the most recent version by default.
  - **eTag (string)** –
The ETag of the Amazon S3 object that represents the bundled artifacts for the application revision.

If the ETag is not specified as an input parameter, ETag validation of the object will be skipped.

- **gitHubLocation (dict)** –
  Information about the location of application artifacts that are stored in GitHub.

- **repository (string)** –
  The GitHub account and repository pair that stores a reference to the commit that represents the bundled artifacts for the application revision.

  Specified as account/repository.

- **commitId (string)** –
  The SHA1 commit ID of the GitHub commit that references the that represents the bundled artifacts for the application revision.

### get_deployment_instance(**kwargs)**

Gets information about an instance as part of a deployment.

#### Request Syntax

```python
response = client.get_deployment_instance(
    deploymentId='string',
    instanceId='string'
)
```

**Parameters**

- **deploymentId (string)** – [REQUIRED]
  The unique ID of a deployment.

- **instanceId (string)** – [REQUIRED]
  The unique ID of an instance in the deployment’s deployment group.

**Return type**

dict

**Returns**

**Response Syntax**

```python
{
    'instanceSummary': {
        'deploymentId': 'string',
        'instanceId': 'string',
        'status': 'Pending'|'InProgress'|'Succeeded'|'Failed'|'Skipped'|'Unknown',
        'lastUpdatedAt': datetime(2015, 1, 1),
        'lifecycleEvents': [
            {
                'lifecycleEventName': 'string',
                'diagnostics': {
                    'errorCode': 'Success'|'ScriptMissing'|'ScriptNotExecutable'|'ScriptTimedOut'|'ScriptFailed'|'UnknownError',
                    'scriptName': 'string',
                    'message': 'string',
                    'logTail': 'string'
                },
                'startTime': datetime(2015, 1, 1),
            }
        ]
    }
}
```
Response Structure

- (dict) –

  Represents the output of a get deployment instance operation.

  - instanceSummary (dict) –

    Information about the instance.

    - deploymentId (string) –
      The deployment ID.

    - instanceId (string) –
      The instance ID.

    - status (string) –
      The deployment status for this instance:
      - Pending: The deployment is pending for this instance.
      - In Progress: The deployment is in progress for this instance.
      - Succeeded: The deployment has succeeded for this instance.
      - Failed: The deployment has failed for this instance.
      - Skipped: The deployment has been skipped for this instance.
      - Unknown: The deployment status is unknown for this instance.

    - lastUpdatedAt (datetime) –
      A timestamp indicating when the instance information was last updated.

    - lifecycleEvents (list) –
      A list of lifecycle events for this instance.

      - (dict) –

        Information about a deployment lifecycle event.

        - lifecycleEventName (string) –
          The deployment lifecycle event name, such as Application-Stop, BeforeInstall, AfterInstall, ApplicationStart, or ValidateService.

        - diagnostics (dict) –
          Diagnostic information about the deployment lifecycle event.

        - errorCode (string) –
          The associated error code:
          - Success: The specified script ran.
          - ScriptMissing: The specified script was not found in the specified location.
          - ScriptNotExecutable: The specified script is not a recognized executable file type.
          - ScriptTimedOut: The specified script did not finish running in the specified time period.
          - ScriptFailed: The specified script failed to run as expected.
- UnknownError: The specified script did not run for an unknown reason.
- **scriptName** (string) –
  The name of the script.
- **message** (string) –
  The message associated with the error.
- **logTail** (string) –
  The last portion of the associated diagnostic log.
- **startTime** (datetime) –
  A timestamp indicating when the deployment lifecycle event started.
- **endTime** (datetime) –
  A timestamp indicating when the deployment lifecycle event ended.
- **status** (string) –
  The deployment lifecycle event status:
  - Pending: The deployment lifecycle event is pending.
  - InProgress: The deployment lifecycle event is in progress.
  - Succeeded: The deployment lifecycle event has succeeded.
  - Failed: The deployment lifecycle event has failed.
  - Skipped: The deployment lifecycle event has been skipped.
  - Unknown: The deployment lifecycle event is unknown.

```python
get_on_premises_instance(**kwargs)
```

Gets information about an on-premises instance.

**Request Syntax**

```python
response = client.get_on_premises_instance(
    instanceName='string'  
)
```

**Parameters**

- **instanceName** (string) – [REQUIRED]
  The name of the on-premises instance to get information about

**Return type**: dict

**Returns**

**Response Syntax**

```json
{
    'instanceInfo': {
        'instanceName': 'string',
        'iamUserArn': 'string',
        'instanceArn': 'string',
        'registerTime': datetime(2015, 1, 1),
        'deregisterTime': datetime(2015, 1, 1),
        'tags': [
            {
                'Key': 'string',
                'Value': 'string'
            }
        ]
    }
}
```
Response Structure

- (dict) – Represents the output of a get on-premises instance operation.
  - instanceInfo (dict) – Information about the on-premises instance.
    - instanceName (string) – The name of the on-premises instance.
    - iamUserArn (string) – The IAM user ARN associated with the on-premises instance.
    - instanceArn (string) – The ARN of the on-premises instance.
    - registerTime (datetime) – The time that the on-premises instance was registered.
    - deregisterTime (datetime) – If the on-premises instance was deregistered, the time that the on-premises instance was deregistered.
    - tags (list) – The tags that are currently associated with the on-premises instance.
      - (dict) – Information about a tag.
        - Key (string) – The tag’s key.
        - Value (string) – The tag’s value.

get_paginotor (operation_name)

Create a paginator for an operation.

Parameters

- operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginotor("create_foo").

Raises

- OperationNotPageableError Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

Return type

- L{botocore.paginate.Paginator}

Returns

- A paginator object.

get_waiter (waiter_name)

list_application_revisions (**kwargs)

Lists information about revisions for an application.

Request Syntax

```python
response = client.list_application_revisions(
    applicationName='string',
    sortBy='registerTime'|'firstUsedTime'|'lastUsedTime',
```
Parameters

- **applicationName** *(string)* – [REQUIRED]
  The name of an existing AWS CodeDeploy application associated with the applicable IAM user or AWS account.

- **sortBy** *(string)* – The column name to sort the list results by:
  - registerTime: Sort the list results by when the revisions were registered with AWS CodeDeploy.
  - firstUsedTime: Sort the list results by when the revisions were first used by in a deployment.
  - lastUsedTime: Sort the list results by when the revisions were last used in a deployment.
  If not specified or set to null, the results will be returned in an arbitrary order.

- **sortOrder** *(string)* – The order to sort the list results by:
  - ascending: Sort the list of results in ascending order.
  - descending: Sort the list of results in descending order.
  If not specified, the results will be sorted in ascending order.
  If set to null, the results will be sorted in an arbitrary order.

- **s3Bucket** *(string)* – A specific Amazon S3 bucket name to limit the search for revisions.
  If set to null, then all of the user’s buckets will be searched.

- **s3KeyPrefix** *(string)* – A specific key prefix for the set of Amazon S3 objects to limit the search for revisions.

- **deployed** *(string)* – Whether to list revisions based on whether the revision is the target revision of an deployment group:
  - include: List revisions that are target revisions of a deployment group.
  - exclude: Do not list revisions that are target revisions of a deployment group.
  - ignore: List all revisions, regardless of whether they are target revisions of a deployment group.

- **nextToken** *(string)* – An identifier that was returned from the previous list application revisions call, which can be used to return the next set of applications in the list.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'revisions': [
        {
            'revisionType': 'S3'|'GitHub',
            's3Location': {
                'bucket': 'string',
                'key': 'string',
                'bundleType': 'tar'|'tgz'|'zip',
                'version': 'string',
                'eTag': 'string'
            }
        }
    ]
}
```
Response Structure

- (dict) –
  - (dict) –
    A list of revision locations that contain the matching revisions.
    - (dict) –
      Information about an application revision’s location.
      - **revisionType** (string) –
        The application revision’s type:
        - S3: An application revision stored in Amazon S3.
        - GitHub: An application revision stored in GitHub.
      - **s3Location** (dict) –
        Information about the location of application artifacts that are stored in Amazon S3.
        - **bucket** (string) –
          The name of the Amazon S3 bucket where the application revision is stored.
        - **key** (string) –
          The name of the Amazon S3 object that represents the bundled artifacts for the application revision.
        - **bundleType** (string) –
          The file type of the application revision. Must be one of the following:
          - tar: A tar archive file.
          - tgz: A compressed tar archive file.
        - **version** (string) –
          A specific version of the Amazon S3 object that represents the bundled artifacts for the application revision.
          If the version is not specified, the system will use the most recent version by default.
      - **eTag** (string) –
        The ETag of the Amazon S3 object that represents the bundled artifacts for the application revision.
        If the ETag is not specified as an input parameter, ETag validation of the object will be skipped.
      - **gitHubLocation** (dict) –
Information about the location of application artifacts that are stored in GitHub.

- repository (string)

  The GitHub account and repository pair that stores a reference to the commit that represents the bundled artifacts for the application revision.

  Specified as account/repository.

- commitId (string)

  The SHA1 commit ID of the GitHub commit that references the that represents the bundled artifacts for the application revision.

  - nextToken (string)

    If the amount of information that is returned is significantly large, an identifier will also be returned, which can be used in a subsequent list application revisions call to return the next set of application revisions in the list.

**list_applications(****kwargs**)**

Lists the applications registered with the applicable IAM user or AWS account.

Request Syntax

```python
response = client.list_applications(
    nextToken='string'
)
```

Parameters

- **nextToken** (string) – An identifier that was returned from the previous list applications call, which can be used to return the next set of applications in the list.

Return type

dict

Returns

Response Syntax

```python
{
    'applications': [
        'string',
        'string',
    ],
    'nextToken': 'string'
}
```

Response Structure

- (dict) – Represents the output of a list applications operation.

  - applications (list) – A list of application names.

    - (string) –

      - nextToken (string) –

        If the amount of information that is returned is significantly large, an identifier will also be returned, which can be used in a subsequent list applications call to return the next set of applications in the list.

**list_deployment_configs(****kwargs**)**

Lists the deployment configurations with the applicable IAM user or AWS account.

```python
list_deployment_configs(**kwargs)
```
Request Syntax

response = client.list_deployment_configs(
    nextToken='string'
)

Parameters

nextToken (string) – An identifier that was returned from the previous list deployment configurations call, which can be used to return the next set of deployment configurations in the list.

Return type

dict

Returns

Response Syntax

{
    'deploymentConfigsList': [
        'string',
    ],
    'nextToken': 'string'
}

Response Structure

- (dict) – Represents the output of a list deployment configurations operation.
  - deploymentConfigsList (list) –
      A list of deployment configurations, including the built-in configurations such as CodeDeployDefault.OneAtATime.
      * (string) –
  - nextToken (string) –
      If the amount of information that is returned is significantly large, an identifier will also be returned, which can be used in a subsequent list deployment configurations call to return the next set of deployment configurations in the list.

list_deployment_groups (**kwargs)

Lists the deployment groups for an application registered with the applicable IAM user or AWS account.

Request Syntax

response = client.list_deployment_groups(
    applicationName='string',
    nextToken='string'
)

Parameters

- applicationName (string) – [REQUIRED]
  The name of an existing AWS CodeDeploy application associated with the applicable IAM user or AWS account.
- nextToken (string) – An identifier that was returned from the previous list deployment groups call, which can be used to return the next set of deployment groups in the list.

Return type

dict

Returns

Response Syntax
Response Structure

- (dict) – Represents the output of a list deployment groups operation.
  - applicationName (string) – The application name.
  - deploymentGroups (list) – A list of corresponding deployment group names.
    * (string) –
  - nextToken (string) – If the amount of information that is returned is significantly large, an identifier will also be returned, which can be used in a subsequent list deployment groups call to return the next set of deployment groups in the list.

**list_deployment_instances(**kwargs)**

Lists the instances for a deployment associated with the applicable IAM user or AWS account.

Request Syntax

response = client.list_deployment_instances(  
    deploymentId='string',  
    nextToken='string',  
    instanceStatusFilter=[  
        'Pending'|'InProgress'|'Succeeded'|'Failed'|'Skipped'|'Unknown',  
    ]
)

Parameters

- deploymentId (string) – [REQUIRED]
  The unique ID of a deployment.
- nextToken (string) – An identifier that was returned from the previous list deployment instances call, which can be used to return the next set of deployment instances in the list.
- instanceStatusFilter (list) – A subset of instances to list, by status:
  - Pending: Include in the resulting list those instances with pending deployments.
  - InProgress: Include in the resulting list those instances with in-progress deployments.
  - Succeeded: Include in the resulting list those instances with succeeded deployments.
  - Failed: Include in the resulting list those instances with failed deployments.
  - Skipped: Include in the resulting list those instances with skipped deployments.
  - Unknown: Include in the resulting list those instances with deployments in an unknown state.
Return type  dict

Returns

Response Syntax

```
{
    'instancesList': [
        'string',
    ],
    'nextToken': 'string'
}
```

Response Structure

- (dict) –

Represents the output of a list deployment instances operation.

- instancesList (list) –

A list of instances IDs.

- nextToken (string) –

If the amount of information that is returned is significantly large, an identifier will also be returned, which can be used in a subsequent list deployment instances call to return the next set of deployment instances in the list.

`list_deployments(**kwargs)`

Lists the deployments within a deployment group for an application registered with the applicable IAM user or AWS account.

Request Syntax

```python
response = client.list_deployments(
    applicationName='string',
    deploymentGroupName='string',
    includeOnlyStatuses=[
        'Created'|'Queued'|'InProgress'|'Succeeded'|'Failed'|'Stopped',
    ],
    createTimeRange={
        'start': datetime(2015, 1, 1),
        'end': datetime(2015, 1, 1)
    },
    nextToken='string'
)
```

Parameters

- applicationName (string) – The name of an existing AWS CodeDeploy application associated with the applicable IAM user or AWS account.
- deploymentGroupName (string) – The name of an existing deployment group for the specified application.
- includeOnlyStatuses (list) – A subset of deployments to list, by status:
  - Created: Include in the resulting list created deployments.
  - Queued: Include in the resulting list queued deployments.
  - In Progress: Include in the resulting list in-progress deployments.
  - Succeeded: Include in the resulting list succeeded deployments.
  - Failed: Include in the resulting list failed deployments.
  - Aborted: Include in the resulting list aborted deployments.
• createTimeRange (dict) – A deployment creation start- and end-time range for returning a subset of the list of deployments.
  
  – start (datetime) –
  
  The time range’s start time.

  **Note:** Specify null to leave the time range’s start time open-ended.

  – end (datetime) –
  
  The time range’s end time.

  **Note:** Specify null to leave the time range’s end time open-ended.

• nextToken (string) – An identifier that was returned from the previous list deployments call, which can be used to return the next set of deployments in the list.

**Return type**  dict

**Returns**

**Response Syntax**

```python

{  
  'deployments': [  
    'string',  
  ],  
  'nextToken': 'string'
}
```

**Response Structure**

• (dict) –
  
  Represents the output of a list deployments operation.

  – deployments (list) –
  
  A list of deployment IDs.

  * (string) –

  – nextToken (string) –
  
  If the amount of information that is returned is significantly large, an identifier will also be returned, which can be used in a subsequent list deployments call to return the next set of deployments in the list.

**list_on_premises_instances(**kwargs)**

Gets a list of one or more on-premises instance names.

Unless otherwise specified, both registered and deregistered on-premises instance names will be listed. To list only registered or deregistered on-premises instance names, use the registration status parameter.

**Request Syntax**

```python

response = client.list_on_premises_instances(
    registrationStatus='Registered'|'Deregistered',
    tagFilters=[
      
      'Key': 'string',
      'Value': 'string',
      'Type': 'KEY_ONLY'|'VALUE_ONLY'|'KEY_AND_VALUE'
    ],
)
```
Parameters

- **registrationStatus** *(string)* – The on-premises instances registration status:
  - Deregistered: Include in the resulting list deregistered on-premises instances.
  - Registered: Include in the resulting list registered on-premises instances.
- **tagFilters** *(list)* – The on-premises instance tags that will be used to restrict the corresponding on-premises instance names that are returned.
  - *(dict)* – Information about an on-premises instance tag filter.
    - **Key** *(string)* – The on-premises instance tag filter key.
    - **Value** *(string)* – The on-premises instance tag filter value.
    - **Type** *(string)* – The on-premises instance tag filter type:
      - KEY_ONLY: Key only.
      - VALUE_ONLY: Value only.
      - KEY_AND_VALUE: Key and value.
- **nextToken** *(string)* – An identifier that was returned from the previous list on-premises instances call, which can be used to return the next set of on-premises instances in the list.

Return type  dict

Returns

Response Syntax

```python
{

    'instanceNames': [
        'string',
    ],

    'nextToken': 'string'
}
```

Response Structure

- *(dict)* – Represents the output of list on-premises instances operation.
  - **instanceNames** *(list)* – The list of matching on-premises instance names.
    - *(string)* – **nextToken** *(string)* – If the amount of information that is returned is significantly large, an identifier will also be returned, which can be used in a subsequent list on-premises instances call to return the next set of on-premises instances in the list.

**register_application_revision(** **kwargs)**

Registers with AWS CodeDeploy a revision for the specified application.
Request Syntax

```python
response = client.register_application_revision(
    applicationName='string',
    description='string',
    revision={
        'revisionType': 'S3'|'GitHub',
        's3Location': {
            'bucket': 'string',
            'key': 'string',
            'bundleType': 'tar'|'tgz'|'zip',
            'version': 'string',
            'eTag': 'string'
        },
        'gitHubLocation': {
            'repository': 'string',
            'commitId': 'string'
        }
    }
)
```

Parameters

- **applicationName** *(string)* – [REQUIRED]
  
  The name of an existing AWS CodeDeploy application associated with the applicable IAM user or AWS account.

- **description** *(string)* – A comment about the revision.

- **revision** *(dict)* – [REQUIRED]
  
  Information about the application revision to register, including the revision’s type and its location.
  
  - **revisionType** *(string)* –
    
    The application revision’s type:
    
    * S3: An application revision stored in Amazon S3.
    * GitHub: An application revision stored in GitHub.

  - **s3Location** *(dict)* –
    
    Information about the location of application artifacts that are stored in Amazon S3.
    
    * **bucket** *(string)* –
      
      The name of the Amazon S3 bucket where the application revision is stored.
    
    * **key** *(string)* –
      
      The name of the Amazon S3 object that represents the bundled artifacts for the application revision.
    
    * **bundleType** *(string)* –
      
      The file type of the application revision. Must be one of the following:
      
      - tar: A tar archive file.
      - tgz: A compressed tar archive file.
    
    * **version** *(string)* –
      
      A specific version of the Amazon S3 object that represents the bundled artifacts for the application revision.
If the version is not specified, the system will use the most recent version by default.

* `eTag (string)` –

The ETag of the Amazon S3 object that represents the bundled artifacts for the application revision.

If the ETag is not specified as an input parameter, ETag validation of the object will be skipped.

– `gitHubLocation (dict)` –

Information about the location of application artifacts that are stored in GitHub.

* `repository (string)` –

The GitHub account and repository pair that stores a reference to the commit that represents the bundled artifacts for the application revision.

Specified as account/repository.

* `commitId (string)` –

The SHA1 commit ID of the GitHub commit that references the that represents the bundled artifacts for the application revision.

Returns None

`register_on_premises_instance(**kwargs)`

Registers an on-premises instance.

Request Syntax

```python
response = client.register_on_premises_instance(
    instanceName='string',
    iamUserArn='string'
)
```

Parameters

- `instanceName (string)` – [REQUIRED]

  The name of the on-premises instance to register.

- `iamUserArn (string)` – [REQUIRED]

  The ARN of the IAM user to associate with the on-premises instance.

Returns None

`remove_tags_from_on_premises_instances(**kwargs)`

Removes one or more tags from one or more on-premises instances.

Request Syntax

```python
response = client.remove_tags_from_on_premises_instances(
    tags=[
    
        'Key': 'string',
        'Value': 'string'
    ],
    instanceNames=[
    'string',
    ]
)
```
Parameters

- **tags** *(list) – [REQUIRED]*
  The tag key-value pairs to remove from the on-premises instances.
  - *(dict) –
    Information about a tag.
    - **Key** *(string) –*
      The tag’s key.
    - **Value** *(string) –*
      The tag’s value.

- **instanceNames** *(list) – [REQUIRED]*
  The names of the on-premises instances to remove tags from.
  - *(string) –

Returns  None

`stop_deployment(**kwargs)`
Attempts to stop an ongoing deployment.

Request Syntax

```python
response = client.stop_deployment(
    deploymentId='string'
)
```

Parameters  **deploymentId** *(string) – [REQUIRED]*
  The unique ID of a deployment.

Returns  `dict`

Response Syntax

```json
{
    'status': 'Pending'|'Succeeded',
    'statusMessage': 'string'
}
```

Response Structure

- *(dict) –
  Represents the output of a stop deployment operation.
  - **status** *(string) –*
    The status of the stop deployment operation:
    - Pending: The stop operation is pending.
    - Succeeded: The stop operation succeeded.
  - **statusMessage** *(string) –*
    An accompanying status message.

`update_application(**kwargs)`
Changes an existing application’s name.

Request Syntax
response = client.update_application(
    applicationName='string',
    newApplicationName='string'
)

Parameters

- **applicationName (string)** – The current name of the application that you want to change.
- **newApplicationName (string)** – The new name that you want to change the application to.

Returns

None

update_deployment_group(**kwargs)

Changes information about an existing deployment group.

Request Syntax

response = client.update_deployment_group(
    applicationName='string',
    currentDeploymentGroupName='string',
    newDeploymentGroupName='string',
    deploymentConfigName='string',
    ec2TagFilters=[
        {
            'Key': 'string',
            'Value': 'string',
            'Type': 'KEY_ONLY'|'VALUE_ONLY'|'KEY_AND_VALUE'
        },
    ],
    onPremisesInstanceTagFilters=[
        {
            'Key': 'string',
            'Value': 'string',
            'Type': 'KEY_ONLY'|'VALUE_ONLY'|'KEY_AND_VALUE'
        },
    ],
    autoScalingGroups=[
        'string',
    ],
    serviceRoleArn='string'
)

Parameters

- **applicationName (string)** – [REQUIRED]
  
  The application name corresponding to the deployment group to update.
- **currentDeploymentGroupName (string)** – [REQUIRED]
  
  The current name of the existing deployment group.
- **newDeploymentGroupName (string)** – The new name of the deployment group, if you want to change it.
- **deploymentConfigName (string)** – The replacement deployment configuration name to use, if you want to change it.
- **ec2TagFilters (list)** – The replacement set of Amazon EC2 tags to filter on, if you want to change them.
  - **(dict)** –
    
    Information about a tag filter.
*Key (string)* –
The tag filter key.

*Value (string)* –
The tag filter value.

*Type (string)* –
The tag filter type:
· KEY_ONLY: Key only.
· VALUE_ONLY: Value only.
· KEY_AND_VALUE: Key and value.

**onPremisesInstanceTagFilters (list)** – The replacement set of on-premises instance tags for filter on, if you want to change them.

– (dict) –

Information about an on-premises instance tag filter.

*Key (string)* –
The on-premises instance tag filter key.

*Value (string)* –
The on-premises instance tag filter value.

*Type (string)* –
The on-premises instance tag filter type:
· KEY_ONLY: Key only.
· VALUE_ONLY: Value only.
· KEY_AND_VALUE: Key and value.

**autoScalingGroups (list)** – The replacement list of Auto Scaling groups to be included in the deployment group, if you want to change them.

– (string) –

**serviceRoleArn (string)** – A replacement service role’s ARN, if you want to change it.

Return type  dict

Returns

Response Syntax

```python
{
    'hooksNotCleanedUp': [
        {
            'name': 'string',
            'hook': 'string'
        },
    ]
}
```

Response Structure

* (dict) –

Represents the output of an update deployment group operation.

– **hooksNotCleanedUp (list)** –

If the output contains no data, and the corresponding deployment group contained at least one Auto Scaling group, AWS CodeDeploy successfully removed all corresponding Auto Scaling lifecycle event hooks from the AWS account. If the output does contain data, AWS CodeDeploy could not remove some Auto Scaling lifecycle event hooks from the AWS account.
* (dict) –
  Information about an Auto Scaling group.
  · **name** *(string)* –
    The Auto Scaling group name.
  · **hook** *(string)* –
    An Auto Scaling lifecycle event hook name.

**CodePipeline**

<table>
<thead>
<tr>
<th>Table of Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>• CodePipeline</td>
</tr>
<tr>
<td>– Client</td>
</tr>
</tbody>
</table>

**Client**

class **CodePipeline.Client**

A low-level client representing AWS CodePipeline:

```python
import boto3

client = boto3.client('codepipeline')
```

These are the available methods:

• `acknowledge_job()`
• `acknowledge_third_party_job()`
• `can_paginate()`
• `create_custom_action_type()`
• `create_pipeline()`
• `delete_custom_action_type()`
• `delete_pipeline()`
• `disable_stage_transition()`
• `enable_stage_transition()`
• `generate_presigned_url()`
• `get_job_details()`
• `get_paginators()`
• `get_pipeline()`
• `get_pipeline_state()`
• `get_third_party_job_details()`
• `get_waiter()`
• `list_action_types()`
• `list_pipelines()`
• `poll_for_jobs()`
• `poll_for_third_party_jobs()`
• `put_action_revision()`
• `put_job_failure_result()`
• `put_job_success_result()`
• `put_third_party_job_failure_result()`
• `put_third_party_job_success_result()`
• `start_pipeline_execution()`
update_pipeline()  
acknowledge_job(**kwargs)

Returns information about a specified job and whether that job has been received by the job worker. Only used for custom actions.

Request Syntax

response = client.acknowledge_job(
    jobId='string',
    nonce='string'
)

Parameters

- **jobId** *(string)* – [REQUIRED]
  
The unique system-generated ID of the job for which you want to confirm receipt.

- **nonce** *(string)* – [REQUIRED]
  
A system-generated random number that AWS CodePipeline uses to ensure that the job is being worked on by only one job worker. This number must be returned in the response.

Return type  
dict

Returns

Response Syntax

```python
{
    'status': 'Created'|'Queued'|'Dispatched'|'InProgress'|'TimedOut'|'Succeeded'|'Failed'
}
```

Response Structure

- *(dict)* –
  
  Represents the output of an acknowledge job action.

  - **status** *(string)* –
    
    Whether the job worker has received the specified job.

acknowledge_third_party_job(**kwargs)

Confirms a job worker has received the specified job. Only used for partner actions.

Request Syntax

response = client.acknowledge_third_party_job(
    jobId='string',
    nonce='string',
    clientToken='string'
)

Parameters

- **jobId** *(string)* – [REQUIRED]
  
The unique system-generated ID of the job.

- **nonce** *(string)* – [REQUIRED]
  
A system-generated random number that AWS CodePipeline uses to ensure that the job is being worked on by only one job worker. This number must be returned in the response.
• **clientToken (string) – [REQUIRED]**
  
  The clientToken portion of the clientId and clientToken pair used to verify that the calling entity is allowed access to the job and its details.

**Return type**  dict

**Returns**

**Response Syntax**

```python
{
    'status': 'Created'|'Queued'|'Dispatched'|'InProgress'|'TimedOut'|'Succeeded'
}
```

**Response Structure**

• **(dict)** – Represents the output of an acknowledge third party job action.

  – **status (string)** – The status information for the third party job, if any.

**can_paginate (operation_name)**

Check if an operation can be paginated.

**Parameters**  operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you'd normally invoke the operation as `client.create_foo(**kwars)` if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

**Returns**  True if the operation can be paginated, False otherwise.

**create_custom_action_type (**kwars)**

 Creates a new custom action that can be used in all pipelines associated with the AWS account. Only used for custom actions.

**Request Syntax**

```python
response = client.create_custom_action_type(
    category='Source'|'Build'|'Deploy'|'Test'|'Invoke',
    provider='string',
    version='string',
    settings={
        'thirdPartyConfigurationUrl': 'string',
        'entityUrlTemplate': 'string',
        'executionUrlTemplate': 'string',
        'revisionUrlTemplate': 'string'
    },
    configurationProperties=[
        {
            'name': 'string',
            'required': True|False,
            'key': True|False,
            'secret': True|False,
            'queryable': True|False,
            'description': 'string',
            'type': 'String'|'Number'|'Boolean'
        }
    ],
    inputArtifactDetails={
        'minimumCount': 123,
    }
)
```

---

3.1. Services
Parameters

- **category** *(string)* – [REQUIRED]
  The category of the custom action, such as a source action or a build action.

- **provider** *(string)* – [REQUIRED]
  The provider of the service used in the custom action, such as AWS CodeDeploy.

- **version** *(string)* – [REQUIRED]
  The version number of the custom action.

  Note: A newly-created custom action is always assigned a version number of 1. This is required.

- **settings** *(dict)* – Returns information about the settings for an action type.
  - **thirdPartyConfigurationUrl** *(string)* –
    The URL of a sign-up page where users can sign up for an external service and perform initial configuration of the action provided by that service.
  - **entityUrlTemplate** *(string)* –
    The URL returned to the AWS CodePipeline console that provides a deep link to the resources of the external system, such as the configuration page for an AWS CodeDeploy deployment group. This link is provided as part of the action display within the pipeline.
  - **executionUrlTemplate** *(string)* –
    The URL returned to the AWS CodePipeline console that contains a link to the top-level landing page for the external system, such as console page for AWS CodeDeploy. This link is shown on the pipeline view page in the AWS CodePipeline console and provides a link to the execution entity of the external action.
  - **revisionUrlTemplate** *(string)* –
    The URL returned to the AWS CodePipeline console that contains a link to the page where customers can update or change the configuration of the external action.

- **configurationProperties** *(list)* – The configuration properties for the custom action.
  - *(dict)* –
    Represents information about an action configuration property.
    - **name** *(string)* – [REQUIRED]
      The name of the action configuration property.
    - **required** *(boolean)* – [REQUIRED]
      Whether the configuration property is a required value.
    - **key** *(boolean)* – [REQUIRED]
      Whether the configuration property is a key.
secret (boolean) – [REQUIRED]

Whether the configuration property is secret. Secrets are hidden from all calls except for GetJobDetails, GetThirdPartyJobDetails, PollForJobs, and PollForThirdPartyJobs.

When updating a pipeline, passing ** without changing any other values of the action will preserve the prior value of the secret.

queryable (boolean) –

Indicates that the property will be used in conjunction with PollForJobs. When creating a custom action, an action can have up to one queryable property. If it has one, that property must be both required and not secret.

If you create a pipeline with a custom action type, and that custom action contains a queryable property, the value for that configuration property is subject to additional restrictions. The value must be less than or equal to twenty (20) characters. The value can contain only alphanumeric characters, underscores, and hyphens.

description (string) –

The description of the action configuration property that will be displayed to users.

type (string) –

The type of the configuration property.

inputArtifactDetails (dict) – [REQUIRED]

Returns information about the details of an artifact.

- minimumCount (integer) – [REQUIRED]

The minimum number of artifacts allowed for the action type.

- maximumCount (integer) – [REQUIRED]

The maximum number of artifacts allowed for the action type.

outputArtifactDetails (dict) – [REQUIRED]

Returns information about the details of an artifact.

- minimumCount (integer) – [REQUIRED]

The minimum number of artifacts allowed for the action type.

- maximumCount (integer) – [REQUIRED]

The maximum number of artifacts allowed for the action type.

Return type  dict

Returns

Response Syntax

{
    'actionType': {
        'id': {
            'category': 'Source'|'Build'|'Deploy'|'Test'|'Invoke',
            'owner': 'AWS'|'ThirdParty'|'Custom',
            'provider': 'string',
            'version': 'string'
        },
        'settings': {
            'thirdPartyConfigurationUrl': 'string',
            'entityUrlTemplate': 'string',
        }
    }
}
'executionUrlTemplate': 'string',
'revisionUrlTemplate': 'string'
},
'actionConfigurationProperties': [
{
'name': 'string',
'required': True|False,
'key': True|False,
'secret': True|False,
'queryable': True|False,
'description': 'string',
'type': 'String'|'Number'|'Boolean'
},
],
'inputArtifactDetails': {
'minimumCount': 123,
'maximumCount': 123
},
'outputArtifactDetails': {
'minimumCount': 123,
'maximumCount': 123
}
}

Response Structure

- (dict) –
  Represents the output of a create custom action operation.
  
  - **actionType** (dict) –
    Returns information about the details of an action type.
    
    - **id** (dict) –
      Represents information about an action type.
      
      - **category** (string) –
        A category defines what kind of action can be taken in the stage, and constrains the provider type for the action. Valid categories are limited to one of the values below.
      
      - **owner** (string) –
        The creator of the action being called.
      
      - **provider** (string) –
        The provider of the service being called by the action. Valid providers are determined by the action category. For example, an action in the Deploy category type might have a provider of AWS CodeDeploy, which would be specified as CodeDeploy.
      
      - **version** (string) –
        A string that identifies the action type.
      
    - **settings** (dict) –
      The settings for the action type.
      
      - **thirdPartyConfigurationUrl** (string) –
        The URL of a sign-up page where users can sign up for an external service and perform initial configuration of the action provided by that service.
· **entityUrlTemplate** *(string)* –
  The URL returned to the AWS CodePipeline console that provides a deep link to the resources of the external system, such as the configuration page for an AWS CodeDeploy deployment group. This link is provided as part of the action display within the pipeline.

· **executionUrlTemplate** *(string)* –
  The URL returned to the AWS CodePipeline console that contains a link to the top-level landing page for the external system, such as console page for AWS CodeDeploy. This link is shown on the pipeline view page in the AWS CodePipeline console and provides a link to the execution entity of the external action.

· **revisionUrlTemplate** *(string)* –
  The URL returned to the AWS CodePipeline console that contains a link to the page where customers can update or change the configuration of the external action.

* **actionConfigurationProperties** *(list)* –
  The configuration properties for the action type.
    · *(dict)* –
      Represents information about an action configuration property.
        · **name** *(string)* –
          The name of the action configuration property.
        · **required** *(boolean)* –
          Whether the configuration property is a required value.
        · **key** *(boolean)* –
          Whether the configuration property is a key.
        · **secret** *(boolean)* –
          Whether the configuration property is secret. Secrets are hidden from all calls except for GetJobDetails, GetThirdPartyJobDetails, PollForJobs, and PollForThirdPartyJobs.

When updating a pipeline, passing `* * * * *` without changing any other values of the action will preserve the prior value of the secret.

· **Queryable** *(boolean)* –
  Indicates that the property will be used in conjunction with PollForJobs. When creating a custom action, an action can have up to one queryable property. If it has one, that property must be both required and not secret.

If you create a pipeline with a custom action type, and that custom action contains a queryable property, the value for that configuration property is subject to additional restrictions. The value must be less than or equal to twenty (20) characters. The value can contain only alphanumeric characters, underscores, and hyphens.

· **description** *(string)* –
The description of the action configuration property that will be displayed to users.

- **type (string)** –

  The type of the configuration property.

- **inputArtifactDetails (dict)** –

  The details of the input artifact for the action, such as its commit ID.

  - **minimumCount (integer)** –

    The minimum number of artifacts allowed for the action type.

  - **maximumCount (integer)** –

    The maximum number of artifacts allowed for the action type.

- **outputArtifactDetails (dict)** –

  The details of the output artifact of the action, such as its commit ID.

  - **minimumCount (integer)** –

    The minimum number of artifacts allowed for the action type.

  - **maximumCount (integer)** –

    The maximum number of artifacts allowed for the action type.

```python
create_pipeline(**kwargs)
```

Creates a pipeline.

**Request Syntax**

```python
response = client.create_pipeline(
    pipeline={
        'name': 'string',
        'roleArn': 'string',
        'artifactStore': {
            'type': 'S3',
            'location': 'string',
            'encryptionKey': {
                'id': 'string',
                'type': 'KMS'
            }
        },
        'stages': [
            {
                'name': 'string',
                'blockers': [
                    {
                        'name': 'string',
                        'type': 'Schedule'
                    }
                ],
                'actions': [
                    {
                        'name': 'string',
                        'actionTypeId': {
                            'category': 'Source'|'Build'|'Deploy'|'Test'|'Invoke',
                            'owner': 'AWS'|'ThirdParty'|'Custom',
                            'provider': 'string',
                            'version': 'string'
                        },
                        'runOrder': 123,
                    }
                ]
            }
        ]
    }
)
```
Parameters `pipeline (dict) – [REQUIRED]`

Represents the structure of actions and stages to be performed in the pipeline.

- **name (string) – [REQUIRED]**
  
The name of the action to be performed.

- **roleArn (string) – [REQUIRED]**
  
The Amazon Resource Name (ARN) for AWS CodePipeline to use to either perform actions with no actionRoleArn, or to use to assume roles for actions with an actionRoleArn.

- **artifactStore (dict) – [REQUIRED]**
  
The Amazon S3 location where artifacts are stored for the pipeline. If this Amazon S3 bucket is created manually, it must meet the requirements for AWS CodePipeline. For more information, see the Concepts.
  
  - **type (string) – [REQUIRED]**
    
The type of the artifact store, such as S3.
  
  - **location (string) – [REQUIRED]**
    
The location for storing the artifacts for a pipeline, such as an S3 bucket or folder.
  
  - **encryptionKey (dict) –**
    
The AWS Key Management Service (AWS KMS) key used to encrypt the data in the artifact store. If this is undefined, the default key for Amazon S3 is used.
    
    - **id (string) – [REQUIRED]**
      
The ID of the AWS KMS key.
    
    - **type (string) – [REQUIRED]**
      
The type of AWS KMS key, such as a customer master key.

- **stages (list) – [REQUIRED]**
  
The stage in which to perform the action.
  
  - (dict) –
Represents information about a stage and its definition.

* **name (string)** – [REQUIRED]
  
  The name of the stage.

* **blockers (list)** –
  
  The gates included in a stage.
  
  · **(dict)** –
    
    Represents information about a gate declaration.
    
    · **name (string)** – [REQUIRED]
      
      The name of the gate declaration.
    
    · **type (string)** – [REQUIRED]
      
      The type of the gate declaration.

* **actions (list)** – [REQUIRED]
  
  The actions included in a stage.
  
  · **(dict)** –
    
    Represents information about an action declaration.
    
    · **name (string)** – [REQUIRED]
      
      The action declaration’s name.
    
    · **actionTypeId (dict)** – [REQUIRED]
      
      The configuration information for the action type.
    
    · **category (string)** – [REQUIRED]
      
      A category defines what kind of action can be taken in the stage, and constrains the provider type for the action. Valid categories are limited to one of the values below.
    
    · **owner (string)** – [REQUIRED]
      
      The creator of the action being called.
    
    · **provider (string)** – [REQUIRED]
      
      The provider of the service being called by the action. Valid providers are determined by the action category. For example, an action in the Deploy category type might have a provider of AWS CodeDeploy, which would be specified as CodeDeploy.
    
    · **version (string)** – [REQUIRED]
      
      A string that identifies the action type.
    
    · **runOrder (integer)** –
      
      The order in which actions are run.
    
    · **configuration (dict)** –
      
      The action declaration’s configuration.
    
    · **(string)** –
      
    · **(string)** –
      
    · **outputArtifacts (list)** –
      
      The name or ID of the result of the action declaration, such as a test or build artifact.
    
    · **(dict)** –
      
      Represents information about the output of an action.
    
    · **name (string)** – [REQUIRED]
      
      The name of the output of an artifact, such as “My App”.
The input artifact of an action must exactly match the output artifact declared in a preceding action, but the input artifact does not have to be the next action in strict sequence from the action that provided the output artifact. Actions in parallel can declare different output artifacts, which are in turn consumed by different following actions.

Output artifact names must be unique within a pipeline.

- **inputArtifacts (list)**
  
The name or ID of the artifact consumed by the action, such as a test or build artifact.

- **(dict)**
  
  Represents information about an artifact to be worked on, such as a test or build artifact.

- **name (string) – [REQUIRED]**
  
The name of the artifact to be worked on, for example, “My App”.

The input artifact of an action must exactly match the output artifact declared in a preceding action, but the input artifact does not have to be the next action in strict sequence from the action that provided the output artifact. Actions in parallel can declare different output artifacts, which are in turn consumed by different following actions.

- **roleArn (string)**
  
The ARN of the IAM service role that will perform the declared action. This is assumed through the roleArn for the pipeline.

- **version (integer)**
  
The version number of the pipeline. A new pipeline always has a version number of 1. This number is automatically incremented when a pipeline is updated.

Return type  dict

Returns

Response Structure

• (dict) –

Represents the output of a create pipeline action.

– pipeline (dict) –

Represents the structure of actions and stages to be performed in the pipeline.

* name (string) –

The name of the action to be performed.

* roleArn (string) –

The Amazon Resource Name (ARN) for AWS CodePipeline to use to either perform actions with no actionRoleArn, or to use to assume roles for actions with an actionRoleArn.

* artifactStore (dict) –

The Amazon S3 location where artifacts are stored for the pipeline. If this Amazon S3 bucket is created manually, it must meet the requirements for AWS CodePipeline. For more information, see the Concepts.

* type (string) –
The type of the artifact store, such as S3.

- **location (string)** –
The location for storing the artifacts for a pipeline, such as an S3 bucket or folder.

- **encryptionKey (dict)** –
The AWS Key Management Service (AWS KMS) key used to encrypt the data in the artifact store. If this is undefined, the default key for Amazon S3 is used.

  - **id (string)** –
The ID of the AWS KMS key.
  - **type (string)** –
The type of AWS KMS key, such as a customer master key.

- **stages (list)** –
The stage in which to perform the action.

  - (dict) –
    Represents information about a stage and its definition.
    
    - **name (string)** –
The name of the stage.
    - **blockers (list)** –
The gates included in a stage.
      
      - (dict) –
        Represents information about a gate declaration.
        
        - **name (string)** –
The name of the gate declaration.
        - **type (string)** –
The type of the gate declaration.
        - **actions (list)** –
The actions included in a stage.
          
          - (dict) –
            Represents information about an action declaration.
            
            - **name (string)** –
The action declaration’s name.
            - **actionTypeId (dict)** –
The configuration information for the action type.
              
              - **category (string)** –
                A category defines what kind of action can be taken in the stage, and constrains the provider type for the action. Valid categories are limited to one of the values below.
            - **owner (string)** –
The creator of the action being called.
            - **provider (string)** –
The provider of the service being called by the action. Valid providers are determined by the action category. For example, an action in the Deploy category type might have a provider of AWS CodeDeploy, which would be specified as CodeDeploy.
· **version** *(string)* –
  A string that identifies the action type.

· **runOrder** *(integer)* –
  The order in which actions are run.

· **configuration** *(dict)* –
  The action declaration’s configuration.
  · *(string)* –
  · *(string)* –

· **outputArtifacts** *(list)* –
  The name or ID of the result of the action declaration, such as a test or build artifact.
  · *(dict)* –
  Represents information about the output of an action.

· **name** *(string)* –
  The name of the output of an artifact, such as “My App”.

  The input artifact of an action must exactly match the output artifact declared in a preceding action, but the input artifact does not have to be the next action in strict sequence from the action that provided the output artifact. Actions in parallel can declare different output artifacts, which are in turn consumed by different following actions.

  Output artifact names must be unique within a pipeline.

· **inputArtifacts** *(list)* –
  The name or ID of the artifact consumed by the action, such as a test or build artifact.
  · *(dict)* –
  Represents information about an artifact to be worked on, such as a test or build artifact.

· **name** *(string)* –
  The name of the artifact to be worked on, for example, “My App”.

  The input artifact of an action must exactly match the output artifact declared in a preceding action, but the input artifact does not have to be the next action in strict sequence from the action that provided the output artifact. Actions in parallel can declare different output artifacts, which are in turn consumed by different following actions.

· **roleArn** *(string)* –
  The ARN of the IAM service role that will perform the declared action. This is assumed through the roleArn for the pipeline.

· **version** *(integer)* –
  The version number of the pipeline. A new pipeline always has a version number of 1. This number is automatically incremented when a pipeline is updated.
**delete_custom_action_type(**kwargs)

Marks a custom action as deleted. PollForJobs for the custom action will fail after the action is marked for deletion. Only used for custom actions.

**Warning:** You cannot recreate a custom action after it has been deleted unless you increase the version number of the action.

**Request Syntax**

```python
response = client.delete_custom_action_type(
    category='Source'|'Build'|'Deploy'|'Test'|'Invoke',
    provider='string',
    version='string'
)
```

**Parameters**

- **category (string)** – [REQUIRED]
  The category of the custom action that you want to delete, such as source or deploy.
- **provider (string)** – [REQUIRED]
  The provider of the service used in the custom action, such as AWS CodeDeploy.
- **version (string)** – [REQUIRED]
  The version of the custom action to delete.

**Returns** None

**delete_pipeline(**kwargs)

Deletes the specified pipeline.

**Request Syntax**

```python
response = client.delete_pipeline(
    name='string'
)
```

**Parameters**

- **name (string)** – [REQUIRED]
  The name of the pipeline to be deleted.

**Returns** None

**disable_stage_transition(**kwargs)

Prevents artifacts in a pipeline from transitioning to the next stage in the pipeline.

**Request Syntax**

```python
response = client.disable_stage_transition(
    pipelineName='string',
    stageName='string',
    transitionType='Inbound'|'Outbound',
    reason='string'
)
```

**Parameters**

- **pipelineName (string)** – [REQUIRED]
  The name of the pipeline in which you want to disable the flow of artifacts from one stage to another.
• **stageName (string)** – [REQUIRED]
  The name of the stage where you want to disable the inbound or outbound transition of artifacts.

• **transitionType (string)** – [REQUIRED]
  Specifies whether artifacts will be prevented from transitioning into the stage and being processed by the actions in that stage (inbound), or prevented from transitioning from the stage after they have been processed by the actions in that stage (outbound).

• **reason (string)** – [REQUIRED]
  The reason given to the user why a stage is disabled, such as waiting for manual approval or manual tests. This message is displayed in the pipeline console UI.

Returns None

```python
enable_stage_transition(**kwargs)
```

Enables artifacts in a pipeline to transition to a stage in a pipeline.

Request Syntax

```python
response = client.enable_stage_transition(
    pipelineName='string',
    stageName='string',
    transitionType='Inbound'|'Outbound'
)
```

Parameters

• **pipelineName (string)** – [REQUIRED]
  The name of the pipeline in which you want to enable the flow of artifacts from one stage to another.

• **stageName (string)** – [REQUIRED]
  The name of the stage where you want to enable the transition of artifacts, either into the stage (inbound) or from that stage to the next stage (outbound).

• **transitionType (string)** – [REQUIRED]
  Specifies whether artifacts will be allowed to enter the stage and be processed by the actions in that stage (inbound) or whether already-processed artifacts will be allowed to transition to the next stage (outbound).

Returns None

```python
generate_presigned_url(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)
```

Generate a presigned url given a client, its method, and arguments

Parameters

• **ClientMethod (string)** – The client method to presign for
  
• **Params (dict)** – The parameters normally passed to ClientMethod.

• **ExpiresIn (int)** – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)

• **HttpMethod (string)** – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns The presigned url

```python
get_job_details(**kwargs)
```

Returns information about a job. Only used for custom actions.
**Warning:** When this API is called, AWS CodePipeline returns temporary credentials for the Amazon S3 bucket used to store artifacts for the pipeline, if the action requires access to that Amazon S3 bucket for input or output artifacts. Additionally, this API returns any secret values defined for the action.

### Request Syntax

```python
response = client.get_job_details(
    jobId='string'
)
```

**Parameters**

- **jobId** *(string) – [REQUIRED]*

  The unique system-generated ID for the job.

**Return type**

**dict**

**Returns**

- **Response Syntax**

  ```json
  {
      'jobDetails': {
          'id': 'string',
          'data': {
              'actionTypeId': {
                  'category': 'Source'|'Build'|'Deploy'|'Test'|'Invoke',
                  'owner': 'AWS'|'ThirdParty'|'Custom',
                  'provider': 'string',
                  'version': 'string'
              },
              'actionConfiguration': {
                  'configuration': {
                      'string': 'string'
                  }
              },
              'pipelineContext': {
                  'pipelineName': 'string',
                  'stage': {
                      'name': 'string'
                  },
                  'action': {
                      'name': 'string'
                  }
              },
              'inputArtifacts': [
                  {
                      'name': 'string',
                      'revision': 'string',
                      'location': {
                          'type': 'S3',
                          's3Location': {
                              'bucketName': 'string',
                              'objectKey': 'string'
                          }
                      }
                  },
                  ...  # More input artifacts
              ],
              'outputArtifacts': [
                  {
                      ...  # More output artifacts
                  }
              ]
          }
      }
  }
  ```
Response Structure

- (dict) –

   Represents the output of a get job details action.

   - jobDetails (dict) –

      The details of the job.

      **Note:** If AWSSessionCredentials is used, a long-running job can call GetJobDetails again to obtain new credentials.

      - **id (string)** –

         The unique system-generated ID of the job.

      - **data (dict)** –

         Represents additional information about a job required for a job worker to complete the job.

         - actionTypeId (dict) –

            Represents information about an action type.

         - **category (string)** –

            A category defines what kind of action can be taken in the stage, and constrains the provider type for the action. Valid categories are limited to one of the values below.

         - **owner (string)** –

            The creator of the action being called.

         - **provider (string)** –

            The provider of the service being called by the action. Valid providers are determined by the action category. For example,
an action in the Deploy category type might have a provider of
AWS CodeDeploy, which would be specified as CodeDeploy.

- **version (string)** –
  A string that identifies the action type.

- **actionConfiguration (dict)** –
  Represents information about an action configuration.

  - **configuration (dict)** –
    The configuration data for the action.

    - **(string)** –
    - **(string)** –

  - **pipelineContext (dict)** –
    Represents information about a pipeline to a job worker.

    - **pipelineName (string)** –
      The name of the pipeline. This is a user-specified value.
      Pipeline names must be unique across all pipeline names un-
      der an Amazon Web Services account.

    - **stage (dict)** –
      The stage of the pipeline.

    - **name (string)** –
      The name of the stage.

- **action (dict)** –
  Represents the context of an action within the stage of a
  pipeline to a job worker.

    - **name (string)** –
      The name of the action within the context of a job.

- **inputArtifacts (list)** –
  The artifact supplied to the job.

    - **(dict)** –
    Represents information about an artifact that will be worked
    upon by actions in the pipeline.

    - **name (string)** –
      The artifact’s name.

    - **revision (string)** –
      The artifact’s revision ID. Depending on the type of object,
      this could be a commit ID (GitHub) or a revision ID (Amazon
      S3).

    - **location (dict)** –
      The location of an artifact.

    - **type (string)** –
      The type of artifact in the location.

- **s3Location (dict)** –
  The Amazon S3 bucket that contains the artifact.

    - **bucketName (string)** –
      The name of the Amazon S3 bucket.
- **objectKey** *(string)* –
  The key of the object in the Amazon S3 bucket, which uniquely identifies the object in the bucket.

- **outputArtifacts** *(list)* –
  The output of the job.
  *(dict)* –
  Represents information about an artifact that will be worked upon by actions in the pipeline.
  - **name** *(string)* –
    The artifact’s name.
  - **revision** *(string)* –
    The artifact’s revision ID. Depending on the type of object, this could be a commit ID (GitHub) or a revision ID (Amazon S3).
  - **location** *(dict)* –
    The location of an artifact.
  - **type** *(string)* –
    The type of artifact in the location.
  - **s3Location** *(dict)* –
    The Amazon S3 bucket that contains the artifact.
  - **bucketName** *(string)* –
    The name of the Amazon S3 bucket.
  - **objectKey** *(string)* –
    The key of the object in the Amazon S3 bucket, which uniquely identifies the object in the bucket.
  - **artifactCredentials** *(dict)* –
    Represents an AWS session credentials object. These credentials are temporary credentials that are issued by AWS Secure Token Service (STS). They can be used to access input and output artifacts in the Amazon S3 bucket used to store artifact for the pipeline in AWS CodePipeline.
  - **accessKeyId** *(string)* –
    The access key for the session.
  - **secretAccessKey** *(string)* –
    The secret access key for the session.
  - **sessionToken** *(string)* –
    The token for the session.
  - **continuationToken** *(string)* –
    A system-generated token, such as a AWS CodeDeploy deployment ID, that a job requires in order to continue the job asynchronously.
  - **encryptionKey** *(dict)* –
    Represents information about the AWS Key Management Service (AWS KMS) key used to encrypt data in the artifact store.
· **id (string)** –
  The ID of the AWS KMS key.

· **type (string)** –
  The type of AWS KMS key, such as a customer master key.

* **accountId (string)** –
  The AWS account ID associated with the job.

**get Paginator** *(operation_name)*
Create a paginator for an operation.

**Parameters** `operation_name (string)` – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you'd normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.getPaginator("create_foo")`.

**Raises** `OperationNotPageableError` Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

**Return type** `botocore.paginatePaginator`

**Returns** A paginator object.

**get Pipeline** (**kwargs**)
Returns the metadata, structure, stages, and actions of a pipeline. Can be used to return the entire structure of a pipeline in JSON format, which can then be modified and used to update the pipeline structure with `UpdatePipeline`.

**Request Syntax**

```python
response = client.get_pipeline(
    name='string',
    version=123
)
```

**Parameters**
- **name (string)** – [REQUIRED]
  The name of the pipeline for which you want to get information. Pipeline names must be unique under an Amazon Web Services (AWS) user account.
- **version (integer)** – The version number of the pipeline. If you do not specify a version, defaults to the most current version.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'pipeline': {
        'name': 'string',
        'roleArn': 'string',
        'artifactStore': {
            'type': 'S3',
            'location': 'string',
            'encryptionKey': {
                'id': 'string',
                'type': 'KMS'
            }
        },
        'stages': [
        ]
    }
}
```
Response Structure

* (dict) –

Represents the output of a get pipeline action.

  – pipeline (dict) –

Represents the structure of actions and stages to be performed in the pipeline.

  * name (string) –

The name of the action to be performed.

  * roleArn (string) –

The Amazon Resource Name (ARN) for AWS CodePipeline to use to either perform actions with no actionRoleArn, or to use to assume roles for actions with an actionRoleArn.

  * artifactStore (dict) –

The Amazon S3 location where artifacts are stored for the pipeline.
If this Amazon S3 bucket is created manually, it must meet the requirements for AWS CodePipeline. For more information, see the Concepts.

- **type (string)** –
  The type of the artifact store, such as S3.

- **location (string)** –
  The location for storing the artifacts for a pipeline, such as an S3 bucket or folder.

- **encryptionKey (dict)** –
  The AWS Key Management Service (AWS KMS) key used to encrypt the data in the artifact store. If this is undefined, the default key for Amazon S3 is used.

  - **id (string)** –
    The ID of the AWS KMS key.

  - **type (string)** –
    The type of AWS KMS key, such as a customer master key.

- **stages (list)** –
  The stage in which to perform the action.

  - (dict) –
    Represents information about a stage and its definition.

    - **name (string)** –
      The name of the stage.

    - **blockers (list)** –
      The gates included in a stage.

      - (dict) –
        Represents information about a gate declaration.

        - **name (string)** –
          The name of the gate declaration.

        - **type (string)** –
          The type of the gate declaration.

        - **actions (list)** –
          The actions included in a stage.

      - (dict) –
        Represents information about an action declaration.

        - **name (string)** –
          The action declaration’s name.

        - **actionTypeId (dict)** –
          The configuration information for the action type.

        - **category (string)** –
          A category defines what kind of action can be taken in the stage, and constrains the provider type for the action. Valid categories are limited to one of the values below.

        - **owner (string)** –
          The creator of the action being called.
- **provider** *(string)* –
  The provider of the service being called by the action. Valid providers are determined by the action category. For example, an action in the Deploy category type might have a provider of AWS CodeDeploy, which would be specified as CodeDeploy.

- **version** *(string)* –
  A string that identifies the action type.

- **runOrder** *(integer)* –
  The order in which actions are run.

- **configuration** *(dict)* –
  The action declaration’s configuration.

  - **(string)** –
  - **(string)** –

- **outputArtifacts** *(list)* –
  The name or ID of the result of the action declaration, such as a test or build artifact.

  - **(dict)** –

  Represents information about the output of an action.

- **name** *(string)* –
  The name of the output of an artifact, such as “My App”.

  The input artifact of an action must exactly match the output artifact declared in a preceding action, but the input artifact does not have to be the next action in strict sequence from the action that provided the output artifact. Actions in parallel can declare different output artifacts, which are in turn consumed by different following actions.

  Output artifact names must be unique within a pipeline.

- **inputArtifacts** *(list)* –
  The name or ID of the artifact consumed by the action, such as a test or build artifact.

  - **(dict)** –

  Represents information about an artifact to be worked on, such as a test or build artifact.

- **name** *(string)* –
  The name of the artifact to be worked on, for example, “My App”.

  The input artifact of an action must exactly match the output artifact declared in a preceding action, but the input artifact does not have to be the next action in strict sequence from the action that provided the output artifact. Actions in parallel can declare different output artifacts, which are in turn consumed by different following actions.

- **roleArn** *(string)* –
  The ARN of the IAM service role that will perform the declared action. This is assumed through the roleArn for the pipeline.
* version (integer) –

The version number of the pipeline. A new pipeline always has a version number of 1. This number is automatically incremented when a pipeline is updated.

**get_pipeline_state(**kwargs**)

Returns information about the state of a pipeline, including the stages, actions, and details about the last run of the pipeline.

**Request Syntax**

```python
response = client.get_pipeline_state(
    name='string'
)
```

**Parameters name (string) – [REQUIRED]**

The name of the pipeline about which you want to get information.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'pipelineName': 'string',
    'pipelineVersion': 123,
    'stageStates': [
        {
            'stageName': 'string',
            'inboundTransitionState': {
                'enabled': True|False,
                'lastChangedBy': 'string',
                'lastChangedAt': datetime(2015, 1, 1),
                'disabledReason': 'string'
            },
            'actionStates': [
                {
                    'actionName': 'string',
                    'currentRevision': {
                        'revisionId': 'string',
                        'revisionChangeId': 'string',
                        'created': datetime(2015, 1, 1)
                    },
                    'latestExecution': {
                        'status': 'InProgress'|'Succeeded'|'Failed',
                        'summary': 'string',
                        'lastStatusChange': datetime(2015, 1, 1),
                        'externalExecutionId': 'string',
                        'externalExecutionUrl': 'string',
                        'percentComplete': 123,
                        'errorDetails': {
                            'code': 'string',
                            'message': 'string'
                        }
                    },
                    'entityUrl': 'string',
                    'revisionUrl': 'string'
                }
            ]
        }
    ]
}
```
Response Structure

- `(dict)` –

Represents the output of a get pipeline state action.

  - `pipelineName (string)` –
    The name of the pipeline for which you want to get the state.

  - `pipelineVersion (integer)` –
    The version number of the pipeline.

Note: A newly-created pipeline is always assigned a version number of 1.

- `stageStates (list)` –

A list of the pipeline stage output information, including stage name, state, most recent run details, whether the stage is disabled, and other data.

  - `(dict)` –

Represents information about the state of the stage.

  - `stageName (string)` –
    The name of the stage.

  - `inboundTransitionState (dict)` –
    The state of the inbound transition, which is either enabled or disabled.

  - `enabled (boolean)` –
    Whether the transition between stages is enabled (true) or disabled (false).

  - `lastChangedBy (string)` –
    The ID of the user who last changed the transition state.

  - `lastChangedAt (datetime)` –
    The timestamp when the transition state was last changed.

  - `disabledReason (string)` –
    The user-specified reason why the transition between two stages of a pipeline was disabled.

  - `actionStates (list)` –
    The state of the stage.

  - `(dict)` –

Represents information about the state of an action.

  - `actionName (string)` –
    The name of the action.

  - `currentRevision (dict)` –
    Represents information about the version (or revision) of an action.
· revisionId (string) –
  The system-generated unique ID that identifies the revision number of the action.
· revisionChangeId (string) –
  The unique identifier of the change that set the state to this revision, for example a deployment ID or timestamp.
· created (datetime) –
  The date and time when the most recent version of the action was created, in timestamp format.
· latestExecution (dict) –
  Represents information about how an action runs.
  · status (string) –
    The status of the action, or for a completed action, the last status of the action.
  · summary (string) –
    A summary of the run of the action.
  · lastStatusChange (datetime) –
    The last status change of the action.
· externalExecutionId (string) –
  The external ID of the run of the action.
· externalExecutionUrl (string) –
  The URL of a resource external to AWS that will be used when running the action, for example an external repository URL.
· percentComplete (integer) –
  A percentage of completeness of the action as it runs.
· errorDetails (dict) –
  The details of an error returned by a URL external to AWS.
  · code (string) –
    The system ID or error number code of the error.
  · message (string) –
    The text of the error message.
· entityUrl (string) –
  A URL link for more information about the state of the action, such as a deployment group details page.
· revisionUrl (string) –
  A URL link for more information about the revision, such as a commit details page.
  · created (datetime) –
    The date and time the pipeline was created, in timestamp format.
  · updated (datetime) –
    The date and time the pipeline was last updated, in timestamp format.

get_third_party_job_details(**kwargs)
Requests the details of a job for a third party action. Only used for partner actions.
Warning: When this API is called, AWS CodePipeline returns temporary credentials for the Amazon S3 bucket used to store artifacts for the pipeline, if the action requires access to that Amazon S3 bucket for input or output artifacts. Additionally, this API returns any secret values defined for the action.

Request Syntax

```python
response = client.get_third_party_job_details(
    jobId='string',
    clientToken='string'
)
```

Parameters

- **jobId** (*string*) – [REQUIRED]
  
  The unique system-generated ID used for identifying the job.

- **clientToken** (*string*) – [REQUIRED]
  
  The clientToken portion of the clientId and clientToken pair used to verify that the calling entity is allowed access to the job and its details.

Return type: dict

Returns

Response Syntax

```json
{
   'jobDetails': {
      'id': 'string',
      'data': {
         'actionTypeId': {
            'category': 'Source'|'Build'|'Deploy'|'Test'|'Invoke',
            'owner': 'AWS'|'ThirdParty'|'Custom',
            'provider': 'string',
            'version': 'string'
         },
         'actionConfiguration': {
            'configuration': {
               'string': 'string'
            }
         },
         'pipelineContext': {
            'pipelineName': 'string',
            'stage': {
               'name': 'string'
            },
            'action': {
               'name': 'string'
            }
         },
         'inputArtifacts': [
            {
               'name': 'string',
               'revision': 'string',
               'location': {
                  'type': 'S3',
                  's3Location': {
                     'bucketName': 'string',
                     'objectKey': 'string'
                  }
               }
            }
         ]
      }
   }
}
```

Response Structure

- (dict) – Represents the output of a get third party job details action.

  - jobDetails (dict) –

    The details of the job, including any protected values defined for the job.
    
    * id (string) – The identifier used to identify the job details in AWS CodePipeline.
    * data (dict) – The data to be returned by the third party job worker.

      - actionTypeId (dict) – Represents information about an action type.
      - category (string) – A category defines what kind of action can be taken in the stage, and constrains the provider type for the action. Valid categories are limited to one of the values below.
      - owner (string) – The creator of the action being called.
      - provider (string) – The provider of the service being called by the action. Valid providers are determined by the action category. For example,
an action in the Deploy category type might have a provider of AWS CodeDeploy, which would be specified as CodeDeploy.

- **version** *(string)* –
  A string that identifies the action type.

- **actionConfiguration** *(dict)* –
  Represents information about an action configuration.

  - **configuration** *(dict)* –
    The configuration data for the action.
    - *(string)* –
    - *(string)* –

- **pipelineContext** *(dict)* –
  Represents information about a pipeline to a job worker.

  - **pipelineName** *(string)* –
    The name of the pipeline. This is a user-specified value. Pipeline names must be unique across all pipeline names under an Amazon Web Services account.

  - **stage** *(dict)* –
    The stage of the pipeline.

  - **name** *(string)* –
    The name of the stage.

  - **action** *(dict)* –
    Represents the context of an action within the stage of a pipeline to a job worker.

  - **name** *(string)* –
    The name of the action within the context of a job.

  - **inputArtifacts** *(list)* –
    The name of the artifact that will be worked upon by the action, if any. This name might be system-generated, such as “MyApp”, or might be defined by the user when the action is created. The input artifact name must match the name of an output artifact generated by an action in an earlier action or stage of the pipeline.

    - *(dict)* –
      Represents information about an artifact that will be worked upon by actions in the pipeline.

      - **name** *(string)* –
        The artifact’s name.

      - **revision** *(string)* –
        The artifact’s revision ID. Depending on the type of object, this could be a commit ID (GitHub) or a revision ID (Amazon S3).

      - **location** *(dict)* –
        The location of an artifact.

      - **type** *(string)* –
        The type of artifact in the location.
- **s3Location** (dict) –
  The Amazon S3 bucket that contains the artifact.
- **bucketName** (string) –
  The name of the Amazon S3 bucket.
- **objectKey** (string) –
  The key of the object in the Amazon S3 bucket, which unqiuely identifies the object in the bucket.
- **outputArtifacts** (list) –
  The name of the artifact that will be the result of the action, if any. This name might be system-generated, such as “My-BuiltApp”, or might be defined by the user when the action is created.
- **dict** –
  Represents information about an artifact that will be worked upon by actions in the pipeline.
- **name** (string) –
  The artifact’s name.
- **revision** (string) –
  The artifact’s revision ID. Depending on the type of object, this could be a commit ID (GitHub) or a revision ID (Amazon S3).
- **location** (dict) –
  The location of an artifact.
- **type** (string) –
  The type of artifact in the location.
- **s3Location** (dict) –
  The Amazon S3 bucket that contains the artifact.
- **bucketName** (string) –
  The name of the Amazon S3 bucket.
- **objectKey** (string) –
  The key of the object in the Amazon S3 bucket, which unqiuely identifies the object in the bucket.
- **artifactCredentials** (dict) –
  Represents an AWS session credentials object. These credentials are temporary credentials that are issued by AWS Secure Token Service (STS). They can be used to access input and output artifacts in the Amazon S3 bucket used to store artifact for the pipeline in AWS CodePipeline.
- **accessKeyId** (string) –
  The access key for the session.
- **secretAccessKey** (string) –
  The secret access key for the session.
- **sessionToken** (string) –
  The token for the session.
- **continuationToken** (string) –
A system-generated token, such as a AWS CodeDeploy deployment ID, that a job requires in order to continue the job asynchronously.

- encryptionKey (dict) –
  
  The AWS Key Management Service (AWS KMS) key used to encrypt and decrypt data in the artifact store for the pipeline.
  
  - id (string) –
    
    The ID of the AWS KMS key.
  
  - type (string) –
    
    The type of AWS KMS key, such as a customer master key.
  
- nonce (string) –

  A system-generated random number that AWS CodePipeline uses to ensure that the job is being worked on by only one job worker. This number must be returned in the response.

get_waiter (waiter_name)

list_action_types (**kwargs)

  Gets a summary of all AWS CodePipeline action types associated with your account.

  Request Syntax

  response = client.list_action_types(
    actionOwnerFilter='AWS'|'ThirdParty'|'Custom',
    nextToken='string'
  )

  Parameters

  - actionOwnerFilter (string) – Filters the list of action types to those created by a specified entity.
  
  - nextToken (string) – An identifier that was returned from the previous list action types call, which can be used to return the next set of action types in the list.

  Return type: dict

  Returns

  Response Syntax

  {
    'actionTypes': [
      {
        'id': {
          'category': 'Source'|'Build'|'Deploy'|'Test'|'Invoke',
          'owner': 'AWS'|'ThirdParty'|'Custom',
          'provider': 'string',
          'version': 'string'
        },
        'settings': {
          'thirdPartyConfigurationUrl': 'string',
          'entityUrlTemplate': 'string',
          'executionUrlTemplate': 'string',
          'revisionUrlTemplate': 'string'
        },
        'actionConfigurationProperties': [
          {
            'name': 'string',
            'value': 'string'
          }
        ]
      }
    ]
  }
'required': True|False,
'key': True|False,
'secret': True|False,
'queryable': True|False,
'description': 'string',
'type': 'String'|'Number'|'Boolean'
},

'inputArtifactDetails': {
  'minimumCount': 123,
  'maximumCount': 123
},

'outputArtifactDetails': {
  'minimumCount': 123,
  'maximumCount': 123
}

Response Structure

- (dict) –

  Represents the output of a list action types action.

  - actionTypes (list) –

    Provides details of the action types.

      * (dict) –

        Returns information about the details of an action type.

          - id (dict) –

            Represents information about an action type.

          - category (string) –

            A category defines what kind of action can be taken in the stage, and constrains the provider type for the action. Valid categories are limited to one of the values below.

          - owner (string) –

            The creator of the action being called.

          - provider (string) –

            The provider of the service being called by the action. Valid providers are determined by the action category. For example, an action in the Deploy category type might have a provider of AWS CodeDeploy, which would be specified as CodeDeploy.

          - version (string) –

            A string that identifies the action type.

          - settings (dict) –

            The settings for the action type.

          - thirdPartyConfigurationUrl (string) –

            The URL of a sign-up page where users can sign up for an external service and perform initial configuration of the action provided by that service.

          - entityUrlTemplate (string) –
The URL returned to the AWS CodePipeline console that provides a deep link to the resources of the external system, such as the configuration page for an AWS CodeDeploy deployment group. This link is provided as part of the action display within the pipeline.

- **executionUrlTemplate**(string) –

  The URL returned to the AWS CodePipeline console that contains a link to the top-level landing page for the external system, such as console page for AWS CodeDeploy. This link is shown on the pipeline view page in the AWS CodePipeline console and provides a link to the execution entity of the external action.

- **revisionUrlTemplate**(string) –

  The URL returned to the AWS CodePipeline console that contains a link to the page where customers can update or change the configuration of the external action.

- **actionConfigurationProperties**(list) –

  The configuration properties for the action type.

  - **(dict)** –

    Represents information about an action configuration property.

    - **name**(string) –

      The name of the action configuration property.

    - **required**(boolean) –

      Whether the configuration property is a required value.

    - **key**(boolean) –

      Whether the configuration property is a key.

    - **secret**(boolean) –

      Whether the configuration property is secret. Secrets are hidden from all calls except for GetJobDetails, GetThirdPartyJobDetails, PollForJobs, and PollForThirdPartyJobs.

      When updating a pipeline, passing 
      `* * * * *` without changing any other values of the action will preserve the prior value of the secret.

    - **queryable**(boolean) –

      Indicates that the property will be used in conjunction with PollForJobs. When creating a custom action, an action can have up to one queryable property. If it has one, that property must be both required and not secret.

      If you create a pipeline with a custom action type, and that custom action contains a queryable property, the value for that configuration property is subject to additional restrictions. The value must be less than or equal to twenty (20) characters. The value can contain only alphanumeric characters, underscores, and hyphens.

    - **description**(string) –

      The description of the action configuration property that will be displayed to users.
- **type** *(string)* – The type of the configuration property.
- **inputArtifactDetails** *(dict)* – The details of the input artifact for the action, such as its commit ID.
- **minimumCount** *(integer)* – The minimum number of artifacts allowed for the action type.
- **maximumCount** *(integer)* – The maximum number of artifacts allowed for the action type.
- **outputArtifactDetails** *(dict)* – The details of the output artifact of the action, such as its commit ID.
- **minimumCount** *(integer)* – The minimum number of artifacts allowed for the action type.
- **maximumCount** *(integer)* – The maximum number of artifacts allowed for the action type.

- **nextToken** *(string)* – If the amount of returned information is significantly large, an identifier is also returned which can be used in a subsequent list action types call to return the next set of action types in the list.

**list_pipelines(** **kwargs** **)**

Gets a summary of all of the pipelines associated with your account.

Request Syntax

```python
response = client.list_pipelines(
    nextToken='string'
)
```

**Parameters** **nextToken** *(string)* – An identifier that was returned from the previous list pipelines call, which can be used to return the next set of pipelines in the list.

**Return type** dict

**Returns**

Response Syntax

```python
{
    'pipelines': [
    {
        'name': 'string',
        'version': 123,
        'created': datetime(2015, 1, 1),
        'updated': datetime(2015, 1, 1)
    },
    ],
    'nextToken': 'string'
}
```

**Response Structure**

- *(dict)* – Represents the output of a list pipelines action.

3.1. Services
pipelines (list) –

The list of pipelines.

* (dict) –

Returns a summary of a pipeline.

  - name (string) –
    The name of the pipeline.
  - version (integer) –
    The version number of the pipeline.
  - created (datetime) –
    The date and time the pipeline was created, in timestamp format.
  - updated (datetime) –
    The date and time of the last update to the pipeline, in timestamp format.

nextToken (string) –

If the amount of returned information is significantly large, an identifier is also returned which can be used in a subsequent list pipelines call to return the next set of pipelines in the list.

poll_for_jobs (**kwargs)

Returns information about any jobs for AWS CodePipeline to act upon.

**Warning:** When this API is called, AWS CodePipeline returns temporary credentials for the Amazon S3 bucket used to store artifacts for the pipeline, if the action requires access to that Amazon S3 bucket for input or output artifacts. Additionally, this API returns any secret values defined for the action.

Request Syntax

```python
response = client.poll_for_jobs(
    actionTypeId={
        'category': 'Source'|'Build'|'Deploy'|'Test'|'Invoke',
        'owner': 'AWS'|'ThirdParty'|'Custom',
        'provider': 'string',
        'version': 'string'
    },
    maxBatchSize=123,
    queryParam={
        'string': 'string'
    }
)
```

Parameters

- **actionTypeId (dict)** – [REQUIRED]
  
  Represents information about an action type.

  - **category (string)** – [REQUIRED]
    
    A category defines what kind of action can be taken in the stage, and constrains the provider type for the action. Valid categories are limited to one of the values below.

  - **owner (string)** – [REQUIRED]
    
    The creator of the action being called.
– **provider** *(string)* – [REQUIRED]

The provider of the service being called by the action. Valid providers are determined by the action category. For example, an action in the Deploy category type might have a provider of AWS CodeDeploy, which would be specified as CodeDeploy.

– **version** *(string)* – [REQUIRED]

A string that identifies the action type.

- **maxBatchSize** *(integer)* – The maximum number of jobs to return in a poll for jobs call.
- **QueryParam** *(dict)* – A map of property names and values. For an action type with no queryable properties, this value must be null or an empty map. For an action type with a queryable property, you must supply that property as a key in the map. Only jobs whose action configuration matches the mapped value will be returned.

  – *(string)*

* *(string)*

**Return type**  dict

**Returns**

**Response Syntax**

```json
{
'jobs': [
{
'id': 'string',
'data': {
'actionTypeId': {
'category': 'Source'|'Build'|'Deploy'|'Test'|'Invoke',
'owner': 'AWS'|'ThirdParty'|'Custom',
'provider': 'string',
'version': 'string'
},
'actionConfiguration': {
'configuration': [{
'string': 'string'
}],
'pipelineContext': {
'pipelineName': 'string',
'stage': {
'name': 'string'
},
'action': {
'name': 'string'
}
},
'inputArtifacts': [
{
'name': 'string',
'revision': 'string',
'location': {
'type': 'S3',
's3Location': {
'bucketName': 'string',
'objectKey': 'string'
}
}
}
}
```
Response Structure

- (dict) – Represents the output of a poll for jobs action.
  - jobs (list) – Information about the jobs to take action on.
    * (dict) – Represents information about a job.
      - id (string) – The unique system-generated ID of the job.
      - data (dict) – Additional data about a job.
      - actionTypeId (dict) – Represents information about an action type.
        - category (string) – A category defines what kind of action can be taken in the stage, and constrains the provider type for the action. Valid categories are limited to one of the values below.
        - owner (string) – The creator of the action being called.
- **provider** *(string)* –
  The provider of the service being called by the action. Valid providers are determined by the action category. For example, an action in the Deploy category type might have a provider of AWS CodeDeploy, which would be specified as CodeDeploy.

- **version** *(string)* –
  A string that identifies the action type.

- **actionConfiguration** *(dict)* –
  Represents information about an action configuration.

  - **configuration** *(dict)* –
    The configuration data for the action.

    - **(string)** –
    - **(string)** –

  - **pipelineContext** *(dict)* –
    Represents information about a pipeline to a job worker.

- **pipelineName** *(string)* –
  The name of the pipeline. This is a user-specified value. Pipeline names must be unique across all pipeline names under an Amazon Web Services account.

- **stage** *(dict)* –
  The stage of the pipeline.

  - **name** *(string)* –
    The name of the stage.

  - **action** *(dict)* –
    Represents the context of an action within the stage of a pipeline to a job worker.

  - **name** *(string)* –
    The name of the action within the context of a job.

- **inputArtifacts** *(list)* –
  The artifact supplied to the job.

  - **(dict)** –
    Represents information about an artifact that will be worked upon by actions in the pipeline.

  - **name** *(string)* –
    The artifact’s name.

  - **revision** *(string)* –
    The artifact’s revision ID. Depending on the type of object, this could be a commit ID (GitHub) or a revision ID (Amazon S3).

  - **location** *(dict)* –
    The location of an artifact.

  - **type** *(string)* –
    The type of artifact in the location.

- **s3Location** *(dict)* –
  The Amazon S3 bucket that contains the artifact.
- **bucketName** (*string*) – The name of the Amazon S3 bucket.

- **objectKey** (*string*) – The key of the object in the Amazon S3 bucket, which uniquely identifies the object in the bucket.

- **outputArtifacts** (*list*) – The output of the job.
  
  - (**dict**) – Represents information about an artifact that will be worked upon by actions in the pipeline.

  - **name** (*string*) – The artifact’s name.

  - **revision** (*string*) – The artifact’s revision ID. Depending on the type of object, this could be a commit ID (GitHub) or a revision ID (Amazon S3).

  - **location** (*dict*) – The location of an artifact.

  - **type** (*string*) – The type of artifact in the location.

  - **s3Location** (*dict*) – The Amazon S3 bucket that contains the artifact.

    - **bucketName** (*string*) – The name of the Amazon S3 bucket.

    - **objectKey** (*string*) – The key of the object in the Amazon S3 bucket, which uniquely identifies the object in the bucket.

  - **artifactCredentials** (*dict*) – Represents an AWS session credentials object. These credentials are temporary credentials that are issued by AWS Secure Token Service (STS). They can be used to access input and output artifacts in the Amazon S3 bucket used to store artifact for the pipeline in AWS CodePipeline.

    - **accessKeyId** (*string*) – The access key for the session.

    - **secretAccessKey** (*string*) – The secret access key for the session.

    - **sessionToken** (*string*) – The token for the session.

    - **continuationToken** (*string*) – A system-generated token, such as a AWS CodeDeploy deployment ID, that a job requires in order to continue the job asynchronously.

    - **encryptionKey** (*dict*) –
Represents information about the AWS Key Management Service (AWS KMS) key used to encrypt data in the artifact store.

- **id (string)** –
  The ID of the AWS KMS key.

- **type (string)** –
  The type of AWS KMS key, such as a customer master key.

- **nonce (string)** –
  A system-generated random number that AWS CodePipeline uses to ensure that the job is being worked on by only one job worker. This number must be returned in the response.

- **accountId (string)** –
  The ID of the AWS account to use when performing the job.

### poll_for_third_party_jobs(**kwargs)**

Determines whether there are any third party jobs for a job worker to act on. Only used for partner actions.

**Warning:** When this API is called, AWS CodePipeline returns temporary credentials for the Amazon S3 bucket used to store artifacts for the pipeline, if the action requires access to that Amazon S3 bucket for input or output artifacts.

**Request Syntax**

```python
response = client.poll_for_third_party_jobs(
    actionTypeId={
        'category': 'Source'|'Build'|'Deploy'|'Test'|'Invoke',
        'owner': 'AWS'|'ThirdParty'|'Custom',
        'provider': 'string',
        'version': 'string'
    },
    maxBatchSize=123
)
```

**Parameters**

- **actionTypeId (dict)** – [REQUIRED]
  Represents information about an action type.

  - **category (string)** – [REQUIRED]
    A category defines what kind of action can be taken in the stage, and constrains the provider type for the action. Valid categories are limited to one of the values below.

  - **owner (string)** – [REQUIRED]
    The creator of the action being called.

  - **provider (string)** – [REQUIRED]
    The provider of the service being called by the action. Valid providers are determined by the action category. For example, an action in the Deploy category type might have a provider of AWS CodeDeploy, which would be specified as CodeDeploy.

  - **version (string)** – [REQUIRED]
    A string that identifies the action type.
• **maxBatchSize** (*integer*) – The maximum number of jobs to return in a poll for jobs call.

Return type **dict**

Returns

Response Syntax

```python
{
   'jobs': [
       
           'clientId': 'string',
           'jobId': 'string'
       
   ],
}
```

Response Structure

• *(dict)* – Represents the output of a poll for third party jobs action.

  • **jobs** *(list)* – Information about the jobs to take action on.

    • *(dict)* – A response to a PollForThirdPartyJobs request returned by AWS CodePipeline when there is a job to be worked upon by a partner action.

      • **clientId** *(string)* – The clientToken portion of the clientId and clientToken pair used to verify that the calling entity is allowed access to the job and its details.

      • **jobId** *(string)* – The identifier used to identify the job in AWS CodePipeline.

**put_action_revision(****kwargs**

Provides information to AWS CodePipeline about new revisions to a source.

Request Syntax

```python
response = client.put_action_revision(
    pipelineName='string',
    stageName='string',
    actionName='string',
    actionRevision={
        'revisionId': 'string',
        'revisionChangeId': 'string',
        'created': datetime(2015, 1, 1)
    }
)
```

Parameters

• **pipelineName** *(string)* – [REQUIRED]

  The name of the pipeline that will start processing the revision to the source.

• **stageName** *(string)* – [REQUIRED]

  The name of the stage that contains the action that will act upon the revision.
• **actionName**: *(string)* – [REQUIRED]
The name of the action that will process the revision.

• **actionRevision**: *(dict)* – [REQUIRED]
Represents information about the version (or revision) of an action.
  – **revisionId**: *(string)* – [REQUIRED]
The system-generated unique ID that identifies the revision number of the action.
  – **revisionChangeId**: *(string)* –
The unique identifier of the change that set the state to this revision, for example a deployment ID or timestamp.
  – **created**: *(datetime)* – [REQUIRED]
The date and time when the most recent version of the action was created, in timestamp format.

**Return type**: *dict*
**Returns**

**Response Syntax**

```py
{
    'newRevision': True|False,
    'pipelineExecutionId': 'string'
}
```

**Response Structure**

• *(dict)* –
  Represents the output of a put action revision action.
  – **newRevision**: *(boolean)* –
    The new revision number or ID for the revision after the action completes.
  – **pipelineExecutionId**: *(string)* –
    The ID of the current workflow state of the pipeline.

**put_job_failure_result** (**kwargs**)
Represents the failure of a job as returned to the pipeline by a job worker. Only used for custom actions.

**Request Syntax**

```py
response = client.put_job_failure_result(
    jobId='string',
    failureDetails={
        'type': 'JobFailed'|'ConfigurationError'|'PermissionError'|'RevisionOutOfSync'|'RevisionUnavailable'|'SystemUnavailable',
        'message': 'string',
        'externalExecutionId': 'string'
    }
)
```

**Parameters**

• **jobId**: *(string)* – [REQUIRED]
The unique system-generated ID of the job that failed. This is the same ID returned from PollForJobs.

• **failureDetails**: *(dict)* – [REQUIRED]
The details about the failure of a job.
- **type (string)** – [REQUIRED]
  The type of the failure.
- **message (string)** – [REQUIRED]
  The message about the failure.
- **externalExecutionId (string)** –
  The external ID of the run of the action that failed.

**Returns** None

`put_job_success_result(**kwargs)`

Represents the success of a job as returned to the pipeline by a job worker. Only used for custom actions.

**Request Syntax**

```python
response = client.put_job_success_result(
    jobId='string',
    currentRevision={
        'revision': 'string',
        'changeIdentifier': 'string'
    },
    continuationToken='string',
    executionDetails={
        'summary': 'string',
        'externalExecutionId': 'string',
        'percentComplete': 123
    }
)
```

**Parameters**

- **jobId (string)** – [REQUIRED]
  The unique system-generated ID of the job that succeeded. This is the same ID returned from PollForJobs.
- **currentRevision (dict)** – The ID of the current revision of the artifact successfully worked upon by the job.
  - **revision (string)** – [REQUIRED]
    The revision ID of the current version of an artifact.
  - **changeIdentifier (string)** – [REQUIRED]
    The change identifier for the current revision.
- **continuationToken (string)** – A system-generated token, such as a AWS CodeDeploy deployment ID, that the successful job used to complete a job asynchronously.
- **executionDetails (dict)** – The execution details of the successful job, such as the actions taken by the job worker.
  - **summary (string)** –
    The summary of the current status of the actions.
  - **externalExecutionId (string)** –
    The system-generated unique ID of this action used to identify this job worker in any external systems, such as AWS CodeDeploy.
  - **percentComplete (integer)** –
    The percentage of work completed on the action, represented on a scale of zero to one hundred percent.

**Returns** None
**put_third_party_job_failure_result (**kwargs**)**

Represents the failure of a third party job as returned to the pipeline by a job worker. Only used for partner actions.

**Request Syntax**

```python
response = client.put_third_party_job_failure_result(
    jobId='string',
    clientToken='string',
    failureDetails={
        'type': 'JobFailed'|'ConfigurationError'|'PermissionError'|'RevisionOutOfSync'|'RevisionUnavailable'|'SystemUnavailable',
        'message': 'string',
        'externalExecutionId': 'string'
    }
)
```

**Parameters**

- **jobId (string)** – [REQUIRED]
  
  The ID of the job that failed. This is the same ID returned from PollForThirdPartyJobs.

- **clientToken (string)** – [REQUIRED]
  
  The clientToken portion of the clientId and clientToken pair used to verify that the calling entity is allowed access to the job and its details.

- **failureDetails (dict)** – [REQUIRED]
  
  Represents information about failure details.

  - **type (string)** – [REQUIRED]
    
    The type of the failure.

  - **message (string)** – [REQUIRED]
    
    The message about the failure.

  - **externalExecutionId (string)** –
    
    The external ID of the run of the action that failed.

**Returns**

None

**put_third_party_job_success_result (**kwargs**)**

Represents the success of a third party job as returned to the pipeline by a job worker. Only used for partner actions.

**Request Syntax**

```python
response = client.put_third_party_job_success_result(
    jobId='string',
    clientToken='string',
    currentRevision={
        'revision': 'string',
        'changeIdentifier': 'string'
    },
    continuationToken='string',
    executionDetails={
        'summary': 'string',
        'externalExecutionId': 'string',
        'percentComplete': 123
    }
)
```
Parameters

- **jobId (string)** – [REQUIRED]
  The ID of the job that successfully completed. This is the same ID returned from PollForThirdPartyJobs.
- **clientToken (string)** – [REQUIRED]
  The clientToken portion of the clientId and clientToken pair used to verify that the calling entity is allowed access to the job and its details.
- **currentRevision (dict)** – Represents information about a current revision.
  - **revision (string)** – [REQUIRED]
    The revision ID of the current version of an artifact.
  - **changeIdentifier (string)** – [REQUIRED]
    The change identifier for the current revision.
- **continuationToken (string)** – A system-generated token, such as a AWS CodeDeploy deployment ID, that a job uses in order to continue the job asynchronously.
- **executionDetails (dict)** – The details of the actions taken and results produced on an artifact as it passes through stages in the pipeline.
  - **summary (string)** –
    The summary of the current status of the actions.
  - **externalExecutionId (string)** –
    The system-generated unique ID of this action used to identify this job worker in any external systems, such as AWS CodeDeploy.
  - **percentComplete (integer)** –
    The percentage of work completed on the action, represented on a scale of zero to one hundred percent.

Returns None

**start_pipeline_execution (kwargs)**

Starts the specified pipeline. Specifically, it begins processing the latest commit to the source location specified as part of the pipeline.

Request Syntax

```python
response = client.start_pipeline_execution(
    name='string'
)
```

Parameters **name (string)** – [REQUIRED]

The name of the pipeline to start.

Return type dict

Returns

Response Syntax

```python
{
    'pipelineExecutionId': 'string'
}
```

Response Structure

- **(dict)** –

  Represents the output of a start pipeline execution action.
pipelineExecutionId (string)

The unique system-generated ID of the pipeline that was started.

update_pipeline(**kwargs)

Updates a specified pipeline with edits or changes to its structure. Use a JSON file with the pipeline structure in conjunction with UpdatePipeline to provide the full structure of the pipeline. Updating the pipeline increases the version number of the pipeline by 1.

Request Syntax

```python
response = client.update_pipeline(
    pipeline={
        'name': 'string',
        'roleArn': 'string',
        'artifactStore': {
            'type': 'S3',
            'location': 'string',
            'encryptionKey': {
                'id': 'string',
                'type': 'KMS'
            }
        },
        'stages': [
            {'name': 'string',
             'blockers': [
                {'name': 'string',
                 'type': 'Schedule'}
             ],
             'actions': [
                {'name': 'string',
                 'actionTypeId': {
                     'category': 'Source'|'Build'|'Deploy'|'Test'|'Invoke',
                     'owner': 'AWS'|'ThirdParty'|'Custom',
                     'provider': 'string',
                     'version': 'string'
                 },
                 'runOrder': 123,
                 'configuration': {
                     'string': 'string'
                 },
                 'outputArtifacts': [
                     {'name': 'string'}
                 ],
                 'inputArtifacts': [
                     {'name': 'string'}
                 ],
                 'roleArn': 'string'
             }
         ]
    },
    )
```
Parameters  

**pipeline (dict)** – **[REQUIRED]**

The name of the pipeline to be updated.

- **name (string)** – **[REQUIRED]**
  
The name of the action to be performed.

- **roleArn (string)** – **[REQUIRED]**
  
The Amazon Resource Name (ARN) for AWS CodePipeline to use to either perform actions with no actionRoleArn, or to use to assume roles for actions with an actionRoleArn.

- **artifactStore (dict)** – **[REQUIRED]**
  
The Amazon S3 location where artifacts are stored for the pipeline. If this Amazon S3 bucket is created manually, it must meet the requirements for AWS CodePipeline. For more information, see the Concepts.
    - **type (string)** – **[REQUIRED]**
      
The type of the artifact store, such as S3.
    - **location (string)** – **[REQUIRED]**
      
The location for storing the artifacts for a pipeline, such as an S3 bucket or folder.
    - **encryptionKey (dict)** –
      
The AWS Key Management Service (AWS KMS) key used to encrypt the data in the artifact store. If this is undefined, the default key for Amazon S3 is used.
        - **id (string)** – **[REQUIRED]**
          
The ID of the AWS KMS key.
        - **type (string)** – **[REQUIRED]**
          
The type of AWS KMS key, such as a customer master key.

- **stages (list)** – **[REQUIRED]**
  
The stage in which to perform the action.
    - **(dict)** –
      
      Represents information about a stage and its definition.
        - **name (string)** – **[REQUIRED]**
          
The name of the stage.
        - **blockers (list)** –
          
          The gates included in a stage.
            - **(dict)** –
              
              Represents information about a gate declaration.
                - **name (string)** – **[REQUIRED]**
                  
The name of the gate declaration.
                - **type (string)** – **[REQUIRED]**
                  
The type of the gate declaration.
actions (list) – [REQUIRED]

The actions included in a stage.

- (dict) –

  Represents information about an action declaration.

  - name (string) – [REQUIRED]

    The action declaration’s name.

  - actionTypeId (dict) – [REQUIRED]

    The configuration information for the action type.

  - category (string) – [REQUIRED]

    A category defines what kind of action can be taken in the stage, and constrains the provider type for the action. Valid categories are limited to one of the values below.

  - owner (string) – [REQUIRED]

    The creator of the action being called.

  - provider (string) – [REQUIRED]

    The provider of the service being called by the action. Valid providers are determined by the action category. For example, an action in the Deploy category type might have a provider of AWS CodeDeploy, which would be specified as CodeDeploy.

  - version (string) – [REQUIRED]

    A string that identifies the action type.

  - runOrder (integer) –

    The order in which actions are run.

  - configuration (dict) –

    The action declaration’s configuration.

      - (string) –

      - (string) –

        - outputArtifacts (list) –

          The name or ID of the result of the action declaration, such as a test or build artifact.

          - (dict) –

            Represents information about the output of an action.

          - name (string) – [REQUIRED]

            The name of the output of an artifact, such as “My App”.

            The input artifact of an action must exactly match the output artifact declared in a preceding action, but the input artifact does not have to be the next action in strict sequence from the action that provided the output artifact. Actions in parallel can declare different output artifacts, which are in turn consumed by different following actions.

            Output artifact names must be unique within a pipeline.

          - inputArtifacts (list) –

            The name or ID of the artifact consumed by the action, such as a test or build artifact.
Represents information about an artifact to be worked on, such as a test or build artifact.

- **name (string) – [REQUIRED]**
  
The name of the artifact to be worked on, for example, “My App”.

  The input artifact of an action must exactly match the output artifact declared in a preceding action, but the input artifact does not have to be the next action in strict sequence from the action that provided the output artifact. Actions in parallel can declare different output artifacts, which are in turn consumed by different following actions.

- **roleArn (string) –**
  
The ARN of the IAM service role that will perform the declared action. This is assumed through the roleArn for the pipeline.

- **version (integer) –**
  
The version number of the pipeline. A new pipeline always has a version number of 1. This number is automatically incremented when a pipeline is updated.

**Response Syntax**

```python
{
    'pipeline': {
        'name': 'string',
        'roleArn': 'string',
        'artifactStore': {
            'type': 'S3',
            'location': 'string',
            'encryptionKey': {
                'id': 'string',
                'type': 'KMS'
            }
        },
        'stages': [
            {
                'name': 'string',
                'blockers': [
                    {
                        'name': 'string',
                        'type': 'Schedule'
                    }
                ],
                'actions': [
                    {
                        'name': 'string',
                        'actionTypeId': {
                            'category': 'Source'|'Build'|'Deploy'|'Test'|'Invoke',
                            'owner': 'AWS'|'ThirdParty'|'Custom',
                            'provider': 'string',
                            'version': 'string'
                        },
                        'runOrder': 123,
                        'configuration': {
                            ...
                        }
                    }
                ]
            }
        ]
    }
}
```
Response Structure

• (dict) –

  Represents the output of an update pipeline action.
  
  – pipeline (dict) –

    The structure of the updated pipeline.
    
    * name (string) –
      
      The name of the action to be performed.
    
    * roleArn (string) –
      
      The Amazon Resource Name (ARN) for AWS CodePipeline to use
to either perform actions with no actionRoleArn, or to use to assume
roles for actions with an actionRoleArn.
    
    * artifactStore (dict) –
      
      The Amazon S3 location where artifacts are stored for the pipeline.
      If this Amazon S3 bucket is created manually, it must meet the re-
quirements for AWS CodePipeline. For more information, see the
Concepts.
      
      - type (string) –
        
        The type of the artifact store, such as S3.
      
      - location (string) –
        
        The location for storing the artifacts for a pipeline, such as an
S3 bucket or folder.
      
      - encryptionKey (dict) –
        
        The AWS Key Management Service (AWS KMS) key used to
encrypt the data in the artifact store. If this is undefined, the
default key for Amazon S3 is used.
      
      - id (string) –
        
        The ID of the AWS KMS key.
      
      - type (string) –
        
        The type of AWS KMS key, such as a customer master key.
+ **stages (list)** –

  The stage in which to perform the action.
  
  + (dict) –

  Represents information about a stage and its definition.
  
  + **name (string)** –

  The name of the stage.
  
  + **blockers (list)** –

  The gates included in a stage.
  
  + (dict) –

  Represents information about a gate declaration.
  
  + **name (string)** –

  The name of the gate declaration.
  
  + **type (string)** –

  The type of the gate declaration.
  
  + **actions (list)** –

  The actions included in a stage.
  
  + (dict) –

  Represents information about an action declaration.
  
  + **name (string)** –

  The action declaration’s name.
  
  + **actionTypeId (dict)** –

  The configuration information for the action type.
  
  + **category (string)** –

  A category defines what kind of action can be taken in the stage, and constrains the provider type for the action. Valid categories are limited to one of the values below.
  
  + **owner (string)** –

  The creator of the action being called.
  
  + **provider (string)** –

  The provider of the service being called by the action. Valid providers are determined by the action category. For example, an action in the Deploy category type might have a provider of AWS CodeDeploy, which would be specified as CodeDeploy.
  
  + **version (string)** –

  A string that identifies the action type.
  
  + **runOrder (integer)** –

  The order in which actions are run.
  
  + **configuration (dict)** –

  The action declaration’s configuration.
  
  + **outputArtifacts (list)** –

  The name or ID of the result of the action declaration, such as a test or build artifact.
· *(dict)* –
  Represents information about the output of an action.
  · **name** *(string)* –
    The name of the output of an artifact, such as “My App”.
    The input artifact of an action must exactly match the output artifact declared in a preceding action, but the input artifact does not have to be the next action in strict sequence from the action that provided the output artifact. Actions in parallel can declare different output artifacts, which are in turn consumed by different following actions.
    Output artifact names must be unique within a pipeline.
  · **inputArtifacts** *(list)* –
    The name or ID of the artifact consumed by the action, such as a test or build artifact.
  · *(dict)* –
    Represents information about an artifact to be worked on, such as a test or build artifact.
  · **name** *(string)* –
    The name of the artifact to be worked on, for example, “My App”.
    The input artifact of an action must exactly match the output artifact declared in a preceding action, but the input artifact does not have to be the next action in strict sequence from the action that provided the output artifact. Actions in parallel can declare different output artifacts, which are in turn consumed by different following actions.
  · **roleArn** *(string)* –
    The ARN of the IAM service role that will perform the declared action. This is assumed through the roleArn for the pipeline.
  · **version** *(integer)* –
    The version number of the pipeline. A new pipeline always has a version number of 1. This number is automatically incremented when a pipeline is updated.

**CognitoIdentity**

**Table of Contents**
- CognitoIdentity
  - Client

**Client**

```python
class CognitoIdentity.Client
A low-level client representing Amazon Cognito Identity:
```

3.1. Services
import boto3

client = boto3.client('cognito-identity')

These are the available methods:

- **can_paginate()**
- **create_identity_pool()**
- **delete_identities()**
- **delete_identity_pool()**
- **describe_identity()**
- **describe_identity_pool()**
- **generate_presigned_url()**
- **get_credentials_for_identity()**
- **get_id()**
- **get_identity_pool_roles()**
- **get_open_id_token()**
- **get_open_id_token_for_developer_identity()**
- **getaginator()**
- **get_waiter()**
- **list_identities()**
- **list_identity_pools()**
- **lookup_developer_identity()**
- **merge_developer_identities()**
- **set_identity_pool_roles()**
- **unlink_developer_identity()**
- **unlink_identity()**
- **update_identity_pool()**

**can_paginate(operation_name)**

Check if an operation can be paginated.

**Parameters operation_name (string)** – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

**Returns** True if the operation can be paginated, False otherwise.

**create_identity_pool(**kwargs)**

Creates a new identity pool. The identity pool is a store of user identity information that is specific to your AWS account. The limit on identity pools is 60 per account. The keys for SupportedLoginProviders are as follows:

- **Facebook**: graph.facebook.com
- **Google**: accounts.google.com
- **Amazon**: www.amazon.com
- **Twitter**: api.twitter.com
- **Digits**: www.digits.com

You must use AWS Developer credentials to call this API.

**Request Syntax**

```python
response = client.create_identity_pool(
    IdentityPoolName='string',
    AllowUnauthenticatedIdentities=True|False,
    SupportedLoginProviders={
        'string': 'string'
    },
)```
DeveloperProviderName='string',
OpenIdConnectProviderARNs=[
  'string',
]
)}

Parameters

- **IdentityPoolName (string)** – [REQUIRED]
  A string that you provide.
- **AllowUnauthenticatedIdentities (boolean)** – [REQUIRED]
  TRUE if the identity pool supports unauthenticated logins.
- **SupportedLoginProviders (dict)** – Optional key:value pairs mapping provider names to provider app IDs.
  - *(string)*
  - *(string)*
- **DeveloperProviderName (string)** – The “domain” by which Cognito will refer to your users. This name acts as a placeholder that allows your backend and the Cognito service to communicate about the developer provider. For the DeveloperProviderName, you can use letters as well as period (.), underscore (_), and dash (-).
  Once you have set a developer provider name, you cannot change it. Please take care in setting this parameter.
- **OpenIdConnectProviderARNs (list)** – A list of OpenID Connect provider ARNs.
  - *(string)*

Return type  dict

Response Syntax

```python
{
    'IdentityPoolId': 'string',
    'IdentityPoolName': 'string',
    'AllowUnauthenticatedIdentities': True|False,
    'SupportedLoginProviders': {
        'string': 'string'
    },
    'DeveloperProviderName': 'string',
    'OpenIdConnectProviderARNs': [
        'string',
    ]
}
```

Response Structure

- *(dict)* – An object representing a Cognito identity pool.
  - **IdentityPoolId (string)** – An identity pool ID in the format REGION:GUID.
  - **IdentityPoolName (string)** – A string that you provide.
  - **AllowUnauthenticatedIdentities (boolean)** – TRUE if the identity pool supports unauthenticated logins.
  - **SupportedLoginProviders (dict)** – Optional key:value pairs mapping provider names to provider app IDs.
delete_identities(**kwargs)

Deletes identities from an identity pool. You can specify a list of 1-60 identities that you want to delete.

You must use AWS Developer credentials to call this API.

Request Syntax

```python
response = client.delete_identities(
    IdentityIdsToDelete=
    [  
        'string',  
    ]
)
```

Parameters

**IdentityIdsToDelete (list) – [REQUIRED]**

A list of 1-60 identities that you want to delete.

Return type: dict

Returns

```
{  
    'UnprocessedIdentityIds': [  
        {  
            'IdentityId': 'string',  
            'ErrorCode': 'AccessDenied'|'InternalServerError'  
        },  
    ]
}
```

Response Structure

- (dict) –

Returned in response to a successful `DeleteIdentities` operation.

- **UnprocessedIdentityIds (list) –**

An array of UnprocessedIdentityId objects, each of which contains an ErrorCode and IdentityId.

- (dict) –

An array of UnprocessedIdentityId objects, each of which contains an ErrorCode and IdentityId.

- **IdentityId (string) –**

A unique identifier in the format REGION:GUID.

- **ErrorCode (string) –**

The error code indicating the type of error that occurred.
**delete_identity_pool(**kwargs)**

Deletes a user pool. Once a pool is deleted, users will not be able to authenticate with the pool.

You must use AWS Developer credentials to call this API.

Request Syntax

```python
response = client.delete_identity_pool(
    IdentityPoolId='string'
)
```

**Parameters**

- **IdentityPoolId** *(string)* – [REQUIRED] An identity pool ID in the format REGION:GUID.

**Returns**

None

**describe_identity(**kwargs)**

Returns metadata related to the given identity, including when the identity was created and any associated linked logins.

You must use AWS Developer credentials to call this API.

Request Syntax

```python
response = client.describe_identity(
    IdentityId='string'
)
```

**Parameters**

- **IdentityId** *(string)* – [REQUIRED] A unique identifier in the format REGION:GUID.

**Return type**

dict

**Response Syntax**

```python
{
    'IdentityId': 'string',
    'Logins': [
        'string',
    ],
    'CreationDate': datetime(2015, 1, 1),
    'LastModifiedDate': datetime(2015, 1, 1)
}
```

**Response Structure**

- *(dict)* – A description of the identity.
  - **IdentityId** *(string)* – A unique identifier in the format REGION:GUID.
  - **Logins** *(list)* – A set of optional name-value pairs that map provider names to provider tokens.
  - *(string)* –
  - **CreationDate** *(datetime)* –
    - Date on which the identity was created.
  - **LastModifiedDate** *(datetime)* –
    - Date on which the identity was last modified.

**describe_identity_pool(**kwargs)**

Gets details about a particular identity pool, including the pool name, ID description, creation date, and current number of users.

3.1. Services
You must use AWS Developer credentials to call this API.

**Request Syntax**

```python
response = client.describe_identity_pool(
    IdentityPoolId='string'
)
```

**Parameters**

- **IdentityPoolId** *(string)* – [REQUIRED] An identity pool ID in the format REGION:GUID.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'IdentityPoolId': 'string',
    'IdentityPoolName': 'string',
    'AllowUnauthenticatedIdentities': True|False,
    'SupportedLoginProviders': {
        'string': 'string'
    },
    'DeveloperProviderName': 'string',
    'OpenIdConnectProviderARNs': [
        'string',
    ]
}
```

**Response Structure**

- *(dict)* – An object representing a Cognito identity pool.
  - **IdentityPoolId** *(string)* – An identity pool ID in the format REGION:GUID.
  - **IdentityPoolName** *(string)* – A string that you provide.
  - **AllowUnauthenticatedIdentities** *(boolean)* – TRUE if the identity pool supports unauthenticated logins.
  - **SupportedLoginProviders** *(dict)* – Optional key:value pairs mapping provider names to provider app IDs.
    - *(string)* – *(string)* –
  - **DeveloperProviderName** *(string)* – The “domain” by which Cognito will refer to your users.
  - **OpenIdConnectProviderARNs** *(list)* – A list of OpenID Connect provider ARNs.
    - *(string)* –

**generate_presigned_url** *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

**Parameters**

- **ClientMethod** *(string)* – The client method to presign for
- **Params** *(dict)* – The parameters normally passed to `ClientMethod`.
- **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.
Returns The presigned url

def get_credentials_for_identity(**kwargs)

Returns credentials for the provided identity ID. Any provided logins will be validated against supported
login providers. If the token is for cognito-identity.amazonaws.com, it will be passed through to AWS
Security Token Service with the appropriate role for the token.

This is a public API. You do not need any credentials to call this API.

Request Syntax

```python
response = client.get_credentials_for_identity(
    IdentityId='string',
    Logins={
        'string': 'string'
    }
)
```

Parameters

- **IdentityId** (string) – [REQUIRED]
  
  A unique identifier in the format REGION:GUID.

- **Logins** (dict) – A set of optional name-value pairs that map provider names to
  provider tokens.

  - *(string)* –
    
    - *(string)* –

Return type  dict

Returns

Response Syntax

```python
{
    'IdentityId': 'string',
    'Credentials': {
        'AccessKeyId': 'string',
        'SecretKey': 'string',
        'SessionToken': 'string',
        'Expiration': datetime(2015, 1, 1)
    }
}
```

Response Structure

- *(dict)* –

  Returned in response to a successful GetCredentialsForIdentity oper-
  ation.

  - **IdentityId** (string) –
    
    A unique identifier in the format REGION:GUID.

  - **Credentials** (dict) –

    Credentials for the provided identity ID.

    - **AccessKeyId** (string) –
      
      The Access Key portion of the credentials.

    - **SecretKey** (string) –
      
      The Secret Access Key portion of the credentials

    - **SessionToken** (string) –
      
      The Session Token portion of the credentials
Expiration *(datetime)* –

The date at which these credentials will expire.

**get_id** (**kwargs**)  
Generates (or retrieves) a Cognito ID. Supplying multiple logins will create an implicit linked account.  
This is a public API. You do not need any credentials to call this API.

**Request Syntax**

```python
response = client.get_id(
    AccountId='string',
    IdentityPoolId='string',
    Logins={
        'string': 'string'
    }
)
```

**Parameters**

- **AccountId** *(string)* – A standard AWS account ID (9+ digits).
- **IdentityPoolId** *(string)* – [REQUIRED] An identity pool ID in the format REGION:GUID.
- **Logins** *(dict)* – A set of optional name-value pairs that map provider names to provider tokens.

The available provider names for Logins are as follows:
- Facebook: graph.facebook.com
- Google: accounts.google.com
- Amazon: www.amazon.com
- Twitter: api.twitter.com
- Digits: www.digits.com
- *(string)* – *(string)* –

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'IdentityId': 'string'
}
```

**Response Structure**

- *(dict)* – Returned in response to a GetId request.
- **IdentityId** *(string)* – A unique identifier in the format REGION:GUID.

**get_identity_pool_roles** (**kwargs**)  
Gets the roles for an identity pool.

You must use AWS Developer credentials to call this API.

**Request Syntax**

```python
response = client.get_identity_pool_roles(
    IdentityPoolId='string'
)
```
Parameters  

**IdentityPoolId** *(string)* – [REQUIRED]  
An identity pool ID in the format REGION:GUID.

**Return type**  
dict

**Returns**

**Response Syntax**

```py
{
    'IdentityPoolId': 'string',
    'Roles': {
        'string': 'string'
    }
}
```

**Response Structure**

- *(dict)*  
  Returned in response to a successful `GetIdentityPoolRoles` operation.
  - **IdentityPoolId** *(string)* –  
    An identity pool ID in the format REGION:GUID.
  - **Roles** *(dict)* –  
    The map of roles associated with this pool. Currently only authenticated and unauthenticated roles are supported.
    - *(string)* –  
      - *(string)* –

**get_open_id_token** *(**kwargs]*)

Gets an OpenID token, using a known Cognito ID. This known Cognito ID is returned by `GetId`. You can optionally add additional logins for the identity. Supplying multiple logins creates an implicit link.

The OpenId token is valid for 15 minutes.

This is a public API. You do not need any credentials to call this API.

**Request Syntax**

```py
response = client.get_open_id_token(
    IdentityId='string',
    Logins={
        'string': 'string'
    }
)
```

**Parameters**

- **IdentityId** *(string)* – [REQUIRED]  
  A unique identifier in the format REGION:GUID.
- **Logins** *(dict)* –  
  A set of optional name-value pairs that map provider names to provider tokens. When using graph.facebook.com and www.amazon.com, supply the access_token returned from the provider’s authflow. For accounts.google.com or any other OpenId Connect provider, always include the id_token.
  - *(string)* –  
    - *(string)* –

**Return type**  
dict

**Returns**

**Response Syntax**
get_open_id_token_for_developer_identity(**kwargs)
Registers (or retrieves) a Cognito IdentityId and an OpenID Connect token for a user authenticated by your backend authentication process. Supplying multiple logins will create an implicit linked account. You can only specify one developer provider as part of the Logins map, which is linked to the identity pool. The developer provider is the “domain” by which Cognito will refer to your users.

You can use GetOpenIdTokenForDeveloperIdentity to create a new identity and to link new logins (that is, user credentials issued by a public provider or developer provider) to an existing identity. When you want to create a new identity, the IdentityId should be null. When you want to associate a new login with an existing authenticated/unauthenticated identity, you can do so by providing the existing IdentityId. This API will create the identity in the specified IdentityPoolId.

You must use AWS Developer credentials to call this API.

Response Structure

- (dict) – Returned in response to a successful GetOpenIdToken request.
  - IdentityId (string) – A unique identifier in the format REGION:GUID. Note that the IdentityId returned may not match the one passed on input.
  - Token (string) – An OpenID token, valid for 15 minutes.

Parameters

- **IdentityPoolId (string)** – [REQUIRED]
  An identity pool ID in the format REGION:GUID.
- **IdentityId (string)** – A unique identifier in the format REGION:GUID.
- **Logins (dict)** – [REQUIRED]
  A set of optional name-value pairs that map provider names to provider tokens. Each name-value pair represents a user from a public provider or developer provider. If the user is from a developer provider, the name-value pair will follow the syntax "developer_provider_name": "developer_user_identifier". The developer provider is the “domain” by which Cognito will refer to your users; you provided this domain while creating/updating the identity pool. The developer user identifier is an identifier from your backend that uniquely identifies a user. When you create an identity pool, you can specify the supported logins.
  - (string) –
    * (string) –
- **TokenDuration (integer)** – The expiration time of the token, in seconds. You can specify a custom expiration time for the token so that you can cache it. If you don’t provide an expiration time, the token is valid for 15 minutes. You can
exchange the token with Amazon STS for temporary AWS credentials, which are valid for a maximum of one hour. The maximum token duration you can set is 24 hours. You should take care in setting the expiration time for a token, as there are significant security implications: an attacker could use a leaked token to access your AWS resources for the token’s duration.

Return type  dict  

Returns

Response Syntax

```
{
    'IdentityId': 'string',
    'Token': 'string'
}
```

Response Structure

• (dict) –  

Returned in response to a successful GetOpenIdTokenForDeveloperIdentity request.

  – IdentityId (string) –  

  A unique identifier in the format REGION:GUID.

  – Token (string) –  

  An OpenID token.

get Paginator

Create a paginator for an operation.

Parameters

operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get Paginator("create_foo").

Raises

OperationNotPageableError Raised if the operation is not pageable. You can use the client.can Paginator method to check if an operation is pageable.

Return type  L{botocore.paginate.Paginator}  

Returns  A paginator object.

get_waiter

list_identities(**kwargs)

Lists the identities in a pool.

You must use AWS Developer credentials to call this API.

Request Syntax

```
response = client.list_identities(
    IdentityPoolId='string',
    MaxResults=123,
    NextToken='string',
    HideDisabled=True|False
)
```

Parameters

• IdentityPoolId (string) – [REQUIRED] An identity pool ID in the format REGION:GUID.
• **MaxResults** (*integer*) – [REQUIRED] The maximum number of identities to return.
• **NextToken** (*string*) – A pagination token.
• **HideDisabled** (*boolean*) – An optional boolean parameter that allows you to hide disabled identities. If omitted, the ListIdentities API will include disabled identities in the response.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'IdentityPoolId': 'string',
    'Identities': [
        {
            'IdentityId': 'string',
            'Logins': [
                'string',
            ],
            'CreationDate': datetime(2015, 1, 1),
            'LastModifiedDate': datetime(2015, 1, 1)
        },
    ],
    'NextToken': 'string'
}
```

**Response Structure**

• *(dict)* – The response to a ListIdentities request.
  – **IdentityPoolId** (*string*) – An identity pool ID in the format REGION:GUID.
  – **Identities** *(list)* – An object containing a set of identities and associated mappings.
    * *(dict)* – A description of the identity.
      · **IdentityId** (*string*) – A unique identifier in the format REGION:GUID.
      · **Logins** *(list)* – A set of optional name-value pairs that map provider names to provider tokens.
      · *(string)* –
      · **CreationDate** *(datetime)* – Date on which the identity was created.
      · **LastModifiedDate** *(datetime)* – Date on which the identity was last modified.
  – **NextToken** (*string*) – A pagination token.

**list_identity_pools**(**kwargs)

Lists all of the Cognito identity pools registered for your account.

You must use AWS Developer credentials to call this API.

**Request Syntax**

```python
response = client.list_identity_pools(
    MaxResults=123,
    NextToken='string'
)
```

**Parameters**
- **MaxResults** *(integer)* – [REQUIRED] The maximum number of identities to return.
- **NextToken** *(string)* – A pagination token.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'IdentityPools': [
        {
            'IdentityPoolId': 'string',
            'IdentityPoolName': 'string'
        },
        
    ],
    'NextToken': 'string'
}
```

**Response Structure**

- *(dict)* – The result of a successful ListIdentityPools action.
  - **IdentityPools** *(list)* – The identity pools returned by the ListIdentityPools action.
    - *(dict)* – A description of the identity pool.
      - **IdentityPoolId** *(string)* – An identity pool ID in the format REGION:GUID.
      - **IdentityPoolName** *(string)* – A string that you provide.
    - **NextToken** *(string)* – A pagination token.

**lookup_developer_identity(**kwargs)**

Retrieves the IdentityID associated with a DeveloperUserIdentifier or the list of DeveloperUserIdentifier s associated with an IdentityId for an existing identity. Either IdentityID or DeveloperUserIdentifier must not be null. If you supply only one of these values, the other value will be searched in the database and returned as a part of the response. If you supply both, DeveloperUserIdentifier will be matched against IdentityID. If the values are verified against the database, the response returns both values and is the same as the request. Otherwise a ResourceConflictException is thrown.

You must use AWS Developer credentials to call this API.

**Request Syntax**

```python
response = client.lookup_developer_identity(  
    IdentityPoolId='string',  
    IdentityId='string',  
    DeveloperUserIdentifier='string',  
    MaxResults=123,  
    NextToken='string'
)
```

**Parameters**

- **IdentityPoolId** *(string)* – [REQUIRED]
  
  An identity pool ID in the format REGION:GUID.
- **IdentityId** *(string)* – A unique identifier in the format REGION:GUID.
- **DeveloperUserIdentifier** *(string)* – A unique ID used by your backend authentication process to identify a user. Typically, a developer identity provider would issue many developer user identifiers, in keeping with the number of users.
- **MaxResults** *(integer)* – The maximum number of identities to return.
• **NextToken** (*string*) – A pagination token. The first call you make will have NextToken set to null. After that the service will return NextToken values as needed. For example, let’s say you make a request with MaxResults set to 10, and there are 20 matches in the database. The service will return a pagination token as a part of the response. This token can be used to call the API again and get results starting from the 11th match.

**Return type** **dict**

**Returns**

**Response Syntax**

```python
def response
```

```json
{
    'IdentityId': 'string',
    'DeveloperUserIdentifierList': [
        'string',
    ],
    'NextToken': 'string'
}
```

**Response Structure**

• (*dict*) –

Returned in response to a successful LookupDeveloperIdentity action.

  – **IdentityId** (*string*) –

    A unique identifier in the format REGION:GUID.

  – **DeveloperUserIdentifierList** (*list*) –

    This is the list of developer user identifiers associated with an identity ID. Cognito supports the association of multiple developer user identifiers with an identity ID.

  – **string** –

  – **NextToken** (*string*) –

    A pagination token. The first call you make will have NextToken set to null. After that the service will return NextToken values as needed. For example, let’s say you make a request with MaxResults set to 10, and there are 20 matches in the database. The service will return a pagination token as a part of the response. This token can be used to call the API again and get results starting from the 11th match.

**merge_developer_identities(****kwargs**)**

Merges two users having different IdentityId s, existing in the same identity pool, and identified by the same developer provider. You can use this action to request that discrete users be merged and identified as a single user in the Cognito environment. Cognito associates the given source user (SourceUserIdentifier) with the IdentityId of the DestinationUserIdentifier. Only developer-authenticated users can be merged. If the users to be merged are associated with the same public provider, but as two different users, an exception will be thrown.

You must use AWS Developer credentials to call this API.

**Request Syntax**

```python
response = client.merge_developer_identities(
    SourceUserIdentifier='string',
    DestinationUserIdentifier='string',
    DeveloperProviderName='string',
    IdentityPoolId='string'
)
```
Parameters

- **SourceUserIdentifier** *(string)* – [REQUIRED]
  
  User identifier for the source user. The value should be a `DeveloperUserIdentifier`.

- **DestinationUserIdentifier** *(string)* – [REQUIRED]
  
  User identifier for the destination user. The value should be a `DeveloperUserIdentifier`.

- **DeveloperProviderName** *(string)* – [REQUIRED]
  
  The “domain” by which Cognito will refer to your users. This is a (pseudo) domain name that you provide while creating an identity pool. This name acts as a placeholder that allows your backend and the Cognito service to communicate about the developer provider. For the `DeveloperProviderName`, you can use letters as well as period (.), underscore (_), and dash (-).

- **IdentityPoolId** *(string)* – [REQUIRED]
  
  An identity pool ID in the format REGION:GUID.

Return type  
dict

Returns

Response Syntax

```python
{
    'IdentityId': 'string'
}
```

Response Structure

- *(dict)* –

  Returned in response to a successful `MergeDeveloperIdentities` action.

  - **IdentityId** *(string)* –

    A unique identifier in the format REGION:GUID.

`set_identity_pool_roles(**kwargs)`

Sets the roles for an identity pool. These roles are used when making calls to `GetCredentialsForIdentity` action.

You must use AWS Developer credentials to call this API.

Request Syntax

```python
response = client.set_identity_pool_roles(
    IdentityPoolId='string',
    Roles={
        'string': 'string'
    }
)
```

Parameters

- **IdentityPoolId** *(string)* – [REQUIRED]
  
  An identity pool ID in the format REGION:GUID.

- **Roles** *(dict)* – [REQUIRED]
  
  The map of roles associated with this pool. For a given role, the key will be either “authenticated” or “unauthenticated” and the value will be the Role ARN.

  - *(string)* –

  - *(string)* –
Returns None

unlink_developer_identity(**kwargs)
Unlinks a DeveloperUserIdentifier from an existing identity. Unlinked developer users will be considered new identities next time they are seen. If, for a given Cognito identity, you remove all federated identities as well as the developer user identifier, the Cognito identity becomes inaccessible.

You must use AWS Developer credentials to call this API.

Request Syntax

```python
response = client.unlink_developer_identity(
    IdentityId='string',
    IdentityPoolId='string',
    DeveloperProviderName='string',
    DeveloperUserIdentifier='string'
)
```

Parameters

- **IdentityId** *(string)* – [REQUIRED]
  A unique identifier in the format REGION:GUID.
- **IdentityPoolId** *(string)* – [REQUIRED]
  An identity pool ID in the format REGION:GUID.
- **DeveloperProviderName** *(string)* – [REQUIRED]
  The “domain” by which Cognito will refer to your users.
- **DeveloperUserIdentifier** *(string)* – [REQUIRED]
  A unique ID used by your backend authentication process to identify a user.

Returns None

unlink_identity(**kwargs)
Unlinks a federated identity from an existing account. Unlinked logins will be considered new identities next time they are seen. Removing the last linked login will make this identity inaccessible.

This is a public API. You do not need any credentials to call this API.

Request Syntax

```python
response = client.unlink_identity(
    IdentityId='string',
    Logins={
        'string': 'string'
    },
    LoginsToRemove=['string',
    ]
)
```

Parameters

- **IdentityId** *(string)* – [REQUIRED]
  A unique identifier in the format REGION:GUID.
- **Logins** *(dict)* – [REQUIRED]
  A set of optional name-value pairs that map provider names to provider tokens.
  - *(string)* –
  - *(string)* –
- **LoginsToRemove** *(list)* – [REQUIRED]
  Provider names to unlink from this identity.
  - *(string)* –
**update_identity_pool(**kwargs)

Updates a user pool.

You must use AWS Developer credentials to call this API.

**Request Syntax**

```python
response = client.update_identity_pool(
    IdentityPoolId='string',
    IdentityPoolName='string',
    AllowUnauthenticatedIdentities=True|False,
    SupportedLoginProviders={
        'string': 'string'
    },
    DeveloperProviderName='string',
    OpenIdConnectProviderARNs=[
        'string',
    ]
)
```

**Parameters**

- **IdentityPoolId (string)** – [REQUIRED] An identity pool ID in the format REGION:GUID.
- **IdentityPoolName (string)** – [REQUIRED]
  A string that you provide.
- **AllowUnauthenticatedIdentities (boolean)** – [REQUIRED] TRUE if the identity pool supports unauthenticated logins.
- **SupportedLoginProviders (dict)** – Optional key:value pairs mapping provider names to provider app IDs.
  ```
  - (string)
  ```
  ```
  * (string)
  ```
- **DeveloperProviderName (string)** – The “domain” by which Cognito will refer to your users.
- **OpenIdConnectProviderARNs (list)** – A list of OpenID Connect provider ARNs.
  ```
  - (string)
  ```

**Return type**  dict

**Returns**

**Response Syntax**

```python
{
    'IdentityPoolId': 'string',
    'IdentityPoolName': 'string',
    'AllowUnauthenticatedIdentities': True|False,
    'SupportedLoginProviders': {
        'string': 'string'
    },
    'DeveloperProviderName': 'string',
    'OpenIdConnectProviderARNs': [
        'string',
    ]
}
```

**Response Structure**

- *(dict)* – An object representing a Cognito identity pool.
– **IdentityPoolId** *(string)* – An identity pool ID in the format REGION:GUID.

– **IdentityPoolName** *(string)* – A string that you provide.

– **AllowUnauthenticatedIdentities** *(boolean)* – TRUE if the identity pool supports unauthenticated logins.

– **SupportedLoginProviders** *(dict)* – Optional key:value pairs mapping provider names to provider app IDs.

  * (string) –
  · (string) –

– **DeveloperProviderName** *(string)* – The “domain” by which Cognito will refer to your users.

– **OpenIdConnectProviderARNs** *(list)* – A list of OpenId Connect provider ARNs.

  * (string) –

---

### CognitoSync

#### Table of Contents
- CognitoSync
  - Client

#### Client

**class CognitoSync.Client**

A low-level client representing Amazon Cognito Sync:

```python
import boto3

client = boto3.client('cognito-sync')
```

These are the available methods:

- `bulk_publish()`
- `can_paginate()`
- `delete_dataset()`
- `describe_dataset()`
- `describe_identity_pool_usage()`
- `describe_identity_usage()`
- `generate_presigned_url()`
- `get_bulk_publish_details()`
- `get_cognito_events()`
- `get_identity_pool_configuration()`
- `get_paginators()`
- `get_waiter()`
- `list_datasets()`
- `list_identity_pool_usage()`
- `list_records()`
- `register_device()`
bulk_publish(**kwargs)

Initiates a bulk publish of all existing datasets for an Identity Pool to the configured stream. Customers are limited to one successful bulk publish per 24 hours. Bulk publish is an asynchronous request, customers can see the status of the request via the GetBulkPublishDetails operation.

This API can only be called with developer credentials. You cannot call this API with the temporary user credentials provided by Cognito Identity.

Request Syntax

```python
response = client.bulk_publish(
    IdentityPoolId='string'
)
```

**Parameters**

- **IdentityPoolId (string)** – [REQUIRED] A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.

**Return type**

dict

**Returns**

Response Syntax

```python
{
    'IdentityPoolId': 'string'
}
```

**Response Structure**

- **(dict)** – The output for the BulkPublish operation.
  - **IdentityPoolId (string)** – A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.

**can_paginate(operation_name)**

Check if an operation can be paginated.

**Parameters**

- **operation_name (string)** – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginators("create_foo")`.

**Returns**

True if the operation can be paginated, False otherwise.

**delete_dataset(**kwargs)**

Deletes the specific dataset. The dataset will be deleted permanently, and the action can’t be undone. Datasets that this dataset was merged with will no longer report the merge. Any subsequent operation on this dataset will result in a ResourceNotFoundException.

This API can be called with temporary user credentials provided by Cognito Identity or with developer credentials.

**Request Syntax**
response = client.delete_dataset(
    IdentityPoolId='string',
    IdentityId='string',
    DatasetName='string'
)

Parameters

- **IdentityPoolId (string)** – [REQUIRED] A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
- **IdentityId (string)** – [REQUIRED] A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
- **DatasetName (string)** – [REQUIRED] A string of up to 128 characters. Allowed characters are a-z, A-Z, 0-9, '_' (underscore), '-' (dash), and '.' (dot).

Return type  dict

Returns

Response Syntax

```python
{
    'Dataset': {
        'IdentityId': 'string',
        'DatasetName': 'string',
        'CreationDate': datetime(2015, 1, 1),
        'LastModifiedDate': datetime(2015, 1, 1),
        'LastModifiedBy': 'string',
        'DataStorage': 123,
        'NumRecords': 123
    }
}
```

Response Structure

- *(dict)* – Response to a successful DeleteDataset request.
  - **Dataset (dict)** – A collection of data for an identity pool. An identity pool can have multiple datasets. A dataset is per identity and can be general or associated with a particular entity in an application (like a saved game). Datasets are automatically created if they don’t exist. Data is synced by dataset, and a dataset can hold up to 1MB of key-value pairs.
    - **IdentityId (string)** – A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
    - **DatasetName (string)** – A string of up to 128 characters. Allowed characters are a-z, A-Z, 0-9, '_' (underscore), '-' (dash), and '.' (dot).
    - **CreationDate (datetime)** – Date on which the dataset was created.
    - **LastModifiedDate (datetime)** – Date when the dataset was last modified.
    - **LastModifiedBy (string)** – The device that made the last change to this dataset.
    - **DataStorage (integer)** – Total size in bytes of the records in this dataset.
    - **NumRecords (integer)** – Number of records in this dataset.

**describe_dataset(****kwargs)**

Gets meta data about a dataset by identity and dataset name. With Amazon Cognito Sync, each identity
has access only to its own data. Thus, the credentials used to make this API call need to have access to the identity data.

This API can be called with temporary user credentials provided by Cognito Identity or with developer credentials. You should use Cognito Identity credentials to make this API call.

**Request Syntax**

```python
response = client.describe_dataset(
    IdentityPoolId='string',
    IdentityId='string',
    DatasetName='string'
)
```

**Parameters**

- **IdentityPoolId** *(string)* – [REQUIRED] A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
- **IdentityId** *(string)* – [REQUIRED] A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
- **DatasetName** *(string)* – [REQUIRED] A string of up to 128 characters. Allowed characters are a-z, A-Z, 0-9, '_' (underscore), '-' (dash), and '.' (dot).

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Dataset': {
        'IdentityId': 'string',
        'DatasetName': 'string',
        'CreationDate': datetime(2015, 1, 1),
        'LastModifiedDate': datetime(2015, 1, 1),
        'LastModifiedBy': 'string',
        'DataStorage': 123,
        'NumRecords': 123
    }
}
```

**Response Structure**

- *(dict)* – Response to a successful DescribeDataset request.
  - **Dataset** *(dict)* – Meta data for a collection of data for an identity. An identity can have multiple datasets. A dataset can be general or associated with a particular entity in an application (like a saved game). Datasets are automatically created if they don’t exist. Data is synced by dataset, and a dataset can hold up to 1MB of key-value pairs.
    - **IdentityId** *(string)* – A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
    - **DatasetName** *(string)* – A string of up to 128 characters. Allowed characters are a-z, A-Z, 0-9, '_' (underscore), '-' (dash), and '.' (dot).
    - **CreationDate** *(datetime)* – Date on which the dataset was created.
    - **LastModifiedDate** *(datetime)* – Date when the dataset was last modified.
**LastModifiedBy** *(string)* – The device that made the last change to this dataset.

**DataStorage** *(integer)* – Total size in bytes of the records in this dataset.

**NumRecords** *(integer)* – Number of records in this dataset.

describe_identity_pool_usage(**kwargs**)

Gets usage details (for example, data storage) about a particular identity pool.

This API can only be called with developer credentials. You cannot call this API with the temporary user credentials provided by Cognito Identity.

**Request Syntax**

```python
response = client.describe_identity_pool_usage(
    IdentityPoolId='string'
)
```

**Parameters**

- **IdentityPoolId** *(string)* – [REQUIRED] A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'IdentityPoolUsage': {
        'IdentityPoolId': 'string',
        'SyncSessionsCount': 123,
        'DataStorage': 123,
        'LastModifiedDate': datetime(2015, 1, 1)
    }
}
```

**Response Structure**

- *(dict)* – Response to a successful DescribeIdentityPoolUsage request.
  - **IdentityPoolUsage** *(dict)* – Information about the usage of the identity pool.
    - **IdentityPoolId** *(string)* – A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
    - **SyncSessionsCount** *(integer)* – Number of sync sessions for the identity pool.
    - **DataStorage** *(integer)* – Data storage information for the identity pool.
    - **LastModifiedDate** *(datetime)* – Date on which the identity pool was last modified.

describe_identity_usage(**kwargs**)

Gets usage information for an identity, including number of datasets and data usage.

This API can be called with temporary user credentials provided by Cognito Identity or with developer credentials.

**Request Syntax**
response = client.describe_identity_usage(
    IdentityPoolId='string',
    IdentityId='string'
)

Parameters

- **IdentityPoolId** *(string)* – [REQUIRED] A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
- **IdentityId** *(string)* – [REQUIRED] A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.

Return type  dict

Returns

Response Syntax

```
{
    'IdentityUsage': {
        'IdentityId': 'string',
        'IdentityPoolId': 'string',
        'LastModifiedDate': datetime(2015, 1, 1),
        'DatasetCount': 123,
        'DataStorage': 123
    }
}
```

Response Structure

- *(dict)* – The response to a successful DescribeIdentityUsage request.
  - **IdentityUsage** *(dict)* – Usage information for the identity.
    - **IdentityId** *(string)* – A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
    - **IdentityPoolId** *(string)* – A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
    - **LastModifiedDate** *(datetime)* – Date on which the identity was last modified.
    - **DatasetCount** *(integer)* – Number of datasets for the identity.
    - **DataStorage** *(integer)* – Total data storage for this identity.

**generate_presigned_url** *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

Parameters

- **ClientMethod** *(string)* – The client method to presign for
- **Params** *(dict)* – The parameters normally passed to ClientMethod.
- **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns  The presigned url

**get_bulk_publish_details** (**kwargs**)

Get the status of the last BulkPublish operation for an identity pool.

This API can only be called with developer credentials. You cannot call this API with the temporary user credentials provided by Cognito Identity.
Request Syntax

```python
response = client.get_bulk_publish_details(
    IdentityPoolId='string'
)
```

**Parameters**

- **IdentityPoolId** *(string)* – [REQUIRED] A name-spaced GUID (for example, `us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE`) created by Amazon Cognito. GUID generation is unique within a region.

**Return type**

**dict**

**Returns**

**Response Syntax**

```json
{
    'IdentityPoolId': 'string',
    'BulkPublishStartTime': datetime(2015, 1, 1),
    'BulkPublishCompleteTime': datetime(2015, 1, 1),
    'BulkPublishStatus': 'NOT_STARTED'|'IN_PROGRESS'|'FAILED'|'SUCCEEDED',
    'FailureMessage': 'string'
}
```

**Response Structure**

- *(dict)* – The output for the GetBulkPublishDetails operation.
  - **IdentityPoolId** *(string)* – A name-spaced GUID (for example, `us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE`) created by Amazon Cognito. GUID generation is unique within a region.
  - **BulkPublishStartTime** *(datetime)* – The date/time at which the last bulk publish was initiated.
  - **BulkPublishCompleteTime** *(datetime)* – If BulkPublishStatus is SUCCEEDED, the time the last bulk publish operation completed.
  - **BulkPublishStatus** *(string)* – Status of the last bulk publish operation, valid values are:
    - NOT_STARTED - No bulk publish has been requested for this identity pool
    - IN_PROGRESS - Data is being published to the configured stream
    - SUCCEEDED - All data for the identity pool has been published to the configured stream
    - FAILED - Some portion of the data has failed to publish, check FailureMessage for the cause.
  - **FailureMessage** *(string)* – If BulkPublishStatus is FAILED this field will contain the error message that caused the bulk publish to fail.

**get_cognito_events(**kwargs)**

Gets the events and the corresponding Lambda functions associated with an identity pool.

This API can only be called with developer credentials. You cannot call this API with the temporary user credentials provided by Cognito Identity.

**Request Syntax**

```python
response = client.get_cognito_events(
    IdentityPoolId='string'
)
```
Parameters **IdentityPoolId** *(string)* – [REQUIRED]

The Cognito Identity Pool ID for the request

| Return type | dict |

Returns

Response Syntax

```
{
    'Events': {
        'string': 'string'
    }
}
```

Response Structure

• *(dict)* –
  
  The response from the GetCognitoEvents request
  
  • *(dict)* –
    
    The Cognito Events returned from the GetCognitoEvents request
    
    • *(string)* –
      
      • *(string)* –

get_identity_pool_configuration(**kwargs)**

Gets the configuration settings of an identity pool.

This API can only be called with developer credentials. You cannot call this API with the temporary user credentials provided by Cognito Identity.

Request Syntax

```
response = client.get_identity_pool_configuration(
    IdentityPoolId='string'
)
```

Parameters **IdentityPoolId** *(string)* – [REQUIRED]

A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. This is the ID of the pool for which to return a configuration.

| Return type | dict |

Returns

Response Syntax

```
{
    'IdentityPoolId': 'string',
    'PushSync': {
        'ApplicationArns': [
            'string',
        ],
        'RoleArn': 'string'
    },
    'CognitoStreams': {
        'StreamName': 'string',
        'RoleArn': 'string',
        'StreamingStatus': 'ENABLED'|'DISABLED'
    }
}
```
Response Structure

- **(dict)** –

  The output for the GetIdentityPoolConfiguration operation.

  - **IdentityPoolId (string)** –
    A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito.

  - **PushSync (dict)** –
    Options to apply to this identity pool for push synchronization.
    - **ApplicationArns (list)** –
      List of SNS platform application ARNs that could be used by clients.
      - **(string)** –
    - **RoleArn (string)** –
      A role configured to allow Cognito to call SNS on behalf of the developer.

  - **CognitoStreams (dict)** – Options to apply to this identity pool for Amazon Cognito streams.
    - **StreamName (string)** – The name of the Cognito stream to receive updates. This stream must be in the developers account and in the same region as the identity pool.
    - **RoleArn (string)** – The ARN of the role Amazon Cognito can assume in order to publish to the stream. This role must grant access to Amazon Cognito (cognito-sync) to invoke PutRecord on your Cognito stream.
    - **StreamingStatus (string)** – Status of the Cognito streams. Valid values are:
      - ENABLED - Streaming of updates to identity pool is enabled.
      - DISABLED - Streaming of updates to identity pool is disabled. Bulk publish will also fail if StreamingStatus is DISABLED.

get Paginator (operation_name)

Create a paginator for an operation.

**Parameters**

- **operation_name (string)** – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.getaginator("create_foo").

**Raises**

- **OperationNotPageableError** Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

**Return type**

L{botocore.paginate.Paginator}

**Returns**

A paginator object.

get Waiter (waiter_name)

list_datasets (**kwargs)

Lists datasets for an identity. With Amazon Cognito Sync, each identity has access only to its own data. Thus, the credentials used to make this API call need to have access to the identity data.

ListDatasets can be called with temporary user credentials provided by Cognito Identity or with developer credentials. You should use the Cognito Identity credentials to make this API call.

**Request Syntax**
response = client.list_datasets(
    IdentityPoolId='string',
    IdentityId='string',
    NextToken='string',
    MaxResults=123
)

Parameters

- **IdentityPoolId** *(string)* – [REQUIRED] A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
- **IdentityId** *(string)* – [REQUIRED] A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
- **NextToken** *(string)* – A pagination token for obtaining the next page of results.
- **MaxResults** *(integer)* – The maximum number of results to be returned.

Returns

Response Syntax

```json
{
    "Datasets": [
        {
            "IdentityId": "string",
            "DatasetName": "string",
            "CreationDate": datetime(2015, 1, 1),
            "LastModifiedDate": datetime(2015, 1, 1),
            "LastModifiedBy": "string",
            "DataStorage": 123,
            "NumRecords": 123
        },
    ],
    "Count": 123,
    "NextToken": "string"
}
```

Response Structure

- *(dict)* – Returned for a successful ListDatasets request.
  - **Datasets** *(list)* – A set of datasets.
    - *(dict)* – A collection of data for an identity pool. An identity pool can have multiple datasets. A dataset is per identity and can be general or associated with a particular entity in an application (like a saved game). Datasets are automatically created if they don’t exist. Data is synced by dataset, and a dataset can hold up to 1MB of key-value pairs.
      - **IdentityId** *(string)* – A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
      - **DatasetName** *(string)* – A string of up to 128 characters. Allowed characters are a-z, A-Z, 0-9, ‘_’ (underscore), ‘-’ (dash), and ‘.’ (dot).
      - **CreationDate** *(datetime)* – Date on which the dataset was created.
· **LastModifiedBy** *(string)* – The device that made the last change to this dataset.
· **DataStorage** *(integer)* – Total size in bytes of the records in this dataset.
· **NumRecords** *(integer)* – Number of records in this dataset.

- **Count** *(integer)* – Number of datasets returned.
- **NextToken** *(string)* – A pagination token for obtaining the next page of results.

**list_identity_pool_usage(**

Gets a list of identity pools registered with Cognito.

ListIdentityPoolUsage can only be called with developer credentials. You cannot make this API call with the temporary user credentials provided by Cognito Identity.

**Request Syntax**

```python
response = client.list_identity_pool_usage(
    NextToken='string',
    MaxResults=123
)
```

**Parameters**

- **NextToken** *(string)* – A pagination token for obtaining the next page of results.
- **MaxResults** *(integer)* – The maximum number of results to be returned.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'IdentityPoolUsages': [
        {
            'IdentityPoolId': 'string',
            'SyncSessionsCount': 123,
            'DataStorage': 123,
            'LastModifiedDate': datetime(2015, 1, 1)
        },
    ],
    'MaxResults': 123,
    'Count': 123,
    'NextToken': 'string'
}
```

**Response Structure**

- *(dict)* – Returned for a successful ListIdentityPoolUsage request.
  - **IdentityPoolUsages** *(list)* – Usage information for the identity pools.
    - *(dict)* – Usage information for the identity pool.
      - **IdentityPoolId** *(string)* – A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
      - **SyncSessionsCount** *(integer)* – Number of sync sessions for the identity pool.
      - **DataStorage** *(integer)* – Data storage information for the identity pool.
- **LastModifiedDate** *(datetime)* – Date on which the identity pool was last modified.
- **MaxResults** *(integer)* – The maximum number of results to be returned.
- **Count** *(integer)* – Total number of identities for the identity pool.
- **NextToken** *(string)* – A pagination token for obtaining the next page of results.

`list_records(**kwargs)`

Gets paginated records, optionally changed after a particular sync count for a dataset and identity. With Amazon Cognito Sync, each identity has access only to its own data. Thus, the credentials used to make this API call need to have access to the identity data.

ListRecords can be called with temporary user credentials provided by Cognito Identity or with developer credentials. You should use Cognito Identity credentials to make this API call.

**Request Syntax**

```python
response = client.list_records(
    IdentityPoolId='string',
    IdentityId='string',
    DatasetName='string',
    LastSyncCount=123,
    NextToken='string',
    MaxResults=123,
    SyncSessionToken='string'
)
```

**Parameters**

- **IdentityPoolId** *(string)* – [REQUIRED] A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
- **IdentityId** *(string)* – [REQUIRED] A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
- **DatasetName** *(string)* – [REQUIRED] A string of up to 128 characters. Allowed characters are a-z, A-Z, 0-9, ‘_’ (underscore), ‘-’ (dash), and ‘.’ (dot).
- **LastSyncCount** *(integer)* – The last server sync count for this record.
- **NextToken** *(string)* – A pagination token for obtaining the next page of results.
- **MaxResults** *(integer)* – The maximum number of results to be returned.
- **SyncSessionToken** *(string)* – A token containing a session ID, identity ID, and expiration.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'Records': [
        {
            'Key': 'string',
            'Value': 'string',
            'SyncCount': 123,
            'LastModifiedDate': datetime(2015, 1, 1),
            'LastModifiedBy': 'string',
            'DeviceLastModifiedDate': datetime(2015, 1, 1)
        },
    ],
}
```
Response Structure

- *(dict)* – Returned for a successful ListRecordsRequest.
  - **Records** *(list)* – A list of all records.
    - *(dict)* – The basic data structure of a dataset.
      - **Key** *(string)* – The key for the record.
      - **Value** *(string)* – The value for the record.
      - **SyncCount** *(integer)* – The server sync count for this record.
      - **LastModifiedDate** *(datetime)* – The date on which the record was last modified.
      - **LastModifiedBy** *(string)* – The user/device that made the last change to this record.
      - **DeviceLastModifiedDate** *(datetime)* – The last modified date of the client device.
  - **NextToken** *(string)* – A pagination token for obtaining the next page of results.
  - **Count** *(integer)* – Total number of records.
  - **DatasetSyncCount** *(integer)* – Server sync count for this dataset.
  - **LastModifiedBy** *(string)* – The user/device that made the last change to this record.
  - **MergedDatasetNames** *(list)* – Names of merged datasets.
    - *(string)* –
  - **DatasetExists** *(boolean)* – Indicates whether the dataset exists.
  - **DatasetDeletedAfterRequestedSyncCount** *(boolean)* – A boolean value specifying whether to delete the dataset locally.
  - **SyncSessionToken** *(string)* – A token containing a session ID, identity ID, and expiration.

`register_device(**kwargs)`

Registers a device to receive push sync notifications.

This API can only be called with temporary credentials provided by Cognito Identity. You cannot call this API with developer credentials.

Request Syntax

```python
response = client.register_device(
    IdentityPoolId='string',
    IdentityId='string',
    Platform='APNS'|'APNS_SANDBOX'|'GCM'|'ADM',
    Token='string'
)
```

Parameters

- **IdentityPoolId** *(string)* – [REQUIRED]
A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. Here, the ID of the pool that the identity belongs to.

- **IdentityId** *(string)* – [REQUIRED]
  The unique ID for this identity.

- **Platform** *(string)* – [REQUIRED]
  The SNS platform type (e.g. GCM, SDM, APNS, APNS_SANDBOX).

- **Token** *(string)* – [REQUIRED]
  The push token.

**Return type** `dict`

**Returns**

**Response Syntax**

```
{
    'DeviceId': 'string'
}
```

**Response Structure**

- *(dict)* –
  Response to a RegisterDevice request.
  - **DeviceId** *(string)* –
    The unique ID generated for this device by Cognito.

---

**set_cognito_events** (**kwargs**)

Sets the AWS Lambda function for a given event type for an identity pool. This request only updates the key/value pair specified. Other key/values pairs are not updated. To remove a key value pair, pass a empty value for the particular key.

This API can only be called with developer credentials. You cannot call this API with the temporary user credentials provided by Cognito Identity.

**Request Syntax**

```python
response = client.set_cognito_events(
    IdentityPoolId='string',
    Events={
        'string': 'string'
    }
)
```

**Parameters**

- **IdentityPoolId** *(string)* – [REQUIRED]
  The Cognito Identity Pool to use when configuring Cognito Events

- **Events** *(dict)* – [REQUIRED]
  The events to configure
  - *(string)* –
    *

**Returns** None

---

**set_identity_pool_configuration** (**kwargs**)

Sets the necessary configuration for push sync.
This API can only be called with developer credentials. You cannot call this API with the temporary user credentials provided by Cognito Identity.

Request Syntax

```python
response = client.set_identity_pool_configuration(
    IdentityPoolId='string',
    PushSync={
        'ApplicationArns': ['string'],
        'RoleArn': 'string'
    },
    CognitoStreams={
        'StreamName': 'string',
        'RoleArn': 'string',
        'StreamingStatus': 'ENABLED'|'DISABLED'
    }
)
```

Parameters

- **IdentityPoolId** *(string)* – [REQUIRED]
  A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. This is the ID of the pool to modify.

- **PushSync** *(dict)* – Options to apply to this identity pool for push synchronization.
  - **ApplicationArns** *(list)* – List of SNS platform application ARNs that could be used by clients.
  - **RoleArn** *(string)* – A role configured to allow Cognito to call SNS on behalf of the developer.

- **CognitoStreams** *(dict)* – Options to apply to this identity pool for Amazon Cognito streams.
  - **StreamName** *(string)* – The name of the Cognito stream to receive updates. This stream must be in the developer's account and in the same region as the identity pool.
  - **RoleArn** *(string)* – The ARN of the role Amazon Cognito can assume in order to publish to the stream. This role must grant access to Amazon Cognito (cognito-sync) to invoke PutRecord on your Cognito stream.
  - **StreamingStatus** *(string)* – Status of the Cognito streams. Valid values are:
    - ENABLED - Streaming of updates to identity pool is enabled.
    - DISABLED - Streaming of updates to identity pool is disabled. Bulk publish will also fail if StreamingStatus is DISABLED.

**Return type** dict

**Returns**

Response Syntax

```json
{
    'IdentityPoolId': 'string',
    'PushSync': {
        'ApplicationArns': [
```
def subscribe_to_dataset(**kwargs):
    """Subscribes to receive notifications when a dataset is modified by another device."""

    # This API can only be called with temporary credentials provided by Cognito Identity. You cannot call this API with developer credentials.

    response = client.subscribe_to_dataset(
        IdentityPoolId='string',
        IdentityId='string',
    )

Response Structure

The output for the SetIdentityPoolConfiguration operation

- **IdentityPoolId**(string) –
  A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito.

- **PushSync**(dict) –
  Options to apply to this identity pool for push synchronization.
  
  - **ApplicationArns**(list) –
    List of SNS platform application ARNs that could be used by clients.
    
    - (string) –
      - **RoleArn**(string) –
        A role configured to allow Cognito to call SNS on behalf of the developer.

  - **CognitoStreams**(dict) – Options to apply to this identity pool for Amazon Cognito streams.
    
    - **StreamName**(string) – The name of the Cognito stream to receive updates. This stream must be in the developers account and in the same region as the identity pool.
    
    - **RoleArn**(string) – The ARN of the role Amazon Cognito can assume in order to publish to the stream. This role must grant access to Amazon Cognito (cognito-sync) to invoke PutRecord on your Cognito stream.
    
    - **StreamingStatus**(string) – Status of the Cognito streams. Valid values are:
      
      - ENABLED - Streaming of updates to identity pool is enabled.
      - DISABLED - Streaming of updates to identity pool is disabled. Bulk publish will also fail if StreamingStatus is DISABLED.
Parameters

- **IdentityPoolId** *(string)* – [REQUIRED]
  A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. The ID of the pool to which the identity belongs.

- **IdentityId** *(string)* – [REQUIRED]
  Unique ID for this identity.

- **DatasetName** *(string)* – [REQUIRED]
  The name of the dataset to subscribe to.

- **DeviceId** *(string)* – [REQUIRED]
  The unique ID generated for this device by Cognito.

Return type: dict

Returns:

Response Syntax:

```python
{}
```

Response Structure:

- *(dict)* –
  Response to a SubscribeToDataset request.

**unsubscribe_from_dataset(**kwargs)**

Unsubscribes from receiving notifications when a dataset is modified by another device.

This API can only be called with temporary credentials provided by Cognito Identity. You cannot call this API with developer credentials.

Request Syntax:

```python
response = client.unsubscribe_from_dataset(
    IdentityPoolId='string',
    IdentityId='string',
    DatasetName='string',
    DeviceId='string'
)
```

Parameters:

- **IdentityPoolId** *(string)* – [REQUIRED]
  A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. The ID of the pool to which this identity belongs.

- **IdentityId** *(string)* – [REQUIRED]
  Unique ID for this identity.

- **DatasetName** *(string)* – [REQUIRED]
  The name of the dataset from which to unsubscribe.

- **DeviceId** *(string)* – [REQUIRED]
  The unique ID generated for this device by Cognito.
Return type: dict

Returns

Response Syntax

{}

Response Structure

- (dict) –
  
  Response to an UnsubscribeFromDataset request.

update_records(**kwargs)

Posts updates to records and adds and deletes records for a dataset and user.

The sync count in the record patch is your last known sync count for that record. The server will reject an UpdateRecords request with a ResourceConflictException if you try to patch a record with a new value but a stale sync count.

For example, if the sync count on the server is 5 for a key called highScore and you try and submit a new highScore with sync count of 4, the request will be rejected. To obtain the current sync count for a record, call ListRecords. On a successful update of the record, the response returns the new sync count for that record. You should present that sync count the next time you try to update that same record. When the record does not exist, specify the sync count as 0.

This API can be called with temporary user credentials provided by Cognito Identity or with developer credentials.

Request Syntax

```python
response = client.update_records(
    IdentityPoolId='string',
    IdentityId='string',
    DatasetName='string',
    DeviceId='string',
    RecordPatches=[
        {
            'Op': 'replace'|'remove',
            'Key': 'string',
            'Value': 'string',
            'SyncCount': 123,
            'DeviceLastModifiedDate': datetime(2015, 1, 1)
        },
    ],
    SyncSessionToken='string',
    ClientContext='string'
)
```

Parameters

- **IdentityPoolId (string)** – [REQUIRED] A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
- **IdentityId (string)** – [REQUIRED] A name-spaced GUID (for example, us-east-1:23EC4050-6AEA-7089-A2DD-08002EXAMPLE) created by Amazon Cognito. GUID generation is unique within a region.
- **DatasetName (string)** – [REQUIRED] A string of up to 128 characters. Allowed characters are a-z, A-Z, 0-9, _ (underscore), - (dash), and . (dot).
- **DeviceId (string)** – The unique ID generated for this device by Cognito.
- **RecordPatches (list)** – A list of patch operations.
– (dict) – An update operation for a record.
  * **Key** (string) – [REQUIRED] The key associated with the record patch.
  * **Value** (string) – The value associated with the record patch.
  * **SyncCount** (integer) – [REQUIRED] Last known server sync count for this record. Set to 0 if unknown.
  * **DeviceLastModifiedDate** (datetime) – The last modified date of the client device.

- **SyncSessionToken** (string) – [REQUIRED] The SyncSessionToken returned by a previous call to ListRecords for this dataset and identity.
- **ClientContext** (string) – Intended to supply a device ID that will populate the lastModifiedBy field referenced in other methods. The ClientContext field is not yet implemented.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'Records': [
        {
            'Key': 'string',
            'Value': 'string',
            'SyncCount': 123,
            'LastModifiedDate': datetime(2015, 1, 1),
            'LastModifiedBy': 'string',
            'DeviceLastModifiedDate': datetime(2015, 1, 1)
        }
    ]
}
```

**Response Structure**

- **(dict)** – Returned for a successful UpdateRecordsRequest.
  - **Records** (list) – A list of records that have been updated.
    - **(dict)** – The basic data structure of a dataset.
      - **Key** (string) – The key for the record.
      - **Value** (string) – The value for the record.
      - **SyncCount** (integer) – The server sync count for this record.
      - **LastModifiedDate** (datetime) – The date on which the record was last modified.
      - **LastModifiedBy** (string) – The user/device that made the last change to this record.
      - **DeviceLastModifiedDate** (datetime) – The last modified date of the client device.
Client

class ConfigService.Client
A low-level client representing AWS Config (Config Service):

```python
import boto3

client = boto3.client('config')
```

These are the available methods:

- `can_paginate()`
- `delete_delivery_channel()`
- `deliver_config_snapshot()`
- `describe_configuration_recorder_status()`
- `describe_configuration_recorders()`
- `describe_delivery_channel_status()`
- `describe_delivery_channels()`
- `generate_presigned_url()`
- `get_paginator()`
- `get_resource_config_history()`
- `get_waiter()`
- `list_discovered_resources()`
- `put_configuration_recorder()`
- `put_delivery_channel()`
- `start_configuration_recorder()`
- `stop_configuration_recorder()`

`can_paginate(operation_name)`
Check if an operation can be paginated.

Parameters:
- `operation_name` (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

Returns:
- `True` if the operation can be paginated, `False` otherwise.

`delete_delivery_channel(**kwargs)`
Deletes the specified delivery channel.

The delivery channel cannot be deleted if it is the only delivery channel and the configuration recorder is still running. To delete the delivery channel, stop the running configuration recorder using the StopConfigurationRecorder action.

Request Syntax

```python
response = client.delete_delivery_channel(
    DeliveryChannelName='string'
)
```

Parameters:
- `DeliveryChannelName` (string) – [REQUIRED]

  The name of the delivery channel to delete.

Returns:
- None

`deliver_config_snapshot(**kwargs)`
Schedules delivery of a configuration snapshot to the Amazon S3 bucket in the specified delivery channel. After the delivery has started, AWS Config sends following notifications using an Amazon SNS topic that you have specified.
• Notification of starting the delivery.
• Notification of delivery completed, if the delivery was successfully completed.
• Notification of delivery failure, if the delivery failed to complete.

**Request Syntax**

```python
response = client.deliver_config_snapshot(
    deliveryChannelName='string'
)
```

**Parameters**

- `deliveryChannelName` *(string)* – [REQUIRED]
  
  The name of the delivery channel through which the snapshot is delivered.

**Return type**

`dict`

**Returns**

**Response Syntax**

```python
{
    'configSnapshotId': 'string'
}
```

**Response Structure**

- *(dict)*
  
  The output for the DeliverConfigSnapshot action in JSON format.
  - `configSnapshotId` *(string)* –
    
    The ID of the snapshot that is being created.

### describe_configuration_recorder_status(**kwargs)**

Returns the current status of the specified configuration recorder. If a configuration recorder is not specified, this action returns the status of all configuration recorder associated with the account.

**Note:** Currently, you can specify only one configuration recorder per account.

**Request Syntax**

```python
response = client.describe_configuration_recorder_status(
    ConfigurationRecorderNames=[
        'string',
    ]
)
```

**Parameters**

- `ConfigurationRecorderNames` *(list)* – The name(s) of the configuration recorder. If the name is not specified, the action returns the current status of all the configuration recorders associated with the account.

**Return type**

`dict`

**Returns**

**Response Syntax**

```python
{
    'ConfigurationRecordersStatus': [
        {
            'name': 'string',
            'lastStartTime': datetime(2015, 1, 1),
            'lastStopTime': datetime(2015, 1, 1),
        },
    ]
}
```
Response Structure

- (dict) –
  The output for the DescribeConfigurationRecorderStatus action in JSON format.
  - **ConfigurationRecordersStatus** (list) –
    A list that contains status of the specified recorders.
    * (dict) –
      The current status of the configuration recorder.
      - **name** (string) –
        The name of the configuration recorder.
      - **lastStartTime** (datetime) –
        The time the recorder was last started.
      - **lastStopTime** (datetime) –
        The time the recorder was last stopped.
      - **recording** (boolean) –
        Specifies whether the recorder is currently recording or not.
      - **lastStatus** (string) –
        The last (previous) status of the recorder.
      - **lastErrorCode** (string) –
        The error code indicating that the recording failed.
      - **lastErrorMessage** (string) –
        The message indicating that the recording failed due to an error.
      - **lastStatusChangeTime** (datetime) –
        The time when the status was last changed.

**describe_configuration_recorders** (**kwargs**)

Returns the name of one or more specified configuration recorders. If the recorder name is not specified, this action returns the names of all the configuration recorders associated with the account.

**Note:** Currently, you can specify only one configuration recorder per account.

**Request Syntax**

```python
response = client.describe_configuration_recorders(
    ConfigurationRecorderNames=[
        'string',
    ]
)
```

**Parameters**  
**ConfigurationRecorderNames** (list) – A list of configuration recorder names.

  * (string) –
Return type  dict
Returns

Response Syntax

{
   'ConfigurationRecorders': [ 
   
   
   'name': 'string',
   'roleARN': 'string',
   'recordingGroup': { 
   
   'allSupported': True|False,
   'resourceTypes': [ 
   
   'AWS::EC2::CustomerGateway'|'AWS::EC2::EIP'|'AWS::EC2::Instance'|'AWS::EC2::InternetGateway'|'AWS::EC2::NetworkAcl'|'AWS::EC2::Subnet'|'AWS::CloudTrail::Trail'|'AWS::EC2::Volume'|'AWS::EC2::VPC'|'AWS::EC2::VPNGateway',
   
   ],
   
   
   },
   
   ],
   
   }
}

Response Structure

* (dict) –
   
   The output for the DescribeConfigurationRecorders action.
   
   – ConfigurationRecorders (list) –
      
      A list that contains the descriptions of the specified configuration
      recorders.
      
      * (dict) –
         
         An object that represents the recording of configuration changes of
         an AWS resource.
         
         · name (string) –
            
            The name of the recorder. By default, AWS Config automatically
            assigns the name “default” when creating the configuration
            recorder. You cannot change the assigned name.
         · roleARN (string) –
            
            Amazon Resource Name (ARN) of the IAM role used to de-
            scribe the AWS resources associated with the account.
         · recordingGroup (dict) –
            
            The recording group specifies either to record configurations
            for all supported resources or to provide a list of resource
            types to record. The list of resource types must be a subset
            of supported resource types.
         · allSupported (boolean) –
            
            Records all supported resource types in the recording group.
            For a list of supported resource types, see Supported resource
types . If you specify allSupported , you cannot enumerate a
list of resourceTypes .
         · resourceTypes (list) –
            
            A comma-separated list of strings representing valid AWS
resource types (for example, AWS::EC2::Instance or
AWS::CloudTrail::Trail ). resourceTypes is only
valid if you have chosen not to select allSupported . For
a list of valid resourceTypes values, see the resourceType
**Value** column in the following topic: Supported AWS Resource Types.

- (string) –

**describe_delivery_channel_status** (**kwargs)

Returns the current status of the specified delivery channel. If a delivery channel is not specified, this action returns the current status of all delivery channels associated with the account.

**Note:** Currently, you can specify only one delivery channel per account.

### Request Syntax

```python
response = client.describe_delivery_channel_status(
    DeliveryChannelNames=[
        'string',
    ]
)
```

**Parameters**

- **DeliveryChannelNames** (*list*) – A list of delivery channel names.

**Return type**

- **dict** –

**Returns**

### Response Syntax

```
{
    'DeliveryChannelsStatus': {
        'name': 'string',
        'configSnapshotDeliveryInfo': {
            'lastStatus': 'Success'|'Failure'|'Not_Applicable',
            'lastErrorCode': 'string',
            'lastErrorMessage': 'string',
            'lastAttemptTime': datetime(2015, 1, 1),
            'lastSuccessfulTime': datetime(2015, 1, 1)
        },
        'configHistoryDeliveryInfo': {
            'lastStatus': 'Success'|'Failure'|'Not_Applicable',
            'lastErrorCode': 'string',
            'lastErrorMessage': 'string',
            'lastAttemptTime': datetime(2015, 1, 1),
            'lastSuccessfulTime': datetime(2015, 1, 1)
        },
        'configStreamDeliveryInfo': {
            'lastStatus': 'Success'|'Failure'|'Not_Applicable',
            'lastErrorCode': 'string',
            'lastErrorMessage': 'string',
            'lastStatusChangeTime': datetime(2015, 1, 1)
        }
    }
}
```

**Response Structure**

- (dict) –

The output for the DescribeDeliveryChannelStatus action.
– **DeliveryChannelsStatus** *(list)* –

A list that contains the status of a specified delivery channel.

* *(dict)* –

The status of a specified delivery channel.

**Valid values:** *Success|Failure*

- **name** *(string)* –
  The name of the delivery channel.

- **configSnapshotDeliveryInfo** *(dict)* –
  A list containing the status of the delivery of the snapshot to the specified Amazon S3 bucket.

  - **lastStatus** *(string)* –
    Status of the last attempted delivery.

  - **lastErrorCode** *(string)* –
    The error code from the last attempted delivery.

  - **lastErrorMessage** *(string)* –
    The error message from the last attempted delivery.

  - **lastAttemptTime** *(datetime)* –
    The time of the last attempted delivery.

  - **lastSuccessfulTime** *(datetime)* –
    The time of the last successful delivery.

- **configHistoryDeliveryInfo** *(dict)* –
  A list that contains the status of the delivery of the configuration history to the specified Amazon S3 bucket.

  - **lastStatus** *(string)* –
    Status of the last attempted delivery.

  - **lastErrorCode** *(string)* –
    The error code from the last attempted delivery.

  - **lastErrorMessage** *(string)* –
    The error message from the last attempted delivery.

  - **lastAttemptTime** *(datetime)* –
    The time of the last attempted delivery.

  - **lastSuccessfulTime** *(datetime)* –
    The time of the last successful delivery.

- **configStreamDeliveryInfo** *(dict)* –
  A list containing the status of the delivery of the configuration stream notification to the specified Amazon SNS topic.

  - **lastStatus** *(string)* –
    Status of the last attempted delivery.

  - **lastErrorCode** *(string)* –
    The error code from the last attempted delivery.

  - **lastErrorMessage** *(string)* –
    The error message from the last attempted delivery.

  - **lastAttemptTime** *(datetime)* –
    The time of the last attempted delivery.

  - **lastSuccessfulTime** *(datetime)* –
    The time of the last successful delivery.

**Note** Providing an SNS topic on a **DeliveryChannel** for AWS Config is optional. If the SNS delivery is turned off, the last status will be **Not_Applicable**.

- **lastErrorCode** *(string)* –
  The error code from the last attempted delivery.
describe_delivery_channels(**kwargs)

Returns details about the specified delivery channel. If a delivery channel is not specified, this action returns the details of all delivery channels associated with the account.

**Note:** Currently, you can specify only one delivery channel per account.

**Request Syntax**

```python
response = client.describe_delivery_channels(
    DeliveryChannelNames=['string'],
)
```

**Parameters**

- **DeliveryChannelNames (list)** – A list of delivery channel names.

**Return type**

dict

**Returns**

dict

**Response Syntax**

```json
{
    'DeliveryChannels': [
        {
            'name': 'string',
            's3BucketName': 'string',
            's3KeyPrefix': 'string',
            'snsTopicARN': 'string'
        },
    ],
}
```

**Response Structure**

- **(dict)** –

  The output for the DescribeDeliveryChannels action.

  - **DeliveryChannels (list)** –

    A list that contains the descriptions of the specified delivery channel.

    - **(dict)** –

      A logical container used for storing the configuration changes of an AWS resource.

      - **name (string)** –

        The name of the delivery channel. By default, AWS Config automatically assigns the name “default” when creating the delivery channel. You cannot change the assigned name.

      - **s3BucketName (string)** –

        The name of the Amazon S3 bucket used to store configuration history for the delivery channel.
- **s3KeyPrefix** *(string)* –
  The prefix for the specified Amazon S3 bucket.

- **snsTopicARN** *(string)* –
  The Amazon Resource Name (ARN) of the SNS topic that AWS Config delivers notifications to.

generate_presigned_url *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

**Parameters**

- **ClientMethod** *(string)* – The client method to presign for
- **Params** *(dict)* – The parameters normally passed to ClientMethod.
- **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns**

The presigned url

get_paginator *(operation_name)*

Create a paginator for an operation.

**Parameters** operation_name *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call

```python
client.get_paginator("create_foo")
```

**Raises** OperationNotPageableError

Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

**Return type**

L{botocore.paginate.Paginator}

**Returns**

A paginator object.

get_resource_config_history(**kwargs)**

Returns a list of configuration items for the specified resource. The list contains details about each state of the resource during the specified time interval.

The response is paginated, and by default, AWS Config returns a limit of 10 configuration items per page. You can customize this number with the limit parameter. The response includes a nextToken string, and to get the next page of results, run the request again and enter this string for the nextToken parameter.

**Note:** Each call to the API is limited to span a duration of seven days. It is likely that the number of records returned is smaller than the specified limit. In such cases, you can make another call, using the nextToken.

**Request Syntax**

```python
response = client.get_resource_config_history(
    resourceType='AWS::EC2::CustomerGateway'|'AWS::EC2::EIP'|'AWS::EC2::Instance'|'AWS::EC2::InternetGateway'|'AWS::EC2::NetworkInterface'|'AWS::EC2::RouteTable'|'AWS::EC2::Subnet'|'AWS::CloudTrail::Trail'|'AWS::EC2::Volume'|'AWS::EC2::VPC'|'AWS::EC2::VPNConnection'|'AWS::EC2::VPNGateway',
    resourceId='string',
    laterTime=datetime(2015, 1, 1),
    earlierTime=datetime(2015, 1, 1),
    chronologicalOrder='Reverse'|'Forward',
    limit=123,
    nextToken='string'
)
```

**Parameters**
• **resourceType** *(string)* – [REQUIRED]

The resource type.
• **resourceId** *(string)* – [REQUIRED]

The ID of the resource (for example., `sg-xxxxxx`).
• **laterTime** *(datetime)* – The time stamp that indicates a later time. If not specified, current time is taken.
• **earlierTime** *(datetime)* – The time stamp that indicates an earlier time. If not specified, the action returns paginated results that contain configuration items that start from when the first configuration item was recorded.
• **chronologicalOrder** *(string)* – The chronological order for configuration items listed. By default the results are listed in reverse chronological order.
• **limit** *(integer)* – The maximum number of configuration items returned on each page. The default is 10. You cannot specify a limit greater than 100. If you specify 0, AWS Config uses the default.
• **nextToken** *(string)* – The nextToken string returned on a previous page that you use to get the next page of results in a paginated response.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'configurationItems': [
        {
            'version': 'string',
            'accountId': 'string',
            'configurationItemCaptureTime': datetime(2015, 1, 1),
            'configurationItemStatus': 'Ok'|'Failed'|'Discovered'|'Deleted',
            'configurationStateId': 'string',
            'configurationItemMD5Hash': 'string',
            'arn': 'string',
            'resourceType': ... EC2::Subnet'|'AWS::CloudTrail::Trail'|'AWS::EC2::Volume'|'AWS::EC2::VPC'|'AWS::EC2::VPNConnection'|'AWS::EC2::VPNGateway',
            'resourceId': 'string',
            'resourceName': 'string',
            'awsRegion': 'string',
            'availabilityZone': 'string',
            'resourceCreationTime': datetime(2015, 1, 1),
            'tags': {
                'string': 'string'
            },
            'relatedEvents': [
                'string',
            ],
            'relationships': [
                {
                    'resourceType': ... EC2::Subnet'|'AWS::CloudTrail::Trail'|'AWS::EC2::Volume'|'AWS::EC2::VPC'|'AWS::EC2::VPNConnection'|'AWS::EC2::VPNGateway',
                    'resourceId': 'string',
                    'resourceName': 'string',
                    'relationshipName': 'string'
                },
            ],
            'configuration': 'string'
        },
        ...
    ],
    'nextToken': 'string'
}
```
Response Structure

- (dict) –
  The output for the GetResourceConfigHistory action.

  - configurationItems (list) –
    A list that contains the configuration history of one or more resources.
    - (dict) –
      A list that contains detailed configurations of a specified resource.

  * (dict) –
    A list that contains detailed configurations of a specified resource.

Note: Currently, the list does not contain information about non-
AWS components (for example, applications on your Amazon EC2
instances).

- version (string) –
  The version number of the resource configuration.

- accountId (string) –
  The 12 digit AWS account ID associated with the resource.

- configurationItemCaptureTime (datetime) –
  The time when the configuration recording was initiated.

- configurationItemStatus (string) –
  The configuration item status.

- configurationStateId (string) –
  An identifier that indicates the ordering of the configuration
  items of a resource.

- configurationItemMD5Hash (string) –
  Unique MD5 hash that represents the configuration item’s
  state.

  You can use MD5 hash to compare the states of two or
  more configuration items that are associated with the same
  resource.

- arn (string) –
  The Amazon Resource Name (ARN) of the resource.

- resourceType (string) –
  The type of AWS resource.

- resourceId (string) –
  The ID of the resource (for example., sg-xxxxxx).

- resourceName (string) –
  The custom name of the resource, if available.

- awsRegion (string) –
  The region where the resource resides.

- availabilityZone (string) –
  The Availability Zone associated with the resource.

- resourceCreationTime (datetime) –
  The time stamp when the resource was created.

- tags (dict) –
  A mapping of key value tags associated with the resource.
- `relatedEvents (list)` –

A list of CloudTrail event IDs.

A populated field indicates that the current configuration was initiated by the events recorded in the CloudTrail log. For more information about CloudTrail, see What is AWS CloudTrail?.

An empty field indicates that the current configuration was not initiated by any event.

- `relationships (list)` –

A list of related AWS resources.

- `configuration (string)` –

The description of the resource configuration.

- `nextToken (string)` –

The string that you use in a subsequent request to get the next page of results in a paginated response.

`get_waiter (waiter_name)`

`list_discovered_resources (**kwargs)`

Accepts a resource type and returns a list of resource identifiers for the resources of that type. A resource identifier includes the resource type, ID, and (if available) the custom resource name. The results consist of resources that AWS Config has discovered, including those that AWS Config is not currently recording. You can narrow the results to include only resources that have specific resource IDs or a resource name.

**Note:** You can specify either resource IDs or a resource name but not both in the same request.

The response is paginated, and by default AWS Config lists 100 resource identifiers on each page. You can customize this number with the `limit` parameter. The response includes a `nextToken` string, and to get the next page of results, run the request again and enter this string for the `nextToken` parameter.

**Request Syntax**

```python
response = client.list_discovered_resources(
    resourceType='AWS::EC2::CustomerGateway'|'AWS::EC2::EIP'|'AWS::EC2::Instance'|'AWS::EC2::InternetGateway'|'AWS::EC2::NetworkInterface'|'AWS::EC2::SecurityGroup'|'AWS::EC2::Subnet'|'AWS::CloudTrail::Trail'|'AWS::EC2::Volume'|'AWS::EC2::VPC'|'AWS::EC2::VPNConnection'|'AWS::EC2::VPNGateway',
    resourceIds=['string',
                 ],
...
```

3.1. Services 605
resourceName='string',
limit=123,
includeDeletedResources=True|False,
nextToken='string'
}

Parameters

- **resourceType (string)** – [REQUIRED]
  
  The type of resources that you want AWS Config to list in the response.

- **resourceIds (list)** – The IDs of only those resources that you want AWS Config to list in the response. If you do not specify this parameter, AWS Config lists all resources of the specified type that it has discovered.
  
  - (string)

- **resourceName (string)** – The custom name of only those resources that you want AWS Config to list in the response. If you do not specify this parameter, AWS Config lists all resources of the specified type that it has discovered.

- **limit (integer)** – The maximum number of resource identifiers returned on each page. The default is 100. You cannot specify a limit greater than 100. If you specify 0, AWS Config uses the default.

- **includeDeletedResources (boolean)** – Specifies whether AWS Config includes deleted resources in the results. By default, deleted resources are not included.

- **nextToken (string)** – The nextToken string returned on a previous page that you use to get the next page of results in a paginated response.

Return type  dict

Returns

Response Syntax

```
{
    'resourceIdentifiers': [
    {
        'resourceType': 'AWS::EC2::CustomerGateway'|'AWS::EC2::EIP'|'AWS::EC2::Volume'|'AWS::EC2::VPC'|'AWS::EC2::VPNConnection'|'AWS::EC2::VPNGateway',
        'resourceId': 'string',
        'resourceName': 'string',
        'resourceDeletionTime': datetime(2015, 1, 1)
    },
    ],
    'nextToken': 'string'
}
```

Response Structure

- (dict) –
  
  - resourceIdentifiers (list) –
    
    The details that identify a resource that is discovered by AWS Config, including the resource type, ID, and (if available) the custom resource name.
    
    - (dict) –
      
      The details that identify a resource that is discovered by AWS Con-fig, including the resource type, ID, and (if available) the custom resource name.
      
      - **resourceType (string)** –
        
        The type of resource.
      
      - **resourceId (string)** –
The ID of the resource (for example, sg-xxxxxx).

- **resourceName** *(string)* –
  The custom name of the resource (if available).

- **resourceDeletionTime** *(datetime)* –
  The time that the resource was deleted.

- **nextToken** *(string)* –
  The string that you use in a subsequent request to get the next page of results in a paginated response.

**put_configuration_recorder** (**kwargs**)

Creates a new configuration recorder to record the selected resource configurations.

You can use this action to change the role `roleARN` and/or the `recordingGroup` of an existing recorder. To change the role, call the action on the existing configuration recorder and specify a role.

---

**Note:** Currently, you can specify only one configuration recorder per account.

If `ConfigurationRecorder` does not have the `recordingGroup` parameter specified, the default is to record all supported resource types.

---

**Request Syntax**

```python
response = client.put_configuration_recorder(
    ConfigurationRecorder={
        'name': 'string',
        'roleARN': 'string',
        'recordingGroup': {
            'allSupported': True|False,
            'resourceTypes': [
                'AWS::EC2::CustomerGateway'|'AWS::EC2::EIP'|'AWS::EC2::Instance'|'AWS::EC2::InternetGateway'|'AWS::EC2::NetworkAcl'|'AWS::EC2::RouteTable'|'AWS::EC2::Volume'|'AWS::EC2::VPC'|'AWS::CloudTrail::Trail'|'AWS::EC2::VPNConnection'|'AWS::EC2::VPNGateway',
            ]
        }
    }
)
```

**Parameters**

**ConfigurationRecorder** *(dict)* – [REQUIRED]

The configuration recorder object that records each configuration change made to the resources.

- **name** *(string)* –
  The name of the recorder. By default, AWS Config automatically assigns the name “default” when creating the configuration recorder. You cannot change the assigned name.

- **roleARN** *(string)* –
  Amazon Resource Name (ARN) of the IAM role used to describe the AWS resources associated with the account.

- **recordingGroup** *(dict)* –
  The recording group specifies either to record configurations for all supported resources or to provide a list of resource types to record. The list of resource types must be a subset of supported resource types.

  - **allSupported** *(boolean)* –
    Records all supported resource types in the recording group. For a list of supported resource types, see Supported resource types. If you specify
**allSupported**, you cannot enumerate a list of **resourceTypes**.

- **resourceTypes** *(list)* –

  A comma-separated list of strings representing valid AWS resource types (for example, `AWS::EC2::Instance` or `AWS::CloudTrail::Trail`). **resourceTypes** is only valid if you have chosen not to select **allSupported**. For a list of valid **resourceTypes** values, see the **resourceType Value** column in the following topic: Supported AWS Resource Types.

  - *(string)* –

**Returns** None

**put_delivery_channel** (**kwargs**)

Creates a new delivery channel object to deliver the configuration information to an Amazon S3 bucket, and to an Amazon SNS topic.

You can use this action to change the Amazon S3 bucket or an Amazon SNS topic of the existing delivery channel. To change the Amazon S3 bucket or an Amazon SNS topic, call this action and specify the changed values for the S3 bucket and the SNS topic. If you specify a different value for either the S3 bucket or the SNS topic, this action will keep the existing value for the parameter that is not changed.

**Note:** Currently, you can specify only one delivery channel per account.

**Request Syntax**

```python
response = client.put_delivery_channel(
    DeliveryChannel={
        'name': 'string',
        's3BucketName': 'string',
        's3KeyPrefix': 'string',
        'snsTopicARN': 'string'
    }
)
```

**Parameters**  
**DeliveryChannel** *(dict)* – [REQUIRED]

The configuration delivery channel object that delivers the configuration information to an Amazon S3 bucket, and to an Amazon SNS topic.

- **name** *(string)* –

  The name of the delivery channel. By default, AWS Config automatically assigns the name “default” when creating the delivery channel. You cannot change the assigned name.

- **s3BucketName** *(string)* –

  The name of the Amazon S3 bucket used to store configuration history for the delivery channel.

- **s3KeyPrefix** *(string)* –

  The prefix for the specified Amazon S3 bucket.

- **snsTopicARN** *(string)* –

  The Amazon Resource Name (ARN) of the SNS topic that AWS Config delivers notifications to.

**Returns** None

**start_configuration_recorder** (**kwargs**)

Starts recording configurations of the AWS resources you have selected to record in your AWS account.
You must have created at least one delivery channel to successfully start the configuration recorder.

**Request Syntax**

```python
response = client.start_configuration_recorder(
    ConfigurationRecorderName='string'
)
```

**Parameters**
- **ConfigurationRecorderName (string)** – [REQUIRED]
  
  The name of the recorder object that records each configuration change made to the resources.

**Returns**
- None

**stop_configuration_recorder(**

Stops recording configurations of the AWS resources you have selected to record in your AWS account.

**Request Syntax**

```python
response = client.stop_configuration_recorder(
    ConfigurationRecorderName='string'
)
```

**Parameters**
- **ConfigurationRecorderName (string)** – [REQUIRED]
  
  The name of the recorder object that records each configuration change made to the resources.

**Returns**
- None

---

### DataPipeline

**Table of Contents**

- DataPipeline
  - Client
  - Paginators

---

#### Client

**class** `DataPipeline.Client`

A low-level client representing AWS Data Pipeline:

```python
import boto3

client = boto3.client('datapipeline')
```

These are the available methods:

- `activate_pipeline()`
- `add_tags()`
- `can_paginate()`
- `create_pipeline()`
- `deactivate_pipeline()`
- `delete_pipeline()`
- `describe_objects()`
activate_pipeline(**kwargs)

Activates a pipeline. If the pipeline has not been validated, activation fails.

If you need to pause the pipeline to investigate an issue with a component, such as a data source or script, call DeactivatePipeline.

To activate a finished pipeline, modify the end date for the pipeline and then activate it.

Request Syntax

```python
response = client.activate_pipeline(
    pipelineId='string',
    parameterValues=[
        {
            'id': 'string',
            'stringValue': 'string'
        },
    ],
    startTimestamp=datetime(2015, 1, 1)
)
```

Parameters

- **pipelineId*** (string) – [REQUIRED]

  The ID of the pipeline.

- **parameterValues*** (list) – A list of parameter values to pass to the pipeline at activation.

  - (dict) –

    A value or list of parameter values.

    - **id*** (string) – [REQUIRED]

      The ID of the parameter value.

    - **stringValue*** (string) – [REQUIRED]

      The field value, expressed as a String.

- **startTimestamp*** (datetime) – The date and time to resume the pipeline. By default, the pipeline resumes from the last completed execution.

Return type dict

Returns

Response Syntax
add_tags(**kwargs)

Add or modifies tags for the specified pipeline.

Request Syntax

```
response = client.add_tags(
    pipelineId='string',
    tags=[
        {
            'key': 'string',
            'value': 'string'
        },
    ]
)
```

Parameters

- **pipelineId** *(string)* – [REQUIRED]
  
The ID of the pipeline.
- **tags** *(list)* – [REQUIRED]
  
The tags to add, as key/value pairs.
  
  - *(dict)* –
    
    Tags are key/value pairs defined by a user and associated with a pipeline to control access. AWS Data Pipeline allows you to associate ten tags per pipeline. For more information, see Controlling User Access to Pipelines in the AWS Data Pipeline Developer Guide.
    
    * **key** *(string)* – [REQUIRED]
      
        The key name of a tag defined by a user. For more information, see Controlling User Access to Pipelines in the AWS Data Pipeline Developer Guide.
    
    * **value** *(string)* – [REQUIRED]
      
        The optional value portion of a tag defined by a user. For more information, see Controlling User Access to Pipelines in the AWS Data Pipeline Developer Guide.

Return type  dict

Returns

Response Syntax

```
{}
```

Response Structure

- *(dict)* –
  
  Contains the output of AddTags.

can_paginate(operation_name)

Check if an operation can be paginated.
Parameters **operation_name** *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

Returns `True` if the operation can be paginated, `False` otherwise.

`create_pipeline(**kwargs)`

Creates a new, empty pipeline. Use PutPipelineDefinition to populate the pipeline.

**Request Syntax**

```python
response = client.create_pipeline(
    name='string',
    uniqueId='string',
    description='string',
    tags=[
        {
            'key': 'string',
            'value': 'string'
        },
    ],
)
```

**Parameters**

- **name (string)** – [REQUIRED]
  The name for the pipeline. You can use the same name for multiple pipelines associated with your AWS account, because AWS Data Pipeline assigns each pipeline a unique pipeline identifier.

- **uniqueId (string)** – [REQUIRED]
  A unique identifier. This identifier is not the same as the pipeline identifier assigned by AWS Data Pipeline. You are responsible for defining the format and ensuring the uniqueness of this identifier. You use this parameter to ensure idempotency during repeated calls to `CreatePipeline`. For example, if the first call to `CreatePipeline` does not succeed, you can pass in the same unique identifier and pipeline name combination on a subsequent call to `CreatePipeline`. `CreatePipeline` ensures that if a pipeline already exists with the same name and unique identifier, a new pipeline is not created. Instead, you’ll receive the pipeline identifier from the previous attempt. The uniqueness of the name and unique identifier combination is scoped to the AWS account or IAM user credentials.

- **description (string)** – The description for the pipeline.

- **tags (list)** – A list of tags to associate with the pipeline at creation. Tags let you control access to pipelines. For more information, see Controlling User Access to Pipelines in the AWS Data Pipeline Developer Guide.
  ```python
  tags= [dict]  
  Tags are key/value pairs defined by a user and associated with a pipeline to control access. AWS Data Pipeline allows you to associate ten tags per pipeline. For more information, see Controlling User Access to Pipelines in the AWS Data Pipeline Developer Guide.
  ```

  - **key (string)** – [REQUIRED]
    The key name of a tag defined by a user. For more information, see Controlling User Access to Pipelines in the AWS Data Pipeline Developer Guide.
* value (string) – [REQUIRED]

The optional value portion of a tag defined by a user. For more information, see Controlling User Access to Pipelines in the AWS Data Pipeline Developer Guide.

Return type  dict
Returns

Response Syntax

```json
{
    'pipelineId': 'string'
}
```

Response Structure

- (dict) –
  - pipelineId (string) –
    
    The ID that AWS Data Pipeline assigns the newly created pipeline. For example, df-06372391ZG65EXAMPLE.

**deactivate_pipeline(**kwargs)**

Deactivates the specified running pipeline. The pipeline is set to the DEACTIVATING state until the deactivation process completes.

To resume a deactivated pipeline, use ActivatePipeline. By default, the pipeline resumes from the last completed execution. Optionally, you can specify the date and time to resume the pipeline.

Request Syntax

```python
response = client.deactivate_pipeline(
    pipelineId='string',
    cancelActive=True|False
)
```

Parameters

- pipelineId (string) – [REQUIRED]

  The ID of the pipeline.

- cancelActive (boolean) – Indicates whether to cancel any running objects. The default is true, which sets the state of any running objects to CANCELED. If this value is false, the pipeline is deactivated after all running objects finish.

Return type  dict
Returns

Response Syntax

```json
{}
```

Response Structure

- (dict) –
  
  Contains the output of DeactivatePipeline.

**delete_pipeline(**kwargs)**

Deletes a pipeline, its pipeline definition, and its run history. AWS Data Pipeline attempts to cancel instances associated with the pipeline that are currently being processed by task runners.
Deleting a pipeline cannot be undone. You cannot query or restore a deleted pipeline. To temporarily pause a pipeline instead of deleting it, call SetStatus with the status set to PAUSE on individual components. Components that are paused by SetStatus can be resumed.

**Request Syntax**

```python
def delete_pipeline(client, pipelineId):
    response = client.delete_pipeline(
        pipelineId='string'
    )
```

**Parameters**

- **pipelineId (string)** – [REQUIRED]
  
  The ID of the pipeline.

**Returns**

None

**describe_objects(**kwargs)**

Gets the object definitions for a set of objects associated with the pipeline. Object definitions are composed of a set of fields that define the properties of the object.

**Request Syntax**

```python
def describe_objects(client, pipelineId='string', objectIds=['string'], evaluateExpressions=True|False, marker='string'):
    response = client.describe_objects(
        pipelineId='string',
        objectIds=[
            'string',
        ],
        evaluateExpressions=True|False,
        marker='string'
    )
```

**Parameters**

- **pipelineId (string)** – [REQUIRED]
  
  The ID of the pipeline that contains the object definitions.

- **objectIds (list)** – [REQUIRED]
  
  The IDs of the pipeline objects that contain the definitions to be described. You can pass as many as 25 identifiers in a single call to DescribeObjects.

- **evaluateExpressions (boolean)** – Indicates whether any expressions in the object should be evaluated when the object descriptions are returned.

- **marker (string)** – The starting point for the results to be returned. For the first call, this value should be empty. As long as there are more results, continue to call DescribeObjects with the marker value from the previous call to retrieve the next set of results.

**Return type**

`dict`

**Returns**

Response Syntax

```python
{
    'pipelineObjects': [
        {
            'id': 'string',
            'name': 'string',
            'fields': [
                {
                    'key': 'string',
                    'stringValue': 'string',
                }
            ]
        }
    ]
}
```
Response Structure

- (dict) –
  Contains the output of DescribeObjects.
  
  - pipelineObjects (list) –
    An array of object definitions.
    
    * (dict) –
      Contains information about a pipeline object. This can be a logical, physical, or physical attempt pipeline object. The complete set of components of a pipeline defines the pipeline.
      
      - id (string) –
        The ID of the object.
      
      - name (string) –
        The name of the object.
      
      - fields (list) –
        Key-value pairs that define the properties of the object.
      
      * (dict) –
        A key-value pair that describes a property of a pipeline object. The value is specified as either a string value (StringValue) or a reference to another object (RefValue) but not as both.
        
        - key (string) –
          The field identifier.
        
        - stringValue (string) –
          The field value, expressed as a String.
        
        - refValue (string) –
          The field value, expressed as the identifier of another object.
    
    - marker (string) –
      The starting point for the next page of results. To view the next page of results, call DescribeObjects again with this marker value. If the value is null, there are no more results.
    
    - hasMoreResults (boolean) –
      Indicates whether there are more results to return.

**describe_pipelines** (**kwargs**)

Retrieves metadata about one or more pipelines. The information retrieved includes the name of the pipeline, the pipeline identifier, its current state, and the user account that owns the pipeline. Using account credentials, you can retrieve metadata about pipelines that you or your IAM users have created. If you are using an IAM user account, you can retrieve metadata about only those pipelines for which you have read permissions.
To retrieve the full pipeline definition instead of metadata about the pipeline, call GetPipelineDefinition.

**Request Syntax**

```python
response = client.describe_pipelines(
    pipelineIds=[
        'string',
    ]
)
```

**Parameters**

**pipelineIds** *(list) – [REQUIRED]*

The IDs of the pipelines to describe. You can pass as many as 25 identifiers in a single call. To obtain pipeline IDs, call ListPipelines.

**Return type**

dict

**Returns**

**Response Syntax**

```json
{
    'pipelineDescriptionList': [
        {
            'pipelineId': 'string',
            'name': 'string',
            'fields': [
                {
                    'key': 'string',
                    'stringValue': 'string',
                    'refValue': 'string'
                },
            ],
            'description': 'string',
            'tags': [
                {
                    'key': 'string',
                    'value': 'string'
                },
            ],
        }]
}
```

**Response Structure**

- *(dict) –*

  Contains the output of DescribePipelines.

  - **pipelineDescriptionList** *(list) –*

    An array of descriptions for the specified pipelines.

    - *(dict) –*

      Contains pipeline metadata.

      - **pipelineId** *(string) –*

        The pipeline identifier that was assigned by AWS Data Pipeline. This is a string of the form `df-297EG78HU43EEXAMPLE`.
- **name** *(string)* –
  The name of the pipeline.

- **fields** *(list)* –
  A list of read-only fields that contain metadata about the pipeline: @userId, @accountId, and @pipelineState.

- **(dict)** –
  A key-value pair that describes a property of a pipeline object. The value is specified as either a string value *(StringValue)* or a reference to another object *(RefValue)* but not as both.

- **key** *(string)* –
  The field identifier.

- **stringValue** *(string)* –
  The field value, expressed as a String.

- **refValue** *(string)* –
  The field value, expressed as the identifier of another object.

- **description** *(string)* –
  Description of the pipeline.

- **tags** *(list)* –
  A list of tags to associated with a pipeline. Tags let you control access to pipelines. For more information, see Controlling User Access to Pipelines in the AWS Data Pipeline Developer Guide.

- **(dict)** –
  Tags are key/value pairs defined by a user and associated with a pipeline to control access. AWS Data Pipeline allows you to associate ten tags per pipeline. For more information, see Controlling User Access to Pipelines in the AWS Data Pipeline Developer Guide.

- **key** *(string)* –
  The key name of a tag defined by a user. For more information, see Controlling User Access to Pipelines in the AWS Data Pipeline Developer Guide.

- **value** *(string)* –
  The optional value portion of a tag defined by a user. For more information, see Controlling User Access to Pipelines in the AWS Data Pipeline Developer Guide.

**evaluate_expression** (**kwargs**)

Task runners call EvaluateExpression to evaluate a string in the context of the specified object. For example, a task runner can evaluate SQL queries stored in Amazon S3.

**Request Syntax**

```python
response = client.evaluate_expression(
    pipelineId='string',
    objectId='string',
    expression='string'
)
```
Parameters

- **pipelineId** *(string)* – [REQUIRED]
  The ID of the pipeline.
- **objectId** *(string)* – [REQUIRED]
  The ID of the object.
- **expression** *(string)* – [REQUIRED]
  The expression to evaluate.

Return type  dict

Returns

Response Syntax

```python
{
  'evaluatedExpression': 'string'
}
```

Response Structure

- *(dict)* – Contains the output of EvaluateExpression.
  - **evaluatedExpression** *(string)* – The evaluated expression.

`generate_presigned_url` *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

Parameters

- **ClientMethod** *(string)* – The client method to presign for
- **Params** *(dict)* – The parameters normally passed to ClientMethod.
- **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns  The presigned url

`get_paginator` *(operation_name)*

Create a paginator for an operation.

Parameters **operation_name** *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

Raises **OperationNotPageableError** Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

Return type  L{botocore.paginate.Paginator}

Returns  A paginator object.

`get_pipeline_definition(**kwargs)`

Gets the definition of the specified pipeline. You can call `GetPipelineDefinition` to retrieve the pipeline definition that you provided using `PutPipelineDefinition`.

Request Syntax

```python
response = client.get_pipeline_definition(
    pipelineId='string',
```
version='string'
}

Parameters

- **pipelineId** *(string)* – [REQUIRED]
  
  The ID of the pipeline.
- **version** *(string)* – The version of the pipeline definition to retrieve. Set this parameter to `latest` (default) to use the last definition saved to the pipeline or `active` to use the last definition that was activated.

Return type  **dict**

Returns

**Response Syntax**

```
{
    'pipelineObjects': [  
        {
            'id': 'string',
            'name': 'string',
            'fields': [
                {
                    'key': 'string',
                    'stringValue': 'string',
                    'refValue': 'string'
                }
            ],
        },
    ],
    'parameterObjects': [  
        {
            'id': 'string',
            'attributes': [
                {
                    'key': 'string',
                    'stringValue': 'string'
                }
            ],
        },
    ],
    'parameterValues': [  
        {
            'id': 'string',
            'stringValue': 'string'
        }
    ]
}
```

**Response Structure**

- *(dict)* –
  
  Contains the output of GetPipelineDefinition.
  
  - **pipelineObjects** *(list)* –
    
    The objects defined in the pipeline.
    
    - *(dict)* –
      
      Contains information about a pipeline object. This can be a logical, physical, or physical attempt pipeline object. The complete set of
components of a pipeline defines the pipeline.
  · **id** *(string)* –
    The ID of the object.
  · **name** *(string)* –
    The name of the object.
  · **fields** *(list)* –
    Key-value pairs that define the properties of the object.
  · *(dict)* –
    A key-value pair that describes a property of a pipeline object. The value is specified as either a string value *(StringValue)* or a reference to another object *(RefValue)* but not as both.
  · **key** *(string)* –
    The field identifier.
  · **stringValue** *(string)* –
    The field value, expressed as a String.
  · **refValue** *(string)* –
    The field value, expressed as the identifier of another object.

  – **parameterObjects** *(list)* –
    The parameter objects used in the pipeline definition.
    · *(dict)* –
      Contains information about a parameter object.
      · **id** *(string)* –
        The ID of the parameter object.
      · **attributes** *(list)* –
        The attributes of the parameter object.
      · *(dict)* –
        The attributes allowed or specified with a parameter object.
      · **key** *(string)* –
        The field identifier.
      · **stringValue** *(string)* –
        The field value, expressed as a String.

  – **parameterValues** *(list)* –
    The parameter values used in the pipeline definition.
    · *(dict)* –
      A value or list of parameter values.
      · **id** *(string)* –
        The ID of the parameter value.
      · **stringValue** *(string)* –
        The field value, expressed as a String.

**get_waiter** *(waiter_name)*

**list_pipelines**(**kwargs)**

Lists the pipeline identifiers for all active pipelines that you have permission to access.
Request Syntax

```python
response = client.list_pipelines(
    marker='string'
)
```

**Parameters** `marker (string)` – The starting point for the results to be returned. For the first call, this value should be empty. As long as there are more results, continue to call `ListPipelines` with the marker value from the previous call to retrieve the next set of results.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'pipelineIdList': [
        {
            'id': 'string',
            'name': 'string'
        },
    ],
    'marker': 'string',
    'hasMoreResults': True|False
}
```

**Response Structure**

- `(dict)` – 
  
  Contains the output of `ListPipelines`.
  
  - `pipelineIdList (list)` – 
    
    The pipeline identifiers. If you require additional information about the pipelines, you can use these identifiers to call `DescribePipelines` and `GetPipelineDefinition`.
    
    - `(dict)` – 
      
      Contains the name and identifier of a pipeline.
      
      - `id (string)` – 
        
        The ID of the pipeline that was assigned by AWS Data Pipeline. This is a string of the form `df-297EG78H043EEXAMPLE`.
      
      - `name (string)` – 
        
        The name of the pipeline.
    
    - `marker (string)` – 
      
      The starting point for the next page of results. To view the next page of results, call `ListPipelinesOutput` again with this marker value. If the value is null, there are no more results.
    
    - `hasMoreResults (boolean)` – 
      
      Indicates whether there are more results that can be obtained by a subsequent call.

**poll_for_task(**kwargs)**

Task runners call `PollForTask` to receive a task to perform from AWS Data Pipeline. The task runner specifies which tasks it can perform by setting a value for the `workerGroup` parameter. The task
returned can come from any of the pipelines that match the workerGroup value passed in by the task runner and that was launched using the IAM user credentials specified by the task runner.

If tasks are ready in the work queue, PollForTask returns a response immediately. If no tasks are available in the queue, PollForTask uses long-polling and holds on to a poll connection for up to a 90 seconds, during which time the first newly scheduled task is handed to the task runner. To accommodate this, set the socket timeout in your task runner to 90 seconds. The task runner should not call PollForTask again on the same workerGroup until it receives a response, and this can take up to 90 seconds.

Request Syntax

```python
response = client.poll_for_task(
    workerGroup='string',
    hostname='string',
    instanceIdentity=
    {'document': 'string',
     'signature': 'string'}
)
```

Parameters

- **workerGroup (string)** – [REQUIRED]
  
The type of task the task runner is configured to accept and process. The worker group is set as a field on objects in the pipeline when they are created. You can only specify a single value for workerGroup in the call to PollForTask.
  
  There are no wildcard values permitted in workerGroup; the string must be an exact, case-sensitive, match.

- **hostname (string)** – The public DNS name of the calling task runner.

- **instanceIdentity (dict)** – Identity information for the EC2 instance that is hosting the task runner. You can get this value from the instance using `http://169.254.169.254/latest/meta-data/instance-id`.
  
  For more information, see Instance Metadata in the Amazon Elastic Compute Cloud User Guide. Passing in this value proves that your task runner is running on an EC2 instance, and ensures the proper AWS Data Pipeline service charges are applied to your pipeline.

  - **document (string)** –
    
    A description of an EC2 instance that is generated when the instance is launched and exposed to the instance via the instance metadata service in the form of a JSON representation of an object.

  - **signature (string)** –
    
    A signature which can be used to verify the accuracy and authenticity of the information provided in the instance identity document.

Return type dict

Returns

Response Syntax

```python
{
    'taskObject': {
        'taskId': 'string',
        'pipelineId': 'string',
        'attemptId': 'string',
        'objects': {
            'string': {
                'id': 'string',
            }
        }
    }
}
```
Response Structure

- (dict) –
  Contains the output of PollForTask.
  - taskObject (dict) –
    The information needed to complete the task that is being assigned to the
task runner. One of the fields returned in this object is taskId, which
contains an identifier for the task being assigned. The calling task runner
uses taskId in subsequent calls to ReportTaskProgress and SetTaskSta-
tus.
    * taskId (string) –
      An internal identifier for the task. This ID is passed to the Set-
TaskStatus and ReportTaskProgress actions.
    * pipelineId (string) –
      The ID of the pipeline that provided the task.
    * attemptId (string) –
      The ID of the pipeline task attempt object. AWS Data Pipeline uses
this value to track how many times a task is attempted.
    * objects (dict) –
      Connection information for the location where the task runner will
publish the output of the task.
            · (string) –
            · (dict) –
        Contains information about a pipeline object. This can be
a logical, physical, or physical attempt pipeline object. The
complete set of components of a pipeline defines the pipeline.
            · id (string) –
          The ID of the object.
            · name (string) –
          The name of the object.
            · fields (list) –
          Key-value pairs that define the properties of the object.
            · (dict) –
        A key-value pair that describes a property of a pipeline
object. The value is specified as either a string
value (StringValue) or a reference to another object
(RefValue) but not as both.
**key (string)** –

The field identifier.

**stringValue (string)** –

The field value, expressed as a String.

**refValue (string)** –

The field value, expressed as the identifier of another object.

The put_pipeline_definition (**kwargs**) function adds tasks, schedules, and preconditions to the specified pipeline. You can use PutPipelineDefinition to populate a new pipeline. PutPipelineDefinition also validates the configuration as it adds it to the pipeline. Changes to the pipeline are saved unless one of the following three validation errors exists in the pipeline.

- An object is missing a name or identifier field.
- A string or reference field is empty.
- The number of objects in the pipeline exceeds the maximum allowed objects.
- The pipeline is in a FINISHED state.

Pipeline object definitions are passed to the PutPipelineDefinition action and returned by the GetPipelineDefinition action.

**Request Syntax**

```python
response = client.put_pipeline_definition(
    pipelineId='string',
    pipelineObjects=[
        {
            'id': 'string',
            'name': 'string',
            'fields': [
                {
                    'key': 'string',
                    'stringValue': 'string',
                    'refValue': 'string'
                }
            ]
        },
    ],
    parameterObjects=[
        {
            'id': 'string',
            'attributes': [
                {
                    'key': 'string',
                    'stringValue': 'string'
                }
            ]
        },
    ],
    parameterValues=[
        {
            'id': 'string',
            'stringValue': 'string'
        }
    ]
)
```
Parameters

- **pipelineId** *(string)* – [REQUIRED]
  
The ID of the pipeline.

- **pipelineObjects** *(list)* – [REQUIRED]
  
The objects that define the pipeline. These objects overwrite the existing pipeline definition.
  
  - *(dict)* –
    
    Contains information about a pipeline object. This can be a logical, physical, or physical attempt pipeline object. The complete set of components of a pipeline defines the pipeline.
    
    * **id** *(string)* – [REQUIRED]
      
The ID of the object.
    
    * **name** *(string)* – [REQUIRED]
      
The name of the object.
    
    * **fields** *(list)* – [REQUIRED]
      
      Key-value pairs that define the properties of the object.
      
      - *(dict)* –
        
        A key-value pair that describes a property of a pipeline object. The value is specified as either a string value *(StringValue)* or a reference to another object *(RefValue)* but not as both.
        
        - **key** *(string)* – [REQUIRED]
          
The field identifier.
        
        - **stringValue** *(string)* –
          
The field value, expressed as a String.
        
        - **refValue** *(string)* –
          
The field value, expressed as the identifier of another object.

- **parameterObjects** *(list)* – The parameter objects used with the pipeline.
  
  - *(dict)* –
    
    Contains information about a parameter object.
    
    * **id** *(string)* – [REQUIRED]
      
The ID of the parameter object.
    
    * **attributes** *(list)* – [REQUIRED]
      
      The attributes of the parameter object.
      
      - *(dict)* –
        
        The attributes allowed or specified with a parameter object.
        
        - **key** *(string)* – [REQUIRED]
          
The field identifier.
        
        - **stringValue** *(string)* – [REQUIRED]
          
The field value, expressed as a String.

- **parameterValues** *(list)* – The parameter values used with the pipeline.
  
  - *(dict)* –
    
    A value or list of parameter values.
    
    * **id** *(string)* – [REQUIRED]
      
The ID of the parameter value.
* stringValue (string) – [REQUIRED]

The field value, expressed as a String.

Return type dict

Returns

Response Syntax

```python
{
    'validationErrors': [  
        {  
            'id': 'string',  
            'errors': [  
                'string',  
            ],  
        },  
    ],  
    'validationWarnings': [  
        {  
            'id': 'string',  
            'warnings': [  
                'string',  
            ],  
        },  
    ],  
    'errored': True|False
}
```

Response Structure

- (dict) –

Contains the output of PutPipelineDefinition.

- validationErrors (list) –

The validation errors that are associated with the objects defined in pipelineObjects.

  - (dict) –

  Defines a validation error. Validation errors prevent pipeline activation. The set of validation errors that can be returned are defined by AWS Data Pipeline.

    - id (string) –

      The identifier of the object that contains the validation error.

    - errors (list) –

      A description of the validation error.

- validationWarnings (list) –

The validation warnings that are associated with the objects defined in pipelineObjects.

  - (dict) –

  Defines a validation warning. Validation warnings do not prevent pipeline activation. The set of validation warnings that can be returned are defined by AWS Data Pipeline.

    - id (string) –

      The identifier of the object that contains the validation warning.
query_objects(**kwargs)

Queries the specified pipeline for the names of objects that match the specified set of conditions.

Request Syntax

```python
response = client.query_objects(
    pipelineId='string',
    query={
        'selectors': [
            {
                'fieldName': 'string',
                'operator': {
                    'type': 'EQ'|'REF_EQ'|'LE'|'GE'|'BETWEEN',
                    'values': [...
                },
            },
        ],
    },
    sphere='string',
    marker='string',
    limit=123
)
```

Parameters

- **pipelineId (string)** – [REQUIRED]
  The ID of the pipeline.

- **query (dict)** – The query that defines the objects to be returned. The Query object can contain a maximum of ten selectors. The conditions in the query are limited to top-level String fields in the object. These filters can be applied to components, instances, and attempts.

  - **selectors (list)** –
    List of selectors that define the query. An object must satisfy all of the selectors to match the query.

  - **(dict)** –
    A comparison that is used to determine whether a query should return this object.

    - **fieldName (string)** –
      The name of the field that the operator will be applied to. The field name is the “key” portion of the field definition in the pipeline definition syntax that is used by the AWS Data Pipeline API. If the field is not set on the object, the condition fails.

    - **operator (dict)** –

- **errored (boolean)** –
  Indicates whether there were validation errors, and the pipeline definition is stored but cannot be activated until you correct the pipeline and call PutPipelineDefinition to commit the corrected pipeline.
Contains a logical operation for comparing the value of a field with a specified value.

- **type (string)** –

  The logical operation to be performed: equal (EQ), equal reference (REF_EQ), less than or equal (LE), greater than or equal (GE), or between (BETWEEN). Equal reference (REF_EQ) can be used only with reference fields. The other comparison types can be used only with String fields. The comparison types you can use apply only to certain object fields, as detailed below.

  The comparison operators EQ and REF_EQ act on the following fields:
  - name
  - @sphere
  - parent
  - @componentParent
  - @instanceParent
  - @status
  - @scheduledStartTime
  - @scheduledEndTime
  - @actualStartTime
  - @actualEndTime

  The comparison operators GE, LE, and BETWEEN act on the following fields:
  - @scheduledStartTime
  - @scheduledEndTime
  - @actualStartTime
  - @actualEndTime

  Note that fields beginning with the at sign (@) are read-only and set by the web service. When you name fields, you should choose names containing only alpha-numeric values, as symbols may be reserved by AWS Data Pipeline. User-defined fields that you add to a pipeline should prefix their name with the string “my”.

- **values (list)** –

  The value that the actual field value will be compared with.

- **sphere (string)** – [REQUIRED]

  Indicates whether the query applies to components or instances. The possible values are: COMPONENT, INSTANCE, and ATTEMPT.

- **marker (string)** – The starting point for the results to be returned. For the first call, this value should be empty. As long as there are more results, continue to call QueryObjects with the marker value from the previous call to retrieve the next set of results.

- **limit (integer)** – The maximum number of object names that QueryObjects will return in a single call. The default value is 100.

Return type: dict

Returns

Response Syntax
Boto3 Documentation, Release 1.1.4

```python
{
    'ids': [
        'string',
    ],
    'marker': 'string',
    'hasMoreResults': True|False
}
```

**Response Structure**

- **(dict)** –

  Contains the output of QueryObjects.

  - **ids (list)** –

    The identifiers that match the query selectors.

    * **(string)** –

  - **marker (string)** –

    The starting point for the next page of results. To view the next page of results, call `QueryObjects` again with this marker value. If the value is null, there are no more results.

  - **hasMoreResults (boolean)** –

    Indicates whether there are more results that can be obtained by a subsequent call.

**remove_tags(**kwargs**)**

Removes existing tags from the specified pipeline.

**Request Syntax**

```python
response = client.remove_tags(
    pipelineId='string',
    tagKeys=['string',
             'string',
    ]
)
```

**Parameters**

- **pipelineId (string)** – [REQUIRED]

  The ID of the pipeline.

- **tagKeys (list)** – [REQUIRED]

  The keys of the tags to remove.

**Return type**

**dict**

**Returns**

**Response Syntax**

```python
{}
```

**Response Structure**

- **(dict)** –

  Contains the output of RemoveTags.

**report_task_progress(**kwargs**)**

Task runners call `ReportTaskProgress` when assigned a task to acknowledge that it has the task. If
the web service does not receive this acknowledgement within 2 minutes, it assigns the task in a subsequent PollForTask call. After this initial acknowledgement, the task runner only needs to report progress every 15 minutes to maintain its ownership of the task. You can change this reporting time from 15 minutes by specifying a `reportProgressTimeout` field in your pipeline.

If a task runner does not report its status after 5 minutes, AWS Data Pipeline assumes that the task runner is unable to process the task and reassigns the task in a subsequent response to PollForTask. Task runners should call `ReportTaskProgress` every 60 seconds.

**Request Syntax**

```python
response = client.report_task_progress(
    taskId='string',
    fields=[
        {
            'key': 'string',
            'stringValue': 'string',
            'refValue': 'string'
        },
    ]
)
```

**Parameters**

- **taskId** (*string*) – [REQUIRED]
  
  The ID of the task assigned to the task runner. This value is provided in the response for PollForTask.

- **fields** (*list*) – Key-value pairs that define the properties of the ReportTaskProgressInput object.
  
  - (*dict*) –
    
    A key-value pair that describes a property of a pipeline object. The value is specified as either a string value (`StringValue`) or a reference to another object (`RefValue`) but not as both.
    
    - **key** (*string*) – [REQUIRED]
      
      The field identifier.

    - **stringValue** (*string*) –
      
      The field value, expressed as a String.

    - **refValue** (*string*) –
      
      The field value, expressed as the identifier of another object.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'canceled': True|False
}
```

**Response Structure**

- (*dict*) –
  
  Contains the output of ReportTaskProgress.

    - **canceled** (*boolean*) –
      
      If true, the calling task runner should cancel processing of the task. The task runner does not need to call SetTaskStatus for canceled tasks.
**report_task_runner_heartbeat(**kwargs**)

Task runners call `report_task_runner_heartbeat` every 15 minutes to indicate that they are operational. If the AWS Data Pipeline Task Runner is launched on a resource managed by AWS Data Pipeline, the web service can use this call to detect when the task runner application has failed and restart a new instance.

**Request Syntax**

```python
response = client.report_task_runner_heartbeat(
    taskrunnerId='string',
    workerGroup='string',
    hostname='string'
)
```

**Parameters**

- **taskId** (*string*) – [REQUIRED]
  
  The ID of the task runner. This value should be unique across your AWS account. In the case of AWS Data Pipeline Task Runner launched on a resource managed by AWS Data Pipeline, the web service provides a unique identifier when it launches the application. If you have written a custom task runner, you should assign a unique identifier for the task runner.

- **workerGroup** (*string*) – The type of task the task runner is configured to accept and process. The worker group is set as a field on objects in the pipeline when they are created. You can only specify a single value for `workerGroup`. There are no wildcard values permitted in `workerGroup`; the string must be an exact, case-sensitive, match.

- **hostname** (*string*) – The public DNS name of the task runner.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'terminate': True|False
}
```

**Response Structure**

- `dict` –
  
  Contains the output of `report_task_runner_heartbeat`.

  - `terminate` (*boolean*) –
    
    Indicates whether the calling task runner should terminate.

**set_status(**kwargs**)

Requests that the status of the specified physical or logical pipeline objects be updated in the specified pipeline. This update might not occur immediately, but is eventually consistent. The status that can be set depends on the type of object (for example, DataNode or Activity). You cannot perform this operation on FINISHED pipelines and attempting to do so returns `InvalidRequestException`.

**Request Syntax**

```python
response = client.set_status(
    pipelineId='string',
    objectIds=['string',
               'string'],
)
```
status='string'

Parameters

- **pipelineId** *(string)* – [REQUIRED]
  The ID of the pipeline that contains the objects.
- **objectIds** *(list)* – [REQUIRED]
  The IDs of the objects. The corresponding objects can be either physical or components, but not a mix of both types.
  - *(string)* –
- **status** *(string)* – [REQUIRED]
  The status to be set on all the objects specified in `objectIds`. For components, use `PAUSE` or `RESUME`. For instances, use `TRY_CANCEL`, `RERUN`, or `MARK_FINISHED`.

Returns

None

**set_task_status** (**kwargs)**

Task runners call `SetTaskStatus` to notify AWS Data Pipeline that a task is completed and provide information about the final status. A task runner makes this call regardless of whether the task was successful. A task runner does not need to call `SetTaskStatus` for tasks that are canceled by the web service during a call to `ReportTaskProgress`.

Request Syntax

```python
response = client.set_task_status(
    taskId='string',
    taskStatus='FINISHED'|'FAILED'|'FALSE',
    errorId='string',
    errorMessage='string',
    errorStackTrace='string'
)
```

Parameters

- **taskId** *(string)* – [REQUIRED]
  The ID of the task assigned to the task runner. This value is provided in the response for `PollForTask`.
- **taskStatus** *(string)* – [REQUIRED]
  If `FINISHED`, the task successfully completed. If `FAILED`, the task ended unsuccessfully. Preconditions use `false`.
- **errorId** *(string)* – If an error occurred during the task, this value specifies the error code. This value is set on the physical attempt object. It is used to display error information to the user. It should not start with string “Service_” which is reserved by the system.
- **errorMessage** *(string)* – If an error occurred during the task, this value specifies a text description of the error. This value is set on the physical attempt object. It is used to display error information to the user. The web service does not parse this value.
- **errorStackTrace** *(string)* – If an error occurred during the task, this value specifies the stack trace associated with the error. This value is set on the physical attempt object. It is used to display error information to the user. The web service does not parse this value.

Return type
dict
validate_pipeline_definition(**kwargs)

Validates the specified pipeline definition to ensure that it is well formed and can be run without error.

Request Syntax

```python
response = client.validate_pipeline_definition(
    pipelineId='string',
    pipelineObjects=[
        {
            'id': 'string',
            'name': 'string',
            'fields': [
                {
                    'key': 'string',
                    'stringValue': 'string',
                    'refValue': 'string'
                }
            ]
        },
    ],
    parameterObjects=[
        {
            'id': 'string',
            'attributes': [
                {
                    'key': 'string',
                    'stringValue': 'string'
                }
            ]
        },
    ],
    parameterValues=[
        {
            'id': 'string',
            'stringValue': 'string'
        }
    ]
)
```

Parameters

- **pipelineId (string)** – [REQUIRED]
  
The ID of the pipeline.

- **pipelineObjects (list)** – [REQUIRED]
  
The objects that define the pipeline changes to validate against the pipeline.
Contains information about a pipeline object. This can be a logical, physical, or physical attempt pipeline object. The complete set of components of a pipeline defines the pipeline.

* `id (string)` – [REQUIRED]  
  The ID of the object.

* `name (string)` – [REQUIRED]  
  The name of the object.

* `fields (list)` – [REQUIRED]  
  Key-value pairs that define the properties of the object.

  - (dict) –
    
    A key-value pair that describes a property of a pipeline object. The value is specified as either a string value (`StringValue`) or a reference to another object (`RefValue`) but not as both.

    - `key (string)` – [REQUIRED]  
      The field identifier.

    - `stringValue (string)` –  
      The field value, expressed as a String.

    - `refValue (string)` –  
      The field value, expressed as the identifier of another object.

* `parameterObjects (list)` – The parameter objects used with the pipeline.

  - (dict) –
    
    Contains information about a parameter object.

    * `id (string)` – [REQUIRED]  
      The ID of the parameter object.

    * `attributes (list)` – [REQUIRED]  
      The attributes of the parameter object.

        - (dict) –
          
          The attributes allowed or specified with a parameter object.

          - `key (string)` – [REQUIRED]  
            The field identifier.

          - `stringValue (string)` – [REQUIRED]  
            The field value, expressed as a String.

* `parameterValues (list)` – The parameter values used with the pipeline.

  - (dict) –
    
    A value or list of parameter values.

    * `id (string)` – [REQUIRED]  
      The ID of the parameter value.

    * `stringValue (string)` – [REQUIRED]  
      The field value, expressed as a String.

Return type: `dict`

Returns

Response Syntax
```json
{
    'validationErrors': [
        {
            'id': 'string',
            'errors': ['string'],
        },
    ],
    'validationWarnings': [
        {
            'id': 'string',
            'warnings': ['string'],
        },
    ],
    'errored': True|False
}
```

**Response Structure**

- *(dict)* –
  Contains the output of ValidatePipelineDefinition.
  - **validationErrors** *(list)* –
    Any validation errors that were found.
    - *(dict)* –
      Defines a validation error. Validation errors prevent pipeline activation. The set of validation errors that can be returned are defined by AWS Data Pipeline.
      - **id** *(string)* –
        The identifier of the object that contains the validation error.
      - **errors** *(list)* –
        A description of the validation error.
      - *(string)* –
  - **validationWarnings** *(list)* –
    Any validation warnings that were found.
    - *(dict)* –
      Defines a validation warning. Validation warnings do not prevent pipeline activation. The set of validation warnings that can be returned are defined by AWS Data Pipeline.
      - **id** *(string)* –
        The identifier of the object that contains the validation warning.
      - **warnings** *(list)* –
        A description of the validation warning.
      - *(string)* –
  - **errored** *(boolean)* –
    Indicates whether there were validation errors.
Paginators

The available paginators are:

- `DataPipeline Paginator. DescribeObjects`
- `DataPipeline Paginator. ListPipelines`
- `DataPipeline Paginator. QueryObjects`

```python
class DataPipeline Paginator. DescribeObjects

paginator = client.get_paginator('describe_objects')

paginate (**kwargs)
Creates an iterator that will paginate through responses from
DataPipeline.Client.describe_objects().

Request Syntax

response_iterator = paginator.paginate(
    pipelineId='string',
    objectIds=[
        'string',
    ],
    evaluateExpressions=True|False,
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **pipelineId** *(string) – [REQUIRED]*
  The ID of the pipeline that contains the object definitions.
- **objectIds** *(list) – [REQUIRED]*
  The IDs of the pipeline objects that contain the definitions to be described. You
can pass as many as 25 identifiers in a single call to DescribeObjects.
- **evaluateExpressions** *(boolean)*
  Indicates whether any expressions in the ob-
  ject should be evaluated when the object descriptions are returned.
- **PaginationConfig** *(dict)*
  A dictionary that provides parameters to control pag-
  ination.
  - **MaxItems** *(integer)*
    The total number of items to return. If the total number of items available
    is more than the value specified in max-items then a NextToken will be
    provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)*
    The size of each page.
  - **StartingToken** *(string)*
    A token to specify where to start paginating. This is the NextToken
    from a previous response.

Return type  **dict**
Returns

Response Syntax

```json
{
    'pipelineObjects': [
        {
            'id': 'string',
            'name': 'string',
            'fields': [
                {
                    'key': 'string',
                    'stringValue': 'string',
                    'refValue': 'string'
                },
            ],
        },
    ],
    'hasMoreResults': True|False,
    'NextToken': 'string'
}
```

Response Structure

- *(dict)* –

Contains the output of DescribeObjects.

- **pipelineObjects** *(list)* –

An array of object definitions.

- *(dict)* –

Contains information about a pipeline object. This can be a logical, physical, or physical attempt pipeline object. The complete set of components of a pipeline defines the pipeline.

- **id** *(string)* –

The ID of the object.

- **name** *(string)* –

The name of the object.

- **fields** *(list)* –

Key-value pairs that define the properties of the object.

- *(dict)* –

A key-value pair that describes a property of a pipeline object. The value is specified as either a string value *(StringValue)* or a reference to another object *(RefValue)* but not as both.

- **key** *(string)* –

The field identifier.

- **stringValue** *(string)* –

The field value, expressed as a String.

- **refValue** *(string)* –

The field value, expressed as the identifier of another object.

- **hasMoreResults** *(boolean)* –

Indicates whether there are more results to return.
– **NextToken** *(string)* –

A token to resume pagination.

class DataPipelinePaginator.ListPipelines

```python
paginator = client.get_paginator('list_pipelines')
```

**paginate** (**kwargs)

Creates an iterator that will paginate through responses from *DataPipeline.Client.list_pipelines()*.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

**PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

- **MaxItems** *(integer)* –
  The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

- **PageSize** *(integer)* –
  The size of each page.

- **StartingToken** *(string)* –
  A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** **dict**

**Returns**

**Response Syntax**

```python
{
    'pipelineIdList': [
        {
            'id': 'string',
            'name': 'string'
        },
        ...
    ],
    'hasMoreResults': True|False,
    'NextToken': 'string'
}
```

**Response Structure**

- *(dict)* –
  Contains the output of ListPipelines.
pipelineIdList (list) –

The pipeline identifiers. If you require additional information about the pipelines, you can use these identifiers to call DescribePipelines and GetPipelineDefinition.

* (dict) –

Contains the name and identifier of a pipeline.

  - id (string) –

    The ID of the pipeline that was assigned by AWS Data Pipeline. This is a string of the form df-297EG78HU43EEXAMPLE.

  - name (string) –

    The name of the pipeline.

hasMoreResults (boolean) –

Indicates whether there are more results that can be obtained by a subsequent call.

NextToken (string) –

A token to resume pagination.

class DataPipeline.Paginator.QueryObjects

paginator = client.get_paginator('query_objects')

paginate(**kwargs)

Creates an iterator that will paginate through responses from DataPipeline.Client.query_objects().

Request Syntax

response_iterator = paginator.paginate(
    pipelineId='string',
    query={
        'selectors': [
            {
                'fieldName': 'string',
                'operator': {
                    'type': 'EQ'|'REF_EQ'|'LE'|'GE'|'BETWEEN',
                    'values': [ 'string', ]
                }
            }
        ],
    },
    sphere='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters
• **pipelineId** *(string)* – **[REQUIRED]**

  The ID of the pipeline.

• **query** *(dict)* – The query that defines the objects to be returned. The *Query* object can contain a maximum of ten selectors. The conditions in the query are limited to top-level String fields in the object. These filters can be applied to components, instances, and attempts.

  – **selectors** *(list)* –

    List of selectors that define the query. An object must satisfy all of the selectors to match the query.

    – **(dict)** –

      A comparison that is used to determine whether a query should return this object.

        • **fieldName** *(string)* –

          The name of the field that the operator will be applied to. The field name is the “key” portion of the field definition in the pipeline definition syntax that is used by the AWS Data Pipeline API. If the field is not set on the object, the condition fails.

        • **operator** *(dict)* –

          Contains a logical operation for comparing the value of a field with a specified value.

        • **type** *(string)* –

          The logical operation to be performed: equal *(EQ)*, equal reference *(REF_EQ)*, less than or equal *(LE)*, greater than or equal *(GE)*, or between *(BETWEEN)*. Equal reference *(REF_EQ)* can be used only with reference fields. The other comparison types can be used only with String fields. The comparison types you can use apply only to certain object fields, as detailed below.

          The comparison operators EQ and REF_EQ act on the following fields:

          • name
          • @sphere
          • parent
          • @componentParent
          • @instanceParent
          • @status
          • @scheduledStartTime
          • @scheduledEndTime
          • @actualStartTime
          • @actualEndTime

          The comparison operators GE, LE, and BETWEEN act on the following fields:

          • @scheduledStartTime
          • @scheduledEndTime
          • @actualStartTime
          • @actualEndTime

          Note that fields beginning with the at sign (@) are read-only and set by the web service. When you name fields, you should choose names containing only alpha-numeric values, as sym-
bols may be reserved by AWS Data Pipeline. User-defined fields that you add to a pipeline should prefix their name with the string “my”.

- **values (list)** –
  The value that the actual field value will be compared with.

- **sphere (string)** – [REQUIRED]
  Indicates whether the query applies to components or instances. The possible values are: COMPONENT, INSTANCE, and ATTEMPT.

- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize (integer)** –
    The size of each page.
  - **StartingToken (string)** –
    A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'ids': [
        'string',
    ],
    'hasMoreResults': True|False,
    'NextToken': 'string'
}
```

**Response Structure**

- **(dict)** –
  Contains the output of QueryObjects.
  - **ids (list)** –
    The identifiers that match the query selectors.
  - **hasMoreResults (boolean)** –
    Indicates whether there are more results that can be obtained by a subsequent call.
  - **NextToken (string)** –
    A token to resume pagination.
Client

class DeviceFarm.Client

A low-level client representing AWS Device Farm:

```python
import boto3

client = boto3.client('devicefarm')
```

These are the available methods:

- `can_paginate()`
- `create_device_pool()`
- `create_project()`
- `create_upload()`
- `generate_presigned_url()`
- `get_account_settings()`
- `get_device()`
- `get_device_pool()`
- `get_device_pool_compatibility()`
- `get_job()`
- `get Paginator()`
- `get_project()`
- `get_run()`
- `get_suite()`
- `get_test()`
- `get_upload()`
- `get_wa ter()`
- `list_artifacts()`
- `list_device_pools()`
- `list_devices()`
- `list_jobs()`
- `list_projects()`
- `list_runs()`
- `list_samples()`
- `list_suites()`
- `list_tests()`
- `list_unique_problems()`
- `list_uploads()`
- `schedule_run()`

`can_paginate(operation_name)`

Check if an operation can be paginated.

**Parameters**

- `operation_name` *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you'd normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

**Returns**

- `True` if the operation can be paginated, `False` otherwise.
create_device_pool(**kwargs)
Creates a device pool.

Request Syntax

response = client.create_device_pool(
    projectArn='string',
    name='string',
    description='string',
    rules=[
        {
            'attribute': 'ARN'|'PLATFORM'|'FORM_FACTOR'|'MANUFACTURER',
            'operator': 'EQUALS'|'LESS_THAN'|'GREATER_THAN'|'IN'|'NOT_IN',
            'value': 'string'
        },
    ]
)

Parameters

- **projectArn (string)** – [REQUIRED]
The ARN of the project for the device pool.
- **name (string)** – [REQUIRED]
The device pool’s name.
- **description (string)** – The device pool’s description.
- **rules (list)** – [REQUIRED]
The device pool’s rules.
  - (dict) –
    Represents a condition for a device pool.
    - **attribute (string)** –
      The rule’s attribute.
      Allowed values include:
      - ARN: The ARN.
      - FORM_FACTOR: The form factor (for example, phone or tablet).
      - MANUFACTURER: The manufacturer.
      - PLATFORM: The platform (for example, Android or iOS).
    - **operator (string)** –
      The rule’s operator.
      - EQUALS: The equals operator.
      - GREATER_THAN: The greater-than operator.
      - IN: The in operator.
      - LESS_THAN: The less-than operator.
      - NOT_IN: The not-in operator.
    - **value (string)** –
      The rule’s value.

Return type  dict
Returns

Response Syntax

{
    'devicePool': {
        ...
    }
}
'arn': 'string',
'name': 'string',
'description': 'string',
'type': 'CURATED'|'PRIVATE',
'rules': [
    {
        'attribute': 'ARN'|'PLATFORM'|'FORM_FACTOR'|'MANUFACTURER',
        'operator': 'EQUALS'|'LESS_THAN'|'GREATER_THAN'|'IN'|'NOT_IN',
        'value': 'string'
    },
]
}

Response Structure
* (dict) –
  Represents the result of a create device pool request.
  
  − **devicePool** (dict) –
    The newly created device pool.
    * **arn** (string) –
      The device pool’s ARN.
    * **name** (string) –
      The device pool’s name.
    * **description** (string) –
      The device pool’s description.
    * **type** (string) –
      The device pool’s type.

    Allowed values include:
    * CURATED: A device pool that is created and managed by AWS Device Farm.
    * PRIVATE: A device pool that is created and managed by the device pool developer.

    * **rules** (list) –
      Information about the device pool’s rules.
      * (dict) –
        Represents a condition for a device pool.
        * **attribute** (string) –
          The rule’s attribute.

        Allowed values include:
        * ARN: The ARN.
        * FORM_FACTOR: The form factor (for example, phone or tablet).
        * MANUFACTURER: The manufacturer.
        * PLATFORM: The platform (for example, Android or iOS).
        * **operator** (string) –
          The rule’s operator.

        * EQUALS: The equals operator.
        * GREATER_THAN: The greater-than operator.
        * IN: The in operator.
· LESS_THAN: The less-than operator.
· NOT_IN: The not-in operator.
· value (string) –
  The rule’s value.

create_project(**kwargs)
Create a new project.

Request Syntax

response = client.create_project(
    name='string'
)

Parameters

name (string) – [REQUIRED]
The project’s name.

Return type: dict
Returns

Response Syntax

{
    'project': {
        'arn': 'string',
        'name': 'string',
        'created': datetime(2015, 1, 1)
    }
}

Response Structure

• (dict) –
  Represents the result of a create project request.
  – project (dict) –
    The newly created project.
    * arn (string) –
      The project’s ARN.
    * name (string) –
      The project’s name.
    * created (datetime) –
      When the project was created.

create_upload(**kwargs)
Uploads an app or test scripts.

Request Syntax

response = client.create_upload(
    projectArn='string',
    name='string',
    type='ANDROID_APP'|'IOS_APP'|'EXTERNAL_DATA'|'APPIUM_JAVA_JUNIT_TEST_PACKAGE'|'APPIUM_JAVA_TESTNG_TEST_PACKAGE'|'CALABASH_TEST_PACKAGE'|'INSTRUMENTATION_TEST_PACKAGE'|'UIAUTOMATION_TEST_PACKAGE'|'UIAUTOMATOR_TEST_PACKAGE'|'XCTEST_TEST_PACKAGE',
    contentType='string'
)

Parameters
• projectArn (string) – [REQUIRED]
  The ARN of the project for the upload.
• name (string) – [REQUIRED]
  The upload’s file name.
• type (string) – [REQUIRED]
  The upload’s upload type.
  Must be one of the following values:
  – ANDROID_APP: An Android upload.
  – IOS_APP: An iOS upload.
  – EXTERNAL_DATA: An external data upload.
  – APPIUM_JAVA_JUNIT_TEST_PACKAGE: An Appium Java JUnit test package upload.
  – APPIUM_JAVA_TESTNG_TEST_PACKAGE: An Appium Java TestNG test package upload.
  – CALABASH_TEST_PACKAGE: A Calabash test package upload.
  – INSTRUMENTATION_TEST_PACKAGE: An instrumentation upload.
  – UIAUTOMATOR_TEST_PACKAGE: A uiautomator test package upload.
  – XCTEST_TEST_PACKAGE: An XCode test package upload.
• contentType (string) – The upload’s content type (for example, “application/octet-stream”).

Return type  dict
Returns

Response Syntax

```
{
    'upload': {
        'arn': 'string',
        'name': 'string',
        'created': datetime(2015, 1, 1),
        'type': 'ANDROID_APP'|'IOS_APP'|'EXTERNAL_DATA'|'APPIUM_JAVA_JUNIT_TEST_PACKAGE'|'APPIUM_JAVA_TESTNG_TEST_PACKAGE'|'CALABASH_TEST_PACKAGE'|'INSTRUMENTATION_TEST_PACKAGE'|'UIAUTOMATOR_TEST_PACKAGE'|'XCTEST_TEST_PACKAGE',
        'status': 'INITIALIZED'|'PROCESSING'|'SUCCEEDED'|'FAILED',
        'url': 'string',
        'metadata': 'string',
        'contentType': 'string',
        'message': 'string'
    }
}
```

Response Structure

• (dict) –

  Represents the result of a create upload request.
  – upload (dict) –
    The newly created upload.
      * arn (string) –
        The upload’s ARN.
      * name (string) –
        The upload’s file name.
      * created (datetime) –
        When the upload was created.
**type (string)** –
The upload’s type.

Must be one of the following values:
- ANDROID_APP: An Android upload.
- IOS_APP: An iOS upload.
- EXTERNAL_DATA: An external data upload.
- APPIUM_JAVA_JUNIT_TEST_PACKAGE: An Appium Java JUnit test package upload.
- APPIUM_JAVA_TESTNG_TEST_PACKAGE: An Appium Java TestNG test package upload.
- CALABASH_TEST_PACKAGE: A Calabash test package upload.
- INSTRUMENTATION_TEST_PACKAGE: An instrumentation upload.
- UIAUTOMATOR_TEST_PACKAGE: A uiautomator test package upload.
- XCTEST_TEST_PACKAGE: An XCode test package upload.

**status (string)** –
The upload’s status.

Must be one of the following values:
- FAILED: A failed status.
- INITIALIZED: An initialized status.
- PROCESSING: A processing status.
- SUCCEEDED: A succeeded status.

**url (string)** –
The pre-signed Amazon S3 URL that was used to store a file through a corresponding PUT request.

**metadata (string)** –
The upload’s metadata. For example, for Android, this contains information that is parsed from the manifest and is displayed in the AWS Device Farm console after the associated app is uploaded.

**contentType (string)** –
The upload’s content type (for example, “application/octet-stream”).

**message (string)** –
A message about the upload’s result.

---

**generate_presigned_url** *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

**Parameters**
- **ClientMethod (string)** – The client method to presign for
- **Params (dict)** – The parameters normally passed to ClientMethod.
- **ExpiresIn (int)** – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod (string)** – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns** The presigned url

**get_account_settings** *

Returns the number of unmetered iOS and/or unmetered Android devices that have been purchased by the
account.

Request Syntax

response = client.get_account_settings()

Return type  dict

Returns

Response Syntax

```
{
    'accountSettings': {
        'awsAccountNumber': 'string',
        'unmeteredDevices': {
            'string': 123
        }
    }
}
```

Response Structure

- (dict) –
  - accountSettings (dict) –
    A container for account-level settings within AWS Device Farm.
    - awsAccountNumber (string) –
      The AWS account number specified in the AccountSettings container.
    - unmeteredDevices (dict) –
      Returns the unmetered devices you have purchased.
      - (string) –
      - (integer) –

get_device(**kwargs)

Gets information about a unique device type.

Request Syntax

response = client.get_device(
    arn='string'
)

Parameters  arn (string) – [REQUIRED]

The device type’s ARN.

Return type  dict

Returns

Response Syntax

```
{
    'device': {
        'arn': 'string',
        'name': 'string',
        'manufacturer': 'string',
        'model': 'string',
        'formFactor': 'PHONE'|'TABLET',
        'platform': 'ANDROID'|'IOS',
    }
}
```
{'os': 'string',
'cpu': {
    'frequency': 'string',
    'architecture': 'string',
    'clock': 123.0,
},
'resolution': {
    'width': 123,
    'height': 123
},
'heapSize': 123,
'memory': 123,
'image': 'string',
'carrier': 'string',
'radio': 'string'
}

Response Structure

- (dict) –

  Represents the result of a get device request.

  - device (dict) –

    Represents a device type that an app is tested against.

    - arn (string) –
      The device’s ARN.
    - name (string) –
      The device’s display name.
    - manufacturer (string) –
      The device’s manufacturer name.
    - model (string) –
      The device’s model name.
    - formFactor (string) –
      The device’s form factor.

      Allowed values include:
      - PHONE: The phone form factor.
      - TABLET: The tablet form factor.
    - platform (string) –
      The device’s platform.

      Allowed values include:
      - ANDROID: The Android platform.
      - IOS: The iOS platform.
    - os (string) –
      The device’s operating system type.
    - cpu (dict) –

      Information about the device’s CPU.

      - frequency (string) –
        The CPU’s frequency.
The CPU’s architecture, for example x86 or ARM.

- **clock (float)**

  The clock speed of the device’s CPU, expressed in hertz (Hz). For example, a 1.2 GHz CPU is expressed as 1200000000.

- **resolution (dict)**

  Represents the screen resolution of a device in height and width, expressed in pixels.
  - **width (integer)**
  
    The screen resolution’s width, expressed in pixels.
  - **height (integer)**
  
    The screen resolution’s height, expressed in pixels.

- **heapSize (integer)**

  The device’s heap size, expressed in bytes.

- **memory (integer)**

  The device’s total memory size, expressed in bytes.

- **image (string)**

  The device’s image name.

- **carrier (string)**

  The device’s carrier.

- **radio (string)**

  The device’s radio.

### get_device_pool(**kwargs)**

Gets information about a device pool.

**Request Syntax**

```python
response = client.get_device_pool(
    arn='string'
)
```

**Parameters**

- **arn (string)** – [REQUIRED]

  The device pool’s ARN.

**Return type**

- **dict**

**Returns**

**Response Syntax**

```python
{
    'devicePool': {
        'arn': 'string',
        'name': 'string',
        'description': 'string',
        'type': 'CURATED'|'PRIVATE',
        'rules': [
            {
                'attribute': 'ARN'|'PLATFORM'|'FORM_FACTOR'|'MANUFACTURER',
                'operator': 'EQUALS'|'LESS_THAN'|'GREATER_THAN'|'IN'|'NOT_IN',
                'value': 'string'
            }
        ]
    }
}
```
Response Structure

- **dict** – Represents the result of a get device pool request.
  - **devicePool** (dict) – Represents a collection of device types.
    - **arn** (string) – The device pool’s ARN.
    - **name** (string) – The device pool’s name.
    - **description** (string) – The device pool’s description.
    - **type** (string) – The device pool’s type.

    Allowed values include:
    - CURATED: A device pool that is created and managed by AWS Device Farm.
    - PRIVATE: A device pool that is created and managed by the device pool developer.
    - **rules** (list) – Information about the device pool’s rules.
      - **dict** – Represents a condition for a device pool.
        - **attribute** (string) – The rule’s attribute.
          - **operator** (string) – The rule’s operator.
            - **value** (string) – The rule’s value.

get_device_pool_compatibility(**kwargs)**

Gets information about compatibility with a device pool.
response = client.get_device_pool_compatibility(
    devicePoolArn='string',
    appArn='string',
    testType='BUILTIN_FUZZ'|'BUILTIN_EXPLORER'|'APPIUM_JAVA_JUNIT'|'APPIUM_JAVA_TESTNG'|'CALABASH'|'INSTRUMENTATION'|'UIAUTOMATION'|'UIAUTOMATOR'|'XCTEST'
)

Parameters

- **devicePoolArn** *(string)* – [REQUIRED]
  The device pool’s ARN.

- **appArn** *(string)* – [REQUIRED]
  The ARN of the app that is associated with the specified device pool.

- **testType** *(string)* – The test type for the specified device pool.
  Allowed values include the following:
  - **BUILTIN_FUZZ**: The built-in fuzz type.
  - **BUILTIN_EXPLORER**: For Android, an app explorer that will traverse an Android app, interacting with it and capturing screenshots at the same time.
  - **APPIUM_JAVA_JUNIT**: The Appium Java JUnit type.
  - **APPIUM_JAVA_TESTNG**: The Appium Java TestNG type.
  - **CALABASH**: The Calabash type.
  - **INSTRUMENTATION**: The Instrumentation type.
  - **UIAUTOMATION**: The uiautomation type.
  - **UIAUTOMATOR**: The uiautomator type.
  - **XCTEST**: The XCode test type.

Return type  dict
Returns

Response Syntax

```
{
    'compatibleDevices': [
        {
            'device': {
                'arn': 'string',
                'name': 'string',
                'manufacturer': 'string',
                'model': 'string',
                'formFactor': 'PHONE'|'TABLET',
                'platform': 'ANDROID'|'IOS',
                'os': 'string',
                'cpu': {
                    'frequency': 'string',
                    'architecture': 'string',
                    'clock': 123.0
                },
                'resolution': {
                    'width': 123,
                    'height': 123
                },
                'heapSize': 123,
                'memory': 123,

},
]

Response Structure
- (dict) – Represents the result of describe device pool compatibility request.
  - compatibleDevices (list) – Information about compatible devices.
    * (dict) – Represents a device pool compatibility result.
      - device (dict) – Represents a device type that an app is tested against.
· **arn** *(string)* –
  The device’s ARN.

· **name** *(string)* –
  The device’s display name.

· **manufacturer** *(string)* –
  The device’s manufacturer name.

· **model** *(string)* –
  The device’s model name.

· **formFactor** *(string)* –
  The device’s form factor.

  Allowed values include:
  · PHONE: The phone form factor.
  · TABLET: The tablet form factor.

· **platform** *(string)* –
  The device’s platform.

  Allowed values include:
  · ANDROID: The Android platform.
  · IOS: The iOS platform.

· **os** *(string)* –
  The device’s operating system type.

· **cpu** *(dict)* –
  Information about the device’s CPU.

  · **frequency** *(string)* –
    The CPU’s frequency.

  · **architecture** *(string)* –
    The CPU’s architecture, for example x86 or ARM.

  · **clock** *(float)* –
    The clock speed of the device’s CPU, expressed in hertz (Hz).
    For example, a 1.2 GHz CPU is expressed as 1200000000.

· **resolution** *(dict)* –
  Represents the screen resolution of a device in height and width, expressed in pixels.

  · **width** *(integer)* –
    The screen resolution’s width, expressed in pixels.

  · **height** *(integer)* –
    The screen resolution’s height, expressed in pixels.

  · **heapSize** *(integer)* –
    The device’s heap size, expressed in bytes.

· **memory** *(integer)* –
  The device’s total memory size, expressed in bytes.

· **image** *(string)* –
  The device’s image name.

· **carrier** *(string)* –
  The device’s carrier.
- **radio** *(string)* –
  The device’s radio.
- **compatible** *(boolean)* –
  Whether the result was compatible with the device pool.
- **incompatibilityMessages** *(list)* –
  Information about the compatibility.
  * (dict) –
  Represents information about incompatibility.
- **message** *(string)* –
  A message about the incompatibility.
- **type** *(string)* –
  The type of incompatibility.
  Allowed values include:
  - ARN: The ARN.
  - FORM_FACTOR: The form factor (for example, phone or tablet).
  - MANUFACTURER: The manufacturer.
  - PLATFORM: The platform (for example, Android or iOS).

- **incompatibleDevices** *(list)* –
  Information about incompatible devices.
  * (dict) –
    Represents a device pool compatibility result.
    - **device** *(dict)* –
      Represents a device type that an app is tested against.
      - **arn** *(string)* –
        The device’s ARN.
      - **name** *(string)* –
        The device’s display name.
      - **manufacturer** *(string)* –
        The device’s manufacturer name.
      - **model** *(string)* –
        The device’s model name.
      - **formFactor** *(string)* –
        The device’s form factor.
        Allowed values include:
        - PHONE: The phone form factor.
        - TABLET: The tablet form factor.
      - **platform** *(string)* –
        The device’s platform.
        Allowed values include:
        - ANDROID: The Android platform.
        - IOS: The iOS platform.
      - **os** *(string)* –
        The device’s operating system type.
get_job(**kwargs)

Gets information about a job.
Request Syntax

```python
response = client.get_job(
    arn='string'
)
```

**Parameters**  
**arn (string)** – [REQUIRED]  
The job’s ARN.

**Return type**  
**dict**

**Returns**

Response Syntax

```json
{
    'job': {
        'arn': 'string',
        'name': 'string',
        'type': 'BUILTIN_FUZZ'|'BUILTIN_EXPLORER'|'APPIUM_JAVA_JUNIT'|'APPIUM_JAVA_TESTNG'|'CALABASH'|'INSTRUMENTATION'|'UIAUTOMATION'|'UIAUTOMATOR'|'XCTEST',
        'created': datetime(2015, 1, 1),

        'result': 'PENDING'|'PASSED'|'WARNED'|'FAILED'|'SKIPPED'|'ERRORED'|'STOPPED',
        'started': datetime(2015, 1, 1),
        'stopped': datetime(2015, 1, 1),
        'counters': {
            'total': 123,
            'passed': 123,
            'failed': 123,
            'warned': 123,
            'errored': 123,
            'stopped': 123,
            'skipped': 123
        },
        'message': 'string',
        'device': {
            'arn': 'string',
            'name': 'string',
            'manufacturer': 'string',
            'model': 'string',
            'formFactor': 'PHONE'|'TABLET',
            'platform': 'ANDROID'|'IOS',
            'os': 'string',
            'cpu': {
                'frequency': 'string',
                'architecture': 'string',
                'clock': 123.0
            },
            'resolution': {
                'width': 123,
                'height': 123
            },
            'heapSize': 123,
            'memory': 123,
            'image': 'string',
            'carrier': 'string',
            'radio': 'string'
        }
    }
}
```
Response Structure

• **(dict)** – Represents the result of a get job request.

  – **job (dict)** – Represents a device.

    • **arn (string)** – The job’s ARN.
    • **name (string)** – The job’s name.
    • **type (string)** – The job’s type.

      Allowed values include the following:
      • BUILTIN_FUZZ: The built-in fuzz type.
      • BUILTIN_EXPLORER: For Android, an app explorer that will traverse an Android app, interacting with it and capturing screenshots at the same time.
      • APPIUM_JAVA_JUNIT: The Appium Java JUnit type.
      • APPIUM_JAVA_TESTNG: The Appium Java TestNG type.
      • CALABASH: The Calabash type.
      • INSTRUMENTATION: The Instrumentation type.
      • UIAUTOMATION: The uiautomation type.
      • UIAUTOMATOR: The uiautomator type.
      • XCTEST: The XCode test type.

    • **created (datetime)** – When the job was created.

    • **status (string)** – The job’s status.

      Allowed values include:
      • COMPLETED: A completed status.
      • PENDING: A pending status.
      • PROCESSING: A processing status.
      • RUNNING: A running status.
      • SCHEDULING: A scheduling status.

    • **result (string)** – The job’s result.

      Allowed values include:
      • ERRORED: An error condition.
      • FAILED: A failed condition.
      • SKIPPED: A skipped condition.
      • STOPPED: A stopped condition.
      • PASSED: A passing condition.
      • PENDING: A pending condition.
      • WARNED: A warning condition.

    • **started (datetime)** – The job’s start time.

    • **stopped (datetime)** – The job’s stop time.
* **counters** *(dict)* –
  The job’s result counters.
  - **total** *(integer)* –
    The total number of entities.
  - **passed** *(integer)* –
    The number of passed entities.
  - **failed** *(integer)* –
    The number of failed entities.
  - **warned** *(integer)* –
    The number of warned entities.
  - **errored** *(integer)* –
    The number of errored entities.
  - **stopped** *(integer)* –
    The number of stopped entities.
  - **skipped** *(integer)* –
    The number of skipped entities.

* **message** *(string)* –
  A message about the job’s result.

* **device** *(dict)* –
  Represents a device type that an app is tested against.
  - **arn** *(string)* –
    The device’s ARN.
  - **name** *(string)* –
    The device’s display name.
  - **manufacturer** *(string)* –
    The device’s manufacturer name.
  - **model** *(string)* –
    The device’s model name.
  - **formFactor** *(string)* –
    The device’s form factor.
    Allowed values include:
    - **PHONE**: The phone form factor.
    - **TABLET**: The tablet form factor.
  - **platform** *(string)* –
    The device’s platform.
    Allowed values include:
    - **ANDROID**: The Android platform.
    - **IOS**: The iOS platform.
  - **os** *(string)* –
    The device’s operating system type.
  - **cpu** *(dict)* –
    Information about the device’s CPU.
- **frequency** *(string)* –
  The CPU’s frequency.
- **architecture** *(string)* –
  The CPU’s architecture, for example x86 or ARM.
- **clock** *(float)* –
  The clock speed of the device’s CPU, expressed in hertz (Hz). For example, a 1.2 GHz CPU is expressed as 1200000000.
- **resolution** *(dict)* –
  Represents the screen resolution of a device in height and width, expressed in pixels.
- **width** *(integer)* –
  The screen resolution’s width, expressed in pixels.
- **height** *(integer)* –
  The screen resolution’s height, expressed in pixels.
- **heapSize** *(integer)* –
  The device’s heap size, expressed in bytes.
- **memory** *(integer)* –
  The device’s total memory size, expressed in bytes.
- **image** *(string)* –
  The device’s image name.
- **carrier** *(string)* –
  The device’s carrier.
- **radio** *(string)* –
  The device’s radio.

**get Paginator** *(operation_name)*
Create a paginator for an operation.

**Parameters** operation_name *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

**Raises** OperationNotPageableError Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

**Return type** L{botocore.paginate.Paginator}

**Returns** A paginator object.

**get_project** (**kwargs**)
Gets information about a project.

**Request Syntax**

```python
response = client.get_project(
    arn='string'
)
```

**Parameters** arn *(string)* – [REQUIRED]

  The project’s ARN.

**Return type** dict
Returns

Response Syntax

```python
{
    'project': {
        'arn': 'string',
        'name': 'string',
        'created': datetime(2015, 1, 1)
    }
}
```

Response Structure

- `(dict)` –

  Represents the result of a get project request.

  - `project (dict)` –

    Represents an operating-system neutral workspace for running and managing tests.

    - `arn (string)` –
      
      The project’s ARN.

    - `name (string)` –

      The project’s name.

    - `created (datetime)` –

      When the project was created.

`get_run (**kwargs)`

Gets information about a run.

Request Syntax

```python
response = client.get_run(
    arn='string'
)
```

Parameters `arn (string)` – [REQUIRED]

- The run’s ARN.

Return type `dict`

Returns

Response Syntax

```python
{
    'run': {
        'arn': 'string',
        'name': 'string',
        'type': 'BUILTIN_FUZZ'|'BUILTIN_EXPLORER'|'APPIUM_JAVA_JUNIT'|'APPIUM_JAVA_TESTNG'|'CALABASH'|'INSTRUMENTATION'|'UIAUTOMATION'|'UIAUTOMATOR'|'XCTEST',
        'platform': 'ANDROID'|'IOS',
        'created': datetime(2015, 1, 1),
        'status': 'PENDING'|'PROCESSING'|'SCHEDULING'|'RUNNING'|'COMPLETED',
        'result': 'PENDING'|'PASSED'|'WARNED'|'FAILED'|'SKIPPED'|'ERRORED'|'STOPPED',
        'started': datetime(2015, 1, 1),
        'stopped': datetime(2015, 1, 1),
        'counters': {
            'total': 123,
            'passed': 123,
        }
    }
```

3.1. Services
Response Structure

- (dict) –
  Represents the result of a get run request.
  - run (dict) –
    Represents an app on a set of devices with a specific test and configuration.
      - arn (string) –
        The run’s ARN.
      - name (string) –
        The run’s name.
      - type (string) –
        The run’s type.
        Must be one of the following values:
        - BUILTIN_FUZZ: The built-in fuzz type.
        - BUILTIN_EXPLORER: For Android, an app explorer that will traverse an Android app, interacting with it and capturing screenshots at the same time.
        - APPIUM_JAVA_JUNIT: The Appium Java JUnit type.
        - APPIUM_JAVA_TESTNG: The Appium Java TestNG type.
        - CALABASH: The Calabash type.
        - INSTRUMENTATION: The Instrumentation type.
        - UIAUTOMATION: The uiautomation type.
        - UIAUTOMATOR: The uiautomator type.
        - XCTEST: The XCode test type.
      - platform (string) –
        The run’s platform.
        Allowed values include:
        - ANDROID: The Android platform.
        - IOS: The iOS platform.
      - created (datetime) –
        When the run was created.
      - status (string) –
        The run’s status.
        Allowed values include:
        - COMPLETED: A completed status.
        - PENDING: A pending status.
        - PROCESSING: A processing status.
· RUNNING: A running status.
· SCHEDULING: A scheduling status.

* result (string) –

The run’s result.

Allowed values include:
· ERRORED: An error condition.
· FAILED: A failed condition.
· SKIPPED: A skipped condition.
· STOPPED: A stopped condition.
· PASSED: A passing condition.
· PENDING: A pending condition.
· WARNED: A warning condition.

* started (datetime) –

The run’s start time.

* stopped (datetime) –

The run’s stop time.

* counters (dict) –

The run’s result counters.
· total (integer) –

The total number of entities.
· passed (integer) –

The number of passed entities.
· failed (integer) –

The number of failed entities.
· warned (integer) –

The number of warned entities.
· errored (integer) –

The number of errored entities.
· stopped (integer) –

The number of stopped entities.
· skipped (integer) –

The number of skipped entities.

* message (string) –

A message about the run’s result.

* totalJobs (integer) –

The total number of jobs for the run.

* completedJobs (integer) –

The total number of completed jobs.

* billingMethod (string) –

Specifies the billing method for a test run: metered or unmetered. If the parameter is not specified, the default value is unmetered.

get_suite (**kwargs)

 Gets information about a suite.

Request Syntax
response = client.get_suite(arn='string')

Parameters arn (string) – [REQUIRED]

The suite’s ARN.

Return type dict

Returns

Response Syntax

`
{
'suite': {
    'arn': 'string',
    'name': 'string',
    'type': 'BUILTIN_FUZZ'|'BUILTIN_EXPLORER'|'APPIUM_JAVA_JUNIT'|'APPIUM_JAVA_TESTNG'|'CALABASH'|'INSTRUMENTATION'|'UIAUTOMATION'|'UIAUTOMATOR'|'XCTEST',
    'created': datetime(2015, 1, 1),
    'status': 'PENDING'|'PROCESSING'|'SCHEDULING'|'RUNNING'|'COMPLETED',
    'result': 'PENDING'|'PASSED'|'WARNED'|'FAILED'|'SKIPPED'|'ERRORED'|'STOPPED',
    'started': datetime(2015, 1, 1),
    'stopped': datetime(2015, 1, 1),
    'counters': {
        'total': 123,
        'passed': 123,
        'failed': 123,
        'warned': 123,
        'errored': 123,
        'stopped': 123,
        'skipped': 123
    },
    'message': 'string'
}
}
``

Response Structure

* (dict) –

Represents the result of a get suite request.

  – suite (dict) –

Represents a collection of one or more tests.

  * arn (string) –

The suite’s ARN.

  * name (string) –

The suite’s name.

  * type (string) –

The suite’s type.

Must be one of the following values:

  · BUILTIN_FUZZ: The built-in fuzz type.
  · BUILTIN_EXPLORER: For Android, an app explorer that will traverse an Android app, interacting with it and capturing screenshots at the same time.
  · APPIUM_JAVA_JUNIT: The Appium Java JUnit type.
  · APPIUM_JAVA_TESTNG: The Appium Java TestNG type.
· CALABASH: The Calabash type.
· INSTRUMENTATION: The Instrumentation type.
· UIAUTOMATION: The uiautomation type.
· UIAUTOMATOR: The uiautomator type.
· XCTEST: The XCode test type.

* created (datetime) –

When the suite was created.

* status (string) –

The suite’s status.

Allowed values include:
· COMPLETED: A completed status.
· PENDING: A pending status.
· PROCESSING: A processing status.
· RUNNING: A running status.
· SCHEDULING: A scheduling status.

* result (string) –

The suite’s result.

Allowed values include:
· ERRORED: An error condition.
· FAILED: A failed condition.
· SKIPPED: A skipped condition.
· STOPPED: A stopped condition.
· PASSED: A passing condition.
· PENDING: A pending condition.
· WARNED: A warning condition.

* started (datetime) –

The suite’s start time.

* stopped (datetime) –

The suite’s stop time.

* counters (dict) –

The suite’s result counters.

· total (integer) –

The total number of entities.

· passed (integer) –

The number of passed entities.

· failed (integer) –

The number of failed entities.

· warned (integer) –

The number of warned entities.

· errored (integer) –

The number of errored entities.

· stopped (integer) –

The number of stopped entities.

· skipped (integer) –

The number of skipped entities.
get_test(**kwargs)

Gets information about a test.

**Request Syntax**

```python
response = client.get_test(
    arn='string'
)
```

**Parameters**

- **arn** *(string)* – [REQUIRED]
  
The test’s ARN.

**Return type**

- **dict**

**Returns**

- **Response Syntax**

```python
{
    'test': {
        'arn': 'string',
        'name': 'string',
        'type': 'BUILTIN_FUZZ' | 'BUILTIN_EXPLORER' | 'APPUIUM_JAVA_JUNIT' | 'APPUIUM_JAVA_TESTNG' | 'CALABASH' | 'INSTRUMENTATION' | 'UIAUTOMATION' | 'UIAUTOMATOR' | 'XCTEST',
        'created': datetime(2015, 1, 1),
        'status': 'PENDING' | 'PROCESSING' | 'SCHEDULING' | 'RUNNING' | 'COMPLETED',
        'result': 'PENDING' | 'PASSED' | 'WARNING' | 'FAILED' | 'SKIPPED' | 'ERRORED' | 'STOPPED',
        'started': datetime(2015, 1, 1),
        'stopped': datetime(2015, 1, 1),
        'counters': {
            'total': 123,
            'passed': 123,
            'failed': 123,
            'warned': 123,
            'errored': 123,
            'stopped': 123,
            'skipped': 123
        },
        'message': 'string'
    }
}
```

**Response Structure**

- *(dict)* — Represents the result of a get test request.
  
  - **test**(dict) — Represents a condition that is evaluated.
    
      - **arn** *(string)* — The test’s ARN.
      
      - **name** *(string)* — The test’s name.
      
      - **type** *(string)* — The test’s type.
        
        Must be one of the following values:
· `BUILTIN_FUZZ`: The built-in fuzz type.
· `BUILTIN_EXPLORER`: For Android, an app explorer that will traverse an Android app, interacting with it and capturing screenshots at the same time.
· `APPIUM_JAVA_JUNIT`: The Appium Java JUnit type.
· `APPIUM_JAVA_TESTNG`: The Appium Java TestNG type.
· `CALABASH`: The Calabash type.
· `INSTRUMENTATION`: The Instrumentation type.
· `UIAUTOMATION`: The uiautomation type.
· `UIAUTOMATOR`: The uiautomator type.
· `XCTEST`: The XCode test type.

* `created (datetime)` –

When the test was created.

* `status (string)` –

The test’s status.

Allowed values include:
· `COMPLETED`: A completed status.
· `PENDING`: A pending status.
· `PROCESSING`: A processing status.
· `RUNNING`: A running status.
· `SCHEDULING`: A scheduling status.

* `result (string)` –

The test’s result.

Allowed values include:
· `ERRORED`: An error condition.
· `FAILED`: A failed condition.
· `SKIPPED`: A skipped condition.
· `STOPPED`: A stopped condition.
· `PASSED`: A passing condition.
· `PENDING`: A pending condition.
· `WARNED`: A warning condition.

* `started (datetime)` –

The test’s start time.

* `stopped (datetime)` –

The test’s stop time.

* `counters (dict)` –

The test’s result counters.
· `total (integer)` –

The total number of entities.
· `passed (integer)` –

The number of passed entities.
· `failed (integer)` –

The number of failed entities.
· `warned (integer)` –

The number of warned entities.
· `errored (integer)` –

The number of errored entities.
· **stopped** (integer) –
  The number of stopped entities.

· **skipped** (integer) –
  The number of skipped entities.

* **message** (string) –
  A message about the test’s result.

**get_upload(**kwargs**)**

Gets information about an upload.

**Request Syntax**

```python
response = client.get_upload(
    arn='string'
)
```

**Parameters**

**arn** *(string)* – [REQUIRED]

The upload’s ARN.

**Return type**

dict

**Returns**

**Response Syntax**

```json
{
    'upload': {
        'arn': 'string',
        'name': 'string',
        'created': datetime(2015, 1, 1),
        'type': 'ANDROID_APP'|'IOS_APP'|'EXTERNAL_DATA'|'APPIUM_JAVA_JUNIT_TEST_PACKAGE'|'APPIUM_JAVA_TESTNG_TEST_PACKAGE'|'CALABASH_TEST_PACKAGE'|'INSTRUMENTATION_TEST_PACKAGE'|'UIAUTOMATION_TEST_PACKAGE'|'UIAUTOMATOR_TEST_PACKAGE'|'XCTEST_TEST_PACKAGE',
        'status': 'INITIALIZED'|'PROCESSING'|'SUCCEEDED'|'FAILED',
        'url': 'string',
        'metadata': 'string',
        'contentType': 'string',
        'message': 'string'
    }
}
```

**Response Structure**

* (dict) –

  Represents the result of a get upload request.

  - **upload** (dict) –

    An app or a set of one or more tests to upload or that have been uploaded.

    * **arn** *(string)* –

      The upload’s ARN.

    * **name** *(string)* –

      The upload’s file name.

    * **created** *(datetime)* –

      When the upload was created.

    * **type** *(string)* –

      The upload’s type.

      Must be one of the following values:
· ANDROID_APP: An Android upload.
· IOS_APP: An iOS upload.
· EXTERNAL_DATA: An external data upload.
· APPIUM_JAVA_UNIT_TEST_PACKAGE: An Appium Java JUnit test package upload.
· APPIUM_JAVA_TESTNG_TEST_PACKAGE: An Appium Java TestNG test package upload.
· CALABASH_TEST_PACKAGE: A Calabash test package upload.
· INSTRUMENTATION_TEST_PACKAGE: An instrumentation upload.
· UIAUTOMATOR_TEST_PACKAGE: A uiautomator test package upload.
· XCTEST_TEST_PACKAGE: An XCode test package upload.

* status (string) –
  The upload’s status.
  Must be one of the following values:
  · FAILED: A failed status.
  · INITIALIZED: An initialized status.
  · PROCESSING: A processing status.
  · SUCCEEDED: A succeeded status.

* url (string) –
  The pre-signed Amazon S3 URL that was used to store a file through a corresponding PUT request.

* metadata (string) –
  The upload’s metadata. For example, for Android, this contains information that is parsed from the manifest and is displayed in the AWS Device Farm console after the associated app is uploaded.

* contentType (string) –
  The upload’s content type (for example, “application/octet-stream”).

* message (string) –
  A message about the upload’s result.

get_waiter(waiter_name)

list_artifacts(**kwargs)
  Gets information about artifacts.

Request Syntax

response = client.list_artifacts(
    arn='string',
    type='SCREENSHOT'|'FILE'|'LOG',
    nextToken='string'
)

Parameters
  · arn (string) – [REQUIRED]
    The Run, Job, Suite, or Test ARN.
• **type** (*string*) – [REQUIRED]
  The artifacts’ type.
  Allowed values include:
  - FILE: The artifacts are files.
  - LOG: The artifacts are logs.
  - SCREENSHOT: The artifacts are screenshots.

• **nextToken** (*string*) – An identifier that was returned from the previous call to this operation, which can be used to return the next set of items in the list.

*Return type*  *dict*

*Returns*

**Response Syntax**

```
{
    'artifacts': [
        {
            'arn': 'string',
            'name': 'string',
            'type': ... TPUT'|'CALABASH_JAVA_XML_OUTPUT'|'AUTOMATION_OUTPUT'|'APPIUM_SERVER_OUTPUT'|'APPIUM_JAVA_OUTPUT'|'APPIUM_JAVA_XML_OUTPUT',
            'extension': 'string',
            'url': 'string'
        },
        ...,
    ],
    'nextToken': 'string'
}
```

**Response Structure**

• (*dict*) –
  Represents the result of a list artifacts operation.
  - **artifacts** (*list*) –
    Information about the artifacts.
    - (*dict*) –
      Represents the output of a test. Examples of artifacts include logs and screenshots.
      - **arn** (*string*) –
        The artifact’s ARN.
      - **name** (*string*) –
        The artifact’s name.
      - **type** (*string*) –
        The artifact’s type.
        Allowed values include the following:
        - APPIUM_JAVA_OUTPUT: The Appium Java output type.
        - APPIUM_SERVER_OUTPUT: The Appium server output type.
        - AUTOMATION_OUTPUT: The automation output type.
        - CALABASH_JSON_OUTPUT: The Calabash JSON output type.
        - CALABASH_JAVA_XML_OUTPUT: The Calabash Java XML output type.
- CALABASHPRETTY_OUTPUT: The Calabash pretty output type.
- CALABASH_STANDARD_OUTPUT: The Calabash standard output type.
- DEVICE_LOG: The device log type.
- EXERCISER_MONKEY_OUTPUT: For Android, the artifact (log) generated by an Android fuzz test.
- INSTRUMENTATION_OUTPUT: The instrumentation type.
- MESSAGE_LOG: The message log type.
- RESULT_LOG: The result log type.
- SCREENSHOT: The screenshot type.
- SERVICE_LOG: The service log type.
- UNKNOWN: An unknown type.

- extension (string) –
  The artifact’s file extension.
- url (string) –
  The pre-signed Amazon S3 URL that can be used with a corresponding GET request to download the artifact’s file.

  - nextToken (string) –
    If the number of items that are returned is significantly large, this is an identifier that is also returned, which can be used in a subsequent call to this operation to return the next set of items in the list.

list_device_pools(**kwargs)

Gets information about device pools.

Request Syntax

```python
response = client.list_device_pools(
    arn='string',
    type='CURATED'|'PRIVATE',
    nextToken='string'
)
```

Parameters

- **arn (string)** – [REQUIRED]
  The project ARN.
- **type (string)** – The device pools’ type.

  Allowed values include:

  - CURATED: A device pool that is created and managed by AWS Device Farm.
  - PRIVATE: A device pool that is created and managed by the device pool developer.

- **nextToken (string)** – An identifier that was returned from the previous call to this operation, which can be used to return the next set of items in the list.

Return type  dict

Returns

Response Syntax

```json
{
    'devicePools': [
        
```
Response Structure

- (dict) –

  Represents the result of a list device pools request.

  - devicePools (list) –

    Information about the device pools.

    * (dict) –

      Represents a collection of device types.

      - arn (string) –

        The device pool’s ARN.

      - name (string) –

        The device pool’s name.

      - description (string) –

        The device pool’s description.

      - type (string) –

        The device pool’s type.

        Allowed values include:

        - CURATED: A device pool that is created and managed by AWS Device Farm.
        - PRIVATE: A device pool that is created and managed by the device pool developer.

      - rules (list) –

        Information about the device pool’s rules.

        * (dict) –

          Represents a condition for a device pool.

          - attribute (string) –

            The rule’s attribute.

            Allowed values include:

            - ARN: The ARN.
            - FORM_FACTOR: The form factor (for example, phone or tablet).
            - MANUFACTURER: The manufacturer.
            - PLATFORM: The platform (for example, Android or iOS).
• **operator** *(string)* –

   The rule’s operator.
   - **EQUALS**: The equals operator.
   - **GREATER_THAN**: The greater-than operator.
   - **IN**: The in operator.
   - **LESS_THAN**: The less-than operator.
   - **NOT_IN**: The not-in operator.

• **value** *(string)* –

   The rule’s value.

• **nextToken** *(string)* –

   If the number of items that are returned is significantly large, this is an identifier that is also returned, which can be used in a subsequent call to this operation to return the next set of items in the list.

### list_devices(**kwargs)**

Gets information about unique device types.

**Request Syntax**

```python
response = client.list_devices(
    arn='string',
    nextToken='string'
)
```

**Parameters**

- **arn** *(string)* – The device types’ ARNs.
- **nextToken** *(string)* – An identifier that was returned from the previous call to this operation, which can be used to return the next set of items in the list.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'devices': [
        {
            'arn': 'string',
            'name': 'string',
            'manufacturer': 'string',
            'model': 'string',
            'formFactor': 'PHONE'|'TABLET',
            'platform': 'ANDROID'|'IOS',
            'os': 'string',
            'cpu': {
                'frequency': 'string',
                'architecture': 'string',
                'clock': 123.0
            },
            'resolution': {
                'width': 123,
                'height': 123
            },
            'heapSize': 123,
            'memory': 123,
            'image': 'string',
            'carrier': 'string',
        }
    ]
}
```
Response Structure

- (dict) –
  Represents the result of a list devices operation.
  - devices (list) –
    Information about the devices.
      * (dict) –
        Represents a device type that an app is tested against.
          - arn (string) –
            The device’s ARN.
          - name (string) –
            The device’s display name.
          - manufacturer (string) –
            The device’s manufacturer name.
          - model (string) –
            The device’s model name.
          - formFactor (string) –
            The device’s form factor.
            Allowed values include:
            - PHONE: The phone form factor.
            - TABLET: The tablet form factor.
          - platform (string) –
            The device’s platform.
            Allowed values include:
            - ANDROID: The Android platform.
            - IOS: The iOS platform.
          - os (string) –
            The device’s operating system type.
          - cpu (dict) –
            Information about the device’s CPU.
            - frequency (string) –
              The CPU’s frequency.
            - architecture (string) –
              The CPU’s architecture, for example x86 or ARM.
            - clock (float) –
              The clock speed of the device’s CPU, expressed in hertz (Hz). For example, a 1.2 GHz CPU is expressed as 1200000000.
          - resolution (dict) –
            Represents the screen resolution of a device in height and width, expressed in pixels.
- **width** (integer) –
  The screen resolution’s width, expressed in pixels.
- **height** (integer) –
  The screen resolution’s height, expressed in pixels.
- **heapSize** (integer) –
  The device’s heap size, expressed in bytes.
- **memory** (integer) –
  The device’s total memory size, expressed in bytes.
- **image** (string) –
  The device’s image name.
- **carrier** (string) –
  The device’s carrier.
- **radio** (string) –
  The device’s radio.
- **nextToken** (string) –
  If the number of items that are returned is significantly large, this is an identifier that is also returned, which can be used in a subsequent call to this operation to return the next set of items in the list.

`list_jobs(**kwargs)`

GETS INFORMATION ABOUT JOBS.

**Request Syntax**

```python
response = client.list_jobs(
    arn='string',
    nextToken='string'
)
```

**Parameters**

- **arn** (string) – [REQUIRED]
  The jobs’ ARNs.
- **nextToken** (string) – An identifier that was returned from the previous call to this operation, which can be used to return the next set of items in the list.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'jobs': [
        {
            'arn': 'string',
            'name': 'string',
            'type': 'BUILTIN_FUZZ'|'BUILTIN_EXPLORER'|'APPIUM_JAVA_JUNIT'|'APPIUM_JAVA_TESTNG'|'CALABASH'|'INSTRUMENTATION'|'UIAUTOMATION'|'UIAUTOMATOR'|'XCTEST',
            'created': datetime(2015, 1, 1),
            'status': 'PENDING'|'PROCESSING'|'SCHEDULING'|'RUNNING'|'COMPLETED',
            'result': 'PENDING'|'PASSED'|'WARNED'|'FAILED'|'SKIPPED'|'ERRORED'|'STOPPED',
            'started': datetime(2015, 1, 1),
            'stopped': datetime(2015, 1, 1),
            'counters': {
                'total': 123,

3.1. Services
{'passed': 123,

Response Structure

• (dict) –

Represents the result of a list jobs request.

– jobs (list) –

Information about the jobs.

* (dict) –

Represents a device.

• arn (string) –

The job’s ARN.

• name (string) –

The job’s name.

• type (string) –

The job’s type.

Allowed values include the following:

• BUILTIN_FUZZ: The built-in fuzz type.
• BUILTIN_EXPLORER: For Android, an app explorer that will traverse an Android app, interacting with it and captur-
- created (datetime) –
  When the job was created.
- status (string) –
  The job’s status.
  Allowed values include:
  - COMPLETED: A completed status.
  - PENDING: A pending status.
  - PROCESSING: A processing status.
  - RUNNING: A running status.
  - SCHEDULING: A scheduling status.
- result (string) –
  The job’s result.
  Allowed values include:
  - ERRORED: An error condition.
  - FAILED: A failed condition.
  - SKIPPED: A skipped condition.
  - STOPPED: A stopped condition.
  - PASSED: A passing condition.
  - PENDING: A pending condition.
  - WARNED: A warning condition.
- started (datetime) –
  The job’s start time.
- stopped (datetime) –
  The job’s stop time.
- counters (dict) –
  The job’s result counters.
- total (integer) –
  The total number of entities.
- passed (integer) –
  The number of passed entities.
- failed (integer) –
  The number of failed entities.
- warned (integer) –
  The number of warned entities.
- errored (integer) –
  The number of errored entities.
- stopped (integer) –
  The number of stopped entities.
- **skipped** (integer) –
  The number of skipped entities.
- **message** (string) –
  A message about the job’s result.
- **device** (dict) –
  Represents a device type that an app is tested against.
  - **arn** (string) –
    The device’s ARN.
  - **name** (string) –
    The device’s display name.
  - **manufacturer** (string) –
    The device’s manufacturer name.
  - **model** (string) –
    The device’s model name.
  - **formFactor** (string) –
    The device’s form factor.
    Allowed values include:
    - PHONE: The phone form factor.
    - TABLET: The tablet form factor.
  - **platform** (string) –
    The device’s platform.
    Allowed values include:
    - ANDROID: The Android platform.
    - IOS: The iOS platform.
  - **os** (string) –
    The device’s operating system type.
  - **cpu** (dict) –
    Information about the device’s CPU.
    - **frequency** (string) –
      The CPU’s frequency.
    - **architecture** (string) –
      The CPU’s architecture, for example x86 or ARM.
    - **clock** (float) –
      The clock speed of the device’s CPU, expressed in hertz (Hz). For example, a 1.2 GHz CPU is expressed as 1200000000.
  - **resolution** (dict) –
    Represents the screen resolution of a device in height and width, expressed in pixels.
    - **width** (integer) –
      The screen resolution’s width, expressed in pixels.
    - **height** (integer) –
      The screen resolution’s height, expressed in pixels.
  - **heapSize** (integer) –
    The device’s heap size, expressed in bytes.
· **memory** (*integer*) –
  The device’s total memory size, expressed in bytes.

· **image** (*string*) –
  The device’s image name.

· **carrier** (*string*) –
  The device’s carrier.

· **radio** (*string*) –
  The device’s radio.

  – **nextToken** (*string*) –
    If the number of items that are returned is significantly large, this is an identifier that is also returned, which can be used in a subsequent call to this operation to return the next set of items in the list.

**list_projects(***kwargs**)

Gets information about projects.

**Request Syntax**

```python
response = client.list_projects(
    arn='string',
    nextToken='string'
)
```

**Parameters**

- **arn** (*string*) – The projects’ ARNs.
- **nextToken** (*string*) – An identifier that was returned from the previous call to this operation, which can be used to return the next set of items in the list.

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'projects': [
        {
            'arn': 'string',
            'name': 'string',
            'created': datetime(2015, 1, 1)
        },
    ],
    'nextToken': 'string'
}
```

**Response Structure**

- (**dict**) –
  Represents the result of a list projects request.

  - **projects** (**list**) –
    Information about the projects.

    - (**dict**) –
      Represents an operating-system neutral workspace for running and managing tests.
· **arn** *(string)* –
  The project’s ARN.
· **name** *(string)* –
  The project’s name.
· **created** *(datetime)* –
  When the project was created.

  – **nextToken** *(string)* –

    If the number of items that are returned is significantly large, this is an identifier that is also returned, which can be used in a subsequent call to this operation to return the next set of items in the list.

**list_runs(** **kwargs**)**

  Gets information about runs.

  **Request Syntax**

  ```python
  response = client.list_runs(
      arn='string',
      nextToken='string'
  )
  ```

  **Parameters**

  · **arn** *(string)* – [REQUIRED]
    The runs’ ARNs.
  · **nextToken** *(string)* – An identifier that was returned from the previous call to this operation, which can be used to return the next set of items in the list.

  **Return type**  `dict`

  **Returns**

  **Response Syntax**

  ```json
  {
      'runs': [
          {
              'arn': 'string',
              'name': 'string',
              'type': 'BUILTIN_FUZZ'|'BUILTIN_EXPLORER'|'APPIUM_JAVA_JUNIT'|'APPIUM_JAVA_TESTNG'|'CALABASH'|'INSTRUMENTATION'|'UIAUTOMATION'|'UIAUTOMATOR'|'XCTEST',
              'platform': 'ANDROID'|'IOS',
              'created': datetime(2015, 1, 1),
              'status': 'PENDING'|'PROCESSING'|'SCHEDULING'|'RUNNING'|'COMPLETED',
              'result': 'PENDING'|'PASSED'|'WARNED'|'FAILED'|'ERRORED'|'STOPPED',
              'started': datetime(2015, 1, 1),
              'stopped': datetime(2015, 1, 1),
              'counters': {
                  'total': 123,
                  'passed': 123,
                  'failed': 123,
                  'warned': 123,
                  'errored': 123,
                  'stopped': 123,
                  'skipped': 123
              },
              'message': 'string',
              'totalJobs': 123,
              'completedJobs': 123
          }
      ]
  }
  ```
Response Structure

- (dict) –
  Represents the result of a list runs request.
  - runs (list) –
    Information about the runs.
    * (dict) –
      Represents an app on a set of devices with a specific test and configuration.
      - arn (string) –
        The run’s ARN.
      - name (string) –
        The run’s name.
      - type (string) –
        The run’s type.
      Must be one of the following values:
      - BUILTIN_FUZZ: The built-in fuzz type.
      - BUILTIN_EXPLORER: For Android, an app explorer that will traverse an Android app, interacting with it and capturing screenshots at the same time.
      - APPIUM_JAVA_JUNIT: The Appium Java JUnit type.
      - APPIUM_JAVA_TESTNG: The Appium Java TestNG type.
      - CALABASH: The Calabash type.
      - INSTRUMENTATION: The Instrumentation type.
      - UIAUTOMATION: The uiautomation type.
      - UIAUTOMATOR: The uiautomator type.
      - XCTEST: The XCode test type.
      - platform (string) –
        The run’s platform.
        Allowed values include:
        - ANDROID: The Android platform.
        - IOS: The iOS platform.
      - created (datetime) –
        When the run was created.
      - status (string) –
        The run’s status.
        Allowed values include:
        - COMPLETED: A completed status.
        - PENDING: A pending status.
        - PROCESSING: A processing status.
        - RUNNING: A running status.
        - SCHEDULING: A scheduling status.
- **result** *(string)* –
  The run’s result.
  Allowed values include:
  - **ERRORED**: An error condition.
  - **FAILED**: A failed condition.
  - **SKIPPED**: A skipped condition.
  - **STOPPED**: A stopped condition.
  - **PASSED**: A passing condition.
  - **PENDING**: A pending condition.
  - **WARNED**: A warning condition.
- **started** *(datetime)* –
  The run’s start time.
- **stopped** *(datetime)* –
  The run’s stop time.
- **counters** *(dict)* –
  The run’s result counters.
- **total** *(integer)* –
  The total number of entities.
- **passed** *(integer)* –
  The number of passed entities.
- **failed** *(integer)* –
  The number of failed entities.
- **warned** *(integer)* –
  The number of warned entities.
- **errored** *(integer)* –
  The number of errored entities.
- **stopped** *(integer)* –
  The number of stopped entities.
- **skipped** *(integer)* –
  The number of skipped entities.
- **message** *(string)* –
  A message about the run’s result.
- **totalJobs** *(integer)* –
  The total number of jobs for the run.
- **completedJobs** *(integer)* –
  The total number of completed jobs.
- **billingMethod** *(string)* –
  Specifies the billing method for a test run: *metered* or *unmetered*. If the parameter is not specified, the default value is *unmetered*.
- **nextToken** *(string)* –
  If the number of items that are returned is significantly large, this is an identifier that is also returned, which can be used in a subsequent call to this operation to return the next set of items in the list.
list_samples(**kwargs)

Gets information about samples.

Request Syntax

```python
response = client.list_samples(
    arn='string',
    nextToken='string'
)
```

Parameters

- **arn** *(string)* – [REQUIRED]
  The samples’ ARNs.

- **nextToken** *(string)* – An identifier that was returned from the previous call to this operation, which can be used to return the next set of items in the list.

Return type: dict

Returns

Response Syntax

```python
{
    'samples': [
        {
            'arn': 'string',
            'type': 'CPU'|'MEMORY'|'THREADS'|'RX_RATE'|'TX_RATE'|'RX'|'TX'|'NATIVE_AVG_DRAWTIME'|'NATIVE_FPS'|'NATIVE_FRAMES'|'NATIVE_MAX_DRAWTIME',
            'url': 'string'
        },
        ...
    ],
    'nextToken': 'string'
}
```

Response Structure

- *(dict)* – Represents the result of a list samples request.
  - **samples** *(list)* – Information about the samples.
    - *(dict)* – Represents a sample of performance data.
      - **arn** *(string)* – The sample’s ARN.
      - **type** *(string)* – The sample’s type.
      Must be one of the following values:
      - CPU: A CPU sample type. This is expressed as the app processing CPU time (including child processes) as reported by process, as a percentage.
      - MEMORY: A memory usage sample type. This is expressed as the total proportional set size of an app process, in kilobytes.
      - NATIVE_AVG_DRAWTIME
      - NATIVE_FPS
      - NATIVE_FRAMES
      - NATIVE_MAX_DRAWTIME
- NATIVE_MIN_DRAWTIME
- OPENGL_AVG_DRAWTIME
- OPENGL_FPS
- OPENGL_FRAMES
- OPENGL_MAX_DRAWTIME
- OPENGL_MIN_DRAWTIME
- RX
  - RX_RATE: The total number of bytes per second (TCP and UDP) that are sent, by app process.
- THREADS: A threads sample type. This is expressed as the total number of threads per app process.
- TX
  - TX_RATE: The total number of bytes per second (TCP and UDP) that are received, by app process.
- url (string) –
  - The pre-signed Amazon S3 URL that can be used with a corresponding GET request to download the sample’s file.

- nextToken (string) –
  - If the number of items that are returned is significantly large, this is an identifier that is also returned, which can be used in a subsequent call to this operation to return the next set of items in the list.

list_suites(**kwargs)

Gets information about suites.

Request Syntax

```python
response = client.list_suites(
    arn='string',
    nextToken='string'
)
```

Parameters

- **arn (string) – [REQUIRED]**
  - The suites’ ARNs.
- **nextToken (string) –** An identifier that was returned from the previous call to this operation, which can be used to return the next set of items in the list.

Return type  dict

Returns

Response Syntax

```python
{
    'suites': [
        {
            'arn': 'string',
            'name': 'string',
            'type': 'BUILTIN_FUZZ'|'BUILTIN_EXPLORER'|'APPIUM_JAVA_JUNIT'|'APPIUM_JAVA_TESTNG'|'CALABASH'|'INSTRUMENTATION'|'UIAUTOMATION'|'UIAUTOMATOR'|'XCTEST',
            'created': datetime(2015, 1, 1),
            'status': 'PENDING'|'PROCESSING'|'SCHEDULING'|'RUNNING'|'COMPLETED',
            'result': 'PENDING'|'PASSED'|'WARNED'|'FAILED'|'SKIPPED'|'ERRORED'|'STOPPED',
            'started': datetime(2015, 1, 1),
            'stopped': datetime(2015, 1, 1),
            'counters': {
                'total': 123,
            }
        }
    ]
}
```
"passed": 123,
"failed": 123,
"warned": 123,
"errored": 123,
"stopped": 123,
"skipped": 123
},

'message': 'string'
},

},

'nextToken': 'string'
}

Response Structure

- (dict) –
  Represents the result of a list suites request.
  - suites (list) –
    Information about the suites.
    * (dict) –
      Represents a collection of one or more tests.
      - arn (string) –
        The suite’s ARN.
      - name (string) –
        The suite’s name.
      - type (string) –
        The suite’s type.
% Must be one of the following values:
% - BUILTIN_FUZZ: The built-in fuzz type.
% - BUILTIN_EXPLORER: For Android, an app explorer that will traverse an Android app, interacting with it and capturing screenshots at the same time.
% - APPIUM_JAVA_JUNIT: The Appium Java JUnit type.
% - APPIUM_JAVA_TESTNG: The Appium Java TestNG type.
% - CALABASH: The Calabash type.
% - INSTRUMENTATION: The Instrumentation type.
% - UIAUTOMATION: The uiautomation type.
% - UIAUTOMATOR: The uiautomator type.
% - XCTEST: The XCode test type.
% - created (datetime) –
    When the suite was created.
% - status (string) –
    The suite’s status.
% Allowed values include:
% - COMPLETED: A completed status.
% - PENDING: A pending status.
% - PROCESSING: A processing status.
% - RUNNING: A running status.
% - SCHEDULING: A scheduling status.
% - result (string) –
The suite’s result.

Allowed values include:

- **ERRORED**: An error condition.
- **FAILED**: A failed condition.
- **SKIPPED**: A skipped condition.
- **STOPPED**: A stopped condition.
- **PASSED**: A passing condition.
- **PENDING**: A pending condition.
- **WARNED**: A warning condition.

- **started** *(datetime)* – The suite’s start time.
- **stopped** *(datetime)* – The suite’s stop time.
- **counters** *(dict)* – The suite’s result counters.
  - **total** *(integer)* – The total number of entities.
  - **passed** *(integer)* – The number of passed entities.
  - **failed** *(integer)* – The number of failed entities.
  - **warned** *(integer)* – The number of warned entities.
  - **errored** *(integer)* – The number of errored entities.
  - **stopped** *(integer)* – The number of stopped entities.
  - **skipped** *(integer)* – The number of skipped entities.
  - **message** *(string)* – A message about the suite’s result.

- **nextToken** *(string)* – If the number of items that are returned is significantly large, this is an identifier that is also returned, which can be used in a subsequent call to this operation to return the next set of items in the list.

**list_tests(****kwargs**)**

Gets information about tests.

**Request Syntax**

```python
response = client.list_tests(
    arn='string',
    nextToken='string'
)
```

**Parameters**
• **arn (string)** – [REQUIRED]

  The tests’ ARNs.

• **nextToken (string)** – An identifier that was returned from the previous call to this operation, which can be used to return the next set of items in the list.

Returns

dict

Response Syntax

```python
{
    'tests': [
        {
            'arn': 'string',
            'name': 'string',
            'type': 'BUILTIN_FUZZ'|'BUILTIN_EXPLORER'|'APPIUM_JAVA_JUNIT'|'APPIUM_JAVA_TESTNG'|'CALABASH'|'INSTRUMENTATION'|'UIAUTOMATION'|'UIAUTOMATOR'|'XCTEST',
            'created': datetime(2015, 1, 1),
            'status': 'PENDING'|'PROCESSING'|'SCHEDULING'|'RUNNING'|'COMPLETED',
            'result': 'PENDING'|'PASSED'|'WARNED'|'FAILED'|'SKIPPED'|'ERRORED'|'STOPPED',
            'started': datetime(2015, 1, 1),
            'stopped': datetime(2015, 1, 1),
            'counters': {
                'total': 123,
                'passed': 123,
                'failed': 123,
                'warned': 123,
                'errored': 123,
                'stopped': 123,
                'skipped': 123
            },
            'message': 'string'
        },
        {
            'arn': 'string',
            'name': 'string',
            'type': 'BUILTIN_FUZZ'|'BUILTIN_EXPLORER'|'APPIUM_JAVA_JUNIT'|'APPIUM_JAVA_TESTNG'|'CALABASH'|'INSTRUMENTATION'|'UIAUTOMATION'|'UIAUTOMATOR'|'XCTEST',
            'created': datetime(2015, 1, 1),
            'status': 'PENDING'|'PROCESSING'|'SCHEDULING'|'RUNNING'|'COMPLETED',
            'result': 'PENDING'|'PASSED'|'WARNED'|'FAILED'|'SKIPPED'|'ERRORED'|'STOPPED',
            'started': datetime(2015, 1, 1),
            'stopped': datetime(2015, 1, 1),
            'counters': {
                'total': 123,
                'passed': 123,
                'failed': 123,
                'warned': 123,
                'errored': 123,
                'stopped': 123,
                'skipped': 123
            },
            'message': 'string'
        }
    ],
    'nextToken': 'string'
}
```

Response Structure

• **(dict)** –

  Represents the result of a list tests request.

  – **tests (list)** –

    Information about the tests.

    * **(dict)** –

      Represents a condition that is evaluated.

      • **arn (string)** –

        The test’s ARN.

      • **name (string)** –

        The test’s name.

      • **type (string)** –

        The test’s type.

      Must be one of the following values:

      • BUILTIN_FUZZ: The built-in fuzz type.

      • BUILTIN_EXPLORER: For Android, an app explorer that will traverse an Android app, interacting with it and capturing screenshots at the same time.
- APPIUM_JAVA_JUNIT: The Appium Java JUnit type.
- APPIUM_JAVA_TESTNG: The Appium Java TestNG type.
- CALABASH: The Calabash type.
- INSTRUMENTATION: The Instrumentation type.
- UIAUTOMATION: The uiautomation type.
- UIAUTOMATOR: The uiautomator type.
- XCTEST: The XCode test type.

- **created** *(datetime)* —  
  When the test was created.

- **status** *(string)* —  
  The test’s status.
  Allowed values include:
  - COMPLETED: A completed status.
  - PENDING: A pending status.
  - PROCESSING: A processing status.
  - RUNNING: A running status.
  - SCHEDULING: A scheduling status.

- **result** *(string)* —  
  The test’s result.
  Allowed values include:
  - ERRORED: An error condition.
  - FAILED: A failed condition.
  - SKIPPED: A skipped condition.
  - STOPPED: A stopped condition.
  - PASSED: A passing condition.
  - PENDING: A pending condition.
  - WARNED: A warning condition.

- **started** *(datetime)* —  
  The test’s start time.

- **stopped** *(datetime)* —  
  The test’s stop time.

- **counters** *(dict)* —  
  The test’s result counters.

- **total** *(integer)* —  
  The total number of entities.

- **passed** *(integer)* —  
  The number of passed entities.

- **failed** *(integer)* —  
  The number of failed entities.

- **warned** *(integer)* —  
  The number of warned entities.

- **errored** *(integer)* —  
  The number of errored entities.

- **stopped** *(integer)* —  
  The number of stopped entities.

- **skipped** *(integer)* —
The number of skipped entities.

- `message (string)` –
  A message about the test’s result.

- `nextToken (string)` –
  If the number of items that are returned is significantly large, this is an identifier that is also returned, which can be used in a subsequent call to this operation to return the next set of items in the list.

`list_unique_problems(**kwargs)`

Gets information about unique problems.

**Request Syntax**

```python
response = client.list_unique_problems(
    arn='string',
    nextToken='string'
)
```

**Parameters**

- `arn (string)` – [REQUIRED]
  The unique problems’ ARNs.
- `nextToken (string)` – An identifier that was returned from the previous call to this operation, which can be used to return the next set of items in the list.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'uniqueProblems': {
        'string': [
            {
                'message': 'string',
                'problems': [
                    {
                        'run': {
                            'arn': 'string',
                            'name': 'string'
                        },
                        'job': {
                            'arn': 'string',
                            'name': 'string'
                        },
                        'suite': {
                            'arn': 'string',
                            'name': 'string'
                        },
                        'test': {
                            'arn': 'string',
                            'name': 'string'
                        },
                        'device': {
                            'arn': 'string',
                            'name': 'string',
                            'manufacturer': 'string',
                            'model': 'string',
                        }
                    }
                ]
            }
        ]
    }
}
```
Response Structure

- (dict) –

  Represents the result of a list unique problems request.

  - uniqueProblems (dict) –

    Information about the unique problems.

    Allowed values include:
    * ERRORED: An error condition.
    * FAILED: A failed condition.
    * SKIPPED: A skipped condition.
    * STOPPED: A stopped condition.
    * PASSED: A passing condition.
    * PENDING: A pending condition.
    * WARNED: A warning condition.

    - (string) –
      · (list) –
      · (dict) –

      A collection of one or more problems, grouped by their result.

      - message (string) –

        A message about the unique problems’ result.

      - problems (list) –

        Information about the problems.

      - (dict) –

        Represents a specific warning or failure.

      - run (dict) –
Information about the associated run.

- **arn (string)** –
  The problem detail’s ARN.
- **name (string)** –
  The problem detail’s name.
- **job (dict)** –
  Information about the associated job.
  - **arn (string)** –
    The problem detail’s ARN.
  - **name (string)** –
    The problem detail’s name.
- **suite (dict)** –
  Information about the associated suite.
  - **arn (string)** –
    The problem detail’s ARN.
  - **name (string)** –
    The problem detail’s name.
- **test (dict)** –
  Information about the associated test.
  - **arn (string)** –
    The problem detail’s ARN.
  - **name (string)** –
    The problem detail’s name.
- **device (dict)** –
  Information about the associated device.
  - **arn (string)** –
    The device’s ARN.
  - **name (string)** –
    The device’s display name.
  - **manufacturer (string)** –
    The device’s manufacturer name.
  - **model (string)** –
    The device’s model name.
  - **formFactor (string)** –
    The device’s form factor.
    Allowed values include:
    - PHONE: The phone form factor.
    - TABLET: The tablet form factor.
  - **platform (string)** –
    The device’s platform.
    Allowed values include:
    - ANDROID: The Android platform.
    - IOS: The iOS platform.
- **os** *(string)* –
  The device’s operating system type.
- **cpu** *(dict)* –
  Information about the device’s CPU.
- **frequency** *(string)* –
  The CPU’s frequency.
- **architecture** *(string)* –
  The CPU’s architecture, for example x86 or ARM.
- **clock** *(float)* –
  The clock speed of the device’s CPU, expressed in hertz (Hz).
  For example, a 1.2 GHz CPU is expressed as 1200000000.
- **resolution** *(dict)* –
  Represents the screen resolution of a device in height and width, expressed in pixels.
- **width** *(integer)* –
  The screen resolution’s width, expressed in pixels.
- **height** *(integer)* –
  The screen resolution’s height, expressed in pixels.
- **heapSize** *(integer)* –
  The device’s heap size, expressed in bytes.
- **memory** *(integer)* –
  The device’s total memory size, expressed in bytes.
- **image** *(string)* –
  The device’s image name.
- **carrier** *(string)* –
  The device’s carrier.
- **radio** *(string)* –
  The device’s radio.
- **result** *(string)* –
  The problem’s result.
  Allowed values include:
  - **ERRORED**: An error condition.
  - **FAILED**: A failed condition.
  - **SKIPPED**: A skipped condition.
  - **STOPPED**: A stopped condition.
  - **PASSED**: A passing condition.
  - **PENDING**: A pending condition.
  - **WARNED**: A warning condition.
- **message** *(string)* –
  A message about the problem’s result.
- **nextToken** *(string)* –
  If the number of items that are returned is significantly large, this is an identifier that is also returned, which can be used in a subsequent call to this operation to return the next set of items in the list.
list_uploads(**kwargs)
    Gets information about uploads.

Request Syntax

response = client.list_uploads(
    arn='string',
    nextToken='string'
)

Parameters

• arn (string) – [REQUIRED]
    The uploads’ ARNs.

• nextToken (string) – An identifier that was returned from the previous call to
    this operation, which can be used to return the next set of items in the list.

Return type  dict
Returns

Response Syntax

{
    'uploads': [
        {
            'arn': 'string',
            'name': 'string',
            'created': datetime(2015, 1, 1),

            'url': 'string',
            'metadata': 'string',
            'contentType': 'string',
            'message': 'string'
        }
    ],
    'nextToken': 'string'
}

Response Structure

• (dict) –
    Represents the result of a list uploads request.
    – uploads (list) –
        Information about the uploads.
        • (dict) –
            An app or a set of one or more tests to upload or that have been
            uploaded.
                • arn (string) –
                    The upload’s ARN.
                • name (string) –
                    The upload’s file name.
                • created (datetime) –
                    When the upload was created.
                • type (string) –
                    The upload’s type.
Must be one of the following values:
- ANDROID_APP: An Android upload.
- IOS_APP: An iOS upload.
- EXTERNAL_DATA: An external data upload.
- APPium_JAVA_JUNIT_TEST_PACKAGE: An Appium Java JUnit test package upload.
- APPium_JAVA_TESTNG_TEST_PACKAGE: An Appium Java TestNG test package upload.
- CALABASH_TEST_PACKAGE: A Calabash test package upload.
- INSTRUMENTATION_TEST_PACKAGE: An instrumentation upload.
- UIAUTOMATOR_TEST_PACKAGE: A uiautomator test package upload.
- XCTEST_TEST_PACKAGE: An XCode test package upload.

status (string)

The upload’s status.
Must be one of the following values:
- FAILED: A failed status.
- INITIALIZED: An initialized status.
- PROCESSING: A processing status.
- SUCCEEDED: A succeeded status.

url (string)

The pre-signed Amazon S3 URL that was used to store a file through a corresponding PUT request.

metadata (string)

The upload’s metadata. For example, for Android, this contains information that is parsed from the manifest and is displayed in the AWS Device Farm console after the associated app is uploaded.

contentType (string)

The upload’s content type (for example, “application/octet-stream”).

message (string)

A message about the upload’s result.

- nextToken (string)

If the number of items that are returned is significantly large, this is an identifier that is also returned, which can be used in a subsequent call to this operation to return the next set of items in the list.

**schedule_run(**kwargs)**

Schedules a run.

**Request Syntax**

```python
response = client.schedule_run(
    projectArn='string',
    appArn='string',
    devicePoolArn='string',
    name='string',
    test={
```
Parameters

- **projectArn (string) – [REQUIRED]**
  The ARN of the project for the run to be scheduled.

- **appArn (string) – [REQUIRED]**
  The ARN of the app to schedule a run.

- **devicePoolArn (string) – [REQUIRED]**
  The ARN of the device pool for the run to be scheduled.

- **name (string) –**
  The name for the run to be scheduled.

- **test (dict) – [REQUIRED]**
  Information about the test for the run to be scheduled.
  - **type (string) – [REQUIRED]**
    The test’s type.
  
    Must be one of the following values:
    - BUILTIN_FUZZ: The built-in fuzz type.
    - BUILTIN_EXPLORER: For Android, an app explorer that will traverse an Android app, interacting with it and capturing screenshots at the same time.
    - APPIUM_JAVA_JUNIT: The Appium Java JUnit type.
    - APPIUM_JAVA_TESTNG: The Appium Java TestNG type.
    - CALABASH: The Calabash type.
    - INSTRUMENTATION: The Instrumentation type.
    - UIAUTOMATION: The uiautomation type.
    - UIAUTOMATOR: The uiautomator type.
    - XCTEST: The XCode test type.
    - **testPackageArn (string) –**
The ARN of the uploaded test that will be run.

- **filter** *(string)* –
  
  The test’s filter.

- **parameters** *(dict)* –
  
  The test’s parameters, such as test framework parameters and fixture settings.

  - *(string)* –
    
    • **configuration** *(dict)* – Information about the settings for the run to be scheduled.
    
    - **extraDataPackageArn** *(string)* –
      
      The ARN of the extra data for the run. The extra data is a .zip file that AWS Device Farm will extract to external data for Android or the app’s sandbox for iOS.

    - **networkProfileArn** *(string)* –
      
      Reserved for internal use.

    - **locale** *(string)* –
      
      Information about the locale that is used for the run.

    - **location** *(dict)* –
      
      Information about the location that is used for the run.

      - *(latitude** (float)** – [REQUIRED]*
        
        The latitude.

      - *(longitude** (float)** – [REQUIRED]*
        
        The longitude.

    - **radios** *(dict)* –
      
      Information about the radio states for the run.

      - **wifi** *(boolean)* –
        
        True if Wi-Fi is enabled at the beginning of the test; otherwise, false.

      - **bluetooth** *(boolean)* –
        
        True if Bluetooth is enabled at the beginning of the test; otherwise, false.

      - **nfc** *(boolean)* –
        
        True if NFC is enabled at the beginning of the test; otherwise, false.

      - **gps** *(boolean)* –
        
        True if GPS is enabled at the beginning of the test; otherwise, false.

- **auxiliaryApps** *(list)* –
  
  A list of auxiliary apps for the run.

  - *(string)* –

- **billingMethod** *(string)* –
  
  Specifies the billing method for a test run: **metered** or **unmetered**. If the parameter is not specified, the default value is **unmetered**.

**Return type** `dict`

**Returns** *dict*

**Response Syntax**

```json
{
  'run': {
    'arn': 'string',
    'name': 'string',
    'type': 'BUILTIN_FUZZ'|'BUILTIN_EXPLORER'|'APPIUM_JAVA_JUNIT'|'APPIUM_JAVA_TESTNG'|'CALABASH'|'INSTRUMENTATION'|'UIAUTOMATION'|'UIAUTOMATOR'|'XCTEST',
    'platform': 'ANDROID'|'IOS',
    'created': datetime(2015, 1, 1),
    'status': 'PENDING'|'PROCESSING'|'SCHEDULING'|'RUNNING'|'COMPLETED',
    'result': 'PENDING'|'PASSED'|'WARNED'|'FAILED'|'SKIPPED'|'ERRORED'|'STOPPED',
    'started': datetime(2015, 1, 1),
    'stopped': datetime(2015, 1, 1),
    'counters': {
      'total': 123,
      'passed': 123,
      'failed': 123,
      'warned': 123,
      'errored': 123,
      'stopped': 123,
      'skipped': 123
    },
    'message': 'string',
    'totalJobs': 123,
    'completedJobs': 123,
    'billingMethod': 'METERED'|'UNMETERED'
  }
}
```

**Response Structure**

- *(dict)* – Represents the result of a schedule run request.
  - **run (dict)** – Information about the scheduled run.
    - **arn (string)** – The run’s ARN.
    - **name (string)** – The run’s name.
    - **type (string)** – The run’s type.
      Must be one of the following values:
      - BUILTIN_FUZZ: The built-in fuzz type.
      - BUILTIN_EXPLORER: For Android, an app explorer that will traverse an Android app, interacting with it and capturing screenshots at the same time.
      - APPIUM_JAVA_JUNIT: The Appium Java JUnit type.
      - APPIUM_JAVA_TESTNG: The Appium Java TestNG type.
      - CALABASH: The Calabash type.
      - INSTRUMENTATION: The Instrumentation type.
      - UIAUTOMATION: The uiautomation type.
      - UIAUTOMATOR: The uiautomator type.
      - XCTEST: The XCode test type.
    - **platform (string)** – The run’s platform.
Allowed values include:
- ANDROID: The Android platform.
- IOS: The iOS platform.

* `created (datetime)` –
  When the run was created.

* `status (string)` –
  The run’s status.

  Allowed values include:
  - COMPLETED: A completed status.
  - PENDING: A pending status.
  - PROCESSING: A processing status.
  - RUNNING: A running status.
  - SCHEDULING: A scheduling status.

* `result (string)` –
  The run’s result.

  Allowed values include:
  - ERRORED: An error condition.
  - FAILED: A failed condition.
  - SKIPPED: A skipped condition.
  - STOPPED: A stopped condition.
  - PASSED: A passing condition.
  - PENDING: A pending condition.
  - WARNED: A warning condition.

* `started (datetime)` –
  The run’s start time.

* `stopped (datetime)` –
  The run’s stop time.

* `counters (dict)` –
  The run’s result counters.
  - `total (integer)` –
    The total number of entities.
  - `passed (integer)` –
    The number of passed entities.
  - `failed (integer)` –
    The number of failed entities.
  - `warned (integer)` –
    The number of warned entities.
  - `errored (integer)` –
    The number of errored entities.
  - `stopped (integer)` –
    The number of stopped entities.
  - `skipped (integer)` –
    The number of skipped entities.

* `message (string)` –
  A message about the run’s result.
Boto3 Documentation, Release 1.1.4

* totalJobs (integer) –

The total number of jobs for the run.

* completedJobs (integer) –

The total number of completed jobs.

* billingMethod (string) –

Specifies the billing method for a test run: metered or unmetered. If the parameter is not specified, the default value is unmetered.

DirectConnect

Table of Contents

- DirectConnect
  - Client

Client

class DirectConnect.Client

A low-level client representing AWS Direct Connect:

```python
import boto3

client = boto3.client('directconnect')
```

These are the available methods:

- `allocate_connection_on_interconnect`
- `allocate_private_virtual_interface`
- `allocate_public_virtual_interface`
- `can_paginate`
- `confirm_connection`
- `confirm_private_virtual_interface`
- `confirm_public_virtual_interface`
- `create_connection`
- `create_interconnect`
- `create_private_virtual_interface`
- `create_public_virtual_interface`
- `delete_connection`
- `delete_interconnect`
- `delete_virtual_interface`
- `describe_connections`
- `describe_connections_on_interconnect`
- `describe_interconnects`
- `describe_locations`
- `describe_virtual_gateways`
- `describe_virtual_interfaces`
- `generate_presigned_url`
- `get_paginator`
- `get_waiter`
allocate_connection_on_interconnect(**kwargs)

Creates a hosted connection on an interconnect.

Allocates a VLAN number and a specified amount of bandwidth for use by a hosted connection on the given interconnect.

Request Syntax

```python
response = client.allocate_connection_on_interconnect(
    bandwidth='string',
    connectionName='string',
    ownerAccount='string',
    interconnectId='string',
    vlan=123
)
```

**Parameters**

- **bandwidth (string)** – [REQUIRED]
  
  Bandwidth of the connection.
  
  Example: “500Mbps“
  
  Default: None

- **connectionName (string)** – [REQUIRED]
  
  Name of the provisioned connection.
  
  Example: “500M Connection to AWS“
  
  Default: None

- **ownerAccount (string)** – [REQUIRED]
  
  Numeric account Id of the customer for whom the connection will be provisioned.
  
  Example: 123443215678
  
  Default: None

- **interconnectId (string)** – [REQUIRED]
  
  ID of the interconnect on which the connection will be provisioned.
  
  Example: dxcon-456abc78
  
  Default: None

- **vlan (integer)** – [REQUIRED]
  
  The dedicated VLAN provisioned to the connection.
  
  Example: 101
  
  Default: None

**Return type** dict

**Returns**

Response Syntax

```python
{
    'ownerAccount': 'string',
    'connectionId': 'string',
    'connectionName': 'string',
    'connectionState': 'ordering'|'requested'|'pending'|'available'|'down'|'deleting'|'deleted'|'rejected',
    'region': 'string',
}
```
Response Structure

- (dict) –

A connection represents the physical network connection between the AWS Direct Connect location and the customer.

- ownerAccount (string) –

ID of the connection.

Example: dxcon-fg5678gh

Default: None

- connectionName (string) –

The name of the connection.

Example: “My Connection to AWS”

Default: None

- connectionState (string) – State of the connection.
  
  - Ordering : The initial state of a hosted connection provisioned on an interconnect. The connection stays in the ordering state until the owner of the hosted connection confirms or declines the connection order.
  
  - Requested : The initial state of a standard connection. The connection stays in the requested state until the Letter of Authorization (LOA) is sent to the customer.
  
  - Pending : The connection has been approved, and is being initialized.
  
  - Available : The network link is up, and the connection is ready for use.
  
  - Down : The network link is down.
  
  - Deleted : The connection has been deleted.
  
  - Rejected : A hosted connection in the ‘Ordering’ state will enter the ‘Rejected’ state if it is deleted by the end customer.

- region (string) –

The AWS region where the connection is located.

Example: us-east-1

Default: None

- location (string) –

Where the connection is located.

Example: EqSV5

Default: None

- bandwidth (string) –

Bandwidth of the connection.

Example: 1Gbps (for regular connections), or 500Mbps (for hosted connections)
The owner of a connection calls this function to provision a private virtual interface which will be owned by another AWS customer.

Virtual interfaces created using this function must be confirmed by the virtual interface owner by calling ConfirmPrivateVirtualInterface. Until this step has been completed, the virtual interface will be in 'Confirming' state, and will not be available for handling traffic.

Request Syntax

```python
response = client.allocate_private_virtual_interface(
    connectionId='string',
    ownerAccount='string',
    newPrivateVirtualInterfaceAllocation={
        'virtualInterfaceName': 'string',
        'vlan': 123,
        'asn': 123,
        'authKey': 'string',
        'amazonAddress': 'string',
        'customerAddress': 'string'
    }
)
```

Parameters

- **connectionId (string)** – [REQUIRED]
  
The connection ID on which the private virtual interface is provisioned.
  
  Default: None
- **ownerAccount (string)** – [REQUIRED]
  
The AWS account that will own the new private virtual interface.
  
  Default: None
- **newPrivateVirtualInterfaceAllocation (dict)** – [REQUIRED]
  
  Detailed information for the private virtual interface to be provisioned.
  
  Default: None
  
  - **virtualInterfaceName (string)** – [REQUIRED]
    
    The name of the virtual interface assigned by the customer.
    
    Example: “My VPC”
  - **vlan (integer)** – [REQUIRED]
    
    The VLAN ID.
    
    Example: 101
  - **asn (integer)** – [REQUIRED]
    
    Autonomous system (AS) number for Border Gateway Protocol (BGP) configuration.
Example: 65000

- **authKey** *(string)* –
  Authentication key for BGP configuration.
  Example: asdf34example

- **amazonAddress** *(string)* –
  IP address assigned to the Amazon interface.
  Example: 192.168.1.1/30

- **customerAddress** *(string)* –
  IP address assigned to the customer interface.
  Example: 192.168.1.2/30

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'ownerAccount': 'string',
    'virtualInterfaceId': 'string',
    'location': 'string',
    'connectionId': 'string',
    'virtualInterfaceType': 'string',
    'virtualInterfaceName': 'string',
    'vlan': 123,
    'asn': 123,
    'authKey': 'string',
    'amazonAddress': 'string',
    'customerAddress': 'string',
    'virtualInterfaceState': 'confirming'|'verifying'|'pending'|'available'|'deleting'|'deleted'|'rejected',
    'customerRouterConfig': 'string',
    'virtualGatewayId': 'string',
    'routeFilterPrefixes': [
        {
            'cidr': 'string'
        }
    ]
}
```

**Response Structure**

- *(dict)* –
  A virtual interface (VLAN) transmits the traffic between the AWS Direct Connect location and the customer.
  - **ownerAccount** *(string)* –
  ID of the virtual interface.
  Example: dxvif-123dfg56
  Default: None
  - **virtualInterfaceId** *(string)* –
  Where the connection is located.
  Example: EqSV5
  Default: None
- **connectionId** *(string)*
  ID of the connection.
  Example: dxcon-fg5678gh
  Default: None

- **virtualInterfaceType** *(string)*
  The type of virtual interface.
  Example: private (Amazon VPC) or public (Amazon S3, Amazon DynamoDB, and so on.)

- **virtualInterfaceName** *(string)*
  The name of the virtual interface assigned by the customer.
  Example: “My VPC”

- **vlan** *(integer)*
  The VLAN ID.
  Example: 101

- **asn** *(integer)*
  Autonomous system (AS) number for Border Gateway Protocol (BGP) configuration.
  Example: 65000

- **authKey** *(string)*
  Authentication key for BGP configuration.
  Example: asdf34example

- **amazonAddress** *(string)*
  IP address assigned to the Amazon interface.
  Example: 192.168.1.1/30

- **customerAddress** *(string)*
  IP address assigned to the customer interface.
  Example: 192.168.1.2/30

- **virtualInterfaceState** *(string)* – State of the virtual interface.
  * **Confirming**: The creation of the virtual interface is pending confirmation from the virtual interface owner. If the owner of the virtual interface is different from the owner of the connection on which it is provisioned, then the virtual interface will remain in this state until it is confirmed by the virtual interface owner.
  * **Verifying**: This state only applies to public virtual interfaces. Each public virtual interface needs validation before the virtual interface can be created.
  * **Pending**: A virtual interface is in this state from the time that it is created until the virtual interface is ready to forward traffic.
  * **Available**: A virtual interface that is able to forward traffic.
  * **Deleting**: A virtual interface is in this state immediately after calling `DeleteVirtualInterface` until it can no longer forward traffic.
  * **Deleted**: A virtual interface that cannot forward traffic.
  * **Rejected**: The virtual interface owner has declined creation of the virtual interface. If a virtual interface in the ‘Confirming’ state is
deleted by the virtual interface owner, the virtual interface will enter
the ‘Rejected’ state.

– **customerRouterConfig** *(string)* –

Information for generating the customer router configuration.

– **virtualGatewayId** *(string)* –

The ID of the virtual private gateway to a VPC. This only applies to private
virtual interfaces.

Example: vgw-123er56

– **routeFilterPrefixes** *(list)* –

A list of routes to be advertised to the AWS network in this region (public
virtual interface) or your VPC (private virtual interface).

* *(dict)* –

A route filter prefix that the customer can advertise through Border
Gateway Protocol (BGP) over a public virtual interface.

  · **cidr** *(string)* –

    CIDR notation for the advertised route. Multiple routes are
    separated by commas.

    Example: 10.10.10.0/24,10.10.11.0/24

**allocate_public_virtual_interface**( **kwargs** )

Provisions a public virtual interface to be owned by a different customer.

The owner of a connection calls this function to provision a public virtual interface which will be owned
by another AWS customer.

Virtual interfaces created using this function must be confirmed by the virtual interface owner by calling
ConfirmPublicVirtualInterface. Until this step has been completed, the virtual interface will be in
‘Confirming’ state, and will not be available for handling traffic.

**Request Syntax**

```python
response = client.allocate_public_virtual_interface(
    connectionId='string',
    ownerAccount='string',
    newPublicVirtualInterfaceAllocation={
        'virtualInterfaceName': 'string',
        'vlan': 123,
        'asn': 123,
        'authKey': 'string',
        'amazonAddress': 'string',
        'customerAddress': 'string',
        'routeFilterPrefixes': [
            {'cidr': 'string'}
        ]
    }
)
```

**Parameters**

  · **connectionId** *(string)* – **[REQUIRED]**

    The connection ID on which the public virtual interface is provisioned.

    Default: None
• **ownerAccount** *(string) – [REQUIRED]*
  The AWS account that will own the new public virtual interface.
  Default: None

• **newPublicVirtualInterfaceAllocation** *(dict) – [REQUIRED]*
  Detailed information for the public virtual interface to be provisioned.
  Default: None
  – **virtualInterfaceName** *(string) – [REQUIRED]*
    The name of the virtual interface assigned by the customer.
    Example: “My VPC”
  – **vlan** *(integer) – [REQUIRED]*
    The VLAN ID.
    Example: 101
  – **asn** *(integer) – [REQUIRED]*
    Autonomous system (AS) number for Border Gateway Protocol (BGP) configuration.
    Example: 65000
  – **authKey** *(string) –*
    Authentication key for BGP configuration.
    Example: asdf34example
  – **amazonAddress** *(string) – [REQUIRED]*
    IP address assigned to the Amazon interface.
    Example: 192.168.1.1/30
  – **customerAddress** *(string) – [REQUIRED]*
    IP address assigned to the customer interface.
    Example: 192.168.1.2/30
  – **routeFilterPrefixes** *(list) – [REQUIRED]*
    A list of routes to be advertised to the AWS network in this region (public virtual interface) or your VPC (private virtual interface).
    * *(dict) –*
    A route filter prefix that the customer can advertise through Border Gateway Protocol (BGP) over a public virtual interface.
    · **cidr** *(string) –*
      CIDR notation for the advertised route. Multiple routes are separated by commas.
      Example: 10.10.10.0/24,10.10.11.0/24

**Return type**  dict

**Returns**

**Response Syntax**

```python
{
    'ownerAccount': 'string',
    'virtualInterfaceId': 'string',
    'location': 'string',
}
```
'connectionId': 'string',
'virtualInterfaceType': 'string',
'virtualInterfaceName': 'string',
'vlan': 123,
'asn': 123,
'authKey': 'string',
'amazonAddress': 'string',
'customerAddress': 'string',
'virtualInterfaceState': 'confirming'|'verifying'|'pending'|'available'|'deleting'|'deleted'|'rejected',
'customerRouterConfig': 'string',
'virtualGatewayId': 'string',
'routeFilterPrefixes': [
    
    ]
}

Response Structure

- (dict) –

A virtual interface (VLAN) transmits the traffic between the AWS Direct Connect location and the customer.

- ownerAccount (string) –
- virtualInterfaceId (string) –

ID of the virtual interface.

Example: dxvif-123dfg56

Default: None

- location (string) –

Where the connection is located.

Example: EqSV5

Default: None

- connectionId (string) –

ID of the connection.

Example: dxcon-fg5678gh

Default: None

- virtualInterfaceType (string) –

The type of virtual interface.

Example: private (Amazon VPC) or public (Amazon S3, Amazon DynamoDB, and so on.)

- virtualInterfaceName (string) –

The name of the virtual interface assigned by the customer.

Example: “My VPC”

- vlan (integer) –

The VLAN ID.

Example: 101

- asn (integer) –
Autonomous system (AS) number for Border Gateway Protocol (BGP) configuration.
Example: 65000

- **authKey** *(string)* –
  Authentication key for BGP configuration.
  Example: asdf34example

- **amazonAddress** *(string)* –
  IP address assigned to the Amazon interface.
  Example: 192.168.1.1/30

- **customerAddress** *(string)* –
  IP address assigned to the customer interface.
  Example: 192.168.1.2/30

- **virtualInterfaceState** *(string)* – State of the virtual interface.
  * **Confirming**: The creation of the virtual interface is pending confirmation from the virtual interface owner. If the owner of the virtual interface is different from the owner of the connection on which it is provisioned, then the virtual interface will remain in this state until it is confirmed by the virtual interface owner.
  * **Verifying**: This state only applies to public virtual interfaces. Each public virtual interface needs validation before the virtual interface can be created.
  * **Pending**: A virtual interface is in this state from the time that it is created until the virtual interface is ready to forward traffic.
  * **Available**: A virtual interface that is able to forward traffic.
  * **Deleting**: A virtual interface is in this state immediately after calling `DeleteVirtualInterface` until it can no longer forward traffic.
  * **Deleted**: A virtual interface that cannot forward traffic.
  * **Rejected**: The virtual interface owner has declined creation of the virtual interface. If a virtual interface in the ‘Confirming’ state is deleted by the virtual interface owner, the virtual interface will enter the ‘Rejected’ state.

- **customerRouterConfig** *(string)* –
  Information for generating the customer router configuration.

- **virtualGatewayId** *(string)* –
  The ID of the virtual private gateway to a VPC. This only applies to private virtual interfaces.
  Example: vgw-123er56

- **routeFilterPrefixes** *(list)* –
  A list of routes to be advertised to the AWS network in this region (public virtual interface) or your VPC (private virtual interface).
  *(dict)* –
  A route filter prefix that the customer can advertise through Border Gateway Protocol (BGP) over a public virtual interface.
  · **cidr** *(string)* –
    CIDR notation for the advertised route. Multiple routes are separated by commas.
  Example: 10.10.10.0/24,10.10.11.0/24
can_paginate( operation_name )
    Check if an operation can be paginated.
    Parameters operation_name ( string ) – The operation name. This is the same name as
    the method name on the client. For example, if the method name is create_foo,
    and you’d normally invoke the operation as client.create_foo(**kwargs),
    if the create_foo operation can be paginated, you can use the call
    client.get Paginator(“create_foo”).
    Returns True if the operation can be paginated, False otherwise.

confirm_connection( **kwargs )
    Confirm the creation of a hosted connection on an interconnect.
    Upon creation, the hosted connection is initially in the ‘Ordering’ state, and will remain in this state until
    the owner calls ConfirmConnection to confirm creation of the hosted connection.

    Request Syntax
    response = client.confirm_connection( 
        connectionId=’string’
    )

    Parameters connectionId ( string ) – [REQUIRED]
    ID of the connection.
    Example: dxcon-fg5678gh
    Default: None
    Returns

    Response Syntax
    {
        ‘connectionState’: ‘ordering’|’requested’|’pending’|’available’|’down’|’deleted’
    }

    Response Structure
    • (dict) –
        The response received when ConfirmConnection is called.
        – connectionState ( string ) – State of the connection.
            * Ordering : The initial state of a hosted connection provisioned on
                an interconnect. The connection stays in the ordering state until the
                owner of the hosted connection confirms or declines the connection
                order.
            * Requested : The initial state of a standard connection. The con-
                nection stays in the requested state until the Letter of Authorization
                (LOA) is sent to the customer.
            * Pending : The connection has been approved, and is being initial-
                ized.
            * Available : The network link is up, and the connection is ready for
                use.
            * Down : The network link is down.
            * Deleted : The connection has been deleted.
            * Rejected : A hosted connection in the ‘Ordering’ state will enter
                the ‘Rejected’ state if it is deleted by the end customer.
**confirm_private_virtual_interface(**kwargs**)

Accept ownership of a private virtual interface created by another customer.

After the virtual interface owner calls this function, the virtual interface will be created and attached to
the given virtual private gateway, and will be available for handling traffic.

**Request Syntax**

```python
response = client.confirm_private_virtual_interface(
    virtualInterfaceId='string',
    virtualGatewayId='string'
)
```

**Parameters**

- **virtualInterfaceId** *(string)* – [REQUIRED]
  
  ID of the virtual interface.
  
  Example: dxvif-123dfg56
  
  Default: None

- **virtualGatewayId** *(string)* – [REQUIRED]
  
  ID of the virtual private gateway that will be attached to the virtual interface.
  
  A virtual private gateway can be managed via the Amazon Virtual Private Cloud (VPC) console or the EC2 CreateVpnGateway action.
  
  Default: None

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'virtualInterfaceState': 'confirming'|'verifying'|'pending'|'available'|'deleting'|'deleted'|'rejected'
}
```

**Response Structure**

- *(dict)* –

  The response received when ConfirmPrivateVirtualInterface is called.

  - **virtualInterfaceState** *(string)* – State of the virtual interface.
    
    - **Confirming** : The creation of the virtual interface is pending confirmation from the virtual interface owner. If the owner of the virtual interface is different from the owner of the connection on which it is provisioned, then the virtual interface will remain in this state until it is confirmed by the virtual interface owner.
    
    - **Verifying** : This state only applies to public virtual interfaces. Each public virtual interface needs validation before the virtual interface can be created.
    
    - **Pending** : A virtual interface is in this state from the time that it is created until the virtual interface is ready to forward traffic.
    
    - **Available** : A virtual interface that is able to forward traffic.
    
    - **Deleting** : A virtual interface in this state immediately after calling DeleteVirtualInterface until it can no longer forward traffic.
    
    - **Deleted** : A virtual interface that cannot forward traffic.
    
    - **Rejected** : The virtual interface owner has declined creation of the virtual interface. If a virtual interface in the ‘Confirming’ state is
deleted by the virtual interface owner, the virtual interface will enter the ‘Rejected’ state.

**confirm_public_virtual_interface** (**kwargs**)

Accept ownership of a public virtual interface created by another customer.

After the virtual interface owner calls this function, the specified virtual interface will be created and made available for handling traffic.

**Request Syntax**

```python
response = client.confirm_public_virtual_interface(
    virtualInterfaceId='string'
)
```

**Parameters**

- **virtualInterfaceId** (*string*) – [REQUIRED]
  
  ID of the virtual interface.

  Example: dxvif-123dfg56

  Default: None

**Return type**

- **dict**

**Returns**

**Response Syntax**

```python
{
    'virtualInterfaceState': 'confirming'|'verifying'|'pending'|'available'|'deleting'|'deleted'|'rejected'
}
```

**Response Structure**

- *(dict)* –
  
  The response received when ConfirmPublicVirtualInterface is called.

  - **virtualInterfaceState** (*string*) – State of the virtual interface.
    
    - **Confirming**: The creation of the virtual interface is pending confirmation from the virtual interface owner. If the owner of the virtual interface is different from the owner of the connection on which it is provisioned, then the virtual interface will remain in this state until it is confirmed by the virtual interface owner.
    
    - **Verifying**: This state only applies to public virtual interfaces. Each public virtual interface needs validation before the virtual interface can be created.
    
    - **Pending**: A virtual interface is in this state from the time that it is created until the virtual interface is ready to forward traffic.
    
    - **Available**: A virtual interface that is able to forward traffic.
    
    - **Deleting**: A virtual interface is in this state immediately after calling `DeleteVirtualInterface` until it can no longer forward traffic.
    
    - **Deleted**: A virtual interface that cannot forward traffic.
    
    - **Rejected**: The virtual interface owner has declined creation of the virtual interface. If a virtual interface in the ‘Confirming’ state is deleted by the virtual interface owner, the virtual interface will enter the ‘Rejected’ state.

**create_connection** (**kwargs**)

Creates a new connection between the customer network and a specific AWS Direct Connect location.

A connection links your internal network to an AWS Direct Connect location over a standard 1 gigabit or 10 gigabit Ethernet fiber-optic cable. One end of the cable is connected to your router, the other to an
AWS Direct Connect router. An AWS Direct Connect location provides access to Amazon Web Services in the region it is associated with. You can establish connections with AWS Direct Connect locations in multiple regions, but a connection in one region does not provide connectivity to other regions.

Request Syntax

```python
response = client.create_connection(
    location='string',
    bandwidth='string',
    connectionName='string'
)
```

Parameters

- **location** *(string)* – [REQUIRED]
  
  Where the connection is located.
  
  Example: EqSV5
  
  Default: None
- **bandwidth** *(string)* – [REQUIRED]
  
  Bandwidth of the connection.
  
  Example: 1Gbps
  
  Default: None
- **connectionName** *(string)* – [REQUIRED]
  
  The name of the connection.
  
  Example: “My Connection to AWS”
  
  Default: None

Return type  dict

Returns

Response Syntax

```python
{
    'ownerAccount': 'string',
    'connectionId': 'string',
    'connectionName': 'string',
    'connectionState': 'ordering'|'requested'|'pending'|'available'|'down'|'deleting'|'deleted'|'rejected',
    'region': 'string',
    'location': 'string',
    'bandwidth': 'string',
    'vlan': 123,
    'partnerName': 'string'
}
```

Response Structure

- *(dict)* –

  A connection represents the physical network connection between the AWS Direct Connect location and the customer.
  
  - **ownerAccount** *(string)* –
  
  - **connectionId** *(string)* –

    ID of the connection.

    Example: dxcon-fg5678gh
**create_interconnect** (**kwargs)**

Creates a new interconnect between a AWS Direct Connect partner’s network and a specific AWS Direct Connect location.

An interconnect is a connection which is capable of hosting other connections. The AWS Direct Connect partner can use an interconnect to provide sub-1Gbps AWS Direct Connect service to tier 2 customers who do not have their own connections. Like a standard connection, an interconnect links the AWS Direct Connect partner’s network to an AWS Direct Connect location over a standard 1 Gbps or 10 Gbps bandwidth.
Ethernet fiber-optic cable. One end is connected to the partner’s router, the other to an AWS Direct Connect router.

For each end customer, the AWS Direct Connect partner provisions a connection on their interconnect by calling AllocateConnectionOnInterconnect. The end customer can then connect to AWS resources by creating a virtual interface on their connection, using the VLAN assigned to them by the AWS Direct Connect partner.

**Request Syntax**

```python
response = client.create_interconnect(
    interconnectName='string',
    bandwidth='string',
    location='string'
)
```

**Parameters**

- **interconnectName (string)** – [REQUIRED]
  The name of the interconnect.
  Example: “1G Interconnect to AWS”
  Default: None
- **bandwidth (string)** – [REQUIRED]
  The port bandwidth
  Example: 1Gbps
  Default: None
  Available values: 1Gbps, 10Gbps
- **location (string)** – [REQUIRED]
  Where the interconnect is located
  Example: EqSV5
  Default: None

**Return type**  dict

**Returns**

**Response Syntax**

```json
{
    'interconnectId': 'string',
    'interconnectName': 'string',
    'interconnectState': 'requested' | 'pending' | 'available' | 'down' | 'deleting' | 'deleted',
    'region': 'string',
    'location': 'string',
    'bandwidth': 'string'
}
```

**Response Structure**

- *(dict)* –

  An interconnect is a connection that can host other connections.

  Like a standard AWS Direct Connect connection, an interconnect represents the physical connection between an AWS Direct Connect partner’s network and a specific Direct Connect location. An AWS Direct Connect partner who owns an interconnect can provision hosted connections on the interconnect for their
end customers, thereby providing the end customers with connectivity to AWS services.

The resources of the interconnect, including bandwidth and VLAN numbers, are shared by all of the hosted connections on the interconnect, and the owner of the interconnect determines how these resources are assigned.

- **interconnectId (string)** –
  The ID of the interconnect.
  Example: dxcon-abc123

- **interconnectName (string)** –
  The name of the interconnect.
  Example: “1G Interconnect to AWS”

- **interconnectState (string)** – State of the interconnect.
  * Requested: The initial state of an interconnect. The interconnect stays in the requested state until the Letter of Authorization (LOA) is sent to the customer.
  * Pending: The interconnect has been approved, and is being initialized.
  * Available: The network link is up, and the interconnect is ready for use.
  * Down: The network link is down.
  * Deleted: The interconnect has been deleted.

- **region (string)** –
  The AWS region where the connection is located.
  Example: us-east-1
  Default: None

- **location (string)** –
  Where the connection is located.
  Example: EqSV5
  Default: None

- **bandwidth (string)** –
  Bandwidth of the connection.
  Example: 1Gbps
  Default: None

**create_private_virtual_interface(**kwargs)**

Creates a new private virtual interface. A virtual interface is the VLAN that transports AWS Direct Connect traffic. A private virtual interface supports sending traffic to a single virtual private cloud (VPC).

**Request Syntax**

```python
response = client.create_private_virtual_interface(
    connectionId='string',
    newPrivateVirtualInterface={
        'virtualInterfaceName': 'string',
        'vlan': 123,
        'asn': 123,
        'authKey': 'string',
        'amazonAddress': 'string',
```

Parameters

- **connectionId** *(string)* – [REQUIRED]
  
  ID of the connection.
  
  Example: dxcon-fg5678gh
  
  Default: None

- **newPrivateVirtualInterface** *(dict)* – [REQUIRED]
  
  Detailed information for the private virtual interface to be created.
  
  Default: None
  
  - **virtualInterfaceName** *(string)* – [REQUIRED]
    
    The name of the virtual interface assigned by the customer.
    
    Example: “My VPC”
  
  - **vlan** *(integer)* – [REQUIRED]
    
    The VLAN ID.
    
    Example: 101
  
  - **asn** *(integer)* – [REQUIRED]
    
    Autonomous system (AS) number for Border Gateway Protocol (BGP) configuration.
    
    Example: 65000
  
  - **authKey** *(string)* –
    
    Authentication key for BGP configuration.
    
    Example: asdf34example
  
  - **amazonAddress** *(string)* –
    
    IP address assigned to the Amazon interface.
    
    Example: 192.168.1.1/30
  
  - **customerAddress** *(string)* –
    
    IP address assigned to the customer interface.
    
    Example: 192.168.1.2/30
  
  - **virtualGatewayId** *(string)* – [REQUIRED]
    
    The ID of the virtual private gateway to a VPC. This only applies to private virtual interfaces.
    
    Example: vgw-123er56

**Return type**  

dict

**Returns**

**Response Syntax**

```python
{
    'ownerAccount': 'string',
    'virtualInterfaceId': 'string',
    'location': 'string',
}
```
'connectionId': 'string',
'virtualInterfaceType': 'string',
'virtualInterfaceName': 'string',
'vlan': 123,
'asn': 123,
'authKey': 'string',
'amazonAddress': 'string',
'customerAddress': 'string',
'virtualInterfaceState': 'confirming'|'verifying'|'pending'|'available'|'deleting'|'deleted'|'rejected',
'customerRouterConfig': 'string',
'virtualGatewayId': 'string',
'routeFilterPrefixes': [
  {
    'cidr': 'string'
  },
]
)

Response Structure

- (dict) –

A virtual interface (VLAN) transmits the traffic between the AWS Direct Connect location and the customer:

  - ownerAccount (string) –
  - virtualInterfaceId (string) –
    ID of the virtual interface.
    Example: dxvif-123dfg56
    Default: None
  - location (string) –
    Where the connection is located.
    Example: EqSV5
    Default: None
  - connectionId (string) –
    ID of the connection.
    Example: dxcon-kg5678gh
    Default: None
  - virtualInterfaceType (string) –
    The type of virtual interface.
    Example: private (Amazon VPC) or public (Amazon S3, Amazon DynamoDB, and so on.)
  - virtualInterfaceName (string) –
    The name of the virtual interface assigned by the customer.
    Example: “My VPC”
  - vlan (integer) –
    The VLAN ID.
    Example: 101
  - asn (integer) –
Autonomous system (AS) number for Border Gateway Protocol (BGP) configuration.
Example: 65000

- **authKey** *(string)*
  Authentication key for BGP configuration.
  Example: asdf34example

- **amazonAddress** *(string)*
  IP address assigned to the Amazon interface.
  Example: 192.168.1.1/30

- **customerAddress** *(string)*
  IP address assigned to the customer interface.
  Example: 192.168.1.2/30

- **virtualInterfaceState** *(string)* – State of the virtual interface.
  * **Confirming**: The creation of the virtual interface is pending confirmation from the virtual interface owner. If the owner of the virtual interface is different from the owner of the connection on which it is provisioned, then the virtual interface will remain in this state until it is confirmed by the virtual interface owner.
  * **Verifying**: This state only applies to public virtual interfaces. Each public virtual interface needs validation before the virtual interface can be created.
  * **Pending**: A virtual interface is in this state from the time that it is created until the virtual interface is ready to forward traffic.
  * **Available**: A virtual interface that is able to forward traffic.
  * **Deleting**: A virtual interface is in this state immediately after calling `DeleteVirtualInterface` until it can no longer forward traffic.
  * **Deleted**: A virtual interface that cannot forward traffic.
  * **Rejected**: The virtual interface owner has declined creation of the virtual interface. If a virtual interface in the ‘Confirming’ state is deleted by the virtual interface owner, the virtual interface will enter the ‘Rejected’ state.

- **customerRouterConfig** *(string)*
  Information for generating the customer router configuration.

- **virtualGatewayId** *(string)*
  The ID of the virtual private gateway to a VPC. This only applies to private virtual interfaces.
  Example: vgw-123er56

- **routeFilterPrefixes** *(list)*
  A list of routes to be advertised to the AWS network in this region (public virtual interface) or your VPC (private virtual interface).
  
  * *(dict)*
    A route filter prefix that the customer can advertise through Border Gateway Protocol (BGP) over a public virtual interface.
    
    - **cidr** *(string)*
      CIDR notation for the advertised route. Multiple routes are separated by commas.
      Example: 10.10.10.0/24,10.10.11.0/24
create_public_virtual_interface(**kwargs)

Creates a new public virtual interface. A virtual interface is the VLAN that transports AWS Direct Connect traffic. A public virtual interface supports sending traffic to public services of AWS such as Amazon Simple Storage Service (Amazon S3).

Request Syntax

```python
response = client.create_public_virtual_interface(
    connectionId='string',
    newPublicVirtualInterface={
        'virtualInterfaceName': 'string',
        'vlan': 123,
        'asn': 123,
        'authKey': 'string',
        'amazonAddress': 'string',
        'customerAddress': 'string',
        'routeFilterPrefixes': [
            {
                'cidr': 'string'
            }
        ]
    }
)
```

Parameters

- **connectionId** (string) – [REQUIRED]
  
  ID of the connection.
  
  Example: dxcon-fg5678gh
  
  Default: None

- **newPublicVirtualInterface** (dict) – [REQUIRED]
  
  Detailed information for the public virtual interface to be created.
  
  Default: None

  - **virtualInterfaceName** (string) – [REQUIRED]
    
    The name of the virtual interface assigned by the customer.
    
    Example: “My VPC”

  - **vlan** (integer) – [REQUIRED]
    
    The VLAN ID.
    
    Example: 101

  - **asn** (integer) – [REQUIRED]
    
    Autonomous system (AS) number for Border Gateway Protocol (BGP) configuration.
    
    Example: 65000

  - **authKey** (string) –
    
    Authentication key for BGP configuration.
    
    Example: asdf34example

  - **amazonAddress** (string) – [REQUIRED]
    
    IP address assigned to the Amazon interface.
    
    Example: 192.168.1.1/30
– **customerAddress (string)** – [REQUIRED]
  IP address assigned to the customer interface.
  Example: 192.168.1.2/30

– **routeFilterPrefixes (list)** – [REQUIRED]
  A list of routes to be advertised to the AWS network in this region (public virtual interface) or your VPC (private virtual interface).
  *
  **(dict)** –
  A route filter prefix that the customer can advertise through Border Gateway Protocol (BGP) over a public virtual interface.
  · **cidr (string)** –
    CIDR notation for the advertised route. Multiple routes are separated by commas.
    Example: 10.10.10.0/24, 10.10.11.0/24

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'ownerAccount': 'string',
    'virtualInterfaceId': 'string',
    'location': 'string',
    'connectionId': 'string',
    'virtualInterfaceType': 'string',
    'virtualInterfaceName': 'string',
    'vlan': 123,
    'asn': 123,
    'authKey': 'string',
    'amazonAddress': 'string',
    'customerAddress': 'string',
    'virtualInterfaceState': 'confirming'|'verifying'|'pending'|'available'|'deleting'|'deleted'|'rejected',
    'customerRouterConfig': 'string',
    'virtualGatewayId': 'string',
    'routeFilterPrefixes': [
        {
            'cidr': 'string'
        }
    ]
}
```

**Response Structure**

* **(dict)** –
  A virtual interface (VLAN) transmits the traffic between the AWS Direct Connect location and the customer.
  – **ownerAccount (string)** –
  – **virtualInterfaceId (string)** –
    ID of the virtual interface.
    Example: dxvif-123dfg56
    Default: None
  – **location (string)** –
    Where the connection is located.
Example: EqSV5

Default: None

- **connectionId (string)** –

  ID of the connection.

  Example: dxcon-fg5678gh

  Default: None

- **virtualInterfaceType (string)** –

  The type of virtual interface.

  Example: private (Amazon VPC) or public (Amazon S3, Amazon DynamoDB, and so on.)

- **virtualInterfaceName (string)** –

  The name of the virtual interface assigned by the customer.

  Example: “My VPC”

- **vlan (integer)** –

  The VLAN ID.

  Example: 101

- **asn (integer)** –

  Autonomous system (AS) number for Border Gateway Protocol (BGP) configuration.

  Example: 65000

- **authKey (string)** –

  Authentication key for BGP configuration.

  Example: asdf34example

- **amazonAddress (string)** –

  IP address assigned to the Amazon interface.

  Example: 192.168.1.1/30

- **customerAddress (string)** –

  IP address assigned to the customer interface.

  Example: 192.168.1.2/30

- **virtualInterfaceState (string)** – State of the virtual interface.
  
  - **Confirming** : The creation of the virtual interface is pending confirmation from the virtual interface owner. If the owner of the virtual interface is different from the owner of the connection on which it is provisioned, then the virtual interface will remain in this state until it is confirmed by the virtual interface owner.
  
  - **Verifying** : This state only applies to public virtual interfaces. Each public virtual interface needs validation before the virtual interface can be created.
  
  - **Pending** : A virtual interface is in this state from the time that it is created until the virtual interface is ready to forward traffic.
  
  - **Available** : A virtual interface that is able to forward traffic.
  
  - **Deleting** : A virtual interface is in this state immediately after calling `DeleteVirtualInterface` until it can no longer forward traffic.
  
  - **Deleted** : A virtual interface that cannot forward traffic.
* **Rejected**: The virtual interface owner has declined creation of the virtual interface. If a virtual interface in the ‘Confirming’ state is deleted by the virtual interface owner, the virtual interface will enter the ‘Rejected’ state.

- **customerRouterConfig**(string) –
  Information for generating the customer router configuration.

- **virtualGatewayId**(string) –
  The ID of the virtual private gateway to a VPC. This only applies to private virtual interfaces.
  Example: vgw-123er56

- **routeFilterPrefixes**(list) –
  A list of routes to be advertised to the AWS network in this region (public virtual interface) or your VPC (private virtual interface).
  * (dict) –
    A route filter prefix that the customer can advertise through Border Gateway Protocol (BGP) over a public virtual interface.
    - **cidr**(string) –
      CIDR notation for the advertised route. Multiple routes are separated by commas.
      Example: 10.10.10.0/24,10.10.11.0/24

**delete_connection**(**kwargs**)  
Deletes the connection.

Deleting a connection only stops the AWS Direct Connect port hour and data transfer charges. You need to cancel separately with the providers any services or charges for cross-connects or network circuits that connect you to the AWS Direct Connect location.

**Request Syntax**

```python
response = client.delete_connection(
    connectionId='string'
)
```

**Parameters** **connectionId**(string) – [REQUIRED]

ID of the connection.

Example: dxcon-fg5678gh

Default: None

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'ownerAccount': 'string',
    'connectionId': 'string',
    'connectionName': 'string',
    'connectionState': 'ordering'|'requested'|'pending'|'available'|'down'|'deleting'|'deleted'|'rejected',
    'region': 'string',
    'location': 'string',
    'bandwidth': 'string',
    'vlan': 123,
}
```
'partnerName': 'string'
}

**Response Structure**

- (dict) –

  A connection represents the physical network connection between the AWS Direct Connect location and the customer.

  - **ownerAccount** *(string)* –

  - **connectionId** *(string)* –

    ID of the connection.

    Example: dxcon-fg5678gh

    Default: None

  - **connectionName** *(string)* –

    The name of the connection.

    Example: “My Connection to AWS”

    Default: None

  - **connectionState** *(string)* – State of the connection.

    * **Ordering**: The initial state of a hosted connection provisioned on an interconnect. The connection stays in the ordering state until the owner of the hosted connection confirms or declines the connection order.

    * **Requested**: The initial state of a standard connection. The connection stays in the requested state until the Letter of Authorization (LOA) is sent to the customer.

    * **Pending**: The connection has been approved, and is being initialized.

    * **Available**: The network link is up, and the connection is ready for use.

    * **Down**: The network link is down.

    * **Deleted**: The connection has been deleted.

    * **Rejected**: A hosted connection in the ‘Ordering’ state will enter the ‘Rejected’ state if it is deleted by the end customer.

  - **region** *(string)* –

    The AWS region where the connection is located.

    Example: us-east-1

    Default: None

  - **location** *(string)* –

    Where the connection is located.

    Example: EqSV5

    Default: None

  - **bandwidth** *(string)* –

    Bandwidth of the connection.

    Example: 1Gbps (for regular connections), or 500Mbps (for hosted connections)

    Default: None
– **vlan** *(integer)* –
  The VLAN ID.
  Example: 101

– **partnerName** *(string)* –

### delete_interconnect(**kwargs)**
Deletes the specified interconnect.

#### Request Syntax
```
response = client.delete_interconnect(
    interconnectId='string'
)
```

#### Parameters
- **interconnectId** *(string)* – [REQUIRED]
  The ID of the interconnect.
  Example: dxcon-abc123

#### Return type
- dict

#### Returns
- Response Syntax
```
{  
    'interconnectState': 'requested'|'pending'|'available'|'down'|'deleting'|'deleted'
}
```

#### Response Structure
- *(dict)* –
  The response received when DeleteInterconnect is called.
- **interconnectState** *(string)* – State of the interconnect.
  - **Requested** : The initial state of an interconnect. The interconnect stays in the requested state until the Letter of Authorization (LOA) is sent to the customer.
  - **Pending** : The interconnect has been approved, and is being initialized.
  - **Available** : The network link is up, and the interconnect is ready for use.
  - **Down** : The network link is down.
  - **Deleted** : The interconnect has been deleted.

### delete_virtual_interface(**kwargs)**
Deletes a virtual interface.

#### Request Syntax
```
response = client.delete_virtual_interface(
    virtualInterfaceId='string'
)
```

#### Parameters
- **virtualInterfaceId** *(string)* – [REQUIRED]
  ID of the virtual interface.
  Example: dxvif-123dfg56
  Default: None
Return type  dict

Returns

Response Syntax

```
{
    'virtualInterfaceState': 'confirming'|'verifying'|'pending'|'available'|'deleting'|'deleted'|'rejected'
}
```

Response Structure

- (dict) –
  
The response received when DeleteVirtualInterface is called.

  - virtualInterfaceState (string) – State of the virtual interface.
    
    * Confirming: The creation of the virtual interface is pending confirmation from the virtual interface owner. If the owner of the virtual interface is different from the owner of the connection on which it is provisioned, then the virtual interface will remain in this state until it is confirmed by the virtual interface owner.
    
    * Verifying: This state only applies to public virtual interfaces. Each public virtual interface needs validation before the virtual interface can be created.
    
    * Pending: A virtual interface is in this state from the time that it is created until the virtual interface is ready to forward traffic.
    
    * Available: A virtual interface that is able to forward traffic.
    
    * Deleting: A virtual interface is in this state immediately after calling DeleteVirtualInterface until it can no longer forward traffic.
    
    * Deleted: A virtual interface that cannot forward traffic.
    
    * Rejected: The virtual interface owner has declined creation of the virtual interface. If a virtual interface in the 'Confirming' state is deleted by the virtual interface owner, the virtual interface will enter the 'Rejected' state.

**describe_connections(**kwargs?)**

Displays all connections in this region.

If a connection ID is provided, the call returns only that particular connection.

Request Syntax

```
response = client.describe_connections(
    connectionId='string'
)
```

Parameters

- connectionId (string) – ID of the connection.

  Example: dxcon-fg5678gh

  Default: None

Return type  dict

Returns

Response Syntax

```
{
    'connections': [
        {
            'ownerAccount': 'string',
            'connectionId': 'string',
            ...
        }
    ]
}
```
Response Structure

- **(dict)** –
  A structure containing a list of connections.
  - **connections (list)** –
    A list of connections.
    - **(dict)** –
      A connection represents the physical network connection between the AWS Direct Connect location and the customer.
      - **ownerAccount (string)** –
      - **connectionId (string)** –
        ID of the connection.
        Example: dxcon-fg5678gh
        Default: None
      - **connectionName (string)** –
        The name of the connection.
        Example: “My Connection to AWS “
        Default: None
      - **connectionState (string)** – State of the connection.
      - **Ordering** : The initial state of a hosted connection provisioned on an interconnect. The connection stays in the ordering state until the owner of the hosted connection confirms or declines the connection order.
      - **Requested** : The initial state of a standard connection. The connection stays in the requested state until the Letter of Authorization (LOA) is sent to the customer.
      - **Pending** : The connection has been approved, and is being initialized.
      - **Available** : The network link is up, and the connection is ready for use.
      - **Down** : The network link is down.
      - **Deleted** : The connection has been deleted.
      - **Rejected** : A hosted connection in the ‘Ordering’ state will enter the ‘Rejected’ state if it is deleted by the end customer.
      - **region (string)** –
        The AWS region where the connection is located.
        Example: us-east-1
        Default: None
· **location** *(string)* –
  Where the connection is located.
  Example: EqSV5
  Default: None

· **bandwidth** *(string)* –
  Bandwidth of the connection.
  Example: 1Gbps (for regular connections), or 500Mbps (for hosted connections)
  Default: None

· **vlan** *(integer)* –
  The VLAN ID.
  Example: 101

· **partnerName** *(string)* –

**describe_connections_on_interconnect** (**kwargs**)
Return a list of connections that have been provisioned on the given interconnect.

**Request Syntax**
```python
response = client.describe_connections_on_interconnect(
    interconnectId='string'
)
```

**Parameters**

**interconnectId** *(string)* – [REQUIRED]
ID of the interconnect on which a list of connection is provisioned.
Example: dxcon-abc123
Default: None

**Return type**
`dict`

**Returns**

**Response Syntax**
```python
{
    'connections': [
        {
            'ownerAccount': 'string',
            'connectionId': 'string',
            'connectionName': 'string',
            'connectionState': 'ordering'|'requested'|'pending'|'available'|'down'|'deleting'|'deleted'|'rejected',
            'region': 'string',
            'location': 'string',
            'bandwidth': 'string',
            'vlan': 123,
            'partnerName': 'string'
        },
    ],
}
```

**Response Structure**

· *(dict)* –
A structure containing a list of connections.
– **connections** *(list)* –

A list of connections.

* *(dict)* –

A connection represents the physical network connection between the AWS Direct Connect location and the customer.

- **ownerAccount** *(string)* –
- **connectionId** *(string)* –

ID of the connection.

Example: dxcon-fg5678gh

Default: None

- **connectionName** *(string)* –

The name of the connection.

Example: “My Connection to AWS “

Default: None

- **connectionState** *(string)* – State of the connection.
- **Ordering**: The initial state of a hosted connection provisioned on an interconnect. The connection stays in the ordering state until the owner of the hosted connection confirms or declines the connection order.
- **Requested**: The initial state of a standard connection. The connection stays in the requested state until the Letter of Authorization (LOA) is sent to the customer.
- **Pending**: The connection has been approved, and is being initialized.
- **Available**: The network link is up, and the connection is ready for use.
- **Down**: The network link is down.
- **Deleted**: The connection has been deleted.
- **Rejected**: A hosted connection in the ‘Ordering’ state will enter the ‘Rejected’ state if it is deleted by the end customer.

- **region** *(string)* –

The AWS region where the connection is located.

Example: us-east-1

Default: None

- **location** *(string)* –

Where the connection is located.

Example: EqSV5

Default: None

- **bandwidth** *(string)* –

Bandwidth of the connection.

Example: 1Gbps (for regular connections), or 500Mbps (for hosted connections)

Default: None

- **vlan** *(integer)* –

The VLAN ID.
Example: 101
· **partnerName** *(string)* –

```python
describe_interconnects(**kwargs)
```

Returns a list of interconnects owned by the AWS account.

If an interconnect ID is provided, it will only return this particular interconnect.

**Request Syntax**

```python
response = client.describe_interconnects(
    interconnectId='string'
)
```

**Parameters**

- **interconnectId** *(string)* – The ID of the interconnect.

  Example: dxcon-abc123

**Return type**

- **dict**

**Response Syntax**

```python
{
    'interconnects': [
        {
            'interconnectId': 'string',
            'interconnectName': 'string',
            'interconnectState': 'requested'|'pending'|'available'|'down'|'deleting',
            'region': 'string',
            'location': 'string',
            'bandwidth': 'string'
        },
    ]
}
```

**Response Structure**

- *(dict)* –

  A structure containing a list of interconnects.

  - **interconnects** *(list)* –

    A list of interconnects.

    - *(dict)* –

      An interconnect is a connection that can host other connections.

      Like a standard AWS Direct Connect connection, an interconnect represents the physical connection between an AWS Direct Connect partner's network and a specific Direct Connect location. An AWS Direct Connect partner who owns an interconnect can provision hosted connections on the interconnect for their end customers, thereby providing the end customers with connectivity to AWS services.

      The resources of the interconnect, including bandwidth and VLAN numbers, are shared by all of the hosted connections on the interconnect, and the owner of the interconnect determines how these resources are assigned.

      - **interconnectId** *(string)* –

        The ID of the interconnect.
Example: dxcon-abc123

- **interconnectName** *(string)* – The name of the interconnect.

  Example: “1G Interconnect to AWS”

- **interconnectState** *(string)* – State of the interconnect.

  - **Requested**: The initial state of an interconnect. The interconnect stays in the requested state until the Letter of Authorization (LOA) is sent to the customer.
  - **Pending**: The interconnect has been approved, and is being initialized.
  - **Available**: The network link is up, and the interconnect is ready for use.
  - **Down**: The network link is down.
  - **Deleted**: The interconnect has been deleted.

- **region** *(string)* – The AWS region where the connection is located.

  Example: us-east-1

  Default: None

- **location** *(string)* – Where the connection is located.

  Example: EqSV5

  Default: None

- **bandwidth** *(string)* – Bandwidth of the connection.

  Example: 1Gbps

  Default: None

### describe_locations()

Returns the list of AWS Direct Connect locations in the current AWS region. These are the locations that may be selected when calling CreateConnection or CreateInterconnect.

#### Request Syntax

```python
response = client.describe_locations()
```

#### Return type
dict

#### Returns

**Response Syntax**

```python
{
    'locations': [
        {
            'locationCode': 'string',
            'locationName': 'string'
        },
    ]
}
```

#### Response Structure

- **(dict)** –
An AWS Direct Connect location where connections and interconnects can be requested.

- **locationCode** *(string)* –
  The code used to indicate the AWS Direct Connect location.

- **locationName** *(string)* –
  The name of the AWS Direct Connect location. The name includes the colocation partner name and the physical site of the lit building.

### describe_virtual_gateways()

Returns a list of virtual private gateways owned by the AWS account.

You can create one or more AWS Direct Connect private virtual interfaces linking to a virtual private gateway. A virtual private gateway can be managed via Amazon Virtual Private Cloud (VPC) console or the EC2 CreateVpnGateway action.

#### Request Syntax

```python
response = client.describe_virtual_gateways()
```

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'virtualGateways': [
        {
            'virtualGatewayId': 'string',
            'virtualGatewayState': 'string'
        },
    ]
}
```

**Response Structure**

- **(dict)* –
  A structure containing a list of virtual private gateways.
  
  - **virtualGateways** *(list)* –
    A list of virtual private gateways.
    
    - **(dict)* –
      You can create one or more AWS Direct Connect private virtual interfaces linking to your virtual private gateway.

      Virtual private gateways can be managed using the Amazon Virtual Private Cloud (Amazon VPC) console or the Amazon EC2 CreateVpnGateway action.

      - **virtualGatewayId** *(string)* –
        The ID of the virtual private gateway to a VPC. This only applies to private virtual interfaces.

        Example: vgw-123er56
virtualGatewayState (string) – State of the virtual private gateway.
- Pending: This is the initial state after calling CreateVpnGateway.
- Available: Ready for use by a private virtual interface.
- Deleting: This is the initial state after calling DeleteVpnGateway.
- Deleted: In this state, a private virtual interface is unable to send traffic over this gateway.

describe_virtual_interfaces(**kwargs)
Displays all virtual interfaces for an AWS account. Virtual interfaces deleted fewer than 15 minutes before DescribeVirtualInterfaces is called are also returned. If a connection ID is included then only virtual interfaces associated with this connection will be returned. If a virtual interface ID is included then only a single virtual interface will be returned.

A virtual interface (VLAN) transmits the traffic between the AWS Direct Connect location and the customer.

If a connection ID is provided, only virtual interfaces provisioned on the specified connection will be returned. If a virtual interface ID is provided, only this particular virtual interface will be returned.

Request Syntax

response = client.describe_virtual_interfaces(
    connectionId='string',
    virtualInterfaceId='string'
)

Parameters
- connectionId (string) – ID of the connection.
  Example: dxcon-fg5678gh
  Default: None
- virtualInterfaceId (string) – ID of the virtual interface.
  Example: dxvif-123dfg56
  Default: None

Return type dict

Returns

Response Syntax

{
    'virtualInterfaces': [
        {
            'ownerAccount': 'string',
            'virtualInterfaceId': 'string',
            'location': 'string',
            'connectionId': 'string',
            'virtualInterfaceType': 'string',
            'virtualInterfaceName': 'string',
            'vlan': 123,
            'asn': 123,
            'authKey': 'string',
            'amazonAddress': 'string',
            'customerAddress': 'string',
            'virtualInterfaceState': 'confirming'|'verifying'|'pending'|'available'
        }
    ]
}
'customerRouterConfig': 'string',
'virtualGatewayId': 'string',
'routeFilterPrefixes': [
    {'cidr': 'string'}
],
}
}

Response Structure

• (dict) –

A structure containing a list of virtual interfaces.
  – virtualInterfaces (list) –

A list of virtual interfaces.
  • (dict) –

A virtual interface (VLAN) transmits the traffic between the AWS Direct Connect location and the customer.
  • ownerAccount (string) –
  • virtualInterfaceId (string) –

ID of the virtual interface.
Example: dxvif-123dfg56
Default: None
  • location (string) –

Where the connection is located.
Example: EqSV5
Default: None
  • connectionId (string) –

ID of the connection.
Example: dxcon-fg5678gh
Default: None
  • virtualInterfaceType (string) –

The type of virtual interface.
Example: private (Amazon VPC) or public (Amazon S3, Amazon DynamoDB, and so on.)
  • virtualInterfaceName (string) –

The name of the virtual interface assigned by the customer.
Example: “My VPC”
  • vlan (integer) –

The VLAN ID.
Example: 101
  • asn (integer) –

Autonomous system (AS) number for Border Gateway Protocol (BGP) configuration.
Example: 65000
- **authKey** *(string)* –
  
  Authentication key for BGP configuration.
  
  Example: asdf34example
- **amazonAddress** *(string)* –
  
  IP address assigned to the Amazon interface.
  
  Example: 192.168.1.1/30
- **customerAddress** *(string)* –
  
  IP address assigned to the customer interface.
  
  Example: 192.168.1.2/30
- **virtualInterfaceState** *(string)* – State of the virtual interface.
  
  - **Confirming** : The creation of the virtual interface is pending confirmation from the virtual interface owner. If the owner of the virtual interface is different from the owner of the connection on which it is provisioned, then the virtual interface will remain in this state until it is confirmed by the virtual interface owner.
  
  - **Verifying** : This state only applies to public virtual interfaces. Each public virtual interface needs validation before the virtual interface can be created.
  
  - **Pending** : A virtual interface is in this state from the time that it is created until the virtual interface is ready to forward traffic.
  
  - **Available** : A virtual interface that is able to forward traffic.
  
  - **Deleting** : A virtual interface is in this state immediately after calling `DeleteVirtualInterface` until it can no longer forward traffic.
  
  - **Deleted** : A virtual interface that cannot forward traffic.
  
  - **Rejected** : The virtual interface owner has declined creation of the virtual interface. If a virtual interface in the ‘Confirming’ state is deleted by the virtual interface owner, the virtual interface will enter the ‘Rejected’ state.
- **customerRouterConfig** *(string)* –
  
  Information for generating the customer router configuration.
- **virtualGatewayId** *(string)* –
  
  The ID of the virtual private gateway to a VPC. This only applies to private virtual interfaces.
  
  Example: vgw-123er56
- **routeFilterPrefixes** *(list)* –
  
  A list of routes to be advertised to the AWS network in this region (public virtual interface) or your VPC (private virtual interface).
  
  *(dict)* –
  
  A route filter prefix that the customer can advertise through Border Gateway Protocol (BGP) over a public virtual interface.
- **cidr** *(string)* –
CIDR notation for the advertised route. Multiple routes are separated by commas.

Example: 10.10.10.0/24,10.10.11.0/24

generate_presigned_url (ClientMethod, Params= None, ExpiresIn = 3600, HttpMethod= None)
Generate a presigned url given a client, its method, and arguments

Parameters
- ClientMethod (string) – The client method to presign for
- Params (dict) – The parameters normally passed to ClientMethod.
- ExpiresIn (int) – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- HttpMethod (string) – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns The presigned url

generate_waiter (waiter_name)
Create a waiter for an operation.

Parameters waiter_name (string) – The waiter name. This is the same name as the method name.

Raises OperationNotPageableError Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

Returns A waiter object.

DirectoryService

Client

class DirectoryService.Client
A low-level client representing AWS Directory Service:

    import boto3
    client = boto3.client('ds')

These are the available methods:
- can_paginate()
- connect_directory()
- create_alias()
- create_computer()
- create_directory()
- create_snapshot()
can_paginate(operation_name)
  Check if an operation can be paginated.

  Parameters operation_name (string) – The operation name. This is the same name as
  the method name on the client. For example, if the method name is create_foo,
  and you’d normally invoke the operation as client.create_foo(**kwargs),
  if the create_foo operation can be paginated, you can use the call
  client.get_paginator("create_foo").

  Returns True if the operation can be paginated, False otherwise.

connect_directory(**kwargs)
  Creates an AD Connector to connect an on-premises directory.

  Request Syntax

  response = client.connect_directory(
      Name='string',
      ShortName='string',
      Password='string',
      Description='string',
      Size='Small'|'Large',
      ConnectSettings={
          'VpcId': 'string',
          'SubnetIds': [ 'string',
          ],
          'CustomerDnsIps': [ 'string',
          ],
          'CustomerUserName': 'string'
      }
  )

  Parameters

  • Name (string) – [REQUIRED]
      The fully-qualified name of the on-premises directory, such as
      corp.example.com.
  • ShortName (string) – The NetBIOS name of the on-premises directory, such as
      CORP.
  • Password (string) – [REQUIRED]
      The password for the on-premises user account.
• **Description** *(string)* – A textual description for the directory.

• **Size** *(string)* – [REQUIRED]

The size of the directory.

• **ConnectSettings** *(dict)* – [REQUIRED]

A DirectoryConnectSettings object that contains additional information for the operation.

  – **VpcId** *(string)* – [REQUIRED]

    The identifier of the VPC that the AD Connector is created in.

  – **SubnetIds** *(list)* – [REQUIRED]

    A list of subnet identifiers in the VPC that the AD Connector is created in.

    * *(string)* –

  – **CustomerDnsIps** *(list)* – [REQUIRED]

    A list of one or more IP addresses of DNS servers or domain controllers in the on-premises directory.

    * *(string)* –

  – **CustomerUserName** *(string)* – [REQUIRED]

    The username of an account in the on-premises directory that is used to connect to the directory. This account must have the following privileges:

    * Read users and groups
    * Create computer objects
    * Join computers to the domain

**Return type** dict

**Response Syntax**

```python
{
    'DirectoryId': 'string'
}
```

**Response Structure**

• *(dict)* –

  Contains the results of the ConnectDirectory operation.

  – **DirectoryId** *(string)* –

    The identifier of the new directory.

**create_alias**(**kwargs**)  

Creates an alias for a directory and assigns the alias to the directory. The alias is used to construct the access URL for the directory, such as `http://alias.awsapps.com`.

**Warning:** After an alias has been created, it cannot be deleted or reused, so this operation should only be used when absolutely necessary.
• **DirectoryId** *(string)* – [REQUIRED]
  The identifier of the directory to create the alias for.

• **Alias** *(string)* – [REQUIRED]
  The requested alias.

  The alias must be unique amongst all aliases in AWS. This operation will throw an `EntityAlreadyExistsException` if this alias already exists.

Return type: dict

Returns:

**Response Syntax**

```python
{
    'DirectoryId': 'string',
    'Alias': 'string'
}
```

**Response Structure**

- *(dict)* –
  Contains the results of the CreateAlias operation.
  
  - **DirectoryId** *(string)* –
    The identifier of the directory.
  
  - **Alias** *(string)* –
    The alias for the directory.

---

**create_computer**( **kwargs)**

Creates a computer account in the specified directory, and joins the computer to the directory.

**Request Syntax**

```python
response = client.create_computer(
    DirectoryId='string',
    ComputerName='string',
    Password='string',
    OrganizationalUnitDistinguishedName='string',
    ComputerAttributes=[
        {
            'Name': 'string',
            'Value': 'string'
        }
    ]
)
```

**Parameters**

- **DirectoryId** *(string)* – [REQUIRED]
  The identifier of the directory to create the computer account in.

- **ComputerName** *(string)* – [REQUIRED]
  The name of the computer account.

- **Password** *(string)* – [REQUIRED]
  A one-time password that is used to join the computer to the directory. You should generate a random, strong password to use for this parameter.

- **OrganizationalUnitDistinguishedName** *(string)* – The fully-qualified distinguished name of the organizational unit to place the computer account in.
• **ComputerAttributes** *(list)* – An array of Attribute objects that contain any LDAP attributes to apply to the computer account.
  
  – *(dict)* –

  Represents a named directory attribute.
  
  * **Name** *(string)* –
    
    The name of the attribute.
  
  * **Value** *(string)* –
    
    The value of the attribute.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
  'Computer': {
    'ComputerId': 'string',
    'ComputerName': 'string',
    'ComputerAttributes': [
      {
        'Name': 'string',
        'Value': 'string'
      },
      {
        'Name': 'string',
        'Value': 'string'
      }
    ]
  }
}
```

**Response Structure**

• *(dict)* –

  Contains the results for the CreateComputer operation.

  – **Computer** *(dict)* –

  A Computer object the represents the computer account.

  * **ComputerId** *(string)* –
    
    The identifier of the computer.
  
  * **ComputerName** *(string)* –
    
    The computer name.
  
  * **ComputerAttributes** *(list)* –

    An array of Attribute objects that contain the LDAP attributes that belong to the computer account.
    
    • *(dict)* –

      Represents a named directory attribute.
    
    • **Name** *(string)* –
      
      The name of the attribute.
    
    • **Value** *(string)* –
      
      The value of the attribute.

**create_directory(**kwargs**)**

Creates a Simple AD directory.

**Request Syntax**
response = client.create_directory(
    Name='string',
    ShortName='string',
    Password='string',
    Description='string',
    Size='Small'|'Large',
    VpcSettings={
        'VpcId': 'string',
        'SubnetIds': [
            'string',
        ]
    }
)

Parameters

- **Name** *(string)* – [REQUIRED]
  The fully qualified name for the directory, such as corp.example.com.
- **ShortName** *(string)* – The short name of the directory, such as CORP.
- **Password** *(string)* – [REQUIRED]
  The password for the directory administrator. The directory creation process creates a directory administrator account with the username Administrator and this password.
- **Description** *(string)* – A textual description for the directory.
- **Size** *(string)* – [REQUIRED]
  The size of the directory.
- **VpcSettings** *(dict)* – A DirectoryVpcSettings object that contains additional information for the operation.
  - **VpcId** *(string)* – [REQUIRED]
    The identifier of the VPC to create the Simple AD directory in.
  - **SubnetIds** *(list)* – [REQUIRED]
    The identifiers of the subnets for the directory servers. The two subnets must be in different Availability Zones. AWS Directory Service creates a directory server and a DNS server in each of these subnets.

Return type: dict

Returns

Response Syntax

```python
{
    'DirectoryId': 'string'
}
```

Response Structure

- *(dict)* –
  Contains the results of the CreateDirectory operation.
  - **DirectoryId** *(string)* –
    The identifier of the directory that was created.

create_snapshot(**kwargs)**

Creates a snapshot of an existing directory.

You cannot take snapshots of extended or connected directories.
Request Syntax

```python
response = client.create_snapshot(  
    DirectoryId='string',  
    Name='string'
)
```

**Parameters**

- **DirectoryId** *(string)* – [REQUIRED]
  
  The identifier of the directory to take a snapshot of.

- **Name** *(string)* – The descriptive name to apply to the snapshot.

**Return type**  dict

**Returns**

**Response Syntax**

```python
{
    'SnapshotId': 'string'
}
```

**Response Structure**

- *(dict)* –
  
  Contains the results of the CreateSnapshot operation.

  - **SnapshotId** *(string)* –
    
    The identifier of the snapshot that was created.

---

**delete_directory(**kwargs**)**

Deletes an AWS Directory Service directory.

**Request Syntax**

```python
response = client.delete_directory(  
    DirectoryId='string'
)
```

**Parameters**

- **DirectoryId** *(string)* – [REQUIRED]
  
  The identifier of the directory to delete.

**Return type**  dict

**Returns**

**Response Syntax**

```python
{
    'DirectoryId': 'string'
}
```

**Response Structure**

- *(dict)* –
  
  Contains the results of the DeleteDirectory operation.

  - **DirectoryId** *(string)* –
    
    The directory identifier.
`delete_snapshot(**kwargs)`
Deletes a directory snapshot.

**Request Syntax**

```python
response = client.delete_snapshot(
    SnapshotId='string'
)
```

**Parameters**

`SnapshotId (string)` – [REQUIRED]

The identifier of the directory snapshot to be deleted.

**Return type**
dict

**Returns**

**Response Syntax**

```python
{
    'SnapshotId': 'string'
}
```

**Response Structure**

- (dict) –

  Contains the results of the DeleteSnapshot operation.

  - `SnapshotId (string)` –

    The identifier of the directory snapshot that was deleted.

`describe_directories(**kwargs)`
Obtains information about the directories that belong to this account.

You can retrieve information about specific directories by passing the directory identifiers in the `DirectoryIds` parameter. Otherwise, all directories that belong to the current account are returned.

This operation supports pagination with the use of the `NextToken` request and response parameters. If more results are available, the `DescribeDirectoriesResult.NextToken` member contains a token that you pass in the next call to DescribeDirectories to retrieve the next set of items.

You can also specify a maximum number of return results with the `Limit` parameter.

**Request Syntax**

```python
response = client.describe_directories(
    DirectoryIds=[
        'string',
    ],
    NextToken='string',
    Limit=123
)
```

**Parameters**

- `DirectoryIds (list)` – A list of identifiers of the directories to obtain the information for. If this member is null, all directories that belong to the current account are returned.

  An empty list results in an `InvalidParameterException` being thrown.

- `NextToken (string)` – The `DescribeDirectoriesResult.NextToken` value from a previous call to DescribeDirectories. Pass null if this is the first call.
Limit (integer) – The maximum number of items to return. If this value is zero, the maximum number of items is specified by the limitations of the operation.

Return type  dict

Returns

Response Syntax

```python
{
    'DirectoryDescriptions': [
        {
            'DirectoryId': 'string',
            'Name': 'string',
            'ShortName': 'string',
            'Size': 'Small'|'Large',
            'Alias': 'string',
            'AccessUrl': 'string',
            'Description': 'string',
            'DnsIpAddrs': [ 'string', ],
            'Stage': 'Requested'|'Creating'|'Created'|'Active'|'Inoperable'|'Impaired',
            'LaunchTime': datetime(2015, 1, 1),
            'StageLastUpdatedDateTime': datetime(2015, 1, 1),
            'Type': 'SimpleAD'|'ADConnector',
            'VpcSettings': {
                'VpcId': 'string',
                'SubnetIds': [ 'string', ],
                'SecurityGroupId': 'string',
                'AvailabilityZones': [ 'string', ],
            },
            'ConnectSettings': {
                'VpcId': 'string',
                'SubnetIds': [ 'string', ],
                'CustomerUserName': 'string',
                'SecurityGroupId': 'string',
                'AvailabilityZones': [ 'string', ],
                'ConnectIps': [ 'string', ],
            },
            'RadiusSettings': {
                'RadiusServers': [ 'string', ],
                'RadiusPort': 123,
                'RadiusTimeout': 123,
                'RadiusRetries': 123,
                'SharedSecret': 'string',
                'AuthenticationProtocol': 'PAP'|'CHAP'|'MS-CHAPv1'|'MS-CHAPv2',
                'DisplayLabel': 'string',
            },
        },
    ],
}
```
'UseSameUsername': True|False
,'RadiusStatus': 'Creating'|'Completed'|'Failed','StageReason': 'string',
'SsoEnabled': True|False
},
:'NextToken': 'string'
}

Response Structure

• (dict) –

Contains the results of the DescribeDirectories operation.

– DirectoryDescriptions (list) –

The list of DirectoryDescription objects that were retrieved.

It is possible that this list contains less than the number of items specified in the Limit member of the request. This occurs if there are less than the requested number of items left to retrieve, or if the limitations of the operation have been exceeded.

* (dict) –

Contains information about an AWS Directory Service directory.

• DirectoryId (string) –

The directory identifier.

• Name (string) –

The fully-qualified name of the directory.

• ShortName (string) –

The short name of the directory.

• Size (string) –

The directory size.

• Alias (string) –

The alias for the directory.

• AccessUrl (string) –

The access URL for the directory, such as http://alias.awsapps.com.

• Description (string) –

The textual description for the directory.

• DnsIpAddr (list) –

The IP addresses of the DNS servers for the directory. For a Simple AD directory, these are the IP addresses of the Simple AD directory servers. For an AD Connector directory, these are the IP addresses of the DNS servers or domain controllers in the on-premises directory that the AD Connector is connected to.

• (string) –

• Stage (string) –

The current stage of the directory.

• LaunchTime (datetime) –
specifies when the directory was created.

- **StageLastUpdatedDateTime** *(datetime)* —
  The date and time that the stage was last updated.

- **Type** *(string)* —
  The directory size.

- **VpcSettings** *(dict)* —
  A DirectoryVpcSettingsDescription object that contains additional information about a Simple AD directory. This member is only present if the directory is a Simple AD directory.

  - **VpcId** *(string)* —
    The identifier of the VPC that the directory is in.

- **SubnetIds** *(list)* —
  The identifiers of the subnets for the directory servers.

- **SecurityGroupId** *(string)* —
  The security group identifier for the directory.

- **AvailabilityZones** *(list)* —
  The list of Availability Zones that the directory is in.

- **ConnectSettings** *(dict)* —
  A DirectoryConnectSettingsDescription object that contains additional information about an AD Connector directory. This member is only present if the directory is an AD Connector directory.

  - **VpcId** *(string)* —
    The identifier of the VPC that the AD Connector is in.

  - **SubnetIds** *(list)* —
    A list of subnet identifiers in the VPC that the AD connector is in.

  - **CustomerUserName** *(string)* —
    The username of the service account in the on-premises directory.

  - **SecurityGroupId** *(string)* —
    The security group identifier for the AD Connector directory.

  - **AvailabilityZones** *(list)* —
    A list of the Availability Zones that the directory is in.

  - **ConnectIps** *(list)* —
    The IP addresses of the AD Connector servers.

- **RadiusSettings** *(dict)* —
  A RadiusSettings object that contains information about the RADIUS server configured for this directory.

  - **RadiusServers** *(list)* —
An array of strings that contains the IP addresses of the RADIUS server endpoints, or the IP addresses of your RADIUS server load balancer.

- **RadiusPort** (integer) –
  The port that your RADIUS server is using for communications. Your on-premises network must allow inbound traffic over this port from the AWS Directory Service servers.

- **RadiusTimeout** (integer) –
  The amount of time, in seconds, to wait for the RADIUS server to respond.

- **RadiusRetries** (integer) –
  The maximum number of times that communication with the RADIUS server is attempted.

- **SharedSecret** (string) –
  The shared secret code that was specified when your RADIUS endpoints were created.

- **AuthenticationProtocol** (string) –
  The protocol specified for your RADIUS endpoints.

- **DisplayLabel** (string) –
  Not currently used.

- **UseSameUsername** (boolean) –
  Not currently used.

- **RadiusStatus** (string) –
  The status of the RADIUS MFA server connection.

- **StageReason** (string) –
  Additional information about the directory stage.

- **SsoEnabled** (boolean) –
  Indicates if single-sign on is enabled for the directory. For more information, see EnableSso and DisableSso.

- **NextToken** (string) –
  If not null, more results are available. Pass this value for the NextToken parameter in a subsequent call to DescribeDirectories to retrieve the next set of items.

### describe_snapshots(**kwargs)**
Obtains information about the directory snapshots that belong to this account.

This operation supports pagination with the use of the NextToken request and response parameters. If more results are available, the DescribeSnapshots.NextToken member contains a token that you pass in the next call to DescribeSnapshots to retrieve the next set of items.

You can also specify a maximum number of return results with the Limit parameter.

#### Request Syntax

```python
def response = client.describe_snapshots(
    DirectoryId='string',
    SnapshotIds=[
        'string',
    ],
)```

---

**NextToken** (string) –
If not null, more results are available. Pass this value for the NextToken parameter in a subsequent call to DescribeDirectories to retrieve the next set of items.

### describe_snapshots(**kwargs)**
Obtains information about the directory snapshots that belong to this account.

This operation supports pagination with the use of the NextToken request and response parameters. If more results are available, the DescribeSnapshots.NextToken member contains a token that you pass in the next call to DescribeSnapshots to retrieve the next set of items.

You can also specify a maximum number of return results with the Limit parameter.

#### Request Syntax

```python
def response = client.describe_snapshots(
    DirectoryId='string',
    SnapshotIds=[
        'string',
    ],
)```
Parameters

- **DirectoryId** *(string)* – The identifier of the directory to retrieve snapshot information for.
- **SnapshotIds** *(list)* – A list of identifiers of the snapshots to obtain the information for. If this member is null or empty, all snapshots are returned using the `Limit` and `NextToken` members.
  - *(string)* –
- **NextToken** *(string)* – The `DescribeSnapshotsResult.NextToken` value from a previous call to `DescribeSnapshots`. Pass null if this is the first call.
- **Limit** *(integer)* – The maximum number of objects to return.

Return type  dict

Returns

Response Syntax

```python
{
    'Snapshots': [
        {
            'DirectoryId': 'string',
            'SnapshotId': 'string',
            'Type': 'Auto'|'Manual',
            'Name': 'string',
            'Status': 'Creating'|'Completed'|'Failed',
            'StartTime': datetime(2015, 1, 1)
        },
        ...
    ],
    'NextToken': 'string'
}
```

Response Structure

- *(dict)* –
  
  Contains the results of the `DescribeSnapshots` operation.
  
  - **Snapshots** *(list)* –
    
    The list of Snapshot objects that were retrieved.
    
    It is possible that this list contains less than the number of items specified in the `Limit` member of the request. This occurs if there are less than the requested number of items left to retrieve, or if the limitations of the operation have been exceeded.
    
    - *(dict)* –
      
      Describes a directory snapshot.
      
      - **DirectoryId** *(string)* –
        
        The directory identifier.
      
      - **SnapshotId** *(string)* –
        
        The snapshot identifier.
      
      - **Type** *(string)* –
        
        The snapshot type.
**disable_radius**(**kwargs**)
Disables multi-factor authentication (MFA) with Remote Authentication Dial In User Service (RADIUS) for an AD Connector directory.

**Request Syntax**

```python
response = client.disable_radius(
    DirectoryId='string'
)
```

**Parameters**
- **DirectoryId** *(string)* – [REQUIRED]
  The identifier of the directory to disable MFA for.

**Return type**
dict

**Returns**

**Response Syntax**

```python
{}
```

**Response Structure**
- *(dict)* –
  Contains the results of the DisableRadius operation.

**disable_sso**(**kwargs**)
Disables single-sign on for a directory.

**Request Syntax**

```python
response = client.disable_sso(
    DirectoryId='string',
    UserName='string',
    Password='string'
)
```

**Parameters**
- **DirectoryId** *(string)* – [REQUIRED]
  The identifier of the directory to disable single-sign on for.
- **UserName** *(string)* – The username of an alternate account to use to disable single-sign on. This is only used for AD Connector directories. This account must have privileges to remove a service principle name. If the AD Connector service account does not have privileges to remove a service principle name, you can specify an alternate account with the **UserName** and **Password** parameters. These credentials are only used to disable single sign-on
and are not stored by the service. The AD Connector service account is not changed.

- **Password** *(string)* – The password of an alternate account to use to disable single-sign on. This is only used for AD Connector directories. See the User-Name parameter for more information.

**Return type** *dict*

**Returns**

**Response Syntax**

```{}```

**Response Structure**

- *(dict)* –

  Contains the results of the DisableSso operation.

**enable_radius(**

Enables multi-factor authentication (MFA) with Remote Authentication Dial In User Service (RADIUS) for an AD Connector directory.

**Request Syntax**

```python
response = client.enable_radius(
    DirectoryId='string',
    RadiusSettings={
        'RadiusServers': ['string'],
        'RadiusPort': 123,
        'RadiusTimeout': 123,
        'RadiusRetries': 123,
        'SharedSecret': 'string',
        'AuthenticationProtocol': 'PAP'/'CHAP'/'MS-CHAPv1'/'MS-CHAPv2',
        'DisplayLabel': 'string',
        'UseSameUsername': True|False
    }
)
```  

**Parameters**

- **DirectoryId** *(string)* – [REQUIRED]

  The identifier of the directory to enable MFA for.

- **RadiusSettings** *(dict)* – [REQUIRED]

  A RadiusSettings object that contains information about the RADIUS server.

  - **RadiusServers** *(list)* –

    An array of strings that contains the IP addresses of the RADIUS server endpoints, or the IP addresses of your RADIUS server load balancer.

    - *(string)* –

  - **RadiusPort** *(integer)* –

    The port that your RADIUS server is using for communications. Your on-premises network must allow inbound traffic over this port from the AWS Directory Service servers.

  - **RadiusTimeout** *(integer)* –

    The amount of time, in seconds, to wait for the RADIUS server to respond.
– **RadiusRetries** *(integer)* –

The maximum number of times that communication with the RADIUS server is attempted.

– **SharedSecret** *(string)* –

The shared secret code that was specified when your RADIUS endpoints were created.

– **AuthenticationProtocol** *(string)* –

The protocol specified for your RADIUS endpoints.

– **DisplayLabel** *(string)* –

Not currently used.

– **UseSameUsername** *(boolean)* –

Not currently used.

Returns

**Response Syntax**

```
{}  
```

**Response Structure**

- *(dict)* –

Contains the results of the EnableRadius operation.

**enable_sso(****kwargs**

Enables single-sign on for a directory.

**Request Syntax**

```python
response = client.enable_sso(
    DirectoryId='string',
    UserName='string',
    Password='string'
)
```

**Parameters**

- **DirectoryId** *(string)* – [REQUIRED]

The identifier of the directory to enable single-sign on for.

- **UserName** *(string)* – The username of an alternate account to use to enable single-sign on. This is only used for AD Connector directories. This account must have privileges to add a service principle name.

If the AD Connector service account does not have privileges to add a service principle name, you can specify an alternate account with the **UserName** and **Password** parameters. These credentials are only used to enable single sign-on and are not stored by the service. The AD Connector service account is not changed.

- **Password** *(string)* – The password of an alternate account to use to enable single-sign on. This is only used for AD Connector directories. See the **UserName** parameter for more information.
Response Structure

- *(dict)* –
  
  Contains the results of the EnableSso operation.

**generate_presigned_url** *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

**Parameters**

- **ClientMethod** *(string)* – The client method to presign for
- **Params** *(dict)* – The parameters normally passed to **ClientMethod**.
- **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns**

The presigned url

**get_directory_limits()**

Obtains directory limit information for the current region.

**Request Syntax**

```python
response = client.get_directory_limits()
```

**Return type**

**dict**

**Returns**

**Response Syntax**

```python
{

    'DirectoryLimits': {
    'CloudOnlyDirectoriesLimit': 123,
    'CloudOnlyDirectoriesCurrentCount': 123,
    'CloudOnlyDirectoriesLimitReached': True|False,
    'ConnectedDirectoriesLimit': 123,
    'ConnectedDirectoriesCurrentCount': 123,
    'ConnectedDirectoriesLimitReached': True|False

    }

}
```

**Response Structure**

- *(dict)* –
  
  Contains the results of the GetDirectoryLimits operation.

  - **DirectoryLimits** *(dict)* –
    
    A DirectoryLimits object that contains the directory limits for the current region.
    
    - **CloudOnlyDirectoriesLimit** *(integer)* –
      
      The maximum number of cloud directories allowed in the region.
    
    - **CloudOnlyDirectoriesCurrentCount** *(integer)* –
      
      The current number of cloud directories in the region.
    
    - **CloudOnlyDirectoriesLimitReached** *(boolean)* –
      
      Indicates if the cloud directory limit has been reached.
* **ConnectedDirectoriesLimit** (*integer*) –
  The maximum number of connected directories allowed in the region.
* **ConnectedDirectoriesCurrentCount** (*integer*) –
  The current number of connected directories in the region.
* **ConnectedDirectoriesLimitReached** (*boolean*) –
  Indicates if the connected directory limit has been reached.

`getPaginator` *(operation_name)*
Create a paginator for an operation.

**Parameters**
operation_name *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

**Raises**
`OperationNotPageableError` Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

**Return type**
L{botocore.paginate.Paginator}

**Returns**
A paginator object.

`get_snapshot_limits` (**kwargs**)
Obtains the manual snapshot limits for a directory.

**Request Syntax**

```python
response = client.get_snapshot_limits(
    DirectoryId='string'
)
```

**Parameters**
DirectoryId *(string)* – [REQUIRED]

Contains the identifier of the directory to obtain the limits for.

**Return type**
dict

**Returns**

**Response Syntax**

```python
{
    'SnapshotLimits': {
        'ManualSnapshotsLimit': 123,
        'ManualSnapshotsCurrentCount': 123,
        'ManualSnapshotsLimitReached': True|False
    }
}
```

**Response Structure**

- *(dict)* –
  Contains the results of the GetSnapshotLimits operation.
    - **SnapshotLimits** *(dict)* –
      A SnapshotLimits object that contains the manual snapshot limits for the specified directory.
    - **ManualSnapshotsLimit** *(integer)* –
      The maximum number of manual snapshots allowed.
* **ManualSnapshotsCurrentCount** *(integer)* — The current number of manual snapshots of the directory.

* **ManualSnapshotsLimitReached** *(boolean)* — Indicates if the manual snapshot limit has been reached.

get_waiter *(waiter_name)*

restore_from_snapshot (**kwargs**)

Restores a directory using an existing directory snapshot.

When you restore a directory from a snapshot, any changes made to the directory after the snapshot date are overwritten.

This action returns as soon as the restore operation is initiated. You can monitor the progress of the restore operation by calling the DescribeDirectories operation with the directory identifier. When the DirectoryDescription.Stage value changes to Active, the restore operation is complete.

**Request Syntax**

```python
response = client.restore_from_snapshot(
    SnapshotId='string'
)
```

**Parameters**

**SnapshotId** *(string)* — [REQUIRED]

The identifier of the snapshot to restore from.

**Return type**

**dict**

**Returns**

**Response Syntax**

```python
{}
```

**Response Structure**

* (dict) — Contains the results of the RestoreFromSnapshot operation.

update_radius (**kwargs**)

Updates the Remote Authentication Dial In User Service (RADIUS) server information for an AD Connector directory.

**Request Syntax**

```python
response = client.update_radius(
    DirectoryId='string',
    RadiusSettings={
        'RadiusServers': ['string'],
        'RadiusPort': 123,
        'RadiusTimeout': 123,
        'RadiusRetries': 123,
        'SharedSecret': 'string',
        'AuthenticationProtocol': 'PAP'|'CHAP'|'MS-CHAPv1'|'MS-CHAPv2',
        'DisplayLabel': 'string',
        'UseSameUsername': True|False
    }
)
```
Parameters

- **DirectoryId (string)** – [REQUIRED]
  The identifier of the directory to update the RADIUS server information for.

- **RadiusSettings (dict)** – [REQUIRED]
  A RadiusSettings object that contains information about the RADIUS server.
  - **RadiusServers (list)** –
    An array of strings that contains the IP addresses of the RADIUS server endpoints, or the IP addresses of your RADIUS server load balancer.
  - **RadiusPort (integer)** –
    The port that your RADIUS server is using for communications. Your on-premises network must allow inbound traffic over this port from the AWS Directory Service servers.
  - **RadiusTimeout (integer)** –
    The amount of time, in seconds, to wait for the RADIUS server to respond.
  - **RadiusRetries (integer)** –
    The maximum number of times that communication with the RADIUS server is attempted.
  - **SharedSecret (string)** –
    The shared secret code that was specified when your RADIUS endpoints were created.
  - **AuthenticationProtocol (string)** –
    The protocol specified for your RADIUS endpoints.
  - **DisplayLabel (string)** –
    Not currently used.
  - **UseSameUsername (boolean)** –
    Not currently used.

**Return type** `dict`

**Returns**

**Response Syntax**

```
{}
```

**Response Structure**

- **(dict)** –
  Contains the results of the UpdateRadius operation.

DynamoDB
Client

class DynamoDB.Client

A low-level client representing Amazon DynamoDB:

```python
import boto3

client = boto3.client('dynamodb')
```

These are the available methods:
- `batch_get_item()`
- `batch_write_item`
- `can_paginate`
- `create_table`
- `delete_item`
- `delete_table`
- `describe_table`
- `generate_presigned_url`
- `get_item`
- `get_paginate`
- `get_waiter`
- `list_tables`
- `put_item`
- `query`
- `scan`
- `update_item`
- `update_table`

**batch_get_item(**kwargs**)

The `BatchGetItem` operation returns the attributes of one or more items from one or more tables. You identify requested items by primary key.

A single operation can retrieve up to 16 MB of data, which can contain as many as 100 items. `BatchGetItem` will return a partial result if the response size limit is exceeded, the table’s provisioned throughput is exceeded, or an internal processing failure occurs. If a partial result is returned, the operation returns a value for `UnprocessedKeys`. You can use this value to retry the operation starting with the next item to get.

**Warning:** If you request more than 100 items `BatchGetItem` will return a `ValidationException` with the message “Too many items requested for the BatchGetItem call”.

For example, if you ask to retrieve 100 items, but each individual item is 300 KB in size, the system returns 52 items (so as not to exceed the 16 MB limit). It also returns an appropriate `UnprocessedKeys` value so you can get the next page of results. If desired, your application can include its own logic to assemble the pages of results into one data set.
If none of the items can be processed due to insufficient provisioned throughput on all of the tables in the request, then BatchGetItem will return a ProvisionedThroughputExceededException. If at least one of the items is successfully processed, then BatchGetItem completes successfully, while returning the keys of the unread items in UnprocessedKeys.

**Warning:** If DynamoDB returns any unprocessed items, you should retry the batch operation on those items. However, we strongly recommend that you use an exponential backoff algorithm. If you retry the batch operation immediately, the underlying read or write requests can still fail due to throttling on the individual tables. If you delay the batch operation using exponential backoff, the individual requests in the batch are much more likely to succeed.

For more information, see Batch Operations and Error Handling in the Amazon DynamoDB Developer Guide.

By default, BatchGetItem performs eventually consistent reads on every table in the request. If you want strongly consistent reads instead, you can set ConsistentRead to true for any or all tables.

In order to minimize response latency, BatchGetItem retrieves items in parallel.

When designing your application, keep in mind that DynamoDB does not return attributes in any particular order. To help parse the response by item, include the primary key values for the items in your request in the AttributesToGet parameter.

If a requested item does not exist, it is not returned in the result. Requests for nonexistent items consume the minimum read capacity units according to the type of read. For more information, see Capacity Units Calculations in the Amazon DynamoDB Developer Guide.

**Request Syntax**

```python
response = client.batch_get_item(
    RequestItems={
        'string': {
            'Keys': [
                {'string': {
                    'S': 'string',
                    'N': 'string',
                    'B': b'bytes',
                    'SS': [
                        'string',
                    ],
                    'NS': [
                        'string',
                    ],
                    'BS': [
                        b'bytes',
                    ],
                    'M': {
                        'string': {'... recursive ...'}
                    },
                    'L': [{'... recursive ...'},
                    'NULL': True|False,
                    'BOOL': True|False
                }
            ],
            'AttributesToGet': [
            ]
        }
    }
)
```
'string',
],
'ConsistentRead': True|False,
'ProjectionExpression': 'string',
'ExpressionAttributeNames': {
  'string': 'string'
}
}
}
ReturnConsumedCapacity='INDEXES'|'TOTAL'|'NONE'

Parameters

• **RequestItems (dict) – [REQUIRED]**

A map of one or more table names and, for each table, a map that describes one or more items to retrieve from that table. Each table name can be used only once per `BatchGetItem` request.

Each element in the map of items to retrieve consists of the following:

- **ConsistentRead** - If `true`, a strongly consistent read is used; if `false` (the default), an eventually consistent read is used.

- **ExpressionAttributeNames** - One or more substitution tokens for attribute names in the `ProjectionExpression` parameter. The following are some use cases for using `ExpressionAttributeNames`: * To access an attribute whose name conflicts with a DynamoDB reserved word.
  
- To create a placeholder for repeating occurrences of an attribute name in an expression.

- To prevent special characters in an attribute name from being misinterpreted in an expression.

Use the `#` character in an expression to dereference an attribute name. For example, consider the following attribute name:

- **Percentile**

The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see Reserved Words in the *Amazon DynamoDB Developer Guide*). To work around this, you could specify the following for `ExpressionAttributeNames`:

- `{"#P":"Percentile"}`

You could then use this substitution in an expression, as in this example:

- `#P = :val`

**Note:** Tokens that begin with the `:` character are expression attribute values, which are placeholders for the actual value at runtime.

For more information on expression attribute names, see Accessing Item Attributes in the *Amazon DynamoDB Developer Guide*.

- **Keys** - An array of primary key attribute values that define specific items in the table. For each primary key, you must provide all of the key attributes. For example, with a hash type primary key, you only need to provide the hash attribute. For a hash-and-range type primary key, you must provide both the hash attribute and the range attribute.

- **ProjectionExpression** - A string that identifies one or more attributes to retrieve from the table. These attributes can include scalars, sets, or elements of a JSON document. The attributes in the expression must be separated by commas. If no attribute names are specified, then all attributes will be returned. If any of the requested attributes are not found, they will not
appear in the result. For more information, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

- **AttributesToGet** – .. warning:: This is a legacy parameter, for backward compatibility. New applications should use ProjectionExpression instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a ValidationException exception. This parameter allows you to retrieve attributes of type List or Map; however, it cannot retrieve individual elements within a List or a Map. The names of one or more attributes to retrieve. If no attribute names are provided, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result. Note that AttributesToGet has no effect on provisioned throughput consumption. DynamoDB determines capacity units consumed based on item size, not on the amount of data that is returned to an application.

- *(string)* –
  * *(dict)* –

  Represents a set of primary keys and, for each key, the attributes to retrieve from the table.

  For each primary key, you must provide all of the key attributes. For example, with a hash type primary key, you only need to provide the hash attribute. For a hash-and-range type primary key, you must provide both the hash attribute and the range attribute.

  - **Keys** *(list)* – [REQUIRED]
    
    The primary key attribute values that define the items and the attributes associated with the items.
    
    - *(dict)* –
      - *(string)* –
      - *(dict)* –

    Represents the data for an attribute. You can set one, and only one, of the elements.

    Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

    - **S** *(string)* –
      
      A String data type.

    - **N** *(string)* –
      
      A Number data type.

    - **B** *(bytes)* –
      
      A Binary data type.

    - **SS** *(list)* –
      
      A String Set data type.

    - **NS** *(list)* –
      
      A Number Set data type.
A Binary Set data type.
- **(bytes)** –
- **M (dict)** –

A Map of attribute values.
- **(string)** –
- **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.
- **L (list)** –

A List of attribute values.
- **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.
- **NULL (boolean)** –

A Null data type.
- **BOOL (boolean)** –

A Boolean data type.
- **AttributesToGet (list)** –

One or more attributes to retrieve from the table or index. If no attribute names are specified then all attributes will be returned. If any of the specified attributes are not found, they will not appear in the result.
- **(string)** –
- **ConsistentRead (boolean)** –

The consistency of a read operation. If set to `true`, then a strongly consistent read is used; otherwise, an eventually consistent read is used.
- **ProjectionExpression (string)** –

A string that identifies one or more attributes to retrieve from the table. These attributes can include scalars, sets, or elements of a JSON document. The attributes in the `ProjectionExpression` must be separated by commas.

If no attribute names are specified, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

For more information, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.
Note: ProjectionExpression replaces the legacy AttributesToGet parameter.

- **ExpressionAttributeNames (dict)** –

  One or more substitution tokens for attribute names in an expression. The following are some use cases for using ExpressionAttributeNames:
  - To access an attribute whose name conflicts with a DynamoDB reserved word.
  - To create a placeholder for repeating occurrences of an attribute name in an expression.
  - To prevent special characters in an attribute name from being misinterpreted in an expression.

  Use the # character in an expression to dereference an attribute name. For example, consider the following attribute name:
  - Percentile

  The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see Reserved Words in the Amazon DynamoDB Developer Guide). To work around this, you could specify the following for ExpressionAttributeNames:
  - {"#P":"Percentile"}

  You could then use this substitution in an expression, as in this example:
  - #P = :val

Note: Tokens that begin with the : character are expression attribute values, which are placeholders for the actual value at runtime.

For more information on expression attribute names, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

- (string) –

- (string) –

- **ReturnConsumedCapacity (string)** – Determines the level of detail about provisioned throughput consumption that is returned in the response:
  - INDEXES - The response includes the aggregate ConsumedCapacity for the operation, together with ConsumedCapacity for each table and secondary index that was accessed. Note that some operations, such as GetItem and BatchGetItem, do not access any indexes at all. In these cases, specifying INDEXES will only return ConsumedCapacity information for table(s).
  - TOTAL - The response includes only the aggregate ConsumedCapacity for the operation.
  - NONE - No ConsumedCapacity details are included in the response.

**Return type** dict

**Returns**

**Response Syntax**

```python
{}
```
'Responses': {
    'string': {
        'string': {
            'S': 'string',
            'N': 'string',
            'B': b'bytes',
            'SS': [
                'string',
            ],
            'NS': [
                'string',
            ],
            'BS': [
                b'bytes',
            ],
            'M': {
                'string': {'... recursive ...'},
            },
            'L': [
                {'... recursive ...'},
            ],
            'NULL': True|False,
            'BOOL': True|False
        },
    },
},
'UnprocessedKeys': {
    'string': {
        'Keys': [
            'string': {
                'Keys': [
                    'string': {
                        'S': 'string',
                        'N': 'string',
                        'B': b'bytes',
                        'SS': [
                            'string',
                        ],

},

Response Structure

- (dict) –

  Represents the output of a BatchGetItem operation.

  Responses (dict) –

  A map of table name to a list of items. Each object in Responses consists of a table name, along with a map of attribute data consisting of the data type and attribute value.

  - (string) –
    - (list) –
    - (dict) –
    - (string) –
    - (dict) –

    Represents the data for an attribute. You can set one, and only one, of the elements.

    Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

    - S (string) –

      A String data type.

    - N (string) –

      A Number data type.

    - B (bytes) –
A Binary data type.

- **SS** (list) – 
  A String Set data type.
  - *(string)* –
  - **NS** (list) – 
    A Number Set data type.
    - *(string)* –
    - **BS** (list) – 
      A Binary Set data type.
      - *(bytes)* –
      - **M** (dict) – 
        A Map of attribute values.
        - *(string)* –
        - *(dict)* – 

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L** (list) – 
  A List of attribute values.
  - *(dict)* – 

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL** (boolean) – 
  A Null data type.
- **BOOL** (boolean) – 
  A Boolean data type.

- **UnprocessedKeys** (dict) –

A map of tables and their respective keys that were not processed with the current response. The UnprocessedKeys value is in the same form as RequestItems, so the value can be provided directly to a subsequent BatchGetItem operation. For more information, see RequestItems in the Request Parameters section.

Each element consists of:

* **Keys** - An array of primary key attribute values that define specific items in the table.
* **AttributesToGet** - One or more attributes to be retrieved from the table or index. By default, all attributes are returned. If a requested attribute is not found, it does not appear in the result.
* **ConsistentRead** - The consistency of a read operation. If set to `true`, then a strongly consistent read is used; otherwise, an eventually consistent read is used.

If there are no unprocessed keys remaining, the response contains an empty `UnprocessedKeys` map.

* (string) –
  * (dict) –

  Represents a set of primary keys and, for each key, the attributes to retrieve from the table.

  For each primary key, you must provide all of the key attributes. For example, with a hash type primary key, you only need to provide the hash attribute. For a hash-and-range type primary key, you must provide both the hash attribute and the range attribute.

  * **Keys** (list) –

    The primary key attribute values that define the items and the attributes associated with the items.

    * (dict) –
    * (string) –
    * (dict) –

    Represents the data for an attribute. You can set one, and only one, of the elements.

    Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

    * **S** (string) –

      A String data type.

    * **N** (string) –

      A Number data type.

    * **B** (bytes) –

      A Binary data type.

    * **SS** (list) –

      A String Set data type.

    * (string) –
    * **NS** (list) –

      A Number Set data type.

    * (string) –
    * **BS** (list) –

      A Binary Set data type.

    * (bytes) –
    * **M** (dict) –

      A Map of attribute values.

    * (string) –
    * (dict) –
Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L (list)** –
  A List of attribute values.

- **(dict)** –
  Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL (boolean)** –
  A Null data type.

- **BOOL (boolean)** –
  A Boolean data type.

- **AttributesToGet (list)** –
  One or more attributes to retrieve from the table or index. If no attribute names are specified then all attributes will be returned. If any of the specified attributes are not found, they will not appear in the result.

- **(string)** –

- **ConsistentRead (boolean)** –
  The consistency of a read operation. If set to `true`, then a strongly consistent read is used; otherwise, an eventually consistent read is used.

- **ProjectionExpression (string)** –
  A string that identifies one or more attributes to retrieve from the table. These attributes can include scalars, sets, or elements of a JSON document. The attributes in the `ProjectionExpression` must be separated by commas.

If no attribute names are specified, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

For more information, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

**Note:** `ProjectionExpression` replaces the legacy `AttributesToGet` parameter.

- **ExpressionAttributeNames (dict)** –
  One or more substitution tokens for attribute names in an expression. The following are some use cases for using `Expr
sionAttributeNames:
  · To access an attribute whose name conflicts with a DynamoDB reserved word.
  · To create a placeholder for repeating occurrences of an attribute name in an expression.
  · To prevent special characters in an attribute name from being misinterpreted in an expression.

Use the # character in an expression to dereference an attribute name. For example, consider the following attribute name:

  · Percentile

  The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see Reserved Words in the Amazon DynamoDB Developer Guide). To work around this, you could specify the following for ExpressionAttributeNames:

  · {"#P":"Percentile"}

  You could then use this substitution in an expression, as in this example:

  · #P = :val

Note: Tokens that begin with the : character are expression attribute values, which are placeholders for the actual value at runtime.

For more information on expression attribute names, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

– ConsumedCapacity (list) –

The read capacity units consumed by the operation.

Each element consists of:

  * TableName - The table that consumed the provisioned throughput.
  * CapacityUnits - The total number of capacity units consumed.
  * (dict) –

The capacity units consumed by an operation. The data returned includes the total provisioned throughput consumed, along with statistics for the table and any indexes involved in the operation. ConsumedCapacity is only returned if the request asked for it. For more information, see Provisioned Throughput in the Amazon DynamoDB Developer Guide.

  · TableName (string) –

  The name of the table that was affected by the operation.

  · CapacityUnits (float) –

  The total number of capacity units consumed by the operation.

  · Table (dict) –

  The amount of throughput consumed on the table affected by the operation.

  · CapacityUnits (float) –
The total number of capacity units consumed on a table or an index.

- **LocalSecondaryIndexes** *(dict)*

  The amount of throughput consumed on each local index affected by the operation.
  
  - *(string)*
  
  Represents the amount of provisioned throughput capacity consumed on a table or an index.

- **CapacityUnits** *(float)*

  The total number of capacity units consumed on a table or an index.

- **GlobalSecondaryIndexes** *(dict)*

  The amount of throughput consumed on each global index affected by the operation.
  
  - *(string)*
  
  Represents the amount of provisioned throughput capacity consumed on a table or an index.

- **CapacityUnits** *(float)*

  The total number of capacity units consumed on a table or an index.

---

**batch_write_item(**kwargs**)

The `BatchWriteItem` operation puts or deletes multiple items in one or more tables. A single call to `BatchWriteItem` can write up to 16 MB of data, which can comprise as many as 25 put or delete requests. Individual items to be written can be as large as 400 KB.

**Note:** `BatchWriteItem` cannot update items. To update items, use the `UpdateItem` API.

The individual `PutItem` and `DeleteItem` operations specified in `BatchWriteItem` are atomic; however `BatchWriteItem` as a whole is not. If any requested operations fail because the table’s provisioned throughput is exceeded or an internal processing failure occurs, the failed operations are returned in the `UnprocessedItems` response parameter. You can investigate and optionally resend the requests. Typically, you would call `BatchWriteItem` in a loop. Each iteration would check for unprocessed items and submit a new `BatchWriteItem` request with those unprocessed items until all items have been processed.

Note that if *none* of the items can be processed due to insufficient provisioned throughput on all of the tables in the request, then `BatchWriteItem` will return a `ProvisionedThroughputExceededError`.

**Warning:** If DynamoDB returns any unprocessed items, you should retry the batch operation on those items. However, *we strongly recommend that you use an exponential backoff algorithm*. If you retry the batch operation immediately, the underlying read or write requests can still fail due to throttling on the individual tables. If you delay the batch operation using exponential backoff, the individual requests in the batch are much more likely to succeed.

For more information, see *Batch Operations and Error Handling* in the *Amazon DynamoDB Developer Guide*.

With `BatchWriteItem`, you can efficiently write or delete large amounts of data, such as from Amazon Elastic MapReduce (EMR), or copy data from another database into DynamoDB. In order to improve performance with these large-scale operations, `BatchWriteItem` does not behave in the same way as indi-
individual PutItem and DeleteItem calls would. For example, you cannot specify conditions on individual put and delete requests, and BatchWriteItem does not return deleted items in the response.

If you use a programming language that supports concurrency, you can use threads to write items in parallel. Your application must include the necessary logic to manage the threads. With languages that don’t support threading, you must update or delete the specified items one at a time. In both situations, BatchWriteItem provides an alternative where the API performs the specified put and delete operations in parallel, giving you the power of the thread pool approach without having to introduce complexity into your application.

Parallel processing reduces latency, but each specified put and delete request consumes the same number of write capacity units whether it is processed in parallel or not. Delete operations on nonexistent items consume one write capacity unit.

If one or more of the following is true, DynamoDB rejects the entire batch write operation:

- One or more tables specified in the BatchWriteItem request does not exist.
- Primary key attributes specified on an item in the request do not match those in the corresponding table’s primary key schema.
- You try to perform multiple operations on the same item in the same BatchWriteItem request. For example, you cannot put and delete the same item in the same BatchWriteItem request.
- There are more than 25 requests in the batch.
- Any individual item in a batch exceeds 400 KB.
- The total request size exceeds 16 MB.

**Request Syntax**

```python
response = client.batch_write_item(
    RequestItems=
        {'string': [
            {'PutRequest': {
                'Item': {
                    'string': {
                        'S': 'string',
                        'N': 'string',
                        'B': b'bytes',
                        'SS': [
                            'string',
                        ],
                        'NS': [
                            'string',
                        ],
                        'BS': [
                            b'bytes',
                        ],
                        'M': {
                            'string': {'... recursive ...'}
                        },
                        'L': [
                            {'... recursive ...'}
                        ],
                        'NULL': True|False,
                        'BOOL': True|False
                    }
                }
            },
            {'DeleteRequest': {
                'Key': {
                    'string': {
                    }
                }
            }
        ]}
)
```
Parameters

- RequestItems (dict) – [REQUIRED]

A map of one or more table names and, for each table, a list of operations to be performed (DeleteRequest or PutRequest). Each element in the map consists of the following:

- **DeleteRequest** - Perform a DeleteItem operation on the specified item. The item to be deleted is identified by a Key subelement: * Key - A map of primary key attribute values that uniquely identify the item. Each entry in this map consists of an attribute name and an attribute value. For each primary key, you must provide all of the key attributes. For example, with a hash type primary key, you only need to provide the hash attribute. For a hash-and-range type primary key, you must provide both the hash attribute and the range attribute.

- **PutRequest** - Perform a PutItem operation on the specified item. The item to be put is identified by an Item subelement: * Item - A map of attributes and their values. Each entry in this map consists of an attribute name and an attribute value. Attribute values must not be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests that contain empty values will be rejected with a ValidationException exception. If you specify any attributes that are part of an index key, then the data types for those attributes must match those of the schema in the table’s attribute definition.

- (string)
  - *(list) –
    - *(dict) –
Represents an operation to perform - either DeleteItem or PutItem. You can only request one of these operations, not both, in a single WriteRequest. If you do need to perform both of these operations, you will need to provide two separate WriteRequest objects.

- **PutRequest (dict)** –
  A request to perform a PutItem operation.

- **Item (dict)** – [REQUIRED]
  A map of attribute name to attribute values, representing the primary key of an item to be processed by PutItem. All of the table’s primary key attributes must be specified, and their data types must match those of the table’s key schema. If any attributes are present in the item which are part of an index key schema for the table, their types must match the index key schema.
  - (string) –
  - (dict) –

  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.
  - S (string) –
    - A String data type.
  - N (string) –
    - A Number data type.
  - B (bytes) –
    - A Binary data type.
  - SS (list) –
    - A String Set data type.
  - (string) –
  - NS (list) –
    - A Number Set data type.
  - (string) –
  - BS (list) –
    - A Binary Set data type.
  - (bytes) –
  - M (dict) –
    - A Map of attribute values.
  - (string) –
  - (dict) –

  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book
item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L (list)** —

A List of attribute values.

- **(dict)** —

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL (boolean)** —

A Null data type.

- **BOOL (boolean)** —

A Boolean data type.

- **DeleteRequest (dict)** —

A request to perform a `DeleteItem` operation.

- **Key (dict)** — [REQUIRED]

A map of attribute name to attribute values, representing the primary key of the item to delete. All of the table’s primary key attributes must be specified, and their data types must match those of the table’s key schema.

- **(string)** —

- **(dict)** —

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **S (string)** —

A String data type.

- **N (string)** —

A Number data type.

- **B (bytes)** —

A Binary data type.

- **SS (list)** —

A String Set data type.

- **(string)** —

- **NS (list)** —

A Number Set data type.

- **BS (list)** —
A Binary Set data type.
- (bytes)
- M (dict)

A Map of attribute values.
- (string)
- (dict)

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.
- L (list)

A List of attribute values.
- (dict)

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.
- NULL (boolean)

A Null data type.
- BOOL (boolean)

A Boolean data type.

- **ReturnConsumedCapacity**(string) – Determines the level of detail about provisioned throughput consumption that is returned in the response:
  - **INDEXES** - The response includes the aggregate ConsumedCapacity for the operation, together with ConsumedCapacity for each table and secondary index that was accessed. Note that some operations, such as GetItem and BatchGetItem, do not access any indexes at all. In these cases, specifying INDEXES will only return ConsumedCapacity information for table(s).
  - **TOTAL** - The response includes only the aggregate ConsumedCapacity for the operation.
  - **NONE** - No ConsumedCapacity details are included in the response.
- **ReturnItemCollectionMetrics**(string) – Determines whether item collection metrics are returned. If set to SIZE, the response includes statistics about item collections, if any, that were modified during the operation are returned in the response. If set to NONE (the default), no statistics are returned.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'UnprocessedItems': {
        'string': []
    }
}```
`PutRequest`: {
  'Item': {
    'string': {
      'S': 'string',

      'L': [
        {'... recursive ...'},
      ],
      'NULL': True|False,
      'BOOL': True|False
    }
  },
}

`ItemCollectionMetrics`: {
  'string': [3.1. Services 773]
Response Structure

- (dict) –

  Represents the output of a BatchWriteItem operation.

  - UnprocessedItems (dict) –

    A map of tables and requests against those tables that were not processed.
The `UnprocessedItems` value is in the same form as `RequestItems`, so you can provide this value directly to a subsequent `BatchGetItem` operation. For more information, see `RequestItems` in the Request Parameters section.

Each `UnprocessedItems` entry consists of a table name and, for that table, a list of operations to perform (`DeleteRequest` or `PutRequest`).

* `DeleteRequest` - Perform a `DeleteItem` operation on the specified item. The item to be deleted is identified by a `Key` subelement:
  * `Key` - A map of primary key attribute values that uniquely identify the item. Each entry in this map consists of an attribute name and an attribute value.

* `PutRequest` - Perform a `PutItem` operation on the specified item. The item to be put is identified by an `Item` subelement:
  * `Item` - A map of attributes and their values. Each entry in this map consists of an attribute name and an attribute value. Attribute values must not be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests that contain empty values will be rejected with a `ValidationException` exception. If you specify any attributes that are part of an index key, then the data types for those attributes must match those of the schema in the table’s attribute definition.

If there are no unprocessed items remaining, the response contains an empty `UnprocessedItems` map.

* `(string)` –
  · `(list)` –
  · `(dict)` –

  Represents an operation to perform - either `DeleteItem` or `PutItem`. You can only request one of these operations, not both, in a single `WriteRequest`. If you do need to perform both of these operations, you will need to provide two separate `WriteRequest` objects.

* `PutRequest (dict)` –

  A request to perform a `PutItem` operation.

* `Item (dict)` –

  A map of attribute name to attribute values, representing the primary key of an item to be processed by `PutItem`. All of the table’s primary key attributes must be specified, and their data types must match those of the table’s key schema. If any attributes are present in the item which are part of an index key schema for the table, their types must match the index key schema.

  * `(string)` –
  * `(dict)` –

  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

  · `S (string)` –
A String data type.
- **N** *(string)* –
  A Number data type.
- **B** *(bytes)* –
  A Binary data type.
- **SS** *(list)* –
  A String Set data type.
  - *(string)* –
  - **NS** *(list)* –
    A Number Set data type.
  - *(string)* –
  - **BS** *(list)* –
    A Binary Set data type.
  - *(bytes)* –
  - **M** *(dict)* –
    A Map of attribute values.
  - *(string)* –
  - *(dict)* –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L** *(list)* –
  A List of attribute values.
  - *(dict)* –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL** *(boolean)* –
  A Null data type.
- **BOOL** *(boolean)* –
  A Boolean data type.
- **DeleteRequest** *(dict)* –
  A request to perform a *DeleteItem* operation.
- **Key** *(dict)* –
  A map of attribute name to attribute values, representing the primary key of the item to delete. All of the table’s primary key attributes must be specified, and their data types must match those of the table’s key schema.
· (string) –
· (dict) –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

· S (string) –
  A String data type.
· N (string) –
  A Number data type.
· B (bytes) –
  A Binary data type.
· SS (list) –
  A String Set data type.
· (string) –
· NS (list) –
  A Number Set data type.
· (string) –
· BS (list) –
  A Binary Set data type.
· (bytes) –
· M (dict) –
  A Map of attribute values.
· (dict) –
· (dict) –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

A Null data type.
- **BOOL (boolean)** –
  A Boolean data type.

- **ItemCollectionMetrics (dict)** –
  A list of tables that were processed by `BatchWriteItem` and, for each table, information about any item collections that were affected by individual `DeleteItem` or `PutItem` operations.

Each entry consists of the following subelements:
- **ItemCollectionKey** - The hash key value of the item collection. This is the same as the hash key of the item.
- **SizeEstimateRange** - An estimate of item collection size, expressed in GB. This is a two-element array containing a lower bound and an upper bound for the estimate. The estimate includes the size of all the items in the table, plus the size of all attributes projected into all of the local secondary indexes on the table. Use this estimate to measure whether a local secondary index is approaching its size limit. The estimate is subject to change over time; therefore, do not rely on the precision or accuracy of the estimate.

- **(string)** –
  - **(list)** –
    - **(dict)** –
      Information about item collections, if any, that were affected by the operation. `ItemCollectionMetrics` is only returned if the request asked for it. If the table does not have any local secondary indexes, this information is not returned in the response.

- **ItemCollectionKey (dict)** –
  The hash key value of the item collection. This value is the same as the hash key of the item.

- **(string)** –
  - **(dict)** –
    Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **S (string)** –
  A String data type.

- **N (string)** –
  A Number data type.

- **B (bytes)** –
  A Binary data type.

- **SS (list)** –
  A String Set data type.
- **NS (list)** –
  A Number Set data type.
- **(string)** –
- **BS (list)** –
  A Binary Set data type.
- **(bytes)** –
- **M (dict)** –
  A Map of attribute values.
- **(string)** –
- **(dict)** –
  Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.
- **L (list)** –
  A List of attribute values.
- **(dict)** –
  Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.
- **NULL (boolean)** –
  A Null data type.
- **BOOL (boolean)** –
  A Boolean data type.
- **SizeEstimateRangeGB (list)** –
  An estimate of item collection size, in gigabytes. This value is a two-element array containing a lower bound and an upper bound for the estimate. The estimate includes the size of all the items in the table, plus the size of all attributes projected into all of the local secondary indexes on that table. Use this estimate to measure whether a local secondary index is approaching its size limit.

  The estimate is subject to change over time; therefore, do not rely on the precision or accuracy of the estimate.
- **(float)** –
  - **ConsumedCapacity (list)** –
    The capacity units consumed by the operation.

    Each element consists of:
    * **TableName** - The table that consumed the provisioned throughput.
    * **CapacityUnits** - The total number of capacity units consumed.
can_paginate (operation_name)
Check if an operation can be paginated.

Parameters operation_name (string) – The operation name. This is the same name as
the method name on the client. For example, if the method name is create_foo,
and you’d normally invoke the operation as client.create_foo(**kwargs),
if the create_foo operation can be paginated, you can use the call
client.get_paginated("create_foo").

Returns True if the operation can be paginated, False otherwise.
**create_table(**\*kwargs\*)**

The `create_table` operation adds a new table to your account. In an AWS account, table names must be unique within each region. That is, you can have two tables with same name if you create the tables in different regions.

`create_table` is an asynchronous operation. Upon receiving a `create_table` request, DynamoDB immediately returns a response with a `TableStatus` of CREATING. After the table is created, DynamoDB sets the `TableStatus` to ACTIVE. You can perform read and write operations only on an ACTIVE table.

You can optionally define secondary indexes on the new table, as part of the `create_table` operation. If you want to create multiple tables with secondary indexes on them, you must create the tables sequentially. Only one table with secondary indexes can be in the CREATING state at any given time.

You can use the `describe_table` API to check the table status.

**Request Syntax**

```python
response = client.create_table(
    AttributeDefinitions=[
        {
            'AttributeName': 'string',
            'AttributeType': 'S'|'N'|'B'
        },
    ],
    TableName='string',
    KeySchema=[
        {
            'AttributeName': 'string',
            'KeyType': 'HASH'|'RANGE'
        },
    ],
    LocalSecondaryIndexes=[
        {
            'IndexName': 'string',
            'KeySchema': [
                {
                    'AttributeName': 'string',
                    'KeyType': 'HASH'|'RANGE'
                },
            ],
            'Projection': {
                'ProjectionType': 'ALL'|'KEYS_ONLY'|'INCLUDE',
                'NonKeyAttributes': ['string',
            ]
        },
    ],
    GlobalSecondaryIndexes=[
        {
            'IndexName': 'string',
            'KeySchema': [
                {
                    'AttributeName': 'string',
                    'KeyType': 'HASH'|'RANGE'
                },
            ],
            'Projection': {
                'ProjectionType': 'ALL'|'KEYS_ONLY'|'INCLUDE',
            }
        },
    ]
)
```
'NonKeyAttributes': [ 'string', ],
'ProvisionedThroughput': { 'ReadCapacityUnits': 123, 'WriteCapacityUnits': 123 },
ProvisionedThroughput={
  'ReadCapacityUnits': 123,
  'WriteCapacityUnits': 123 },
StreamSpecification={
  'StreamEnabled': True|False,
  'StreamViewType': 'NEW_IMAGE'|'OLD_IMAGE'|'NEW_AND_OLD_IMAGES'|'KEYS_ONLY'
}

Parameters

- **AttributeDefinitions (list)** – [REQUIRED]
  An array of attributes that describe the key schema for the table and indexes.
  - (dict) –
    Represents an attribute for describing the key schema for the table and indexes.
    - **AttributeName (string)** – [REQUIRED]
      A name for the attribute.
    - **AttributeType (string)** – [REQUIRED]
      The data type for the attribute.

- **TableName (string)** – [REQUIRED]
  The name of the table to create.

- **KeySchema (list)** – [REQUIRED]
  Specifies the attributes that make up the primary key for a table or an index. The attributes in KeySchema must also be defined in the AttributeDefinitions array. For more information, see Data Model in the Amazon DynamoDB Developer Guide.

  Each KeySchemaElement in the array is composed of:
  - **AttributeName** - The name of this key attribute.
  - **KeyType** - Determines whether the key attribute is HASH or RANGE.

  For a primary key that consists of a hash attribute, you must provide exactly one element with a KeyType of HASH.

  For a primary key that consists of hash and range attributes, you must provide exactly two elements, in this order: The first element must have a KeyType of HASH, and the second element must have a KeyType of RANGE.

  For more information, see Specifying the Primary Key in the Amazon DynamoDB Developer Guide.

  - (dict) –
    Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of
A *KeySchemaElement* represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one *KeySchemaElement*. A hash-and-range type primary key would require one *KeySchemaElement* for the hash attribute, and another *KeySchemaElement* for the range attribute.

- **AttributeName (string)** – [REQUIRED]
  The name of a key attribute.
- **KeyType (string)** – [REQUIRED]
  The attribute data, consisting of the data type and the attribute value itself.

- **LocalSecondaryIndexes (list)** – One or more local secondary indexes (the maximum is five) to be created on the table. Each index is scoped to a given hash key value. There is a 10 GB size limit per hash key; otherwise, the size of a local secondary index is unconstrained.

Each local secondary index in the array includes the following:

- **IndexName** - The name of the local secondary index. Must be unique only for this table.
- **KeySchema** - Specifies the key schema for the local secondary index. The key schema must begin with the same hash key attribute as the table.
- **Projection** - Specifies attributes that are copied (projected) from the table into the index. These are in addition to the primary key attributes and index key attributes, which are automatically projected. Each attribute specification is composed of:
  - **ProjectionType** - One of the following:
    - **KEYS_ONLY** - Only the index and primary keys are projected into the index.
    - **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in `NonKeyAttributes`.
    - **ALL** - All of the table attributes are projected into the index.
- **NonKeyAttributes** - A list of one or more non-key attribute names that are projected into the secondary index. The total count of attributes provided in `NonKeyAttributes`, summed across all of the secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

- **(dict)** –
  Represents the properties of a local secondary index.
  - **IndexName (string)** – [REQUIRED]
    The name of the local secondary index. The name must be unique among all other indexes on this table.
  - **KeySchema (list)** – [REQUIRED]
    The complete key schema for the local secondary index, consisting of one or more pairs of attribute names and key types (`HASH` or `RANGE`).

* (dict) –
  Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

A *KeySchemaElement* represents exactly one attribute of the primary key. For example, a hash type primary key would be
represented by one `KeySchemaElement`. A hash-and-range type primary key would require one `KeySchemaElement` for the hash attribute, and another `KeySchemaElement` for the range attribute.

- **AttributeName** *(string) – [REQUIRED]*
  The name of a key attribute.

- **KeyType** *(string) – [REQUIRED]*
  The attribute data, consisting of the data type and the attribute value itself.

* **Projection** *(dict) – [REQUIRED]*
  Represents attributes that are copied (projected) from the table into an index. These are in addition to the primary key attributes and index key attributes, which are automatically projected.

  - **ProjectionType** *(string) –*
    The set of attributes that are projected into the index:
    - **KEYS_ONLY** - Only the index and primary keys are projected into the index.
    - **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in `NonKeyAttributes`.
    - **ALL** - All of the table attributes are projected into the index.

  - **NonKeyAttributes** *(list) –*
    Represents the non-key attribute names which will be projected into the index.

    For local secondary indexes, the total count of `NonKeyAttributes` summed across all of the local secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

- **GlobalSecondaryIndexes** *(list) – One or more global secondary indexes (the maximum is five) to be created on the table. Each global secondary index in the array includes the following:
  - **IndexName** - The name of the global secondary index. Must be unique only for this table.
  - **KeySchema** - Specifies the key schema for the global secondary index.
  - **Projection** - Specifies attributes that are copied (projected) from the table into the index. These are in addition to the primary key attributes and index key attributes, which are automatically projected. Each attribute specification is composed of:
    - **ProjectionType** - One of the following:
      - **KEYS_ONLY** - Only the index and primary keys are projected into the index.
      - **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in `NonKeyAttributes`.
      - **ALL** - All of the table attributes are projected into the index.
  - **NonKeyAttributes** - A list of one or more non-key attribute names that are projected into the secondary index. The total count of attributes provided in `NonKeyAttributes`, summed across all of the secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.
- **ProvisionedThroughput** - The provisioned throughput settings for the global secondary index, consisting of read and write capacity units.

- (dict) –

  Represents the properties of a global secondary index.

  * **IndexName** *(string)* – [REQUIRED]
    
    The name of the global secondary index. The name must be unique among all other indexes on this table.

  * **KeySchema** *(list)* – [REQUIRED]
    
    The complete key schema for a global secondary index, which consists of one or more pairs of attribute names and key types *(HASH or RANGE)*.

    · (dict) –

      Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

      A **KeySchemaElement** represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one **KeySchemaElement**. A hash-and-range type primary key would require one **KeySchemaElement** for the hash attribute, and another **KeySchemaElement** for the range attribute.

    · **AttributeName** *(string)* – [REQUIRED]
      
      The name of a key attribute.

    · **KeyType** *(string)* – [REQUIRED]
      
      The attribute data, consisting of the data type and the attribute value itself.

  * **Projection** *(dict)* – [REQUIRED]
    
    Represents attributes that are copied (projected) from the table into an index. These are in addition to the primary key attributes and index key attributes, which are automatically projected.

    · **ProjectionType** *(string)* –
      
      The set of attributes that are projected into the index:

      · **KEYS_ONLY** - Only the index and primary keys are projected into the index.

      · **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in **NonKeyAttributes**.

      · **ALL** - All of the table attributes are projected into the index.

    · **NonKeyAttributes** *(list)* –
      
      Represents the non-key attribute names which will be projected into the index.

      For local secondary indexes, the total count of **NonKeyAttributes** summed across all of the local secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

    · *(string)* –
• **ProvisionedThroughput (dict) – [REQUIRED]**

Represents the provisioned throughput settings for a specified table or index. The settings can be modified using the `UpdateTable` operation.

For current minimum and maximum provisioned throughput values, see `Limits` in the *Amazon DynamoDB Developer Guide*.

– **ReadCapacityUnits (integer) – [REQUIRED]**

The maximum number of strongly consistent reads consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see `Specifying Read and Write Requirements` in the *Amazon DynamoDB Developer Guide*.

– **WriteCapacityUnits (integer) – [REQUIRED]**

The maximum number of writes consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see `Specifying Read and Write Requirements` in the *Amazon DynamoDB Developer Guide*.

• **ProvisionedThroughput (dict) – [REQUIRED]**

Represents the provisioned throughput settings for a specified table or index. The settings can be modified using the `UpdateTable` operation.

For current minimum and maximum provisioned throughput values, see `Limits` in the *Amazon DynamoDB Developer Guide*.

– **ReadCapacityUnits (integer) – [REQUIRED]**

The maximum number of strongly consistent reads consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see `Specifying Read and Write Requirements` in the *Amazon DynamoDB Developer Guide*.

– **WriteCapacityUnits (integer) – [REQUIRED]**

The maximum number of writes consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see `Specifying Read and Write Requirements` in the *Amazon DynamoDB Developer Guide*.

• **StreamSpecification (dict) – The settings for DynamoDB Streams on the table.**

These settings consist of:

– **StreamEnabled** - Indicates whether Streams is to be enabled (true) or disabled (false).

– **StreamViewType** - When an item in the table is modified, `StreamViewType` determines what information is written to the table’s stream. Valid values for `StreamViewType` are: *KEYS_ONLY* - Only the key attributes of the modified item are written to the stream.

– **NEW_IMAGE** - The entire item, as it appears after it was modified, is written to the stream.

– **OLD_IMAGE** - The entire item, as it appeared before it was modified, is written to the stream.

– **NEW_AND_OLD_IMAGES** - Both the new and the old item images of the item are written to the stream.

– **StreamEnabled (boolean) –**

Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.

– **StreamViewType (string) –**
The DynamoDB Streams settings for the table. These settings consist of:

- **StreamEnabled** - Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.
- **StreamViewType** - When an item in the table is modified, **StreamViewType** determines what information is written to the stream for this table. Valid values for **StreamViewType** are:
  - **KEYS_ONLY** - Only the key attributes of the modified item are written to the stream.
  - **NEW_IMAGE** - The entire item, as it appears after it was modified, is written to the stream.
  - **OLD_IMAGE** - The entire item, as it appeared before it was modified, is written to the stream.
  - **NEW_AND_OLD_IMAGES** - Both the new and the old item images of the item are written to the stream.

**Return type** dict

**Returns**

**Response Structure**

- *(dict)* – Represents the output of a `CreateTable` operation.
  - **TableDescription** *(dict)* – Represents the properties of a table.
    - **AttributeDefinitions** *(list)* – An array of `AttributeDefinition` objects. Each of these objects describes one attribute in the table and index key schema.
Each `AttributeDefinition` object in this array is composed of:

- `AttributeName` - The name of the attribute.
- `AttributeType` - The data type for the attribute.

- `(dict)`

  Represents an attribute for describing the key schema for the table and indexes.

  - `AttributeName` *(string)* –

    A name for the attribute.

  - `AttributeType` *(string)* –

    The data type for the attribute.

* `TableName` *(string)* –

  The name of the table.

* `KeySchema` *(list)* –

  The primary key structure for the table. Each `KeySchemaElement` consists of:

  - `AttributeName` - The name of the attribute.
  - `KeyType` - The key type for the attribute. Can be either `HASH` or `RANGE`.

  For more information about primary keys, see Primary Key in the Amazon DynamoDB Developer Guide.

- `(dict)`

  Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

  A `KeySchemaElement` represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one `KeySchemaElement`. A hash-and-range type primary key would require one `KeySchemaElement` for the hash attribute, and another `KeySchemaElement` for the range attribute.

  - `AttributeName` *(string)* –

    The name of a key attribute.

  - `KeyType` *(string)* –

    The attribute data, consisting of the data type and the attribute value itself.

* `TableStatus` *(string)* –

  The current state of the table:

  - `CREATING` - The table is being created.
  - `UPDATING` - The table is being updated.
  - `DELETING` - The table is being deleted.
  - `ACTIVE` - The table is ready for use.

* `CreationDateTime` *(datetime)* –

  The date and time when the table was created, in UNIX epoch time format.

* `ProvisionedThroughput` *(dict)* –

  The provisioned throughput settings for the table, consisting of read
and write capacity units, along with data about increases and decreases.

- **LastIncreaseDateTime** *(datetime)* –
  The date and time of the last provisioned throughput increase for this table.

- **LastDecreaseDateTime** *(datetime)* –
  The date and time of the last provisioned throughput decrease for this table.

- **NumberOfDecreasesToday** *(integer)* –
  The number of provisioned throughput decreases for this table during this UTC calendar day. For current maximums on provisioned throughput decreases, see Limits in the Amazon DynamoDB Developer Guide.

- **ReadCapacityUnits** *(integer)* –
  The maximum number of strongly consistent reads consumed per second before DynamoDB returns a ThrottlingException. Eventually consistent reads require less effort than strongly consistent reads, so a setting of 50 **ReadCapacityUnits** per second provides 100 eventually consistent **ReadCapacityUnits** per second.

- **WriteCapacityUnits** *(integer)* –
  The maximum number of writes consumed per second before DynamoDB returns a ThrottlingException.

- **TableSizeBytes** *(integer)* –
  The total size of the specified table, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **ItemCount** *(integer)* –
  The number of items in the specified table. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **TableArn** *(string)* –
  The Amazon Resource Name (ARN) that uniquely identifies the table.

- **LocalSecondaryIndexes** *(list)* –
  Represents one or more local secondary indexes on the table. Each index is scoped to a given hash key value. Tables with one or more local secondary indexes are subject to an item collection size limit, where the amount of data within a given item collection cannot exceed 10 GB. Each element is composed of:
  - **IndexName** - The name of the local secondary index.
  - **KeySchema** - Specifies the complete index key schema. The attribute names in the key schema must be between 1 and 255 characters (inclusive). The key schema must begin with the same hash key attribute as the table.
  - **Projection** - Specifies attributes that are copied (projected) from the table into the index. These are in addition to the primary key attributes and index key attributes, which are automatically projected. Each attribute specification is composed
of: * ProjectionType - One of the following:
  - KEYS_ONLY - Only the index and primary keys are projected into the index.
  - INCLUDE - Only the specified table attributes are projected into the index. The list of projected attributes are in *NonKeyAttributes*.
  - ALL - All of the table attributes are projected into the index.
  - NonKeyAttributes - A list of one or more non-key attribute names that are projected into the secondary index. The total count of attributes provided in *NonKeyAttributes*, summed across all of the secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.
  - IndexSizeBytes - Represents the total size of the index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.
  -ItemCount - Represents the number of items in the index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

If the table is in the **DELETING** state, no information about indexes will be returned.

- *(dict)* -
  - Represents the properties of a local secondary index.
  - **IndexName** *(string)* -
    - Represents the name of the local secondary index.
  - **KeySchema** *(list)* -
    - The complete index key schema, which consists of one or more pairs of attribute names and key types (**HASH** or **RANGE**).
  - *(dict)* -
    - Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

A **KeySchemaElement** represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one **KeySchemaElement**. A hash-and-range type primary key would require one **KeySchemaElement** for the hash attribute, and another **KeySchemaElement** for the range attribute.

- **AttributeName** *(string)* -
  - The name of a key attribute.
- **KeyType** *(string)* -
  - The attribute data, consisting of the data type and the attribute value itself.
- **Projection** *(dict)* -
  - Represents attributes that are copied (projected) from the table into an index. These are in addition to the primary key attributes and index key attributes, which are automatically projected.
- **ProjectionType** *(string)* -
The set of attributes that are projected into the index:
- **KEYS_ONLY** - Only the index and primary keys are projected into the index.
- **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in `NonKeyAttributes`.
- **ALL** - All of the table attributes are projected into the index.

`NonKeyAttributes (list)`

Represents the non-key attribute names which will be projected into the index.

For local secondary indexes, the total count of `NonKeyAttributes` summed across all of the local secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

- *(string)*
- **IndexSizeBytes (integer)**

The total size of the specified index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **ItemCount (integer)**

The number of items in the specified index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **IndexArn (string)**

The Amazon Resource Name (ARN) that uniquely identifies the index.

*GlobalSecondaryIndexes (list)*

The global secondary indexes, if any, on the table. Each index is scoped to a given hash key value. Each element is composed of:

- **Backfilling** - If true, then the index is currently in the backfilling phase. Backfilling occurs only when a new global secondary index is added to the table; it is the process by which DynamoDB populates the new index with data from the table. (This attribute does not appear for indexes that were created during a `CreateTable` operation.)
- **IndexName** - The name of the global secondary index.
- **IndexSizeBytes** - The total size of the global secondary index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.
- **IndexStatus** - The current status of the global secondary index:
  * **CREATING** - The index is being created.
  * **UPDATING** - The index is being updated.
  * **DELETING** - The index is being deleted.
  * **ACTIVE** - The index is ready for use.
- **ItemCount** - The number of items in the global secondary index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.
- **KeySchema** - Specifies the complete index key schema. The attribute names in the key schema must be between 1 and 255 characters (inclusive). The key schema must begin with the
same hash key attribute as the table.

- **Projection** - Specifies attributes that are copied (projected) from the table into the index. These are in addition to the primary key attributes and index key attributes, which are automatically projected. Each attribute specification is composed of:
  - **ProjectionType** - One of the following:
    - **KEYS_ONLY** - Only the index and primary keys are projected into the index.
    - **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in **NonKeyAttributes**.
    - **ALL** - All of the table attributes are projected into the index.
    - **NonKeyAttributes** - A list of one or more non-key attribute names that are projected into the secondary index. The total count of attributes provided in **NonKeyAttributes**, summed across all of the secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.
  - **ProvisionedThroughput** - The provisioned throughput settings for the global secondary index, consisting of read and write capacity units, along with data about increases and decreases.

If the table is in the **DELETING** state, no information about indexes will be returned.

- (dict) –
  - **IndexName** *(string)* –
    - The name of the global secondary index.
  - **KeySchema** *(list)* –
    - The complete key schema for the global secondary index, consisting of one or more pairs of attribute names and key types (**HASH** or **RANGE**).
  - (dict) –
    - Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

A **KeySchemaElement** represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one **KeySchemaElement**. A hash-and-range type primary key would require one **KeySchemaElement** for the hash attribute, and another **KeySchemaElement** for the range attribute.

- **AttributeName** *(string)* –
  - The name of a key attribute.
- **KeyType** *(string)* –
  - The attribute data, consisting of the data type and the attribute value itself.
- **Projection** *(dict)* –
  - Represents attributes that are copied (projected) from the table into an index. These are in addition to the primary key attributes and index key attributes, which are automatically projected.
- **ProjectionType (string)** –
  The set of attributes that are projected into the index:
  - **KEYS_ONLY** - Only the index and primary keys are projected into the index.
  - **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in **NonKeyAttributes**.
  - **ALL** - All of the table attributes are projected into the index.

- **NonKeyAttributes (list)** –
  Represents the non-key attribute names which will be projected into the index.

For local secondary indexes, the total count of **NonKeyAttributes** summed across all of the local secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

- **IndexStatus (string)** –
  The current state of the global secondary index:
  - **CREATING** - The index is being created.
  - **UPDATING** - The index is being updated.
  - **DELETING** - The index is being deleted.
  - **ACTIVE** - The index is ready for use.

- **Backfilling (boolean)** –
  Indicates whether the index is currently backfilling. Backfilling is the process of reading items from the table and determining whether they can be added to the index. (Not all items will qualify: For example, a hash key attribute cannot have any duplicates.) If an item can be added to the index, DynamoDB will do so. After all items have been processed, the backfilling operation is complete and **Backfilling** is false.

  **Note:** For indexes that were created during a **CreateTable** operation, the **Backfilling** attribute does not appear in the **DescribeTable** output.

- **ProvisionedThroughput (dict)** –
  Represents the provisioned throughput settings for the table, consisting of read and write capacity units, along with data about increases and decreases.

- **LastIncreaseDateTime (datetime)** –
  The date and time of the last provisioned throughput increase for this table.

- **LastDecreaseDateTime (datetime)** –
  The date and time of the last provisioned throughput decrease for this table.

- **NumberOfDecreasesToday (integer)** –
  The number of provisioned throughput decreases for this table during this UTC calendar day. For current maximums on
provisioned throughput decreases, see Limits in the Amazon DynamoDB Developer Guide.

- **ReadCapacityUnits (integer)** –
  The maximum number of strongly consistent reads consumed per second before DynamoDB returns a ThrottlingException. Eventually consistent reads require less effort than strongly consistent reads, so a setting of 50 ReadCapacityUnits per second provides 100 eventually consistent ReadCapacityUnits per second.

- **WriteCapacityUnits (integer)** –
  The maximum number of writes consumed per second before DynamoDB returns a ThrottlingException.

- **IndexSizeBytes (integer)** –
  The total size of the specified index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **ItemCount (integer)** –
  The number of items in the specified index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **IndexArn (string)** –
  The Amazon Resource Name (ARN) that uniquely identifies the index.

- **StreamSpecification (dict)** –
  The current DynamoDB Streams configuration for the table.
  - **StreamEnabled (boolean)** –
    Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.
  - **StreamViewType (string)** –
    The DynamoDB Streams settings for the table. These settings consist of:
    - **StreamEnabled** - Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.
    - **StreamViewType** - When an item in the table is modified, **StreamViewType** determines what information is written to the stream for this table. Valid values for **StreamViewType** are:
      * **KEYS_ONLY** - Only the key attributes of the modified item are written to the stream.
      * **NEW_IMAGE** - The entire item, as it appears after it was modified, is written to the stream.
      * **OLD_IMAGE** - The entire item, as it appeared before it was modified, is written to the stream.
      * **NEW_AND_OLD_IMAGES** - Both the new and the old item images of the item are written to the stream.

- **LatestStreamLabel (string)** –
  A timestamp, in ISO 8601 format, for this stream.
  Note that **LatestStreamLabel** is not a unique identifier for the stream, because it is possible that a stream from another table might have the
same timestamp. However, the combination of the following three elements is guaranteed to be unique:

- the AWS customer ID.
- the table name.
- the StreamLabel.

* LatestStreamArn *(string)* –

The Amazon Resource Name (ARN) that uniquely identifies the latest stream for this table.

**delete_item**: (**kwargs**)

Deletes a single item in a table by primary key. You can perform a conditional delete operation that deletes the item if it exists, or if it has an expected attribute value.

In addition to deleting an item, you can also return the item’s attribute values in the same operation, using the `ReturnValues` parameter.

Unless you specify conditions, the `DeleteItem` is an idempotent operation; running it multiple times on the same item or attribute does not result in an error response.

Conditional deletes are useful for deleting items only if specific conditions are met. If those conditions are met, DynamoDB performs the delete. Otherwise, the item is not deleted.

**Request Syntax**

```python
response = client.delete_item(
    TableName='string',
    Key={
        'string': {
            'S': 'string',
            'N': 'string',
            'B': b'bytes',
            'SS': [
                'string',
            ],
            'NS': [
                'string',
            ],
            'BS': [
                b'bytes',
            ],
            'M': {
                'string': {'... recursive ...'},
            },
            'L': [
                {'... recursive ...'},
            ],
            'NULL': True|False,
            'BOOL': True|False
        }
    },
    Expected={
        'string': {
            'Value': {
                'S': 'string',
                'N': 'string',
                'B': b'bytes',
                'SS': [
                    'string',
                ],
            }
        }
    }
)
```
Boto3 Documentation, Release 1.1.4

3.1. Services

3.1. Services
Parameters

- **TableName** *(string) – [REQUIRED]*
  
The name of the table from which to delete the item.

- **Key** *(dict) – [REQUIRED]*
  
  A map of attribute names to *AttributeValue* objects, representing the primary key of the item to delete.

  For the primary key, you must provide all of the attributes. For example, with a hash type primary key, you only need to provide the hash attribute. For a hash-and-range type primary key, you must provide both the hash attribute and the range attribute.

  - *(string) –
    
    - *(dict) –
      
      Represents the data for an attribute. You can set one, and only one, of the elements.

      Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

      - **S** *(string) –
        
        A String data type.

      - **N** *(string) –
        
        A Number data type.

      - **B** *(bytes) –
        
        A Binary data type.

      - **SS** *(list) –
        
        A String Set data type.

      - *(string) –
        
        - **NS** *(list) –
          
          A Number Set data type.
· **(string)** –  
· **(bytes)** –  
· **M (dict)** –  
A Map of attribute values.
· **(string)** –  
· **(dict)** –  
Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.
· **L (list)** –  
A List of attribute values.
· **(dict)** –  
Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.
· **NULL (boolean)** –  
A Null data type.
· **BOOL (boolean)** –  
A Boolean data type.

**Warning**: This is a legacy parameter, for backward compatibility. New applications should use `ConditionExpression` instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a `ValidationException` exception.

**Expected (dict)** –  
A map of attribute/condition pairs. `Expected` provides a conditional block for the `DeleteItem` operation.

Each element of `Expected` consists of an attribute name, a comparison operator, and one or more values. DynamoDB compares the attribute with the value(s) you supplied, using the comparison operator. For each `Expected` element, the result of the evaluation is either true or false.

If you specify more than one element in the `Expected` map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the `ConditionalOperator` parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

If the `Expected` map evaluates to true, then the conditional operation succeeds; otherwise, it fails.
Expected contains the following:

- **AttributeValueList** - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the `ComparisonOperator` being used. For type Number, value comparisons are numeric. String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and a is greater than b. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters). For type Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- **ComparisonOperator** - A comparator for evaluating attributes in the `AttributeValueList`. When performing the comparison, DynamoDB uses strongly consistent reads. The following comparison operators are available: `EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN`. The following are descriptions of each comparison operator. * `EQ` : Equal. `EQ` is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.

- **NE** : Not equal. `NE` is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.

- **LE** : Less than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **LT** : Less than. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **GE** : Greater than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **GT** : Greater than. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.
- **NOT_NULL**: The attribute exists. **NOT_NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the existence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NOT_NULL**, the result is a Boolean *true*. This result is because the attribute “a” exists; its data type is not relevant to the **NOT_NULL** comparison operator.

- **NULL**: The attribute does not exist. **NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NULL**, the result is a Boolean *false*. This is because the attribute “a” exists; its data type is not relevant to the **NULL** comparison operator.

- **CONTAINS**: Checks for a subsequence, or value in a set. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set (“**SS**”, “**NS**”, or “**BS**”), then the operator evaluates to true if it finds an exact match with any member of the set. **CONTAINS** is supported for lists: When evaluating “a **CONTAINS** b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

- **NOT_CONTAINS**: Checks for absence of a subsequence, or absence of a value in a set. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set (“**SS**”, “**NS**”, or “**BS**”), then the operator evaluates to true if it does not find an exact match with any member of the set. **NOT_CONTAINS** is supported for lists: When evaluating “a **NOT CONTAINS** b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

- **BEGINS_WITH**: Checks for a prefix. **AttributeValueList** can contain only one **AttributeValue** of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- **IN**: Checks for matching elements within two sets. **AttributeValueList** can contain one or more **AttributeValue** elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

- **BETWEEN**: Greater than or equal to the first value, and less than or equal to the second value. **AttributeValueList** must contain two **AttributeValue** elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{ "S": "6" }` does not compare to `{ "N": "6" }`. Also, `{ "N": "6" }` does not compare to `{ "NS": ["6", "2", "1"] }`.

For usage examples of **AttributeValueList** and **ComparisonOperator**, see Legacy Conditional Parameters in the Amazon DynamoDB Developer Guide.
For backward compatibility with previous DynamoDB releases, the following parameters can be used instead of `AttributeValueList` and `ComparisonOperator`:

- **Value** - A value for DynamoDB to compare with an attribute.
- **Exists** - A Boolean value that causes DynamoDB to evaluate the value before attempting the conditional operation: *
  - If `Exists` is `true`, DynamoDB will check to see if that attribute value already exists in the table. If it is found, then the condition evaluates to true; otherwise the condition evaluate to false.
  - If `Exists` is `false`, DynamoDB assumes that the attribute value does not exist in the table. If in fact the value does not exist, then the assumption is valid and the condition evaluates to true. If the value is found, despite the assumption that it does not exist, the condition evaluates to false.

Note that the default value for `Exists` is `true`.

The `Value` and `Exists` parameters are incompatible with `AttributeValueList` and `ComparisonOperator`. Note that if you use both sets of parameters at once, DynamoDB will return a `ValidationException` exception.

**Note:** This parameter does not support attributes of type List or Map.

- (string) –
  * (dict) –

Represents a condition to be compared with an attribute value. This condition can be used with `DeleteItem`, `PutItem` or `UpdateItem` operations; if the comparison evaluates to true, the operation succeeds; if not, the operation fails. You can use `ExpectedAttributeValue` in one of two different ways:

- Use `AttributeValueList` to specify one or more values to compare against an attribute. Use `ComparisonOperator` to specify how you want to perform the comparison. If the comparison evaluates to true, then the conditional operation succeeds.
- Use `Value` to specify a value that DynamoDB will compare against an attribute. If the values match, then `ExpectedAttributeValue` evaluates to true and the conditional operation succeeds. Optionally, you can also set `Exists` to false, indicating that you do not expect to find the attribute value in the table. In this case, the conditional operation succeeds only if the comparison evaluates to false.

Value and `Exists` are incompatible with `AttributeValueList` and `ComparisonOperator`. Note that if you use both sets of parameters at once, DynamoDB will return a `ValidationException` exception.

- **Value** (dict) –

  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **S** (string) –

  A String data type.

- **N** (string) –
A Number data type.
- **B** *(bytes)* –
  A Binary data type.
- **SS** *(list)* –
  A String Set data type.
  - *(string)* –
  - **NS** *(list)* –
  A Number Set data type.
  - *(string)* –
  - **BS** *(list)* –
  A Binary Set data type.
  - *(bytes)* –
  - **M** *(dict)* –
  A Map of attribute values.
  - *(string)* –
  - *(dict)* –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L** *(list)* –
  A List of attribute values.
  - *(dict)* –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL** *(boolean)* –
  A Null data type.
- **BOOL** *(boolean)* –
  A Boolean data type.
- **Exists** *(boolean)* –

Causes DynamoDB to evaluate the value before attempting a conditional operation:
- If **Exists** is `true`, DynamoDB will check to see if that attribute value already exists in the table. If it is found, then the operation succeeds. If it is not found, the operation fails with a `ConditionalCheckFailedException`.
- If **Exists** is `false`, DynamoDB assumes that the attribute value does not exist in the table. If in fact the value does not exist, then the assumption is valid and the operation succeeds.
If the value is found, despite the assumption that it does not exist, the operation fails with a `ConditionalCheckFailedException`.

The default setting for `Exists` is `true`. If you supply a `Value` all by itself, DynamoDB assumes the attribute exists: You don’t have to set `Exists` to `true`, because it is implied.

DynamoDB returns a `ValidationException` if:
- `Exists` is `true` but there is no `Value` to check. (You expect a value to exist, but don’t specify what that value is.)
- `Exists` is `false` but you also provide a `Value`. (You cannot expect an attribute to have a value, while also expecting it not to exist.)

**ComparisonOperator (string)**

A comparator for evaluating attributes in the `AttributeValueList`. For example, equals, greater than, less than, etc.

The following comparison operators are available:

- **EQ**: Equal. `EQ` is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.
- **NE**: Not equal. `NE` is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.
- **LE**: Less than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.
- **LT**: Less than. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.
- **GE**: Greater than or equal. `AttributeValueList` can contain
only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **GT**: Greater than. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **NOT_NULL**: The attribute exists. `NOT_NULL` is supported for all datatypes, including lists and maps. .. note:: This operator tests for the existence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using `NOT_NULL`, the result is a Boolean `true`. This result is because the attribute “a” exists; its data type is not relevant to the `NOT_NULL` comparison operator.

- **NULL**: The attribute does not exist. `NULL` is supported for all datatypes, including lists and maps. .. note:: This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using `NULL`, the result is a Boolean `false`. This is because the attribute “a” exists; its data type is not relevant to the `NULL` comparison operator.

- **CONTAINS**: Checks for a subsequence, or value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set (“SS”, “NS”, or “BS”), then the operator evaluates to true if it finds an exact match with any member of the set. CONTAINS is supported for lists: When evaluating “a CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

- **NOT_CONTAINS**: Checks for absence of a subsequence, or absence of a value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set (“SS”, “NS”, or “BS”), then the operator evaluates to true if it does not find an exact match with any member of the set. NOT_CONTAINS is supported for lists: When evaluating “a NOT CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

- **BEGINS_WITH**: Checks for a prefix. `AttributeValueList` can
contain only one `AttributeValue` of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- **IN**: Checks for matching elements within two sets. `AttributeValueList` can contain one or more `AttributeValue` elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

- **BETWEEN**: Greater than or equal to the first value, and less than or equal to the second value. `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{ "S": "6" }` does not compare to `{ "N": "6" }`. Also, `{ "N": "6" }` does not compare to `{ "NS": [ "6", "2", "1" ] }`.

- **AttributeValueList (list)** –

  One or more values to evaluate against the supplied attribute. The number of values in the list depends on the `Comparison-Operator` being used.

  For type Number, value comparisons are numeric.

  String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, `a` is greater than `A`, and `a` is greater than `B`. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters).

  For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

  For information on specifying data types in JSON, see JSON Data Format in the [Amazon DynamoDB Developer Guide](https://docs.aws.amazon.com/dynamodb/latest/developerguide/).

- **(dict)** –

  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

  - **S (string)** –

    A String data type.

  - **N (string)** –

    A Number data type.

  - **B (bytes)** –

    A Binary data type.
**SS** (list) –
A String Set data type.

- **(string)** –

**NS** (list) –
A Number Set data type.

- **(string)** –

**BS** (list) –
A Binary Set data type.

- **(bytes)** –

**M** (dict) –
A Map of attribute values.

- **(string)** –

- **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

**L** (list) –
A List of attribute values.

- **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

**NULL** (boolean) –
A Null data type.

**BOOL** (boolean) –
A Boolean data type.

**ConditionalOperator** (string) –

A logical operator to apply to the conditions in the *Expected* map:

- **AND** - If all of the conditions evaluate to true, then the entire map evaluates to true.

- **OR** - If at least one of the conditions evaluate to true, then the entire map evaluates to true.

If you omit *ConditionalOperator*, then **AND** is the default.

The operation will succeed only if the entire map evaluates to true.

---

**Warning:** This is a legacy parameter, for backward compatibility. New applications should use *ConditionExpression* instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, **DynamoDB** will return a **ValidationException** exception.
Note: This parameter does not support attributes of type List or Map.

- **ReturnValues** *(string)* – Use **ReturnValues** if you want to get the item attributes as they appeared before they were deleted. For **DeleteItem**, the valid values are:
  - **NONE** - If **ReturnValues** is not specified, or if its value is **NONE**, then nothing is returned. (This setting is the default for **ReturnValues**.)
  - **ALL_OLD** - The content of the old item is returned.

- **ReturnConsumedCapacity** *(string)* – Determines the level of detail about provisioned throughput consumption that is returned in the response:
  - **INDEXES** - The response includes the aggregate **ConsumedCapacity** for the operation, together with **ConsumedCapacity** for each table and secondary index that was accessed. Note that some operations, such as **GetItem** and **BatchGetItem**, do not access any indexes at all. In these cases, specifying **INDEXES** will only return **ConsumedCapacity** information for table(s).
  - **TOTAL** - The response includes only the aggregate **ConsumedCapacity** for the operation.
  - **NONE** - No **ConsumedCapacity** details are included in the response.

- **ReturnItemCollectionMetrics** *(string)* – Determines whether item collection metrics are returned. If set to **SIZE**, the response includes statistics about item collections, if any, that were modified during the operation are returned in the response. If set to **NONE** (the default), no statistics are returned.

- **ConditionExpression** *(string)* – A condition that must be satisfied in order for a conditional **DeleteItem** to succeed.

  An expression can contain any of the following:
  - **Functions**: `attribute_exists | attribute_not_exists | attribute_type | contains | begins_with | size`
    These function names are case-sensitive.
  - **Comparison operators**: `= | = | = = | BETWEEN | IN`
  - **Logical operators**: `AND | OR | NOT`

  For more information on condition expressions, see Specifying Conditions in the Amazon DynamoDB Developer Guide.

Note: **ConditionExpression** replaces the legacy **ConditionalOperator** and **Expected** parameters.

- **ExpressionAttributeNames** *(dict)* – One or more substitution tokens for attribute names in an expression. The following are some use cases for using **ExpressionAttributeNames**:
  - To access an attribute whose name conflicts with a DynamoDB reserved word.
  - To create a placeholder for repeating occurrences of an attribute name in an expression.
  - To prevent special characters in an attribute name from being misinterpreted in an expression.

Use the **#** character in an expression to dereference an attribute name. For example, consider the following attribute name:

- **Percentile**

  The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see Reserved Words in the Amazon DynamoDB Developer Guide.) To work around this, you could specify the following for **ExpressionAttributeNames**:

  ```
  { "#P": "Percentile" }
  ```

  You could then use this substitution in an expression, as in this example:
Note: Tokens that begin with the : character are expression attribute values, which are placeholders for the actual value at runtime.

For more information on expression attribute names, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

- (string) –
  * (string) –

• ExpressionAttributeValue (dict) – One or more values that can be substituted in an expression.

Use the : (colon) character in an expression to dereference an attribute value. For example, suppose that you wanted to check whether the value of the ProductStatus attribute was one of the following:

Available | Backordered | Discontinued

You would first need to specify ExpressionAttributeValue as follows:

```
{ "avail":"S":"Available"}, "back":{"S":"Backordered"},
"disc":{"S":"Discontinued"} }
```

You could then use these values in an expression, such as this:

ProductStatus IN (:avail, :back, :disc)

For more information on expression attribute values, see Specifying Conditions in the Amazon DynamoDB Developer Guide.

- (string) –
  * (dict) –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- S (string) –
  A String data type.
- N (string) –
  A Number data type.
- B (bytes) –
  A Binary data type.
- SS (list) –
  A String Set data type.
- (string) –
- NS (list) –
  A Number Set data type.
- (string) –
- BS (list) –
  A Binary Set data type.
· **M** *(dict)* –
  A Map of attribute values.
· **(string)** –
  · **(dict)** –
  Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

· **L** *(list)* –
  A List of attribute values.
· **(dict)** –
  · **(dict)** –
  Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

· **NULL** *(boolean)* –
  A Null data type.
· **BOOL** *(boolean)* –
  A Boolean data type.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'Attributes': {
        'string': {
            'S': 'string',

      'BOOL': True|False
    }
  },
  'SizeEstimateRangeGB': [123.0,
  ]
}

**Response Structure**

- *(dict)* – Represents the output of a *DeleteItem* operation.
  - **Attributes (dict)** – A map of attribute names to *AttributeValue* objects, representing the item as it appeared before the *DeleteItem* operation. This map appears in the
response only if `ReturnValues` was specified as `ALL_OLD` in the request.

* (string) –
  · (dict) –
    Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

  · `S (string)` –
    A String data type.

  · `N (string)` –
    A Number data type.

  · `B (bytes)` –
    A Binary data type.

  · `SS (list)` –
    A String Set data type.

  · `(string)` –
  · `NS (list)` –
    A Number Set data type.

  · `(string)` –
  · `BS (list)` –
    A Binary Set data type.

  · `(bytes)` –
  · `M (dict)` –
    A Map of attribute values.

  · `(string)` –
  · `(dict)` –
    Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

  · `L (list)` –
    A List of attribute values.

  · `(dict)` –
    Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.
- **NULL** *(boolean)* –
  A Null data type.
- **BOOL** *(boolean)* –
  A Boolean data type.

- **ConsumedCapacity** *(dict)* –
  The capacity units consumed by an operation. The data returned includes the total provisioned throughput consumed, along with statistics for the table and any indexes involved in the operation. *ConsumedCapacity* is only returned if the request asked for it. For more information, see [Provisioned Throughput](#) in the *Amazon DynamoDB Developer Guide*.
  
  * **TableName** *(string)* –
    The name of the table that was affected by the operation.
  
  * **CapacityUnits** *(float)* –
    The total number of capacity units consumed by the operation.
  
  * **Table** *(dict)* –
    The amount of throughput consumed on the table affected by the operation.
    
    * **CapacityUnits** *(float)* –
      The total number of capacity units consumed on a table or an index.

  * **LocalSecondaryIndexes** *(dict)* –
    The amount of throughput consumed on each local index affected by the operation.
    
    * (string) –
    * (dict) –
      Represents the amount of provisioned throughput capacity consumed on a table or an index.
    
    * **CapacityUnits** *(float)* –
      The total number of capacity units consumed on a table or an index.

  * **GlobalSecondaryIndexes** *(dict)* –
    The amount of throughput consumed on each global index affected by the operation.
    
    * (string) –
    * (dict) –
      Represents the amount of provisioned throughput capacity consumed on a table or an index.
    
    * **CapacityUnits** *(float)* –
      The total number of capacity units consumed on a table or an index.

- **ItemCollectionMetrics** *(dict)* –
  Information about item collections, if any, that were affected by the operation. *ItemCollectionMetrics* is only returned if the request asked for it. If the table does not have any local secondary indexes, this information is not returned in the response.

  Each *ItemCollectionMetrics* element consists of:
- **ItemCollectionKey** - The hash key value of the item collection. This is the same as the hash key of the item.
- **SizeEstimateRange** - An estimate of item collection size, in gigabytes. This value is a two-element array containing a lower bound and an upper bound for the estimate. The estimate includes the size of all the items in the table, plus the size of all attributes projected into all of the local secondary indexes on that table. Use this estimate to measure whether a local secondary index is approaching its size limit. The estimate is subject to change over time; therefore, do not rely on the precision or accuracy of the estimate.

- **ItemCollectionKey** *(dict)* –
  
The hash key value of the item collection. This value is the same as the hash key of the item.
  
  - *(string)* –
  
  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.
  
  - **S** *(string)* –
    
    A String data type.
  
  - **N** *(string)* –
    
    A Number data type.
  
  - **B** *(bytes)* –
    
    A Binary data type.
  
  - **SS** *(list)* –
    
    A String Set data type.
  
  - **NS** *(list)* –
    
    A Number Set data type.
  
  - **BS** *(list)* –
    
    A Binary Set data type.
  
  - **M** *(dict)* –
    
    A Map of attribute values.

  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one
title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L** *(list)* – A List of attribute values.
- **(dict)** – Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL** *(boolean)* – A Null data type.
- **BOOL** *(boolean)* – A Boolean data type.

* **SizeEstimateRangeGB** *(list)* – An estimate of item collection size, in gigabytes. This value is a two-element array containing a lower bound and an upper bound for the estimate. The estimate includes the size of all the items in the table, plus the size of all attributes projected into all of the local secondary indexes on that table. Use this estimate to measure whether a local secondary index is approaching its size limit.

The estimate is subject to change over time; therefore, do not rely on the precision or accuracy of the estimate.

- **(float)** –

```python
def delete_table(**kwargs):
    The DeleteTable operation deletes a table and all of its items. After a DeleteTable request, the specified table is in the DELETING state until DynamoDB completes the deletion. If the table is in the ACTIVE state, you can delete it. If a table is in CREATING or UPDATING states, then DynamoDB returns a ResourceInUseException. If the specified table does not exist, DynamoDB returns a ResourceNotFoundException. If table is already in the DELETING state, no error is returned.

Note: DynamoDB might continue to accept data read and write operations, such as GetItem and PutItem, on a table in the DELETING state until the table deletion is complete.
```

When you delete a table, any indexes on that table are also deleted.

If you have DynamoDB Streams enabled on the table, then the corresponding stream on that table goes into the DISABLED state, and the stream is automatically deleted after 24 hours.

Use the DescribeTable API to check the status of the table.

**Request Syntax**

```python
response = client.delete_table(
    TableName='string'
)
```

**Parameters**

- **TableName** *(string)* – [REQUIRED]
  The name of the table to delete.
Return type  dict
Returns
Response Syntax

```python
{
    'TableDescription': {
        'AttributeDefinitions': [
            {
                'AttributeName': 'string',
                'AttributeType': 'S'|'N'|'B'
            }
        ],
        'TableName': 'string',
        'KeySchema': [
            {
                'AttributeName': 'string',
                'KeyType': 'HASH'|'RANGE'
            }
        ],
        'TableStatus': 'CREATING'|'UPDATING'|'DELETING'|'ACTIVE',
        'CreationDateTime': datetime(2015, 1, 1),
        'ProvisionedThroughput': {
            'LastIncreaseDateTime': datetime(2015, 1, 1),
            'LastDecreaseDateTime': datetime(2015, 1, 1),
            'NumberOfDecreasesToday': 123,
            'ReadCapacityUnits': 123,
            'WriteCapacityUnits': 123
        },
        'TableSizeBytes': 123,
        'ItemCount': 123,
        'TableArn': 'string',
        'LocalSecondaryIndexes': [
            {
                'IndexName': 'string',
                'KeySchema': [
                    {
                        'AttributeName': 'string',
                        'KeyType': 'HASH'|'RANGE'
                    }
                ],
                'Projection': {
                    'ProjectionType': 'ALL'|'KEYS_ONLY'|'INCLUDE',
                    'NonKeyAttributes': ['string'],
                },
                'IndexSizeBytes': 123,
                'ItemCount': 123,
                'IndexArn': 'string'
            }
        ],
        'GlobalSecondaryIndexes': [
            {

                        'KeyType': 'HASH'|'RANGE'
                    }
                ],
                'Projection': {
                    'ProjectionType': 'ALL'|'KEYS_ONLY'|'INCLUDE',
                    'NonKeyAttributes': ['string'],
                },
                'IndexSizeBytes': 123,
                'ItemCount': 123,
                'IndexArn': 'string'
            }
        ]
    }
}
```
Response Structure

• (dict) – Represents the output of a DeleteTable operation.

  – TableDescription (dict) –

  Represents the properties of a table.

    • AttributeDefinitions (list) –

      An array of AttributeDefinition objects. Each of these objects describes one attribute in the table and index key schema.

      Each AttributeDefinition object in this array is composed of:

      ∙ AttributeName (string) – The name of the attribute.
      ∙ AttributeType (string) – The data type for the attribute.

      (dict) –

      Represents an attribute for describing the key schema for the table and indexes.

      ∙ AttributeName (string) –

        A name for the attribute.

      ∙ AttributeType (string) –

        The data type for the attribute.

    • TableName (string) –

      The name of the table.
* **KeySchema** (list) –

The primary key structure for the table. Each **KeySchemaElement** consists of:

- **AttributeName** - The name of the attribute.
- **KeyType** - The key type for the attribute. Can be either **HASH** or **RANGE**.

For more information about primary keys, see **Primary Key** in the *Amazon DynamoDB Developer Guide*.

* **TableStatus** (string) –

The current state of the table:

- **CREATING** - The table is being created.
- **UPDATING** - The table is being updated.
- **DELETING** - The table is being deleted.
- **ACTIVE** - The table is ready for use.

* **CreationDateTime** (datetime) –

The date and time when the table was created, in UNIX epoch time format.

* **ProvisionedThroughput** (dict) –

The provisioned throughput settings for the table, consisting of read and write capacity units, along with data about increases and decreases.

- **LastIncreaseDateTime** (datetime) –

  The date and time of the last provisioned throughput increase for this table.

- **LastDecreaseDateTime** (datetime) –

  The date and time of the last provisioned throughput decrease for this table.

- **NumberOfDecreasesToday** (integer) –

  The number of provisioned throughput decreases for this table during this UTC calendar day. For current maximums on provisioned throughput decreases, see Limits in the *Amazon DynamoDB Developer Guide*.

- **ReadCapacityUnits** (integer) –
The maximum number of strongly consistent reads consumed per second before DynamoDB returns a *ThrottlingException*. Eventually consistent reads require less effort than strongly consistent reads, so a setting of 50 *ReadCapacityUnits* per second provides 100 eventually consistent *ReadCapacityUnits* per second.

- **WriteCapacityUnits (integer)**
  
  The maximum number of writes consumed per second before DynamoDB returns a *ThrottlingException*.

- **TableSizeBytes (integer)**
  
  The total size of the specified table, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **ItemCount (integer)**
  
  The number of items in the specified table. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **TableArn (string)**
  
  The Amazon Resource Name (ARN) that uniquely identifies the table.

- **LocalSecondaryIndexes (list)**
  
  Represents one or more local secondary indexes on the table. Each index is scoped to a given hash key value. Tables with one or more local secondary indexes are subject to an item collection size limit, where the amount of data within a given item collection cannot exceed 10 GB. Each element is composed of:
  
  - **IndexName** - The name of the local secondary index.
  
  - **KeySchema** - Specifies the complete index key schema. The attribute names in the key schema must be between 1 and 255 characters (inclusive). The key schema must begin with the same hash key attribute as the table.
  
  - **Projection** - Specifies attributes that are copied (projected) from the table into the index. These are in addition to the primary key attributes and index key attributes, which are automatically projected. Each attribute specification is composed of: * ProjectionType - One of the following: * KEYS_ONLY - Only the index and primary keys are projected into the index. * INCLUDE - Only the specified table attributes are projected into the index. * ALL - All of the table attributes are projected into the index. * NonKeyAttributes - A list of one or more non-key attribute names that are projected into the secondary index. The total count of attributes provided in *NonKeyAttributes*, summed across all of the secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.
  
  - **IndexSizeBytes** - Represents the total size of the index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.
  
  - **ItemCount** - Represents the number of items in the index. Dy-
namoDB updates this value approximately every six hours. Recent changes might not be reflected in this value. If the table is in the \texttt{DELETING} state, no information about indexes will be returned.

- \texttt{(dict)} – Represents the properties of a local secondary index.
  - \texttt{IndexName (string)} – Represents the name of the local secondary index.
  - \texttt{KeySchema (list)} – The complete index key schema, which consists of one or more pairs of attribute names and key types (\texttt{HASH} or \texttt{RANGE}).
  - \texttt{(dict)} – Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

A \texttt{KeySchemaElement} represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one \texttt{KeySchemaElement}. A hash-and-range type primary key would require one \texttt{KeySchemaElement} for the hash attribute, and another \texttt{KeySchemaElement} for the range attribute.

- \texttt{AttributeName (string)} – The name of a key attribute.
  - \texttt{KeyType (string)} – The attribute data, consisting of the data type and the attribute value itself.
  - \texttt{Projection (dict)} – Represents attributes that are copied (projected) from the table into an index. These are in addition to the primary key attributes and index key attributes, which are automatically projected.
  - \texttt{ProjectionType (string)} – The set of attributes that are projected into the index:
    - \texttt{KEYS\_ONLY} - Only the index and primary keys are projected into the index.
    - \texttt{INCLUDE} - Only the specified table attributes are projected into the index. The list of projected attributes are in \texttt{NonKeyAttributes}.
    - \texttt{ALL} - All of the table attributes are projected into the index.
  - \texttt{NonKeyAttributes (list)} – Represents the non-key attribute names which will be projected into the index.

For local secondary indexes, the total count of \texttt{NonKeyAttributes} summed across all of the local secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.
- (string) –
- IndexSizeBytes (integer) –

The total size of the specified index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- ItemCount (integer) –

The number of items in the specified index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- IndexArn (string) –

The Amazon Resource Name (ARN) that uniquely identifies the index.

* GlobalSecondaryIndexes (list) –

The global secondary indexes, if any, on the table. Each index is scoped to a given hash key value. Each element is composed of:

- Backfilling - If true, then the index is currently in the backfilling phase. Backfilling occurs only when a new global secondary index is added to the table; it is the process by which DynamoDB populates the new index with data from the table. (This attribute does not appear for indexes that were created during a CreateTable operation.)
- IndexName - The name of the global secondary index.
- IndexSizeBytes - The total size of the global secondary index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.
- IndexStatus - The current status of the global secondary index:
  * CREATING - The index is being created.
  * UPDATING - The index is being updated.
  * DELETING - The index is being deleted.
  * ACTIVE - The index is ready for use.
- ItemCount - The number of items in the global secondary index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.
- KeySchema - Specifies the complete index key schema. The attribute names in the key schema must be between 1 and 255 characters (inclusive). The key schema must begin with the same hash key attribute as the table.
- Projection - Specifies attributes that are copied (projected) from the table into the index. These are in addition to the primary key attributes and index key attributes, which are automatically projected. Each attribute specification is composed of:
  * ProjectionType - One of the following:
    * KEYS_ONLY - Only the index and primary keys are projected into the index.
    * INCLUDE - Only the specified table attributes are projected into the index. The list of projected attributes are in NonKeyAttributes.
    * ALL - All of the table attributes are projected into the index.
  * NonKeyAttributes - A list of one or more non-key attribute names that are projected into the secondary index. The total count of attributes provided in NonKeyAttributes, summed across all of the secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this
counts as two distinct attributes when determining the total.

- **ProvisionedThroughput** - The provisioned throughput settings for the global secondary index, consisting of read and write capacity units, along with data about increases and decreases.

If the table is in the **DELETING** state, no information about indexes will be returned.

- **(dict)** –

  Represents the properties of a global secondary index.

- **IndexName (string)** –

  The name of the global secondary index.

- **KeySchema (list)** –

  The complete key schema for the global secondary index, consisting of one or more pairs of attribute names and key types (**HASH** or **RANGE**).

- **(dict)** –

  Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

  A **KeySchemaElement** represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one **KeySchemaElement**. A hash-and-range type primary key would require one **KeySchemaElement** for the hash attribute, and another **KeySchemaElement** for the range attribute.

- **AttributeName (string)** –

  The name of a key attribute.

- **KeyType (string)** –

  The attribute data, consisting of the data type and the attribute value itself.

- **Projection (dict)** –

  Represents attributes that are copied (projected) from the table into an index. These are in addition to the primary key attributes and index key attributes, which are automatically projected.

- **ProjectionType (string)** –

  The set of attributes that are projected into the index:

  - **KEYS_ONLY** - Only the index and primary keys are projected into the index.
  - **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in **NonKeyAttributes**.
  - **ALL** - All of the table attributes are projected into the index.

- **NonKeyAttributes (list)** –

  Represents the non-key attribute names which will be projected into the index.

  For local secondary indexes, the total count of **NonKeyAttributes** summed across all of the local secondary indexes, must not exceed 20. If you project the same attribute into two
different indexes, this counts as two distinct attributes when
determining the total.
· (string) –
· **IndexStatus** *(string)* –

The current state of the global secondary index:
· **CREATING** - The index is being created.
· **UPDATING** - The index is being updated.
· **DELETING** - The index is being deleted.
· **ACTIVE** - The index is ready for use.
· **Backfilling** *(boolean)* –

Indicates whether the index is currently backfilling. Backfill-
ing is the process of reading items from the table and deter-
mining whether they can be added to the index. (Not all items
will qualify: For example, a hash key attribute cannot have
any duplicates.) If an item can be added to the index, Dy-
namoDB will do so. After all items have been processed, the
backfilling operation is complete and **Backfilling** is false.

**Note:** For indexes that were created during a **CreateTable**
operation, the **Backfilling** attribute does not appear in the **De-
scribeTable** output.

· **ProvisionedThroughput** *(dict)* –

Represents the provisioned throughput settings for the table,
consisting of read and write capacity units, along with data
about increases and decreases.
· **LastIncreaseDateTime** *(datetime)* –

The date and time of the last provisioned throughput increase
for this table.
· **LastDecreaseDateTime** *(datetime)* –

The date and time of the last provisioned throughput decrease
for this table.
· **NumberOfDecreasesToday** *(integer)* –

The number of provisioned throughput decreases for this ta-
ble during this UTC calendar day. For current maximums on
provisioned throughput decreases, see Limits in the **Amazon
DynamoDB Developer Guide** .
· **ReadCapacityUnits** *(integer)* –

The maximum number of strongly consistent reads consumed
per second before DynamoDB returns a **ThrottlingException**
. Eventually consistent reads require less effort than strongly
consistent reads, so a setting of 50 **ReadCapacityUnits** per
second provides 100 eventually consistent **ReadCapacityU-
its** per second.
· **WriteCapacityUnits** *(integer)* –

The maximum number of writes consumed per second before
DynamoDB returns a **ThrottlingException**
· **IndexSizeBytes** *(integer)* –

The total size of the specified index, in bytes. DynamoDB
updates this value approximately every six hours. Recent
changes might not be reflected in this value.

- **ItemCount (integer)** –
  The number of items in the specified index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **IndexArn (string)** –
  The Amazon Resource Name (ARN) that uniquely identifies the index.

**StreamSpecification (dict)** –

The current DynamoDB Streams configuration for the table.

- **StreamEnabled (boolean)** –
  Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.

- **StreamViewType (string)** –
  The DynamoDB Streams settings for the table. These settings consist of:
  - **StreamEnabled** - Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.
  - **StreamViewType** - When an item in the table is modified, *StreamViewType* determines what information is written to the stream for this table. Valid values for *StreamViewType* are:
    - **KEYS_ONLY** - Only the key attributes of the modified item are written to the stream.
    - **NEW_IMAGE** - The entire item, as it appears after it was modified, is written to the stream.
    - **OLD_IMAGE** - The entire item, as it appeared before it was modified, is written to the stream.
    - **NEW_AND_OLD_IMAGES** - Both the new and the old item images of the item are written to the stream.

- **LatestStreamLabel (string)** –
  A timestamp, in ISO 8601 format, for this stream.

  Note that *LatestStreamLabel* is not a unique identifier for the stream, because it is possible that a stream from another table might have the same timestamp. However, the combination of the following three elements is guaranteed to be unique:
  - the AWS customer ID.
  - the table name.
  - the *StreamLabel*.

- **LatestStreamArn (string)** –
  The Amazon Resource Name (ARN) that uniquely identifies the latest stream for this table.

`describe_table(**kwargs)`

Returns information about the table, including the current status of the table, when it was created, the primary key schema, and any indexes on the table.

**Note:** If you issue a DescribeTable request immediately after a CreateTable request, DynamoDB might return a ResourceNotFoundException. This is because DescribeTable uses an eventually consistent query, and the metadata for your table might not be available at that moment. Wait for a few seconds, and then try the DescribeTable request again.
Request Syntax

```python
response = client.describe_table(
    TableName='string'
)
```

**Parameters**  
**TableName** *(string)* – [REQUIRED]

The name of the table to describe.

**Return type**  
**dict**

**Returns**

Response Syntax

Response Structure

- (dict) –

  Represents the output of a DescribeTable operation.
  - Table (dict) –

    Represents the properties of a table.
    * AttributeDefinitions (list) –

      An array of AttributeDefinition objects. Each of these objects describes one attribute in the table and index key schema.

      Each AttributeDefinition object in this array is composed of:
      - AttributeName - The name of the attribute.
      - AttributeType - The data type for the attribute.
      - (dict) –

        Represents an attribute for describing the key schema for the table and indexes.
```
AttributeName (string) –
A name for the attribute.
AttributeType (string) –
The data type for the attribute.
**TableName (string) –**
The name of the table.
**KeySchema (list) –**
The primary key structure for the table. Each KeySchemaElement consists of:
- AttributeName - The name of the attribute.
- KeyType - The key type for the attribute. Can be either HASH or RANGE.

For more information about primary keys, see Primary Key in the Amazon DynamoDB Developer Guide.

(dict) –
Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

A KeySchemaElement represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one KeySchemaElement. A hash-and-range type primary key would require one KeySchemaElement for the hash attribute, and another KeySchemaElement for the range attribute.

- AttributeName (string) –
The name of a key attribute.
- KeyType (string) –
The attribute data, consisting of the data type and the attribute value itself.

**TableStatus (string) –**
The current state of the table:
- CREATING - The table is being created.
- UPDATING - The table is being updated.
- DELETING - The table is being deleted.
- ACTIVE - The table is ready for use.

**CreationDateTime (datetime) –**
The date and time when the table was created, in UNIX epoch time format.

**ProvisionedThroughput (dict) –**
The provisioned throughput settings for the table, consisting of read and write capacity units, along with data about increases and decreases.

- LastIncreaseDateTime (datetime) –
The date and time of the last provisioned throughput increase for this table.
- LastDecreaseDateTime (datetime) –
The date and time of the last provisioned throughput decrease for this table.

- **NumberOfDecreasesToday (integer)** –

  The number of provisioned throughput decreases for this table during this UTC calendar day. For current maximums on provisioned throughput decreases, see Limits in the Amazon DynamoDB Developer Guide.

- **ReadCapacityUnits (integer)** –

  The maximum number of strongly consistent reads consumed per second before DynamoDB returns a ThrottlingException. Eventually consistent reads require less effort than strongly consistent reads, so a setting of 50 ReadCapacityUnits per second provides 100 eventually consistent ReadCapacityUnits per second.

- **WriteCapacityUnits (integer)** –

  The maximum number of writes consumed per second before DynamoDB returns a ThrottlingException.

- **TableSizeBytes (integer)** –

  The total size of the specified table, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **ItemCount (integer)** –

  The number of items in the specified table. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **TableArn (string)** –

  The Amazon Resource Name (ARN) that uniquely identifies the table.

- **LocalSecondaryIndexes (list)** –

  Represents one or more local secondary indexes on the table. Each index is scoped to a given hash key value. Tables with one or more local secondary indexes are subject to an item collection size limit, where the amount of data within a given item collection cannot exceed 10 GB. Each element is composed of:
  - **IndexName** - The name of the local secondary index.
  - **KeySchema** - Specifies the complete index key schema. The attribute names in the key schema must be between 1 and 255 characters (inclusive). The key schema must begin with the same hash key attribute as the table.
  - **Projection** - Specifies attributes that are copied (projected) from the table into the index. These are in addition to the primary key attributes and index key attributes, which are automatically projected. Each attribute specification is composed of:
    - **ProjectionType** - One of the following: *KEYS_ONLY* - Only the index and primary keys are projected into the index.
    - **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in **NonKeyAttributes**.
    - **ALL** - All of the table attributes are projected into the index.
    - **NonKeyAttributes** - A list of one or more non-key attribute
names that are projected into the secondary index. The total count of attributes provided in `NonKeyAttributes` summing across all of the secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

- **IndexSizeBytes** - Represents the total size of the index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.
- **ItemCount** - Represents the number of items in the index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

If the table is in the `DELETING` state, no information about indexes will be returned.

- **(dict)** –
  - Represents the properties of a local secondary index.
  - **IndexName (string)** –
    - Represents the name of the local secondary index.
  - **KeySchema (list)** –
    - The complete index key schema, which consists of one or more pairs of attribute names and key types (`HASH` or `RANGE`).
  - **(dict)** –
    - Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

A `KeySchemaElement` represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one `KeySchemaElement`. A hash-and-range type primary key would require one `KeySchemaElement` for the hash attribute, and another `KeySchemaElement` for the range attribute.

- **AttributeName (string)** –
  - The name of a key attribute.
- **KeyType (string)** –
  - The attribute data, consisting of the data type and the attribute value itself.
- **Projection (dict)** –
  - Represents attributes that are copied (projected) from the table into an index. These are in addition to the primary key attributes and index key attributes, which are automatically projected.
- **ProjectionType (string)** –
  - The set of attributes that are projected into the index:
    - **KEYS_ONLY** - Only the index and primary keys are projected into the index.
    - **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in `NonKeyAttributes`.
    - **ALL** - All of the table attributes are projected into the index.
**NonKeyAttributes (list)** –

Represents the non-key attribute names which will be projected into the index.

For local secondary indexes, the total count of `NonKeyAttributes` summed across all of the local secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

**IndexSizeBytes (integer)** –

The total size of the specified index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

**ItemCount (integer)** –

The number of items in the specified index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

**IndexArn (string)** –

The Amazon Resource Name (ARN) that uniquely identifies the index.

**GlobalSecondaryIndexes (list)** –

The global secondary indexes, if any, on the table. Each index is scoped to a given hash key value. Each element is composed of:

- **Backfilling** - If true, then the index is currently in the backfilling phase. Backfilling occurs only when a new global secondary index is added to the table; it is the process by which DynamoDB populates the new index with data from the table. (This attribute does not appear for indexes that were created during a `CreateTable` operation.)
- **IndexName** - The name of the global secondary index.
- **IndexSizeBytes** - The total size of the global secondary index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.
- **IndexStatus** - The current status of the global secondary index:
  - **CREATING** - The index is being created.
  - **UPDATING** - The index is being updated.
  - **DELETING** - The index is being deleted.
  - **ACTIVE** - The index is ready for use.
- **ItemCount** - The number of items in the global secondary index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.
- **KeySchema** - Specifies the complete index key schema. The attribute names in the key schema must be between 1 and 255 characters (inclusive). The key schema must begin with the same hash key attribute as the table.
- **Projection** - Specifies attributes that are copied (projected) from the table into the index. These are in addition to the primary key attributes and index key attributes, which are automatically projected. Each attribute specification is composed of:
  - **ProjectionType** - One of the following:
    - **KEYS_ONLY** - Only the index and primary keys are projected into the index.
· **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in `NonKeyAttributes`.
· **ALL** - All of the table attributes are projected into the index.
· **NonKeyAttributes** - A list of one or more non-key attribute names that are projected into the secondary index. The total count of attributes provided in `NonKeyAttributes`, summed across all of the secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.
· **ProvisionedThroughput** - The provisioned throughput settings for the global secondary index, consisting of read and write capacity units, along with data about increases and decreases.

If the table is in the **DELETING** state, no information about indexes will be returned.

· (dict) –

  Represents the properties of a global secondary index.

  · **IndexName** *(string)* –

    The name of the global secondary index.

  · **KeySchema** *(list)* –

    The complete key schema for the global secondary index, consisting of one or more pairs of attribute names and key types (HASH or RANGE).

  · (dict) –

    Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

    A `KeySchemaElement` represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one `KeySchemaElement`. A hash-and-range type primary key would require one `KeySchemaElement` for the hash attribute, and another `KeySchemaElement` for the range attribute.

  · **AttributeName** *(string)* –

    The name of a key attribute.

  · **KeyType** *(string)* –

    The attribute data, consisting of the data type and the attribute value itself.

  · **Projection** *(dict)* –

    Represents attributes that are copied (projected) from the table into an index. These are in addition to the primary key attributes and index key attributes, which are automatically projected.

  · **ProjectionType** *(string)* –

    The set of attributes that are projected into the index:

    · **KEYS_ONLY** - Only the index and primary keys are projected into the index.

    · **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in `NonKeyAttributes`.
Attributes:

- **ALL** - All of the table attributes are projected into the index.
- **NonKeyAttributes** (list) –
  
  Represents the non-key attribute names which will be projected into the index.

For local secondary indexes, the total count of **NonKeyAttributes** summed across all of the local secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

- **IndexStatus** (string) –

  The current state of the global secondary index:
  - **CREATING** - The index is being created.
  - **UPDATING** - The index is being updated.
  - **DELETING** - The index is being deleted.
  - **ACTIVE** - The index is ready for use.
- **Backfilling** (boolean) –

  Indicates whether the index is currently backfilling. Backfilling is the process of reading items from the table and determining whether they can be added to the index. (Not all items will qualify: For example, a hash key attribute cannot have any duplicates.) If an item can be added to the index, DynamoDB will do so. After all items have been processed, the backfilling operation is complete and Backfilling is false.

  **Note:** For indexes that were created during a **CreateTable** operation, the Backfilling attribute does not appear in the **DescribeTable** output.

- **ProvisionedThroughput** (dict) –

  Represents the provisioned throughput settings for the table, consisting of read and write capacity units, along with data about increases and decreases.

- **LastIncreaseDateTime** (datetime) –

  The date and time of the last provisioned throughput increase for this table.

- **LastDecreaseDateTime** (datetime) –

  The date and time of the last provisioned throughput decrease for this table.

- **NumberOfDecreasesToday** (integer) –

  The number of provisioned throughput decreases for this table during this UTC calendar day. For current maximums on provisioned throughput decreases, see Limits in the Amazon DynamoDB Developer Guide.

- **ReadCapacityUnits** (integer) –

  The maximum number of strongly consistent reads consumed per second before DynamoDB returns a ThrottlingException. Eventually consistent reads require less effort than strongly consistent reads, so a setting of 50 ReadCapacityUnits per
second provides 100 eventually consistent ReadCapacityUnits per second.

- **WriteCapacityUnits (integer)** –
  
The maximum number of writes consumed per second before DynamoDB returns a ThrottlingException.

- **IndexSizeBytes (integer)** –
  
The total size of the specified index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **ItemCount (integer)** –
  
The number of items in the specified index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **IndexArn (string)** –
  
The Amazon Resource Name (ARN) that uniquely identifies the index.

* **StreamSpecification (dict)** –
  
The current DynamoDB Streams configuration for the table.
  
  - **StreamEnabled (boolean)** –
    
    Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.

  - **StreamViewType (string)** –
    
    The DynamoDB Streams settings for the table. These settings consist of:
    
    - **StreamEnabled** - Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.
    - **StreamViewType** - When an item in the table is modified, StreamViewType determines what information is written to the stream for this table. Valid values for StreamViewType are: *
      
      - **KEYS_ONLY** - Only the key attributes of the modified item are written to the stream.
      - **NEW_IMAGE** - The entire item, as it appears after it was modified, is written to the stream.
      - **OLD_IMAGE** - The entire item, as it appeared before it was modified, is written to the stream.
      - **NEW_AND_OLD_IMAGES** - Both the new and the old item images of the item are written to the stream.

* **LatestStreamLabel (string)** –
  
  A timestamp, in ISO 8601 format, for this stream.

  Note that LatestStreamLabel is not a unique identifier for the stream, because it is possible that a stream from another table might have the same timestamp. However, the combination of the following three elements is guaranteed to be unique:

  - the AWS customer ID.
  - the table name.
  - the StreamLabel.

* **LatestStreamArn (string)** –
  
  The Amazon Resource Name (ARN) that uniquely identifies the latest stream for this table.
generate_presigned_url \( (\text{ClientMethod}, \text{Params}=\text{None}, \text{ExpiresIn}=3600, \text{HttpMethod}=\text{None}) \)

Generate a presigned url given a client, its method, and arguments

**Parameters**

- **ClientMethod** *(string)* – The client method to presign for
- **Params** *(dict)* – The parameters normally passed to *ClientMethod*.
- **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns** The presigned url

get_item (**kwargs**)

The *GetItem* operation returns a set of attributes for the item with the given primary key. If there is no matching item, *GetItem* does not return any data.

*GetItem* provides an eventually consistent read by default. If your application requires a strongly consistent read, set *ConsistentRead* to *true*. Although a strongly consistent read might take more time than an eventually consistent read, it always returns the last updated value.

**Request Syntax**

```python
response = client.get_item(
    TableName='string',
    Key={
        'string': {
            'S': 'string',
            'N': 'string',
            'B': b'bytes',
            'SS': [
                'string',
            ],
            'NS': [
                'string',
            ],
            'BS': [
                b'bytes',
            ],
            'M': {
                'string': {'... recursive ...'},
            },
            'L': [
                {'... recursive ...'},
            ],
            'NULL': True|False,
            'BOOL': True|False
        }
    },
    AttributesToGet=[
        'string',
    ],
    ConsistentRead=True|False,
    ReturnConsumedCapacity='INDEXES'|'TOTAL'|'NONE',
    ProjectionExpression='string',
    ExpressionAttributeNames={
        'string': 'string'
    }
)
```
Parameters

- **TableName** *(string)* – [REQUIRED]
  
The name of the table containing the requested item.

- **Key** *(dict)* – [REQUIRED]
  
  A map of attribute names to `AttributeValue` objects, representing the primary key of the item to retrieve.

  For the primary key, you must provide all of the attributes. For example, with a hash type primary key, you only need to provide the hash attribute. For a hash-and-range type primary key, you must provide both the hash attribute and the range attribute.
  
  - *(string)* –
    
    * *(dict)* –
      
      Represents the data for an attribute. You can set one, and only one, of the elements.

      Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

      - **S** *(string)* –
        
        A String data type.

      - **N** *(string)* –
        
        A Number data type.

      - **B** *(bytes)* –
        
        A Binary data type.

      - **SS** *(list)* –
        
        A String Set data type.

      - *(string)* –
        
        - **NS** *(list)* –
          
          A Number Set data type.

      - *(string)* –
        
        - **BS** *(list)* –
          
          A Binary Set data type.

      - *(bytes)* –
        
        - **M** *(dict)* –
          
          A Map of attribute values.

      - *(string)* –
        
        - *(dict)* –
          
          Represents the data for an attribute. You can set one, and only one, of the elements.

      Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L** *(list)* –
A List of attribute values.

- **(dict)** –

  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL (boolean)** –

  A Null data type.

- **BOOL (boolean)** –

  A Boolean data type.

- **AttributesToGet (list)** –

  The names of one or more attributes to retrieve. If no attribute names are provided, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

  Note that AttributesToGet has no effect on provisioned throughput consumption. DynamoDB determines capacity units consumed based on item size, not on the amount of data that is returned to an application.

- **(string)** –

- **ConsistentRead (boolean)** – Determines the read consistency model: If set to true, then the operation uses strongly consistent reads; otherwise, the operation uses eventually consistent reads.

- **ReturnConsumedCapacity (string)** – Determines the level of detail about provisioned throughput consumption that is returned in the response:

  - **INDEXES** - The response includes the aggregate ConsumedCapacity for the operation, together with ConsumedCapacity for each table and secondary index that was accessed. Note that some operations, such as GetItem and BatchGetItem, do not access any indexes at all. In these cases, specifying INDEXES will only return ConsumedCapacity information for table(s).
  
  - **TOTAL** - The response includes only the aggregate ConsumedCapacity for the operation.
  
  - **NONE** - No ConsumedCapacity details are included in the response.

- **ProjectionExpression (string)** – A string that identifies one or more attributes to retrieve from the table. These attributes can include scalars, sets, or elements of a JSON document. The attributes in the expression must be separated by commas.

  If no attribute names are specified, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

  For more information, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

  **Note:** ProjectionExpression replaces the legacy AttributesToGet parameter.
• **ExpressionAttributeNames** *(dict)* – One or more substitution tokens for attribute names in an expression. The following are some use cases for using *ExpressionAttributeNames*:
  - To access an attribute whose name conflicts with a DynamoDB reserved word.
  - To create a placeholder for repeating occurrences of an attribute name in an expression.
  - To prevent special characters in an attribute name from being misinterpreted in an expression.

Use the `#` character in an expression to dereference an attribute name. For example, consider the following attribute name:

- **Percentile**

The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see **Reserved Words** in the *Amazon DynamoDB Developer Guide*). To work around this, you could specify the following for *ExpressionAttributeNames*:

- `{"#P":"Percentile"}`

You could then use this substitution in an expression, as in this example:

- `#P = :val`

**Note:** Tokens that begin with the `:` character are *expression attribute values*, which are placeholders for the actual value at runtime.

For more information on expression attribute names, see **Accessing Item Attributes** in the *Amazon DynamoDB Developer Guide*.

- *(string)* –
  **Return type** dict

**Response Syntax**

```json
{
  'Item': {
    'string': {
      'S': 'string',
      'N': 'string',
      'B': b'bytes',
      'SS': [],
      'string',
    ],
    'NS': [
      'string',
    ],
    'BS': [
      b'bytes',
    ],
    'M': {
      'string': {'... recursive ...'}
    },
    'L': [
      {'... recursive ...'},
    ],
    'NULL': True|False,
    'BOOL': True|False
  }
```

3.1. Services
Response Structure

- (dict) –
  Represents the output of a GetItem operation.

  - Item (dict) –
    A map of attribute names to AttributeValue objects, as specified by AttributesToGet.

      * (string) –
        · (dict) –
          Represents the data for an attribute. You can set one, and only one, of the elements.

          Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

          · S (string) –
            A String data type.

          · N (string) –
            A Number data type.

          · B (bytes) –
            A Binary data type.

          · SS (list) –
            A String Set data type.

          · (string) –

          · NS (list) –
            A Number Set data type.

          · (string) –

          · BS (list) –
            A Binary Set data type.

          · (bytes) –
- **M (dict)** –
  A Map of attribute values.
- **(string)** –
- **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L (list)** –

A List of attribute values.
- **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL (boolean)** –

A Null data type.
- **BOOL (boolean)** –

A Boolean data type.

- **ConsumedCapacity (dict)** –

The capacity units consumed by an operation. The data returned includes the total provisioned throughput consumed, along with statistics for the table and any indexes involved in the operation. `ConsumedCapacity` is only returned if the request asked for it. For more information, see Provisioned Throughput in the *Amazon DynamoDB Developer Guide*.

  - **TableName (string)** –
    The name of the table that was affected by the operation.
  - **CapacityUnits (float)** –
    The total number of capacity units consumed by the operation.
  - **Table (dict)** –
    The amount of throughput consumed on the table affected by the operation.
    - **CapacityUnits (float)** –
      The total number of capacity units consumed on a table or an index.
  - **LocalSecondaryIndexes (dict)** –
    The amount of throughput consumed on each local index affected by the operation.
    - **(string)** –
    - **(dict)** –
Represents the amount of provisioned throughput capacity consumed on a table or an index.

- **CapacityUnits (float)** –

  The total number of capacity units consumed on a table or an index.

- **GlobalSecondaryIndexes (dict)** –

  The amount of throughput consumed on each global index affected by the operation.

  - (string) –
  - (dict) –

  Represents the amount of provisioned throughput capacity consumed on a table or an index.

  - **CapacityUnits (float)** –

    The total number of capacity units consumed on a table or an index.

---

**get_paginate** (operation_name)

Create a paginator for an operation.

**Parameters**

- **operation_name (string)** – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you'd normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

**Raises**

- **OperationNotPageableError** Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

**Return type**

- L{botocore.paginate.Paginator}

**Returns**

A paginator object.

**get_waiter** (waiter_name)

**list_tables** (**kwargs)

Returns an array of table names associated with the current account and endpoint. The output from `ListTables` is paginated, with each page returning a maximum of 100 table names.

**Request Syntax**

```python
response = client.list_tables(
    ExclusiveStartTableName='string',
    Limit=123
)
```

**Parameters**

- **ExclusiveStartTableName (string)** – The first table name that this operation will evaluate. Use the value that was returned for `LastEvaluatedTableName` in a previous operation, so that you can obtain the next page of results.
- **Limit (integer)** – A maximum number of table names to return. If this parameter is not specified, the limit is 100.

**Return type**

- dict

**Returns**

**Response Syntax**

```python
{
    'TableNames': [ 'string',
```
Response Structure

- (dict) – Represents the output of a ListTables operation.
  - TableNames (list) –
    - The names of the tables associated with the current account at the current endpoint. The maximum size of this array is 100.
    - If LastEvaluatedTableName also appears in the output, you can use this value as the ExclusiveStartTableName parameter in a subsequent ListTables request and obtain the next page of results.
  - (string) –
    - LastEvaluatedTableName (string) –
      - The name of the last table in the current page of results. Use this value as the ExclusiveStartTableName in a new request to obtain the next page of results, until all the table names are returned.
      - If you do not receive a LastEvaluatedTableName value in the response, this means that there are no more table names to be retrieved.

**put_item(**kwargs**)

Creates a new item, or replaces an old item with a new item. If an item that has the same primary key as the new item already exists in the specified table, the new item completely replaces the existing item. You can perform a conditional put operation (add a new item if one with the specified primary key doesn’t exist), or replace an existing item if it has certain attribute values.

In addition to putting an item, you can also return the item’s attribute values in the same operation, using the ReturnValues parameter.

When you add an item, the primary key attribute(s) are the only required attributes. Attribute values cannot be null. String and Binary type attributes must have lengths greater than zero. Set type attributes cannot be empty. Requests with empty values will be rejected with a ValidationException exception.

You can request that PutItem return either a copy of the original item (before the update) or a copy of the updated item (after the update). For more information, see the ReturnValues description below.

**Note:** To prevent a new item from replacing an existing item, use a conditional put operation with ComparisonOperator set to NULL for the primary key attribute, or attributes.

For more information about using this API, see Working with Items in the Amazon DynamoDB Developer Guide.

**Request Syntax**

```python
response = client.put_item(
    TableName='string',
    Item={
        'string': {
            'S': 'string',
            'N': 'string',
            'B': b'bytes',
            'SS': [
                'string',
            ]
        }
    }
)
```
Expected={
  'string': {
    'Value': {
      'S': 'string',
      'N': 'string',
      'B': b'bytes',
      'SS': [],
      'string': {
        'Value': {
          'S': 'string',
          'N': 'string',
          'B': b'bytes',
          'SS': [],
        },
      },
      'string': {
        'Value': {
          'S': 'string',
          'N': 'string',
          'B': b'bytes',
          'SS': [],
        },
      },
    },
    'string': {
      'Value': {
        'S': 'string',
        'N': 'string',
        'B': b'bytes',
        'SS': [],
      },
    },
  },
  'Exists': True|False,
  'ComparisonOperator': 'EQ'|'NE'|'IN'|'LE'|'LT'|'GE'|'GT'|'BETWEEN'|'NOT_NULL'|'NULL'|'CONTAINS'|'NOT_CONTAINS'|'BEGINS_WITH',
  'AttributeValueList': [
    {
      'S': 'string',
      'N': 'string',
      'B': b'bytes',
      'SS': [],
      'string': {
        'Value': {
          'S': 'string',
          'N': 'string',
          'B': b'bytes',
          'SS': [],
        },
      },
    }
  ]
}
Parameters

- **TableName** *(string)* – [REQUIRED]
  
  The name of the table to contain the item.

- **Item** *(dict)* – [REQUIRED]
  
  A map of attribute name/value pairs, one for each attribute. Only the primary key attributes are required; you can optionally provide other attribute name-value pairs for the item.

  You must provide all of the attributes for the primary key. For example, with a hash type primary key, you only need to provide the hash attribute. For a hash-and-range type primary key, you must provide both the hash attribute and the range attribute.
If you specify any attributes that are part of an index key, then the data types for those attributes must match those of the schema in the table’s attribute definition.

For more information about primary keys, see Primary Key in the Amazon DynamoDB Developer Guide.

Each element in the Item map is an AttributeValue object.

- (string) –
  * (dict) –
  
  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.
  - S (string) –
    A String data type.
  - N (string) –
    A Number data type.
  - B (bytes) –
    A Binary data type.
  - SS (list) –
    A String Set data type.
  - (string) –
  - NS (list) –
    A Number Set data type.
  - (string) –
  - BS (list) –
    A Binary Set data type.
  - (bytes) –
  - M (dict) –
    A Map of attribute values.
  - (string) –
  - (dict) –

  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.
  - L (list) –
    A List of attribute values.
  - (dict) –

  Represents the data for an attribute. You can set one, and only one, of the elements.
Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL (boolean)** –
  A Null data type.
- **BOOL (boolean)** –
  A Boolean data type.

**Warning:** This is a legacy parameter, for backward compatibility. New applications should use `ConditionExpression` instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a `ValidationException` exception.

- **Expected (dict)** –

  A map of attribute/condition pairs. `Expected` provides a conditional block for the `PutItem` operation.

**Note:** This parameter does not support attributes of type List or Map.

Each element of `Expected` consists of an attribute name, a comparison operator, and one or more values. DynamoDB compares the attribute with the value(s) you supplied, using the comparison operator. For each `Expected` element, the result of the evaluation is either true or false.

If you specify more than one element in the `Expected` map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the `ConditionalOperator` parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

If the `Expected` map evaluates to true, then the conditional operation succeeds; otherwise, it fails.

`Expected` contains the following:

- **AttributeValueList** - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the `ComparisonOperator` being used. For type Number, value comparisons are numeric. String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, “a” is greater than “A”, and “a” is greater than “B”. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters). For type Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- **ComparisonOperator** - A comparator for evaluating attributes in the `AttributeValueList`. When performing the comparison, DynamoDB uses strongly consistent reads. The following comparison operators are available: `EQ` | `NE` | `LE` | `LT` | `GE` | `GT` | `NOT_NULL` | `NULL` | `CONTAINS` | `NOT_CONTAINS` | `BEGINS_WITH` | `IN` | `BETWEEN` The following are descriptions of each comparison operator. * `EQ`: Equal. `EQ` is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` element of a different type than
the one provided in the request, the value does not match. For example, 
{"S":"6"} does not equal{"N":"6"} . Also,{"N":"6"} does not equal
{"NS": ["6", "2", "1"]}.

– NE : Not equal. NE is supported for all datatypes, including lists and maps. AttributeValueList can contain only one AttributeValue of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an AttributeValue of a different type than the one provided in the request, the value does not match. For example, {"S":"6"} does not equal{"N":"6"} . Also,{"N":"6"} does not equal{"NS": ["6", "2", "1"]}.

– LE : Less than or equal. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, {"S":"6"} does not equal{"N":"6"} . Also,{"N":"6"} does not compare to {"NS": ["6", "2", "1"]}.

– LT : Less than. AttributeValueList can contain only one AttributeValue of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, {"S":"6"} does not equal{"N":"6"} . Also,{"N":"6"} does not compare to {"NS": ["6", "2", "1"]}.

– GE : Greater than or equal. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, {"S":"6"} does not equal{"N":"6"} . Also,{"N":"6"} does not compare to {"NS": ["6", "2", "1"]}.

– GT : Greater than. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, {"S":"6"} does not equal{"N":"6"} . Also,{"N":"6"} does not compare to {"NS": ["6", "2", "1"]}.

– NOT_NULL : The attribute exists. NOT_NULL is supported for all datatypes, including lists and maps. .. note::This operator tests for the existence of an attribute, not its data type. If the data type of attribute “a ” is null, and you evaluate it using NOT_NULL , the result is a Boolean true . This result is because the attribute “a ” exists; its data type is not relevant
to the NOT_NULL comparison operator.

– NULL : The attribute does not exist. NULL is supported for all datatypes, including lists and maps. .. note::This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a ” is null, and you evaluate it using NULL , the result is a Boolean false . This is because the attribute “a ” exists; its data type is not relevant to the NULL comparison operator.

– CONTAINS : Checks for a subsequence, or value in a set. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it finds an exact match with any member of the set.
CONTAINS is supported for lists: When evaluating "a CONTAINS b ", "a " can be a list; however, "b " cannot be a set, a map, or a list.

- **NOT_CONTAINS**: Checks for absence of a subsequence, or absence of a value in a set. *AttributeValueList* can contain only one *AttributeValue* element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS ", "NS ", or "BS "), then the operator evaluates to true if it does not find an exact match with any member of the set. **NOT_CONTAINS** is supported for lists: When evaluating "a NOT CONTAINS b ", "a " can be a list; however, "b " cannot be a set, a map, or a list.

- **BEGINS_WITH**: Checks for a prefix. *AttributeValueList* can contain only one *AttributeValue* of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- **IN**: Checks for matching elements within two sets. *AttributeValueList* can contain one or more *AttributeValue* elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

- **BETWEEN**: Greater than or equal to the first value, and less than or equal to the second value. *AttributeValueList* must contain two *AttributeValue* elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an *AttributeValue* element of a different type than the one provided in the request, the value does not match. For example, { "S": "6"} does not compare to { "N": "6"}. Also, { "N": "6"} does not compare to { "NS": ["6", "2", "1"]}

For usage examples of *AttributeValueList* and *ComparisonOperator*, see Legacy Conditional Parameters in the Amazon DynamoDB Developer Guide.

For backward compatibility with previous DynamoDB releases, the following parameters can be used instead of *AttributeValueList* and *ComparisonOperator*:

- **Value** - A value for DynamoDB to compare with an attribute.
- **Exists** - A Boolean value that causes DynamoDB to evaluate the value before attempting the conditional operation: * If **Exists** is true , DynamoDB will check to see if that attribute value already exists in the table. If it is found, then the condition evaluates to true; otherwise the condition evaluates to false.

- If **Exists** is false, DynamoDB assumes that the attribute value does not exist in the table. If in fact the value does not exist, then the assumption is valid and the condition evaluates to true. If the value is found, despite the assumption that it does not exist, the condition evaluates to false.

Note that the default value for **Exists** is true .

The **Value** and **Exists** parameters are incompatible with *AttributeValueList* and *ComparisonOperator*. Note that if you use both sets of parameters at once, DynamoDB will return a ValidationException exception.

```
– (string) –
  * (dict) –
```

Represents a condition to be compared with an attribute value. This
condition can be used with \code{DeleteItem}, \code{PutItem} or \code{UpdateItem} operations; if the comparison evaluates to true, the operation succeeds; if not, the operation fails. You can use \code{ExpectedAttributeValue} in one of two different ways:

- Use \code{AttributeValueList} to specify one or more values to compare against an attribute. Use \code{ComparisonOperator} to specify how you want to perform the comparison. If the comparison evaluates to true, then the conditional operation succeeds.
- Use \code{Value} to specify a value that DynamoDB will compare against an attribute. If the values match, then \code{ExpectedAttributeValue} evaluates to true and the conditional operation succeeds. Optionally, you can also set \code{Exists} to false, indicating that you do not expect to find the attribute value in the table. In this case, the conditional operation succeeds only if the comparison evaluates to false.

\code{Value} and \code{Exists} are incompatible with \code{AttributeValueList} and \code{ComparisonOperator}. Note that if you use both sets of parameters at once, DynamoDB will return a \code{ValidationException} exception.

- \code{Value (dict)} –

  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- \code{S (string)} –

  A String data type.

- \code{N (string)} –

  A Number data type.

- \code{B (bytes)} –

  A Binary data type.

- \code{SS (list)} –

  A String Set data type.

- \code{(string)} –

  \code{NS (list)} –

  A Number Set data type.

- \code{(string)} –

  \code{BS (list)} –

  A Binary Set data type.

- \code{(bytes)} –

  \code{M (dict)} –

  A Map of attribute values.

- \code{(string)} –

  \code{(dict)} –

  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute
can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L (list)** –
  A List of attribute values.

- **(dict)** –
  Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL (boolean)** –
  A Null data type.

- **BOOL (boolean)** –
  A Boolean data type.

- **Exists (boolean)** –
  Causes DynamoDB to evaluate the value before attempting a conditional operation:
  - If `Exists` is `true`, DynamoDB will check to see if that attribute value already exists in the table. If it is found, then the operation succeeds. If it is not found, the operation fails with a `ConditionalCheckFailedException`.
  - If `Exists` is `false`, DynamoDB assumes that the attribute value does not exist in the table. If in fact the value does not exist, then the assumption is valid and the operation succeeds. If the value is found, despite the assumption that it does not exist, the operation fails with a `ConditionalCheckFailedException`.

  The default setting for `Exists` is `true`. If you supply a `Value` all by itself, DynamoDB assumes the attribute exists: You don’t have to set `Exists` to `true`, because it is implied.

DynamoDB returns a `ValidationException` if:
  - `Exists` is `true` but there is no `Value` to check. (You expect a value to exist, but don’t specify what that value is.)
  - `Exists` is `false` but you also provide a `Value`. (You cannot expect an attribute to have a value, while also expecting it not to exist.)

- **ComparisonOperator (string)** –
  A comparator for evaluating attributes in the `AttributeValueList`. For example, equals, greater than, less than, etc.

The following comparison operators are available:

```
EQ | NE | LE | LT | GE | GT | NOT_NULL
| NULL | CONTAINS | NOT_CONTAINS |
BEGINS_WITH | IN | BETWEEN
```

The following are descriptions of each comparison operator.
- **EQ**: Equal. **EQ** is supported for all datatypes, including lists and maps. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{ "S": "6" }` does not equal `{ "N": "6" }`. Also, `{ "N": "6" }` does not equal `{ "NS": [ "6", "2", "1" ] }`.

- **NE**: Not equal. **NE** is supported for all datatypes, including lists and maps. **AttributeValueList** can contain only one **AttributeValue** of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{ "S": "6" }` does not equal `{ "N": "6" }`. Also, `{ "N": "6" }` does not equal `{ "NS": [ "6", "2", "1" ] }`.

- **LE**: Less than or equal. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{ "S": "6" }` does not equal `{ "N": "6" }`. Also, `{ "N": "6" }` does not compare to `{ "NS": [ "6", "2", "1" ] }`.

- **LT**: Less than. **AttributeValueList** can contain only one **AttributeValue** of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{ "S": "6" }` does not equal `{ "N": "6" }`. Also, `{ "N": "6" }` does not compare to `{ "NS": [ "6", "2", "1" ] }`.

- **GE**: Greater than or equal. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{ "S": "6" }` does not equal `{ "N": "6" }`. Also, `{ "N": "6" }` does not compare to `{ "NS": [ "6", "2", "1" ] }`.

- **GT**: Greater than. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{ "S": "6" }` does not equal `{ "N": "6" }`. Also, `{ "N": "6" }` does not compare to `{ "NS": [ "6", "2", "1" ] }`.

- **NOT_NULL**: The attribute exists. **NOT_NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the existence of an attribute, not its data type. If the data type of attribute "a" is null, and you evaluate it using **NOT_NULL**, the result is a Boolean true. This result is because the attribute "a" exists; its data type is not relevant to the **NOT_NULL** comparison operator.

- **NULL**: The attribute does not exist. **NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the nonexistence of an attribute, not its data type.
If the data type of attribute “a” is null, and you evaluate it using NULL, the result is a Boolean false. This is because the attribute “a” exists; its data type is not relevant to the NULL comparison operator.

- CONTAINS: Checks for a subsequence, or value in a set. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set (“SS”, “NS”, or “BS”), then the operator evaluates to true if it finds an exact match with any member of the set. CONTAINS is supported for lists: When evaluating “a CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

- NOT_CONTAINS: Checks for absence of a subsequence, or absence of a value in a set. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set (“SS”, “NS”, or “BS”), then the operator evaluates to true if it does not find an exact match with any member of the set. NOT_CONTAINS is supported for lists: When evaluating “a NOT CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

- BEGINS_WITH: Checks for a prefix. AttributeValueList can contain only one AttributeValue of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- IN: Checks for matching elements within two sets. AttributeValueList can contain one or more AttributeValue elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

- BETWEEN: Greater than or equal to the first value, and less than or equal to the second value. AttributeValueList must contain two AttributeValue elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, "S": "6" does not compare to "N": "6".

One or more values to evaluate against the supplied attribute.
The number of values in the list depends on the *Comparison-Operator* being used.

For type Number, value comparisons are numeric.

String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, `a` is greater than `A`, and `a` is greater than `B`. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters.

For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

For information on specifying data types in JSON, see JSON Data Format in the *Amazon DynamoDB Developer Guide*.

- `(dict)` –

  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- `S` *(string)* –
  
  A String data type.

- `N` *(string)* –
  
  A Number data type.

- `B` *(bytes)* –
  
  A Binary data type.

- `SS` *(list)* –
  
  A String Set data type.

- `NS` *(list)* –
  
  A Number Set data type.

- `BS` *(list)* –
  
  A Binary Set data type.

- `M` *(dict)* –
  
  A Map of attribute values.

  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one
title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L** *(list)* –
  A List of attribute values.

- **(dict)** –
  Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL** *(boolean)* –
  A Null data type.

- **BOOL** *(boolean)* –
  A Boolean data type.

- **ReturnValues** *(string)* – Use **ReturnValues** if you want to get the item attributes as they appeared before they were updated with the **PutItem** request. For **PutItem**, the valid values are:
  - **NONE** - If **ReturnValues** is not specified, or if its value is **NONE**, then nothing is returned. (This setting is the default for **ReturnValues**.)
  - **ALL_OLD** - If **PutItem** overwrote an attribute name-value pair, then the content of the old item is returned.

  **Note:** Other “Valid Values” are not relevant to **PutItem**.

- **ReturnConsumedCapacity** *(string)* – Determines the level of detail about provisioned throughput consumption that is returned in the response:
  - **INDEXES** - The response includes the aggregate **ConsumedCapacity** for the operation, together with **ConsumedCapacity** for each table and secondary index that was accessed. Note that some operations, such as **GetItem** and **BatchGetItem**, do not access any indexes at all. In these cases, specifying **INDEXES** will only return **ConsumedCapacity** information for table(s).
  - **TOTAL** - The response includes only the aggregate **ConsumedCapacity** for the operation.
  - **NONE** - No **ConsumedCapacity** details are included in the response.

- **ReturnItemCollectionMetrics** *(string)* – Determines whether item collection metrics are returned. If set to **SIZE**, the response includes statistics about item collections, if any, that were modified during the operation are returned in the response. If set to **NONE** (the default), no statistics are returned.

- **ConditionalOperator** *(string)* –
  A logical operator to apply to the conditions in the **Expected** map:
  - **AND** - If all of the conditions evaluate to true, then the entire map evaluates to true.
  - **OR** - If at least one of the conditions evaluate to true, then the entire map evaluates to true.

**Warning:** This is a legacy parameter, for backward compatibility applications should use **ConditionExpression** instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a **ValidationException** exception.
If you omit `ConditionalOperator`, then AND is the default.

The operation will succeed only if the entire map evaluates to true.

**Note:** This parameter does not support attributes of type List or Map.

- **ConditionExpression (string)** – A condition that must be satisfied in order for a conditional `PutItem` operation to succeed.

  An expression can contain any of the following:
  
  - Functions: `attribute_exists | attribute_not_exists | attribute_type | contains | begins_with | size`  
    These function names are case-sensitive.
  
  - Comparison operators: `| | = | = | BETWEEN | IN`  
  
  - Logical operators: `AND | OR | NOT`  

  For more information on condition expressions, see [Specifying Conditions](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/dynamodb-condition-expressions.html) in the *Amazon DynamoDB Developer Guide*.

  **Note:** `ConditionExpression` replaces the legacy `ConditionalOperator` and `Expected` parameters.

- **ExpressionAttributeNames (dict)** – One or more substitution tokens for attribute names in an expression. The following are some use cases for using `ExpressionAttributeNames`:

  - To access an attribute whose name conflicts with a DynamoDB reserved word.
  
  - To create a placeholder for repeating occurrences of an attribute name in an expression.
  
  - To prevent special characters in an attribute name from being misinterpreted in an expression.

  Use the `#` character in an expression to dereference an attribute name. For example, consider the following attribute name:

  -`Percentile`

  The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see [Reserved Words](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/reserved-words.html) in the *Amazon DynamoDB Developer Guide*). To work around this, you could specify the following for `ExpressionAttributeNames`:

  - `{"#P":"Percentile"}`

  You could then use this substitution in an expression, as in this example:

  - `#P :=val`

  **Note:** Tokens that begin with the `:` character are *expression attribute values*, which are placeholders for the actual value at runtime.

  For more information on expression attribute names, see [Accessing Item Attributes](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/dynamodb-expressions-attribute-names.html) in the *Amazon DynamoDB Developer Guide*.

  - `(string)` –
  
  * (string)* –

- **ExpressionAttributeValues (dict)** – One or more values that can be substituted in an expression.

  Use the `:` (colon) character in an expression to dereference an attribute value. For example, suppose that you wanted to check whether the value of the `ProductStatus` attribute was one of the following:

  `Available | Backordered | Discontinued`
You would first need to specify `ExpressionAttributeValues` as follows:

```{ "avail":{"S":"Available"}, "back":{"S":"Backordered"}, "disc":{"S":"Discontinued"} }
```

You could then use these values in an expression, such as this:

```
ProductStatus IN (:avail, :back, :disc)
```

For more information on expression attribute values, see `Specifying Conditions` in the `Amazon DynamoDB Developer Guide`.

- *(string)*
  - *(dict)*

  Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **S (string)**
  - A String data type.

- **N (string)**
  - A Number data type.

- **B (bytes)**
  - A Binary data type.

- **SS (list)**
  - A String Set data type.

- **NS (list)**
  - A Number Set data type.

- **BS (list)**
  - A Binary Set data type.

- **M (dict)**
  - A Map of attribute values.

- **L (list)**
  - A List of attribute values.
Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL** *(boolean)* –
  A Null data type.

- **BOOL** *(boolean)* –
  A Boolean data type.

**Response Syntax**

```
{
    'Attributes': {
        'string': {
            'S': 'string',

        },
        'LocalSecondaryIndexes': {
            'string': {
                'CapacityUnits': 123.0
            }
        },
        'GlobalSecondaryIndexes': {
            'string': {
                'CapacityUnits': 123.0
            }
        }
    }
}
```
Response Structure

- (dict) –

Represents the output of a `PutItem` operation.

- Attributes (dict) –

The attribute values as they appeared before the `PutItem` operation, but only if `ReturnValues` is specified as `ALL_OLD` in the request. Each element consists of an attribute name and an attribute value.

  * (string) –
    
    Represents the data for an attribute. You can set one, and only one, of the elements.

    Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

    S (string) –

    A String data type.

    N (string) –

    A Number data type.
· **B** (*bytes*) –
  A Binary data type.
· **SS** (*list*) –
  A String Set data type.
· **(string)** –
· **NS** (*list*) –
  A Number Set data type.
· **(string)** –
· **BS** (*list*) –
  A Binary Set data type.
· **(bytes)** –
· **M** (*dict*) –
  A Map of attribute values.
· **(string)** –
· **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

· **L** (*list*) –
  A List of attribute values.
· **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

· **NULL** (*boolean*) –
  A Null data type.
· **BOOL** (*boolean*) –
  A Boolean data type.

· **ConsumedCapacity** (*dict*) –

  The capacity units consumed by an operation. The data returned includes the total provisioned throughput consumed, along with statistics for the table and any indexes involved in the operation. **ConsumedCapacity** is only returned if the request asked for it. For more information, see **Provisioned Throughput** in the *Amazon DynamoDB Developer Guide*.

  * **TableName** (*string*) –
    The name of the table that was affected by the operation.
  * **CapacityUnits** (*float*) –
    The total number of capacity units consumed by the operation.
* **Table** *(dict)* –
  The amount of throughput consumed on the table affected by the operation.
  - **CapacityUnits** *(float)* –
    The total number of capacity units consumed on a table or an index.

* **LocalSecondaryIndexes** *(dict)* –
  The amount of throughput consumed on each local index affected by the operation.
  - **(string)** –
  - **(dict)** –
    Represents the amount of provisioned throughput capacity consumed on a table or an index.
    - **CapacityUnits** *(float)* –
      The total number of capacity units consumed on a table or an index.

* **GlobalSecondaryIndexes** *(dict)* –
  The amount of throughput consumed on each global index affected by the operation.
  - **(string)** –
  - **(dict)** –
    Represents the amount of provisioned throughput capacity consumed on a table or an index.
    - **CapacityUnits** *(float)* –
      The total number of capacity units consumed on a table or an index.

  **ItemCollectionMetrics** *(dict)* –
  Information about item collections, if any, that were affected by the operation. *ItemCollectionMetrics* is only returned if the request asked for it. If the table does not have any local secondary indexes, this information is not returned in the response.

  Each *ItemCollectionMetrics* element consists of:
  * **ItemCollectionKey** *(dict)* - The hash key value of the item collection. This is the same as the hash key of the item.
  * **SizeEstimateRange** - An estimate of item collection size, in gigabytes. This value is a two-element array containing a lower bound and an upper bound for the estimate. The estimate includes the size of all the items in the table, plus the size of all attributes projected into all of the local secondary indexes on that table. Use this estimate to measure whether a local secondary index is approaching its size limit. The estimate is subject to change over time; therefore, do not rely on the precision or accuracy of the estimate.

  * **ItemCollectionKey** *(dict)* –
    The hash key value of the item collection. This value is the same as the hash key of the item.
Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **S** \((\text{string})\) – A String data type.
- **N** \((\text{string})\) – A Number data type.
- **B** \((\text{bytes})\) – A Binary data type.
- **SS** \((\text{list})\) – A String Set data type.
- **NS** \((\text{list})\) – A Number Set data type.
- **BS** \((\text{list})\) – A Binary Set data type.
- **M** \((\text{dict})\) – A Map of attribute values.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L** \((\text{list})\) – A List of attribute values.
- **NULL** \((\text{boolean})\) – A Null data type.
- **BOOL** \((\text{boolean})\) –
A Boolean data type.

* **SizeEstimateRangeGB (list)** –

  An estimate of item collection size, in gigabytes. This value is a two-element array containing a lower bound and an upper bound for the estimate. The estimate includes the size of all the items in the table, plus the size of all attributes projected into all of the local secondary indexes on that table. Use this estimate to measure whether a local secondary index is approaching its size limit.

  The estimate is subject to change over time; therefore, do not rely on the precision or accuracy of the estimate.

  · (float) –

query(**kwargs)

A Query operation uses the primary key of a table or a secondary index to directly access items from that table or index.

Use the KeyConditionExpression parameter to provide a specific hash key value. The Query operation will return all of the items from the table or index with that hash key value. You can optionally narrow the scope of the Query operation by specifying a range key value and a comparison operator in KeyConditionExpression. You can use the ScanIndexForward parameter to get results in forward or reverse order, by range key or by index key.

Queries that do not return results consume the minimum number of read capacity units for that type of read operation.

If the total number of items meeting the query criteria exceeds the result set size limit of 1 MB, the query stops and results are returned to the user with the LastEvaluatedKey element to continue the query in a subsequent operation. Unlike a Scan operation, a Query operation never returns both an empty result set and a LastEvaluatedKey value. LastEvaluatedKey is only provided if the results exceed 1 MB, or if you have used the Limit parameter.

You can query a table, a local secondary index, or a global secondary index. For a query on a table or on a local secondary index, you can set the ConsistentRead parameter to true and obtain a strongly consistent result. Global secondary indexes support eventually consistent reads only, so do not specify ConsistentRead when querying a global secondary index.

**Request Syntax**

```python
response = client.query(
    TableName='string',
    IndexName='string',
    Select='ALL_ATTRIBUTES'|'ALL_PROJECTED_ATTRIBUTES'|'SPECIFIC_ATTRIBUTES'|'COUNT',
    AttributesToGet=[
        'string',
    ],
    Limit=123,
    ConsistentRead=True|False,
    KeyConditions={
        'string': {
            'AttributeValueList': [
                { 'S': 'string',
                  'N': 'string',
                  'B': b'bytes',
                  'SS': [
                    'string',
                  ],
              },
            ]
        }
    }
```
QueryFilter={
    'string': {
        'ComparisonOperator': ['EQ', 'NE', 'IN', 'LE', 'LT', 'GE', 'GT', 'BETWEEN', 'NOT_NULL', 'NULL', 'CONTAINS', 'NOT_CONTAINS', 'BEGINS_WITH']
    }
},

ConditionalOperator='AND'|'OR',
ScanIndexForward=True|False,
ExclusiveStartKey={
    'string': {
        'ComparisonOperator': ['EQ', 'NE', 'IN', 'LE', 'LT', 'GE', 'GT', 'BETWEEN', 'NOT_NULL', 'NULL', 'CONTAINS', 'NOT_CONTAINS', 'BEGINS_WITH']
    }
}
Parameters

- **TableName** *(string)* – [REQUIRED]

  The name of the table containing the requested items.

- **IndexName** *(string)* – The name of an index to query. This index can be any local secondary index or global secondary index on the table. Note that if you use the `IndexName` parameter, you must also provide `TableName`.

- **Select** *(string)* – The attributes to be returned in the result. You can retrieve all item attributes, specific item attributes, the count of matching items, or in the
case of an index, some or all of the attributes projected into the index.

- **ALL_ATTRIBUTES** - Returns all of the item attributes from the specified table or index. If you query a local secondary index, then for each matching item in the index DynamoDB will fetch the entire item from the parent table. If the index is configured to project all item attributes, then all of the data can be obtained from the local secondary index, and no fetching is required.

- **ALL_PROJECTED_ATTRIBUTES** - Allowed only when querying an index. Retrieves all attributes that have been projected into the index. If the index is configured to project all attributes, this return value is equivalent to specifying **ALL_ATTRIBUTES**.

- **COUNT** - Returns the number of matching items, rather than the matching items themselves.

- **SPECIFIC_ATTRIBUTES** - Returns only the attributes listed in **AttributesToGet**. This return value is equivalent to specifying **AttributesToGet** without specifying any value for **Select**. If you query a local secondary index and request only attributes that are projected into that index, the operation will read only the index and not the table. If any of the requested attributes are not projected into the local secondary index, DynamoDB will fetch each of these attributes from the parent table. This extra fetching incurs additional throughput cost and latency. If you query a global secondary index, you can only request attributes that are projected into the index. Global secondary index queries cannot fetch attributes from the parent table.

If neither **Select** nor **AttributesToGet** are specified, DynamoDB defaults to **ALL_ATTRIBUTES** when accessing a table, and **ALL_PROJECTED_ATTRIBUTES** when accessing an index. You cannot use both **Select** and **AttributesToGet** together in a single request, unless the value for **Select** is **SPECIFIC_ATTRIBUTES**. (This usage is equivalent to specifying **AttributesToGet** without any value for **Select**.)

**Note:** If you use the **ProjectionExpression** parameter, then the value for **Select** can only be **SPECIFIC_ATTRIBUTES**. Any other value for **Select** will return an error.

**Warning:** This is a legacy parameter, for backward compatibility. New applications should use **ProjectionExpression** instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a **ValidationException** exception.

This parameter allows you to retrieve attributes of type List or Map; however, it cannot retrieve individual elements within a List or a Map.

- **AttributesToGet** *(list)* –

The names of one or more attributes to retrieve. If no attribute names are provided, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

Note that **AttributesToGet** has no effect on provisioned throughput consumption. DynamoDB determines capacity units consumed based on item size, not on the amount of data that is returned to an application.

You cannot use both **AttributesToGet** and **Select** together in a **Query** request, unless the value for **Select** is **SPECIFIC_ATTRIBUTES**. (This usage is equivalent to specifying **AttributesToGet** without any value for **Select**.)

If you query a local secondary index and request only attributes that are pro-
jected into that index, the operation will read only the index and not the table. If any of the requested attributes are not projected into the local secondary index, DynamoDB will fetch each of these attributes from the parent table. This extra fetching incurs additional throughput cost and latency.

If you query a global secondary index, you can only request attributes that are projected into the index. Global secondary index queries cannot fetch attributes from the parent table.

- **Limit** (integer) – The maximum number of items to evaluate (not necessarily the number of matching items). If DynamoDB processes the number of items up to the limit while processing the results, it stops the operation and returns the matching values up to that point, and a key in `LastEvaluatedKey` to apply in a subsequent operation, so that you can pick up where you left off. Also, if the processed data set size exceeds 1 MB before DynamoDB reaches this limit, it stops the operation and returns the matching values up to the limit, and a key in `LastEvaluatedKey` to apply in a subsequent operation to continue the operation. For more information, see Query and Scan in the Amazon DynamoDB Developer Guide.

- **ConsistentRead** (boolean) – Determines the read consistency model: If set to `true`, then the operation uses strongly consistent reads; otherwise, the operation uses eventually consistent reads.

Strongly consistent reads are not supported on global secondary indexes. If you query a global secondary index with `ConsistentRead` set to `true`, you will receive a `ValidationException`.

- **KeyConditions** (dict) –

The selection criteria for the query. For a query on a table, you can have conditions only on the table primary key attributes. You must provide the hash key attribute name and value as an `EQ` condition. You can optionally provide a second condition, referring to the range key attribute.

**Note:** If you don’t provide a range key condition, all of the items that match the hash key will be retrieved. If a `FilterExpression` or `QueryFilter` is present, it will be applied after the items are retrieved.

For a query on an index, you can have conditions only on the index key attributes. You must provide the index hash attribute name and value as an `EQ` condition. You can optionally provide a second condition, referring to the index key range attribute.

Each `KeyConditions` element consists of an attribute name to compare, along with the following:

- **AttributeValueList** - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the `ComparisonOperator` being used. For type Number, value comparisons are numeric. String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, `a` is greater than `A`, and `a` is greater than `B`. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters. For Bi-
nary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- **ComparisonOperator** - A comparator for evaluating attributes, for example, equals, greater than, less than, and so on. For **KeyConditions**, only the following comparison operators are supported: **EQ | LE | LT | GE | GT | BEGINS_WITH | BETWEEN**

The following are descriptions of these comparison operators.

- **EQ**: Equal. **AttributeValueList** can contain only one **AttributeValue** of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.

- **LE**: Less than or equal. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **LT**: Less than. **AttributeValueList** can contain only one **AttributeValue** of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **GE**: Greater than or equal. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **GT**: Greater than. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **BEGINS_WITH**: Checks for a prefix. **AttributeValueList** can contain only one **AttributeValue** of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- **BETWEEN**: Greater than or equal to the first value, and less than or equal to the second value. **AttributeValueList** must contain two **AttributeValue** elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not compare to `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

For usage examples of **AttributeValueList** and **ComparisonOperator**, see [Legacy Conditional Parameters](#) in the *Amazon DynamoDB Developer Guide*.

- (string) –
  * (dict) –
Represents the selection criteria for a `Query` or `Scan` operation:

- For a `Query` operation, `Condition` is used for specifying the `KeyConditions` to use when querying a table or an index. For `KeyConditions`, only the following comparison operators are supported: `EQ | LE | LT | GE | GT | BEGINS_WITH | BETWEEN`. `Condition` is also used in a `QueryFilter`, which evaluates the query results and returns only the desired values.

- For a `Scan` operation, `Condition` is used in a `ScanFilter`, which evaluates the scan results and returns only the desired values.

- **AttributeValueList** *(list)* –

  One or more values to evaluate against the supplied attribute. The number of values in the list depends on the `ComparisonOperator` being used.

  For type Number, value comparisons are numeric.

  String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, `a` is greater than `A`, and `a` is greater than `B`. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters).

  For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- **(dict)** –

  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

  - **`S` (string)** –
    
    A String data type.

  - **`N` (string)** –
    
    A Number data type.

  - **`B` (bytes)** –
    
    A Binary data type.

  - **`SS` (list)** –
    
    A String Set data type.

  - **`(string)` –**

  - **`NS` (list)` –**

    A Number Set data type.

  - **`BS` (list)` –**

    A Binary Set data type.
· **M (dict)** – A Map of attribute values.
· **(string)** –
· **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

· **L (list)** –

A List of attribute values.

· **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

· **NULL (boolean)** –

A Null data type.

· **BOOL (boolean)** –

A Boolean data type.

· **ComparisonOperator (string)** – [REQUIRED]

A comparator for evaluating attributes. For example, equals, greater than, less than, etc.

The following comparison operators are available:

```plaintext
EQ | NE | LE | LT | GE | GT | NOT_NULL
| NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN
```

The following are descriptions of each comparison operator.

· **EQ** : Equal. EQ is supported for all datatypes, including lists and maps. *AttributeValueList* can contain only one *AttributeValue* element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an *AttributeValue* element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.

· **NE** : Not equal. NE is supported for all datatypes, including lists and maps. *AttributeValueList* can contain only one *AttributeValue* of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an *AttributeValue* of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does
not equal ("N": "6") . Also, ("N": "6") does not equal 
{"NS": ["6", "2", "1"]}.

- **LE** : Less than or equal. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, ("S": "6") does not equal ("N": "6") . Also, ("N": "6") does not compare to 
{"NS": ["6", "2", "1"]}.

- **LT** : Less than. **AttributeValueList** can contain only one **AttributeValue** of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, ("S": "6") does not equal ("N": "6") . Also, ("N": "6") does not compare to 
{"NS": ["6", "2", "1"]}.

- **GE** : Greater than or equal. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, ("S": "6") does not equal ("N": "6") . Also, ("N": "6") does not compare to 
{"NS": ["6", "2", "1"]}.

- **GT** : Greater than. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, ("S": "6") does not equal ("N": "6") . Also, ("N": "6") does not compare to 
{"NS": ["6", "2", "1"]}.

- **NOT_NULL** : The attribute exists. **NOT_NULL** is supported for all datatypes, including lists and maps. .. note::This operator tests for the existence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NOT_NULL**, the result is a Boolean true. This result is because the attribute “a” exists; its data type is not relevant to the **NOT_NULL** comparison operator.

- **NULL** : The attribute does not exist. **NULL** is supported for all datatypes, including lists and maps. .. note::This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NULL**, the result is a Boolean false. This is because the attribute “a” exists; its data type is not relevant to the **NULL** comparison operator.

- **CONTAINS** : Checks for a subsequence, or value in a set. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it finds an exact match with any member of the set. **CONTAINS** is supported.
for lists: When evaluating “a CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.
- `NOT_CONTAINS`: Checks for absence of a subsequence, or absence of a value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set (“SS”, “NS”, or “BS”), then the operator evaluates to true if it does not find an exact match with any member of the set. `NOT_CONTAINS` is supported for lists: When evaluating “a NOT CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.
- `BEGINS_WITH`: Checks for a prefix. `AttributeValueList` can contain only one `AttributeValue` of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).
- `IN`: Checks for matching elements within two sets. `AttributeValueList` can contain one or more `AttributeValue` elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.
- `BETWEEN`: Greater than or equal to the first value, and less than or equal to the second value. `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not compare to `{"N": "6"}`. Also, `{"N": "6"}` does not compare to `{"SS": ["6", "2", "1"]}`

For usage examples of `AttributeValueList` and `Comparison-Operator`, see Legacy Conditional Parameters in the Amazon DynamoDB Developer Guide.

• **QueryFilter** *(dict)* –

A condition that evaluates the query results after the items are read and returns only the desired values.

This parameter does not support attributes of type List or Map.

**Warning:** This is a legacy parameter, for backward compatibility. New applications should use `FilterExpression` instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a `ValidationException` exception.

**Note:** A `QueryFilter` is applied after the items have already been read; the process of filtering does not consume any additional read capacity units.
If you provide more than one condition in the `QueryFilter` map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the `ConditionalOperator` parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

Note that `QueryFilter` does not allow key attributes. You cannot define a filter condition on a hash key or range key.

Each `QueryFilter` element consists of an attribute name to compare, along with the following:

- `AttributeValueList` - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the operator specified in `ComparisonOperator`. For type Number, value comparisons are numeric. String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, `a` is greater than `A`, and `a` is greater than `B`. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters). For type Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values. For information on specifying data types in JSON, see [JSON Data Format](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters) in the Amazon DynamoDB Developer Guide.

- `ComparisonOperator` - A comparator for evaluating attributes. For example, equals, greater than, less than, etc. The following comparison operators are available: `EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN`. For complete descriptions of all comparison operators, see the `Condition` data type.

- `(string)`
  - *(dict)*

  Represents the selection criteria for a `Query` or `Scan` operation:
  - For a `Query` operation, `Condition` is used for specifying the `KeyConditions` to use when querying a table or an index. For `KeyConditions`, only the following comparison operators are supported: `EQ | LE | LT | GE | GT | BEGINS_WITH | BETWEEN`. `Condition` is also used in a `QueryFilter`, which evaluates the query results and returns only the desired values.
  - For a `Scan` operation, `Condition` is used in a `ScanFilter`, which evaluates the scan results and returns only the desired values.

- `AttributeValueList` *(list)*

  One or more values to evaluate against the supplied attribute. The number of values in the list depends on the `ComparisonOperator` being used.

For type Number, value comparisons are numeric.

String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, `a` is greater than `A`, and `a` is greater than `B`. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters).
For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- \( \text{(dict)} \) –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- \( \text{S (string)} \) –

A String data type.

- \( \text{N (string)} \) –

A Number data type.

- \( \text{B (bytes)} \) –

A Binary data type.

- \( \text{SS (list)} \) –

A String Set data type.

- \( \text{(string)} \) –

- \( \text{NS (list)} \) –

A Number Set data type.

- \( \text{(string)} \) –

- \( \text{BS (list)} \) –

A Binary Set data type.

- \( \text{bytes} \) –

- \( \text{M (dict)} \) –

A Map of attribute values.

- \( \text{(string)} \) –

- \( \text{(dict)} \) –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- \( \text{L (list)} \) –

A List of attribute values.

- \( \text{(dict)} \) –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.
• **NULL** *(boolean)* –
  A Null data type.

• **BOOL** *(boolean)* –
  A Boolean data type.

• **ComparisonOperator** *(string)* – [REQUIRED]
  A comparator for evaluating attributes. For example, equals, greater than, less than, etc.

The following comparison operators are available:

```
EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN
```

The following are descriptions of each comparison operator.

• **EQ**: Equal. **EQ** is supported for all datatypes, including lists and maps. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.

• **NE**: Not equal. **NE** is supported for all datatypes, including lists and maps. **AttributeValueList** can contain only one **AttributeValue** of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an **AttributeValue** of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.

• **LE**: Less than or equal. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

• **LT**: Less than. **AttributeValueList** can contain only one **AttributeValue** of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

• **GE**: Greater than or equal. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

• **GT**: Greater than. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.
a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{ "S": "6" \} does not equal \{ "N": "6" \}. Also, \{ "N": "6" \} does not compare to \{ "NS": ["6", "2", "1"] \}.

- **NOT_NULL**: The attribute exists. **NOT_NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the existence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NOT_NULL**, the result is a Boolean true. This result is because the attribute “a” exists; its data type is not relevant to the **NOT_NULL** comparison operator.

- **NULL**: The attribute does not exist. **NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NULL**, the result is a Boolean false. This is because the attribute “a” exists; its data type is not relevant to the **NULL** comparison operator.

- **CONTAINS**: Checks for a subsequence, or value in a set. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set (“SS”, “NS”, or “BS”), then the operator evaluates to true if it finds an exact match with any member of the set. **CONTAINS** is supported for lists: When evaluating “a CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

- **NOT_CONTAINS**: Checks for absence of a subsequence, or absence of a value in a set. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set (“SS”, “NS”, or “BS”), then the operator evaluates to true if it does not find an exact match with any member of the set. **NOT_CONTAINS** is supported for lists: When evaluating “a NOT CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

- **BEGINS_WITH**: Checks for a prefix. **AttributeValueList** can contain only one **AttributeValue** of type String or Binary (not a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- **IN**: Checks for matching elements within two sets. **AttributeValueList** can contain one or more **AttributeValue** elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the
item attribute, the expression evaluates to true.

- **BETWEEN**: Greater than or equal to the first value, and less than or equal to the second value. `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{ "S": "6" }` does not compare to `{ "N": "6" }`. Also, `{ "N": "6" }` does not compare to `{ "NS": [ "6", "2", "1" ] }`.

For usage examples of `AttributeValueList` and `Comparison-Operator`, see Legacy Conditional Parameters in the Amazon DynamoDB Developer Guide.

- **ConditionalOperator** *(string)* –

A logical operator to apply to the conditions in a `QueryFilter` map:

- **AND** - If all of the conditions evaluate to true, then the entire map evaluates to true.
- **OR** - If at least one of the conditions evaluate to true, then the entire map evaluates to true.

If you omit `ConditionalOperator`, then **AND** is the default.

The operation will succeed only if the entire map evaluates to true.

**Note**: This parameter does not support attributes of type List or Map.

- **ScanIndexForward** *(boolean)* – Specifies the order in which to return the query results - either ascending (`true`) or descending (`false`).

Items with the same hash key are stored in sorted order by range key. If the range key data type is Number, the results are stored in numeric order. For type String, the results are returned in order of ASCII character code values. For type Binary, DynamoDB treats each byte of the binary data as unsigned.

If `ScanIndexForward` is **true**, DynamoDB returns the results in order, by range key. This is the default behavior.

If `ScanIndexForward` is **false**, DynamoDB sorts the results in descending order by range key, and then returns the results to the client.

- **ExclusiveStartKey** *(dict)* – The primary key of the first item that this operation will evaluate. Use the value that was returned for `LastEvaluatedKey` in the previous operation.

The data type for `ExclusiveStartKey` must be String, Number or Binary. No set data types are allowed.

- `(string)` –
  - *(dict)* –

  Represents the data for an attribute. You can set one, and only one, of the elements.
Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **S** *(string)* – A String data type.
- **N** *(string)* – A Number data type.
- **B** *(bytes)* – A Binary data type.
- **SS** *(list)* – A String Set data type.
- **NS** *(list)* – A Number Set data type.
- **BS** *(list)* – A Binary Set data type.
- **M** *(dict)* – A Map of attribute values.
- **L** *(list)* – A List of attribute values.
- **NULL** *(boolean)* – A Null data type.
- **BOOL** *(boolean)* – A Boolean data type.

- **ReturnConsumedCapacity** *(string)* – Determines the level of detail about provisioned throughput consumption that is returned in the response:
- **INDEXES** - The response includes the aggregate ConsumedCapacity for the operation, together with ConsumedCapacity for each table and secondary index that was accessed. Note that some operations, such as GetItem and BatchGetItem, do not access any indexes at all. In these cases, specifying INDEXES will only return ConsumedCapacity information for table(s).

- **TOTAL** - The response includes only the aggregate ConsumedCapacity for the operation.

- **NONE** - No ConsumedCapacity details are included in the response.

- **ProjectionExpression** *(string)* – A string that identifies one or more attributes to retrieve from the table. These attributes can include scalars, sets, or elements of a JSON document. The attributes in the expression must be separated by commas.

If no attribute names are specified, all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

For more information, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

**Note:** ProjectionExpression replaces the legacy AttributesToGet parameter.

- **FilterExpression** *(string)* – A string that contains conditions that DynamoDB applies after the Query operation, but before the data is returned to you. Items that do not satisfy the FilterExpression criteria are not returned.

**Note:** A FilterExpression is applied after the items have already been read; the process of filtering does not consume any additional read capacity units.

For more information, see Filter Expressions in the Amazon DynamoDB Developer Guide.

**Note:** FilterExpression replaces the legacy QueryFilter and ConditionalOperator parameters.

- **KeyConditionExpression** *(string)* – The condition that specifies the key value(s) for items to be retrieved by the Query action.

The condition must perform an equality test on a single hash key value. The condition can also perform one of several comparison tests on a single range key value. Query can use KeyConditionExpression to retrieve one item with a given hash and range key value, or several items that have the same hash key value but different range key values.

The hash key equality test is required, and must be specified in the following format:

```plaintext
hashAttributeName = :hashval
```

If you also want to provide a range key condition, it must be combined using AND with the hash key condition. Following is an example, using the = comparison operator for the range key:

```plaintext
hashAttributeName = :hashval  AND  rangeAttributeName = :rangeval
```

Valid comparisons for the range key condition are as follows:

- `rangeAttributeName = :rangeval` - true if the range key is equal to :rangeval.
- `rangeAttributeName ** :rangeval` - true if the range key is less than :rangeval.
- **rangeAttributeName = :rangeval** - true if the range key is less than or equal to :rangeval.
- **rangeAttributeName **:rangeval** - true if the range key is greater than :rangeval.
- **rangeAttributeName = :rangeval** - true if the range key is greater than or equal to :rangeval.
- **rangeAttributeName BETWEEN :rangeval1 AND :rangeval2** - true if the range key is greater than or equal to :rangeval1, and less than or equal to :rangeval2.
- **begins_with ( rangeAttributeName , :rangeval )** - true if the range key begins with a particular operand. (You cannot use this function with a range key that is of type Number.) Note that the function name **begins_with** is case-sensitive.

Use the **ExpressionAttributeValues** parameter to replace tokens such as :hashval and :rangeval with actual values at runtime.

You can optionally use the **ExpressionAttributeNames** parameter to replace the names of the hash and range attributes with placeholder tokens. This option might be necessary if an attribute name conflicts with a DynamoDB reserved word. For example, the following **KeyConditionExpression** parameter causes an error because **Size** is a reserved word:

- **Size = :myval**

To work around this, define a placeholder (such a **#S**) to represent the attribute name **Size**. **KeyConditionExpression** then is as follows:

- **#S = :myval**

For a list of reserved words, see **Reserved Words** in the **Amazon DynamoDB Developer Guide**.

For more information on **ExpressionAttributeNames** and **ExpressionAttributeValues**, see **Using Placeholders for Attribute Names and Values** in the **Amazon DynamoDB Developer Guide**.

**Note:** **KeyConditionExpression** replaces the legacy **KeyConditions** parameter.

• **ExpressionAttributeNames (dict)** – One or more substitution tokens for attribute names in an expression. The following are some use cases for using **ExpressionAttributeNames**:
  - To access an attribute whose name conflicts with a DynamoDB reserved word.
  - To create a placeholder for repeating occurrences of an attribute name in an expression.
  - To prevent special characters in an attribute name from being misinterpreted in an expression.

Use the **#** character in an expression to dereference an attribute name. For example, consider the following attribute name:

- **Percentile**

The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see **Reserved Words** in the **Amazon DynamoDB Developer Guide**). To work around this, you could specify the following for **ExpressionAttributeNames**:

- **{"#P":"Percentile"}**

You could then use this substitution in an expression, as in this example:

- **#P = :val**

**Note:** Tokens that begin with the : character are **expression attribute values**, which are placeholders for the actual value at runtime.
For more information on expression attribute names, see `Accessing Item Attributes` in the *Amazon DynamoDB Developer Guide*.

- *(string)*
  - *(string)*

  **ExpressionAttributeValues (dict)** – One or more values that can be substituted in an expression.

  Use the : (colon) character in an expression to dereference an attribute value. For example, suppose that you wanted to check whether the value of the `ProductStatus` attribute was one of the following:

  Available | Backordered | Discontinued

  You would first need to specify `ExpressionAttributeValues` as follows:

  ```
  { ":avail":{"S":"Available"}, ":back":{"S":"Backordered"}, ":disc":{"S":"Discontinued"} }
  ```

  You could then use these values in an expression, such as this:

  ```
  ProductStatus IN (:avail, :back, :disc)
  ```

  For more information on expression attribute values, see `Specifying Conditions` in the *Amazon DynamoDB Developer Guide*.

- *(string)*
  - *(dict)*

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

  - **S (string)** –
    - A String data type.
  
  - **N (string)** –
    - A Number data type.
  
  - **B (bytes)** –
    - A Binary data type.
  
  - **SS (list)** –
    - A String Set data type.
  
  - **NS (list)** –
    - A Number Set data type.
  
  - **BS (list)** –
    - A Binary Set data type.
  
  - **M (dict)** –
    - A Map of attribute values.
· *(dict)* –
  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

· *(list)* –
  A List of attribute values.

      }},
      'GlobalSecondaryIndexes': { 'string': { 'CapacityUnits': 123.0
      }
   }
   }
}

Response Structure
- (dict) –
  Represents the output of a Query operation.
  - Items (list) –
    An array of item attributes that match the query criteria. Each element in this array consists of an attribute name and the value for that attribute.
    - (dict) –
      - (string) –
      - (dict) –
        Represents the data for an attribute. You can set one, and only
Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **S (string)** – A String data type.
- **N (string)** – A Number data type.
- **B (bytes)** – A Binary data type.
- **SS (list)** – A String Set data type.
- **(string)** – **NS (list)** – A Number Set data type.
- **BS (list)** – A Binary Set data type.
- **M (dict)** – A Map of attribute values.
- **L (list)** – A List of attribute values.
- **NULL (boolean)** – A Null data type.
- **BOOL (boolean)** – A Boolean data type.
- **Count (integer)** –
The number of items in the response.

If you used a `QueryFilter` in the request, then `Count` is the number of items returned after the filter was applied, and `ScannedCount` is the number of matching items before the filter was applied.

If you did not use a filter in the request, then `Count` and `ScannedCount` are the same.

- **ScannedCount (integer)** –
The number of items evaluated, before any `QueryFilter` is applied. A high `ScannedCount` value with few, or no, `Count` results indicates an inefficient `Query` operation. For more information, see Count and ScannedCount in the Amazon DynamoDB Developer Guide.

If you did not use a filter in the request, then `ScannedCount` is the same as `Count`.

- **LastEvaluatedKey (dict)** –
The primary key of the item where the operation stopped, inclusive of the previous result set. Use this value to start a new operation, excluding this value in the new request.

If `LastEvaluatedKey` is empty, then the “last page” of results has been processed and there is no more data to be retrieved.

If `LastEvaluatedKey` is not empty, it does not necessarily mean that there is more data in the result set. The only way to know when you have reached the end of the result set is when `LastEvaluatedKey` is empty.

  * (string) –
    · (dict) –
      · (dict) –

      Represents the data for an attribute. You can set one, and only one, of the elements.

      Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

      · **S (string)** –
        A String data type.

      · **N (string)** –
        A Number data type.

      · **B (bytes)** –
        A Binary data type.

      · **SS (list)** –
        A String Set data type.

      · **NS (list)** –
        A Number Set data type.

      · **BS (list)** –
        A Binary Set data type.
- **(bytes)** –
  
  A Map of attribute values.

- **M (dict)** –

  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L (list)** –

  A List of attribute values.

- **(dict)** –

  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL (boolean)** –

  A Null data type.

- **BOOL (boolean)** –

  A Boolean data type.

- **ConsumedCapacity (dict)** –

  The capacity units consumed by an operation. The data returned includes the total provisioned throughput consumed, along with statistics for the table and any indexes involved in the operation. `ConsumedCapacity` is only returned if the request asked for it. For more information, see Provisioned Throughput in the *Amazon DynamoDB Developer Guide*.

  - **TableName (string)** –

    The name of the table that was affected by the operation.

  - **CapacityUnits (float)** –

    The total number of capacity units consumed by the operation.

  - **Table (dict)** –

    The amount of throughput consumed on the table affected by the operation.

      - **CapacityUnits (float)** –

        The total number of capacity units consumed on a table or an index.

  - **LocalSecondaryIndexes (dict)** –

    The amount of throughput consumed on each local index affected by the operation.

      - **(string)** –
· *(dict)* –
  Represents the amount of provisioned throughput capacity consumed on a table or an index.

  · **CapacityUnits** *(float)* –
  The total number of capacity units consumed on a table or an index.

* **GlobalSecondaryIndexes** *(dict)* –
  The amount of throughput consumed on each global index affected by the operation.
  · *(string)* –
  · *(dict)* –
  Represents the amount of provisioned throughput capacity consumed on a table or an index.

  · **CapacityUnits** *(float)* –
  The total number of capacity units consumed on a table or an index.

**scan** (**kwargs**)

The *Scan* operation returns one or more items and item attributes by accessing every item in a table or a secondary index. To have DynamoDB return fewer items, you can provide a *ScanFilter* operation.

If the total number of scanned items exceeds the maximum data set size limit of 1 MB, the scan stops and results are returned to the user as a *LastEvaluatedKey* value to continue the scan in a subsequent operation. The results also include the number of items exceeding the limit. A scan can result in no table data meeting the filter criteria.

By default, *Scan* operations proceed sequentially; however, for faster performance on a large table or secondary index, applications can request a parallel *Scan* operation by providing the *Segment* and *TotalSegments* parameters. For more information, see Parallel Scan in the Amazon DynamoDB Developer Guide.

By default, *Scan* uses eventually consistent reads when accessing the data in the table or local secondary index. However, you can use strongly consistent reads instead by setting the *ConsistentRead* parameter to *true*.

**Request Syntax**

```python
response = client.scan(
    TableName='string',

Parameters

- **TableName (string)** – [REQUIRED]

  The name of the table containing the requested items; or, if you provide `IndexName`, the name of the table to which that index belongs.

- **IndexName (string)** – The name of a secondary index to scan. This index can be any local secondary index or global secondary index. Note that if you use the `IndexName` parameter, you must also provide `TableName`.

- **AttributesToGet (list)** –

  The names of one or more attributes to retrieve. If no attribute names are provided, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

  Note that `AttributesToGet` has no effect on provisioned throughput consumption. DynamoDB determines capacity units consumed based on item size, not on the amount of data that is returned to an application.

  - (string)

- **Limit (integer)** – The maximum number of items to evaluate (not necessarily the number of matching items). If DynamoDB processes the number of items up to the limit while processing the results, it stops the operation and returns the matching values up to that point, and a key in `LastEvaluatedKey` to apply in a subsequent operation, so that you can pick up where you left off. Also, if the processed data set size exceeds 1 MB before DynamoDB reaches this limit, it stops the operation and returns the matching values up to the limit, and a key in `LastEvaluatedKey` to apply in a subsequent operation to continue the operation. For more information, see Query and Scan in the Amazon DynamoDB Developer Guide.

- **Select (string)** – The attributes to be returned in the result. You can retrieve all item attributes, specific item attributes, or the count of matching items.
- **ALL_ATTRIBUTES** - Returns all of the item attributes.
- **COUNT** - Returns the number of matching items, rather than the matching items themselves.
- **SPECIFIC_ATTRIBUTES** - Returns only the attributes listed in `AttributesToGet` . This return value is equivalent to specifying `AttributesToGet` without specifying any value for `Select`.

If neither `Select` nor `AttributesToGet` are specified, DynamoDB defaults to `ALL_ATTRIBUTES` . You cannot use both `AttributesToGet` and `Select` together in a single request, unless the value for `Select` is `SPECIFIC_ATTRIBUTES` . (This usage is equivalent to specifying `AttributesToGet` without any value for `Select`.)

- **ScanFilter (dict)** –

  A condition that evaluates the scan results and returns only the desired values.

  **Note:** This parameter does not support attributes of type List or Map.

  If you specify more than one condition in the `ScanFilter` map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the `ConditionalOperator` parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

  Each `ScanFilter` element consists of an attribute name to compare, along with the following:

  - **AttributeValueList** - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the operator specified in `ComparisonOperator` . For type Number, value comparisons are numeric. String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, `a` is greater than `A` , and `a` is greater than `B` . For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters). For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values. For information on specifying data types in JSON, see [JSON Data Format](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/JSON.html) in the [Amazon DynamoDB Developer Guide](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/). For comparison operators, see [Condition](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/).

  - **ComparisonOperator** - A comparator for evaluating attributes. For example, equals, greater than, less than, etc. The following comparison operators are available: `EQ` | `NE` | `LE` | `LT` | `GE` | `GT` | `NOT_NULL` | `NULL` | `CONTAINS` | `NOT_CONTAINS` | `BEGINS_WITH` | `IN` | `BETWEEN`. For complete descriptions of all comparison operators, see [Condition](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/). For a `Query` operation, `Condition` is used for specifying the `KeyConditions` to use when querying a table or an index. For `KeyConditions` , only the following comparison operators are supported: `EQ` | `LE` | `LT` | `GE` | `GT` | `BEGINS_WITH` | `BETWEEN`. For a `Scan` operation, `Condition` is also used in a

---

**Warning:** This is a legacy parameter, for backward compatibility. New applications should use `FilterExpression` instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a `ValidationException` exception.
QueryFilter, which evaluates the query results and returns only the desired values.
- For a Scan operation, Condition is used in a ScanFilter, which evaluates the scan results and returns only the desired values.

- **AttributeValueList (list)** –
  One or more values to evaluate against the supplied attribute. The number of values in the list depends on the Comparison-Operator being used.

  For type Number, value comparisons are numeric.

  String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, ‘a’ is greater than ‘A’, and ‘a’ is greater than ‘b’. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters.

  For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- **(dict)** –
  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

  - **S (string)** –
    A String data type.
  
  - **N (string)** –
    A Number data type.
  
  - **B (bytes)** –
    A Binary data type.
  
  - **SS (list)** –
    A String Set data type.
  
  - **(string)** –
  
  - **NS (list)** –
    A Number Set data type.
  
  - **(string)** –
  
  - **BS (list)** –
    A Binary Set data type.
  
  - **(bytes)** –
  
  - **M (dict)** –
    A Map of attribute values.
  
  - **(string)** –
  
  - **(dict)** –
Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L** *(list)* –
  A List of attribute values.

- **(dict)** –
  Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL** *(boolean)* –
  A Null data type.

- **BOOL** *(boolean)* –
  A Boolean data type.

- **ComparisonOperator** *(string)* – [REQUIRED]
  A comparator for evaluating attributes. For example, equals, greater than, less than, etc.

The following comparison operators are available:

- **EQ** | **NE** | **LE** | **LT** | **GE** | **GT** | **NOT_NULL**
  | **NULL** | **CONTAINS** | **NOT_CONTAINS** | **BEGINS_WITH** | **IN** | **BETWEEN**

The following are descriptions of each comparison operator.

- **EQ**: Equal. **EQ** is supported for all datatypes, including lists and maps. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":["6","2","1"]}`.

- **NE**: Not equal. **NE** is supported for all datatypes, including lists and maps. **AttributeValueList** can contain only one **AttributeValue** of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an **AttributeValue** of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":["6","2","1"]}`.

- **LE**: Less than or equal. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, or Binary (not a set type). If an item contains an **AttributeValue** element of a different type than the one provided in the request, the
value does not match. For example, \{"S":"6\}" does not equal \{"N":"6\}". Also, \{"N":"6\}" does not compare to \{"NS\}: ["6", "2", "1"]\}.

- **LT**: Less than. *AttributeValueList* can contain only one *AttributeValue* of type String, Number, or Binary (not a set type). If an item contains an *AttributeValue* element of a different type than the one provided in the request, the value does not match. For example, \{"S":"6\}" does not equal \{"N":"6\}". Also, \{"N":"6\}" does not compare to \{"NS\}: ["6", "2", "1"]\}.

- **GE**: Greater than or equal. *AttributeValueList* can contain only one *AttributeValue* element of type String, Number, or Binary (not a set type). If an item contains an *AttributeValue* element of a different type than the one provided in the request, the value does not match. For example, \{"S":"6\}" does not equal \{"N":"6\}". Also, \{"N":"6\}" does not compare to \{"NS\}: ["6", "2", "1"]\}.

- **GT**: Greater than. *AttributeValueList* can contain only one *AttributeValue* element of type String, Number, or Binary (not a set type). If an item contains an *AttributeValue* element of a different type than the one provided in the request, the value does not match. For example, \{"S":"6\}" does not equal \{"N":"6\}". Also, \{"N":"6\}" does not compare to \{"NS\}: ["6", "2", "1"]\}.

- **NOT_NULL**: The attribute exists. **NOT_NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the existence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NOT_NULL**, the result is a Boolean true. This result is because the attribute “a” exists; its data type is not relevant to the **NOT_NULL** comparison operator.

- **NULL**: The attribute does not exist. **NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NULL**, the result is a Boolean false. This is because the attribute “a” exists; its data type is not relevant to the **NULL** comparison operator.

- **CONTAINS**: Checks for a subsequence, or value in a set. *AttributeValueList* can contain only one *AttributeValue* element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it finds an exact match with any member of the set. **CONTAINS** is supported for lists: When evaluating “a CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

- **NOT_CONTAINS**: Checks for absence of a subsequence, or absence of a value in a set. *AttributeValueList* can contain only one *AttributeValue* element of type String, Number, or Binary (not a set type). If the target attribute of the compar-
ison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it does not find an exact match with any member of the set. NOT_CONTAINS is supported for lists: When evaluating "a NOT CONTAINS b", "a " can be a list; however, "b " cannot be a set, a map, or a list.

· **BEGINS_WITH**: Checks for a prefix. `AttributeValueList` can contain only one `AttributeValue` of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

· **IN**: Checks for matching elements within two sets. `AttributeValueList` can contain one or more `AttributeValue` elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

· **BETWEEN**: Greater than or equal to the first value, and less than or equal to the second value. `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not compare to `{"N": "6"}`. Also, `{"N": "6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

For usage examples of `AttributeValueList` and `ComparisonOperator`, see Legacy Conditional Parameters in the Amazon DynamoDB Developer Guide.

**Warning**: This is a legacy parameter, for backward compatibility. New applications should use `FilterExpression` instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a `ValidationException` exception.

· **ConditionalOperator** (`string`) – A logical operator to apply to the conditions in a `ScanFilter` map:
  - **AND** - If all of the conditions evaluate to true, then the entire map evaluates to true.
  - **OR** - If at least one of the conditions evaluate to true, then the entire map evaluates to true.

If you omit `ConditionalOperator`, then **AND** is the default.

The operation will succeed only if the entire map evaluates to true.

**Note**: This parameter does not support attributes of type List or Map.

· **ExclusiveStartKey** (`dict`) – The primary key of the first item that this operation will evaluate. Use the value that was returned for `LastEvaluatedKey` in the previous operation.
The data type for `ExclusiveStartKey` must be String, Number or Binary. No set data types are allowed.

In a parallel scan, a `Scan` request that includes `ExclusiveStartKey` must specify the same segment whose previous `Scan` returned the corresponding value of `LastEvaluatedKey`.

- `(string)` –
  
  Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- `S (string)` –
  
  A String data type.

- `N (string)` –
  
  A Number data type.

- `B (bytes)` –
  
  A Binary data type.

- `SS (list)` –
  
  A String Set data type.

- `(string)` –
  
  A String data type.

- `NS (list)` –
  
  A Number Set data type.

- `BS (list)` –
  
  A Binary Set data type.

- `(bytes)` –
  
  A Map of attribute values.

- `(dict)` –
  
  Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- `L (list)` –
  
  A List of attribute values.

- `(dict)` –
  
  Represents the data for an attribute. You can set one, and only one, of the elements.
Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL** *(boolean)* – A Null data type.
- **BOOL** *(boolean)* – A Boolean data type.

- **ReturnConsumedCapacity** *(string)* – Determines the level of detail about provisioned throughput consumption that is returned in the response:
  - **INDEXES** - The response includes the aggregate ConsumedCapacity for the operation, together with ConsumedCapacity for each table and secondary index that was accessed. Note that some operations, such as GetItem and BatchGetItem, do not access any indexes at all. In these cases, specifying INDEXES will only return ConsumedCapacity information for table(s).
  - **TOTAL** - The response includes only the aggregate ConsumedCapacity for the operation.
  - **NONE** - No ConsumedCapacity details are included in the response.

- **TotalSegments** *(integer)* – For a parallel Scan request, TotalSegments represents the total number of segments into which the Scan operation will be divided. The value of TotalSegments corresponds to the number of application workers that will perform the parallel scan. For example, if you want to use four application threads to scan a table or an index, specify a TotalSegments value of 4.

  The value for TotalSegments must be greater than or equal to 1, and less than or equal to 1000000. If you specify a TotalSegments value of 1, the Scan operation will be sequential rather than parallel.

  If you specify TotalSegments, you must also specify Segment.

- **Segment** *(integer)* – For a parallel Scan request, Segment identifies an individual segment to be scanned by an application worker.

  Segment IDs are zero-based, so the first segment is always 0. For example, if you want to use four application threads to scan a table or an index, then the first thread specifies a Segment value of 0, the second thread specifies 1, and so on.

  The value of LastEvaluatedKey returned from a parallel Scan request must be used as ExclusiveStartKey with the same segment ID in a subsequent Scan operation.

  The value for Segment must be greater than or equal to 0, and less than the value provided for TotalSegments.

  If you provide Segment, you must also provide TotalSegments.

- **ProjectionExpression** *(string)* – A string that identifies one or more attributes to retrieve from the specified table or index. These attributes can include scalars, sets, or elements of a JSON document. The attributes in the expression must be separated by commas.

  If no attribute names are specified, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

  For more information, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.
**Note:** ProjectionExpression replaces the legacy AttributesToGet parameter.

- **FilterExpression (string)** – A string that contains conditions that DynamoDB applies after the Scan operation, but before the data is returned to you. Items that do not satisfy the FilterExpression criteria are not returned.

**Note:** A FilterExpression is applied after the items have already been read; the process of filtering does not consume any additional read capacity units.

For more information, see Filter Expressions in the *Amazon DynamoDB Developer Guide*.

**Note:** FilterExpression replaces the legacy ScanFilter and ConditionalOperator parameters.

- **ExpressionAttributeNames (dict)** – One or more substitution tokens for attribute names in an expression. The following are some use cases for using ExpressionAttributeNames:
  - To access an attribute whose name conflicts with a DynamoDB reserved word.
  - To create a placeholder for repeating occurrences of an attribute name in an expression.
  - To prevent special characters in an attribute name from being misinterpreted in an expression.

Use the # character in an expression to dereference an attribute name. For example, consider the following attribute name:
  - Percentile

The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see Reserved Words in the *Amazon DynamoDB Developer Guide*). To work around this, you could specify the following for ExpressionAttributeNames:

- `{"#P":"Percentile"}`

You could then use this substitution in an expression, as in this example:

- `#P = :val`

**Note:** Tokens that begin with the : character are expression attribute values, which are placeholders for the actual value at runtime.

For more information on expression attribute names, see Accessing Item Attributes in the *Amazon DynamoDB Developer Guide*.

- (string)
  * (string)

- **ExpressionAttributeValue (dict)** – One or more values that can be substituted in an expression.

Use the : (colon) character in an expression to dereference an attribute value. For example, suppose that you wanted to check whether the value of the ProductStatus attribute was one of the following:

- Available
- Backordered
- Discontinued

You would first need to specify ExpressionAttributeValue as follows:

```
{ ":avail":{"S":"Available"}, ":back":{"S":"Backordered"}, ":disc":{"S":"Discontinued"} }
```

You could then use these values in an expression, such as this:
ProductStatus IN (:avail, :back, :disc)

For more information on expression attribute values, see Specifying Conditions in the Amazon DynamoDB Developer Guide.

- (string) –
  *
  (dict) –

  Represents the data for an attribute. You can set one, and only one,
  of the elements.

  Each attribute in an item is a name-value pair. An attribute can be
  single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

  · S (string) –
    · A String data type.
  · N (string) –
    · A Number data type.
  · B (bytes) –
    · A Binary data type.
  · SS (list) –
    · A String Set data type.
  · (string) –
  · NS (list) –
    · A Number Set data type.
  · (string) –
  · BS (list) –
    · A Binary Set data type.
  · (bytes) –
  · M (dict) –
    · A Map of attribute values.
  · (string) –
  · (dict) –

  Represents the data for an attribute. You can set one, and only one,
  of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

  · L (list) –
    · A List of attribute values.
  · (dict) –

  Represents the data for an attribute. You can set one, and only one,
  of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one
· **NULL** *(boolean)* – A Null data type.

· **BOOL** *(boolean)* – A Boolean data type.

- **ConsistentRead** *(boolean)* – A Boolean value that determines the read consistency model during the scan:
  - If **ConsistentRead** is **false**, then **Scan** will use eventually consistent reads. The data returned from **Scan** might not contain the results of other recently completed write operations (PutItem, UpdateItem or DeleteItem). The **Scan** response might include some stale data.
  - If **ConsistentRead** is **true**, then **Scan** will use strongly consistent reads. All of the write operations that completed before the **Scan** began are guaranteed to be contained in the **Scan** response.

The default setting for **ConsistentRead** is **false**, meaning that eventually consistent reads will be used.

Strongly consistent reads are not supported on global secondary indexes. If you scan a global secondary index with **ConsistentRead** set to true, you will receive a **ValidationException**.

**Return type** `dict`  
**Returns**

**Response Structure**

- *(dict)* – Represents the output of a *Scan* operation.

  - **Items (list)** – An array of item attributes that match the scan criteria. Each element in this array consists of an attribute name and the value for that attribute.

    - *(dict)* –
      - *(string)* –
      - *(dict)* – Represents the data for an attribute. You can set one, and only one, of the elements.

      Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book
item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **S**(string) –
  A String data type.

- **N**(string) –
  A Number data type.

- **B**(bytes) –
  A Binary data type.

- **SS**(list) –
  A String Set data type.

- **(string)** –

- **NS**(list) –
  A Number Set data type.

- **BS**(list) –
  A Binary Set data type.

- **M**(dict) –
  A Map of attribute values.

- **(string)** –

- **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L**(list) –
  A List of attribute values.

- **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL**(boolean) –
  A Null data type.

- **BOOL**(boolean) –
  A Boolean data type.

- **Count**(integer) –
  The number of items in the response.
If you set `ScanFilter` in the request, then `Count` is the number of items returned after the filter was applied, and `ScannedCount` is the number of matching items before the filter was applied.

If you did not use a filter in the request, then `Count` is the same as `ScannedCount`.

- **ScannedCount (integer)** –
  The number of items evaluated, before any `ScanFilter` is applied. A high `ScannedCount` value with few, or no, `Count` results indicates an inefficient `Scan` operation. For more information, see `Count` and `ScannedCount` in the [Amazon DynamoDB Developer Guide](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/).

If you did not use a filter in the request, then `ScannedCount` is the same as `Count`.

- **LastEvaluatedKey (dict)** –
  The primary key of the item where the operation stopped, inclusive of the previous result set. Use this value to start a new operation, excluding this value in the new request.

  If `LastEvaluatedKey` is empty, then the “last page” of results has been processed and there is no more data to be retrieved.

  If `LastEvaluatedKey` is not empty, it does not necessarily mean that there is more data in the result set. The only way to know when you have reached the end of the result set is when `LastEvaluatedKey` is empty.

  * (string) –
    · (dict) –
      Represents the data for an attribute. You can set one, and only one, of the elements.

      Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

      · **S (string)** –
        A String data type.

      · **N (string)** –
        A Number data type.

      · **B (bytes)** –
        A Binary data type.

      · **SS (list)** –
        A String Set data type.

      · **(string)** –

      · **NS (list)** –
        A Number Set data type.

      · **BS (list)** –
        A Binary Set data type.
A Map of attribute values.

- (string) –
- (dict) –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- L (list) –
A List of attribute values.

- (dict) –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- NULL (boolean) –
A Null data type.

- BOOL (boolean) –
A Boolean data type.

- ConsumedCapacity (dict) –

The capacity units consumed by an operation. The data returned includes the total provisioned throughput consumed, along with statistics for the table and any indexes involved in the operation. ConsumedCapacity is only returned if the request asked for it. For more information, see Provisioned Throughput in the Amazon DynamoDB Developer Guide.

- TableName (string) –
The name of the table that was affected by the operation.

- CapacityUnits (float) –
The total number of capacity units consumed by the operation.

- Table (dict) –
The amount of throughput consumed on the table affected by the operation.

- CapacityUnits (float) –
The total number of capacity units consumed on a table or an index.

- LocalSecondaryIndexes (dict) –
The amount of throughput consumed on each local index affected by the operation.

- (string) –
- (dict) –

Represents the amount of provisioned throughput capacity consumed on a table or an index.
- **CapacityUnits (float)** –
  The total number of capacity units consumed on a table or an index.

- **GlobalSecondaryIndexes (dict)** –
  The amount of throughput consumed on each global index affected by the operation.
    - *(string)* –
    - *(dict)* –
      Represents the amount of provisioned throughput capacity consumed on a table or an index.

- **CapacityUnits (float)** –
  The total number of capacity units consumed on a table or an index.

**update_item(**kwargs**)

Edits an existing item's attributes, or adds a new item to the table if it does not already exist. You can put, delete, or add attribute values. You can also perform a conditional update on an existing item (insert a new attribute name-value pair if it doesn’t exist, or replace an existing name-value pair if it has certain expected attribute values). If conditions are specified and the item does not exist, then the operation fails and a new item is not created.

You can also return the item’s attribute values in the same UpdateItem operation using the ReturnValues parameter.

**Request Syntax**

```python
response = client.update_item(
    TableName='string',
    Key={
        'string': {
            'S': 'string',
            'N': 'string',
            'B': b'bytes',
            'SS': [
                'string',
            ],
            'NS': [
                'string',
            ],
            'BS': [
                b'bytes',
            ],
            'M': {
                'string': {...
                },
                'L': [...
                ],
                'NULL': True|False,
                'BOOL': True|False
            }
        },
        AttributeUpdates={
            'string': {
                'Value': {
                    'S': 'string',
                    ...
                }
            }
        }
    }
)
```

        ]
    }
}
Parameters

- **TableName** *(string)* – [REQUIRED]

  The name of the table containing the item to update.

- **Key** *(dict)* – [REQUIRED]

  The primary key of the item to be updated. Each element consists of an attribute
name and a value for that attribute.

For the primary key, you must provide all of the attributes. For example, with a hash type primary key, you only need to provide the hash attribute. For a hash-and-range type primary key, you must provide both the hash attribute and the range attribute.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **S (string)** –
  A String data type.

- **N (string)** –
  A Number data type.

- **B (bytes)** –
  A Binary data type.

- **SS (list)** –
  A String Set data type.

- **(string)** –

- **NS (list)** –
  A Number Set data type.

- **BS (list)** –
  A Binary Set data type.

- **(bytes)** –

- **M (dict)** –
  A Map of attribute values.

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L (list)** –
  A List of attribute values.

- **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.
Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL (boolean)** –
  A Null data type.
- **BOOL (boolean)** –
  A Boolean data type.

```
• AttributeUpdates (dict) –
```

The names of attributes to be modified, the action to perform on each, and the new value for each. If you are updating an attribute that is an index key attribute for any indexes on that table, the attribute type must match the index key type defined in the `AttributesDefinition` of the table description. You can use `UpdateItem` to update any nonkey attributes.

Attribute values cannot be null. String and Binary type attributes must have lengths greater than zero. Set type attributes must not be empty. Requests with empty values will be rejected with a `ValidationException` exception.

Each `AttributeUpdates` element consists of an attribute name to modify, along with the following:

- **Value** - The new value, if applicable, for this attribute.
- **Action** - A value that specifies how to perform the update. This action is only valid for an existing attribute whose data type is Number or is a set; do not use **ADD** for other data types. If an item with the specified primary key is found in the table, the following values perform the following actions:
  - **PUT** - Adds the specified attribute to the item. If the attribute already exists, it is replaced by the new value.
  - **DELETE** - Removes the attribute and its value, if no value is specified for DELETE. The data type of the specified value must match the existing value’s data type. If a set of values is specified, then those values are subtracted from the old set. For example, if the attribute value was the set `[a,b,c]` and the DELETE action specifies `[a,c]`, then the final attribute value is `[b]`. Specifying an empty set is an error.
  - **ADD** - Adds the specified value to the item, if the attribute does not already exist. If the attribute does exist, then the behavior of **ADD** depends on the data type of the attribute: * If the existing attribute is a number, and if `Value` is also a number, then `Value` is mathematically added to the existing attribute. **note:** If you use **ADD** to increment or decrement a number value for an item that doesn’t exist before the update, DynamoDB uses 0 as the initial value. Similarly, if you use **ADD** for an existing item to increment or decrement an attribute value that doesn’t exist before the update, DynamoDB uses 0 as the initial value. For example, suppose that the item you want to update doesn’t have an attribute named `itemcount`, but you decide to **ADD** the number 3 to this attribute anyway. DynamoDB
will create the \texttt{itemcount} attribute, set its initial value to 0, and finally add 3 to it. The result will be a new \texttt{itemcount} attribute, with a value of 3.

- If the existing data type is a set, and if \texttt{Value} is also a set, then \texttt{Value} is appended to the existing set. For example, if the attribute value is the set \([1, 2]\), and the \texttt{ADD} action specified \([3]\), then the final attribute value is \([1, 2, 3]\). An error occurs if an \texttt{ADD} action is specified for a set attribute and the attribute type specified does not match the existing set type. Both sets must have the same primitive data type. For example, if the existing data type is a set of strings, \texttt{Value} must also be a set of strings.

If no item with the specified key is found in the table, the following values perform the following actions:

- \texttt{PUT} - Causes DynamoDB to create a new item with the specified primary key, and then adds the attribute.
- \texttt{DELETE} - Nothing happens, because attributes cannot be deleted from a nonexistent item. The operation succeeds, but DynamoDB does not create a new item.
- \texttt{ADD} - Causes DynamoDB to create an item with the supplied primary key and number (or set of numbers) for the attribute value. The only data types allowed are Number and Number Set.

If you provide any attributes that are part of an index key, then the data types for those attributes must match those of the schema in the table’s attribute definition.

- \texttt{(string)}
- \texttt{* (dict)}

For the \texttt{UpdateItem} operation, represents the attributes to be modified, the action to perform on each, and the new value for each.

\textbf{Note:} You cannot use \texttt{UpdateItem} to update any primary key attributes. Instead, you will need to delete the item, and then use \texttt{PutItem} to create a new item with new attributes.

Attribute values cannot be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests with empty values will be rejected with a \texttt{ValidationException} exception.

- \texttt{Value (dict)}

  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- \texttt{S (string)}

  A String data type.

- \texttt{N (string)}

  A Number data type.

- \texttt{B (bytes)}

  A Binary data type.

- \texttt{SS (list)}

  A String Set data type.
· *(string)* –
· **NS** *(list)* –
  A Number Set data type.
· *(string)* –
  · **BS** *(list)* –
  A Binary Set data type.
· *(bytes)* –
  · **M** *(dict)* –
  A Map of attribute values.
· *(string)* –
  · *(dict)* –
Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

· **L** *(list)* –
  A List of attribute values.
· *(dict)* –
Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

· **NULL** *(boolean)* –
  A Null data type.
· **BOOL** *(boolean)* –
  A Boolean data type.
· **Action** *(string)* –

Specifies how to perform the update. Valid values are **PUT** (default), **DELETE**, and **ADD**. The behavior depends on whether the specified primary key already exists in the table.

**If an item with the specified *Key* is found in the table:**

· **PUT** - Adds the specified attribute to the item. If the attribute already exists, it is replaced by the new value.
· **DELETE** - If no value is specified, the attribute and its value are removed from the item. The data type of the specified value must match the existing value’s data type. If a set of values is specified, then those values are subtracted from the old set. For example, if the attribute value was the set *[a, b, c]* and the **DELETE** action specified *[a, c]*, then the final attribute value would be *[b]*. Specifying an empty set is an error.
- **ADD** - If the attribute does not already exist, then the attribute and its values are added to the item. If the attribute does exist, then the behavior of **ADD** depends on the data type of the attribute: * If the existing attribute is a number, and if **Value** is also a number, then the **Value** is mathematically added to the existing attribute. If **Value** is a negative number, then it is subtracted from the existing attribute. **Note**: If you use **ADD** to increment or decrement a number value for an item that doesn’t exist before the update, DynamoDB uses 0 as the initial value. In addition, if you use **ADD** to update an existing item, and intend to increment or decrement an attribute value which does not yet exist, DynamoDB uses 0 as the initial value. For example, suppose that the item you want to update does not yet have an attribute named **itemcount**, but you decide to **ADD** the number 3 to this attribute anyway, even though it currently does not exist. DynamoDB will create the **itemcount** attribute, set its initial value to 0, and finally add 3 to it. The result will be a new **itemcount** attribute in the item, with a value of 3.

- If the existing data type is a set, and if the **Value** is also a set, then the **Value** is added to the existing set. (This is a set operation, not mathematical addition.) For example, if the attribute value was the set [1, 2], and the **ADD** action specified [3], then the final attribute value would be [1, 2, 3]. An error occurs if an Add action is specified for a set attribute and the attribute type specified does not match the existing set type. Both sets must have the same primitive data type. For example, if the existing data type is a set of strings, the **Value** must also be a set of strings. The same holds true for number sets and binary sets.

This action is only valid for an existing attribute whose data type is number or is a set. Do not use **ADD** for any other data types.

### If no item with the specified *Key* is found:

- **PUT** - DynamoDB creates a new item with the specified primary key, and then adds the attribute.
- **DELETE** - Nothing happens; there is no attribute to delete.
- **ADD** - DynamoDB creates an item with the supplied primary key and number (or set of numbers) for the attribute value. The only data types allowed are number and number set; no other data types can be specified.

### Warning:

- This is a legacy parameter, for backward compatibility. New applications should use **ConditionExpression** instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a **ValidationException** exception.

**Expected** (dict) –

A map of attribute/condition pairs. **Expected** provides a conditional block for the **UpdateItem** operation.

Each element of **Expected** consists of an attribute name, a comparison operator, and one or more values. DynamoDB compares the attribute with the value(s) you supplied, using the comparison operator. For each **Expected** element, the result of the evaluation is either true or false.
If you specify more than one element in the `Expected` map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the `ConditionalOperator` parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

If the `Expected` map evaluates to true, then the conditional operation succeeds; otherwise, it fails.

`Expected` contains the following:

- `AttributeValueList` - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the `ComparisonOperator` being used. For type Number, value comparisons are numeric. String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and a is greater than B. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters). For type Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- `ComparisonOperator` - A comparator for evaluating attributes in the `AttributeValueList`. When performing the comparison, DynamoDB uses strongly consistent reads. The following comparison operators are available: `EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN`. The following are descriptions of each comparison operator.* `EQ`: Equal. `EQ` is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.

- `NE`: Not equal. `NE` is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- `LE`: Less than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- `LT`: Less than. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- `GE`: Greater than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example,
- **GT**: Greater than. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **NOT_NULL**: The attribute exists. `NOT_NULL` is supported for all datatypes, including lists and maps. **note:** This operator tests for the existence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using `NOT_NULL`, the result is a Boolean `true`. This result is because the attribute “a” exists; its data type is not relevant to the `NOT_NULL` comparison operator.

- **NULL**: The attribute does not exist. `NULL` is supported for all datatypes, including lists and maps. **note:** This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using `NULL`, the result is a Boolean `false`. This is because the attribute “a” exists; its data type is not relevant to the `NULL` comparison operator.

- **CONTAINS**: Checks for a subsequence, or value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it finds an exact match with any member of the set. `CONTAINS` is supported for lists: When evaluating “a CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

- **NOT_CONTAINS**: Checks for absence of a subsequence, or absence of a value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it does *not* find an exact match with any member of the set. `NOT_CONTAINS` is supported for lists: When evaluating “a NOT CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

- **BEGINS_WITH**: Checks for a prefix. `AttributeValueList` can contain only one `AttributeValue` of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- **IN**: Checks for matching elements within two sets. `AttributeValueList` can contain one or more `AttributeValue` elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

- **BETWEEN**: Greater than or equal to the first value, and less than or equal to the second value. `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the
first element and less than, or equal to, the second element. If an item contains an attribute value element of a different type than the one provided in the request, the value does not match. For example, \{"S":"6"\} does not compare to \{"N":"6"\}. Also, \{"N":"6"\} does not compare to \{"NS\:["6", "2", "1"]\}.

For usage examples of attributevalue list and comparison operator, see Legacy Conditional Parameters in the Amazon DynamoDB Developer Guide.

For backward compatibility with previous DynamoDB releases, the following parameters can be used instead of attributevalue list and comparison operator:

- **Value** - A value for DynamoDB to compare with an attribute.
- **Exists** - A Boolean value that causes DynamoDB to evaluate the value before attempting the conditional operation: * If **Exists** is true, DynamoDB will check to see if that attribute value already exists in the table. If it is found, then the condition evaluates to true; otherwise the condition evaluate to false.
- If **Exists** is false, DynamoDB assumes that the attribute value does not exist in the table. If in fact the value does not exist, then the assumption is valid and the condition evaluates to true. If the value is found, despite the assumption that it does not exist, the condition evaluates to false.

Note that the default value for **Exists** is true.

The **Value** and **Exists** parameters are incompatible with attributevalue list and comparison operator. Note that if you use both sets of parameters at once, DynamoDB will return a ValidationException exception.

Note: This parameter does not support attributes of type List or Map.

- **(string)**
- **(dict)**

Represents a condition to be compared with an attribute value. This condition can be used with DeleteItem, PutItem or UpdateItem operations; if the comparison evaluates to true, the operation succeeds; if not, the operation fails. You can use ExpectedAttributeValue in one of two different ways:

- **Use AttributeValueList** to specify one or more values to compare against an attribute. **Use ComparisonOperator** to specify how you want to perform the comparison. If the comparison evaluates to true, then the conditional operation succeeds.
- **Use Value** to specify a value that DynamoDB will compare against an attribute. If the values match, then ExpectedAttributeValue evaluates to true and the conditional operation succeeds. Optionally, you can also set **Exists** to false, indicating that you do not expect to find the attribute value in the table. In this case, the conditional operation succeeds only if the comparison evaluates to false.

**Value** and **Exists** are incompatible with AttributeValueList and ComparisonOperator. Note that if you use both sets of parameters at once, DynamoDB will return a ValidationException exception.

- **Value (dict)**

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute
can be single-valued or multi-valued set. For example, a book
item can have title and authors attributes. Each book has one
title but can have many authors. The multi-valued attribute is
a set; duplicate values are not allowed.

- **S** *(string)* –
  A String data type.

- **N** *(string)* –
  A Number data type.

- **B** *(bytes)* –
  A Binary data type.

- **SS** *(list)* –
  A String Set data type.

- **SS** *(list)* –
  A String Set data type.

- **NS** *(list)* –
  A Number Set data type.

- **BS** *(list)* –
  A Binary Set data type.

- **M** *(dict)* –
  A Map of attribute values.

  - **(string)** –
  - **(dict)** –

  Represents the data for an attribute. You can set one, and only
  one, of the elements.

Each attribute in an item is a name-value pair. An attribute
can be single-valued or multi-valued set. For example, a book
item can have title and authors attributes. Each book has one
title but can have many authors. The multi-valued attribute is
a set; duplicate values are not allowed.

- **L** *(list)* –
  A List of attribute values.

  - **(dict)** –

  Represents the data for an attribute. You can set one, and only
  one, of the elements.

Each attribute in an item is a name-value pair. An attribute
can be single-valued or multi-valued set. For example, a book
item can have title and authors attributes. Each book has one
title but can have many authors. The multi-valued attribute is
a set; duplicate values are not allowed.

- **NULL** *(boolean)* –
  A Null data type.

- **BOOL** *(boolean)* –
  A Boolean data type.

- **Exists** *(boolean)* –
Causes DynamoDB to evaluate the value before attempting a conditional operation:
- If `Exists` is `true`, DynamoDB will check to see if that attribute value already exists in the table. If it is found, then the operation succeeds. If it is not found, the operation fails with a `ConditionalCheckFailedException`.
- If `Exists` is `false`, DynamoDB assumes that the attribute value does not exist in the table. If in fact the value does not exist, then the assumption is valid and the operation succeeds. If the value is found, despite the assumption that it does not exist, the operation fails with a `ConditionalCheckFailedException`.

The default setting for `Exists` is `true`. If you supply a `Value` all by itself, DynamoDB assumes the attribute exists: You don’t have to set `Exists` to `true`, because it is implied.

DynamoDB returns a `ValidationException` if:
- `Exists` is `true` but there is no `Value` to check. (You expect a value to exist, but don’t specify what that value is.)
- `Exists` is `false` but you also provide a `Value`. (You cannot expect an attribute to have a value, while also expecting it not to exist.)
- **ComparisonOperator** *(string)* –

A comparator for evaluating attributes in the `AttributeValueList`. For example, equals, greater than, less than, etc.

The following comparison operators are available:

- **EQ**: Equal. `EQ` is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains a `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.
- **NE**: Not equal. `NE` is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.
- **LE**: Less than or equal. `LE` is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.
· LT: Less than. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

· GE: Greater than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

· GT: Greater than. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

· NOT_NULL: The attribute exists. `NOT_NULL` is supported for all datatypes, including lists and maps. .. note:: This operator tests for the existence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using `NOT_NULL`, the result is a Boolean true. This result is because the attribute “a” exists; its data type is not relevant to the `NOT_NULL` comparison operator.

· NULL: The attribute does not exist. `NULL` is supported for all datatypes, including lists and maps. .. note:: This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using `NULL`, the result is a Boolean false. This is because the attribute “a” exists; its data type is not relevant to the `NULL` comparison operator.

· CONTAINS: Checks for a subsequence, or value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it finds an exact match with any member of the set. CONTAINS is supported for lists: When evaluating “a CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

· NOT_CONTAINS: Checks for absence of a subsequence, or absence of a value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison

---

3.1. Services

---

915
is Binary, then the operator checks for the absence of a sub-
sequence of the target that matches the input. If the target
attribute of the comparison is a set (“SS”, “NS”, or “BS”),
then the operator evaluates to true if it does not find an exact
match with any member of the set. NOT_CONTAINS is sup-
ported for lists: When evaluating “a NOT CONTAINS b”,
“a” can be a list; however, “b” cannot be a set, a map, or a
list.

- **begins_with**: Checks for a prefix. **AttributeValueList** can
  contain only one **AttributeValue** of type String or Binary (not a
  Number or a set type). The target attribute of the comparison
  must be of type String or Binary (not a Number or a set type).

- **in**: Checks for matching elements within two sets. **AttributeValue-
  List** can contain one or more **AttributeValue** elements of
type String, Number, or Binary (not a set type). These at-
tributes are compared against an existing set type attribute of
an item. If any elements of the input set are present in the
item attribute, the expression evaluates to true.

- **between**: Greater than or equal to the first value, and less
  than or equal to the second value. **AttributeValueList** must
  contain two **AttributeValue** elements of the same type, either
  String, Number, or Binary (not a set type). A target attribute
  matches if the target value is greater than, or equal to, the
  first element and less than, or equal to, the second element.
  If an item contains an **AttributeValue** element of a different type
  than the one provided in the request, the value does not match.
  For example, {"S":"6"} does not compare to {"N":"6"}
  . Also, {"N":"6"} does not compare to {"NS":["6", "2", "1"]}.

- **AttributeValueList** (list) –
  One or more values to evaluate against the supplied attribute.
  The number of values in the list depends on the **Comparison-
  Operator** being used.

For type Number, value comparisons are numeric.

String value comparisons for greater than, equals, or
less than are based on ASCII character code val-
ues. For example, a is greater than A , and a
is greater than B . For a list of code values, see
http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters

For Binary, DynamoDB treats each byte of the binary data as
unsigned when it compares binary values.

For information on specifying data types in JSON, see JSON
Data Format in the Amazon DynamoDB Developer Guide.

- **(dict)** –
  Represents the data for an attribute. You can set one, and only
  one, of the elements.

Each attribute in an item is a name-value pair. An attribute
can be single-valued or multi-valued set. For example, a book
item can have title and authors attributes. Each book has one
title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **S** (string) –
  A String data type.

- **N** (string) –
  A Number data type.

- **B** (bytes) –
  A Binary data type.

- **SS** (list) –
  A String Set data type.

- **NS** (list) –
  A Number Set data type.

- **BS** (list) –
  A Binary Set data type.

- **M** (dict) –
  A Map of attribute values.

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L** (list) –
  A List of attribute values.

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL** (boolean) –
  A Null data type.

- **BOOL** (boolean) –
  A Boolean data type.

**Warning:** This is a legacy parameter, for backward compatibility applications should use `ConditionExpression` instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a `ValidationException` exception.
A logical operator to apply to the conditions in the `Expected` map:

- **AND** - If all of the conditions evaluate to true, then the entire map evaluates to true.
- **OR** - If at least one of the conditions evaluate to true, then the entire map evaluates to true.

If you omit `ConditionalOperator`, then `AND` is the default.

The operation will succeed only if the entire map evaluates to true.

**Note:** This parameter does not support attributes of type List or Map.

**• ReturnValues (string)** – Use `ReturnValues` if you want to get the item attributes as they appeared either before or after they were updated. For `UpdateItem`, the valid values are:

- **NONE** - If `ReturnValues` is not specified, or if its value is `NONE`, then nothing is returned. (This setting is the default for `ReturnValues`.)
- **ALL_OLD** - If `UpdateItem` overwrote an attribute name-value pair, then the content of the old item is returned.
- **UPDATED_OLD** - The old versions of only the updated attributes are returned.
- **ALL_NEW** - All of the attributes of the new version of the item are returned.
- **UPDATED_NEW** - The new versions of only the updated attributes are returned.

**• ReturnConsumedCapacity (string)** – Determines the level of detail about provisioned throughput consumption that is returned in the response:

- **INDEXES** - The response includes the aggregate `ConsumedCapacity` for the operation, together with `ConsumedCapacity` for each table and secondary index that was accessed. Note that some operations, such as `GetItem` and `BatchGetItem`, do not access any indexes at all. In these cases, specifying `INDEXES` will only return `ConsumedCapacity` information for table(s).
- **TOTAL** - The response includes only the aggregate `ConsumedCapacity` for the operation.
- **NONE** - No `ConsumedCapacity` details are included in the response.

**• ReturnItemCollectionMetrics (string)** – Determines whether item collection metrics are returned. If set to `SIZE`, the response includes statistics about item collections, if any, that were modified during the operation are returned in the response. If set to `NONE` (the default), no statistics are returned.

**• UpdateExpression (string)** – An expression that defines one or more attributes to be updated, the action to be performed on them, and new value(s) for them.

The following action values are available for `UpdateExpression`:

- **SET** - Adds one or more attributes and values to an item. If any of these attribute already exist, they are replaced by the new values. You can also use `SET` to add or subtract from an attribute that is of type Number. For example: `SET myNum = myNum + :val` supports the following functions: `if_not_exists(path, operand)` - if the item does not contain an attribute at the specified path, then `if_not_exists` evaluates to operand; otherwise, it evaluates to path. You can use this function to avoid overwriting an attribute that may already be present in the item.
- `list_append(operand, operand)` - evaluates to a list with a new element added to it. You can append the new element to the start or the end of the list by reversing the order of the operands.

These function names are case-sensitive.
- REMOVE - Removes one or more attributes from an item.
- ADD - Adds the specified value to the item, if the attribute does not already exist. If the attribute does exist, then the behavior of ADD depends on the data type of the attribute: * If the existing attribute is a number, and if Value is also a number, then Value is mathematically added to the existing attribute. If Value is a negative number, then it is subtracted from the existing attribute. .. note:: If you use ADD to increment or decrement a number value for an item that doesn’t exist before the update, DynamoDB uses 0 as the initial value. Similarly, if you use ADD for an existing item to increment or decrement an attribute value that doesn’t exist before the update, DynamoDB uses 0 as the initial value. For example, suppose that the item you want to update doesn’t have an attribute named itemcount, but you decide to ADD the number 3 to this attribute anyway. DynamoDB will create the itemcount attribute, set its initial value to 0, and finally add 3 to it. The result will be a new itemcount attribute in the item, with a value of 3.
- If the existing data type is a set and if Value is also a set, then Value is added to the existing set. For example, if the attribute value is the set [1,2], and the ADD action specified [3], then the final attribute value is [1,2,3]. An error occurs if an ADD action is specified for a set attribute and the attribute type specified does not match the existing set type. Both sets must have the same primitive data type. For example, if the existing data type is a set of strings, the Value must also be a set of strings.

**Warning:** The ADD action only supports Number and set data types. In addition, ADD can only be used on top-level attributes, not nested attributes.

- DELETE - Deletes an element from a set. If a set of values is specified, then those values are subtracted from the old set. For example, if the attribute value was the set [a,b,c] and the DELETE action specified [a,c], then the final attribute value is [b]. Specifying an empty set is an error. .. warning:: The DELETE action only supports set data types. In addition, DELETE can only be used on top-level attributes, not nested attributes.

You can have many actions in a single expression, such as the following: SET a=:value1, b=:value2 DELETE :value3, :value4, :value5

For more information on update expressions, see Modifying Items and Attributes in the Amazon DynamoDB Developer Guide.

**Note:** UpdateExpression replaces the legacy AttributeUpdates parameter.

- **ConditionExpression** (string) – A condition that must be satisfied in order for a conditional update to succeed.

An expression can contain any of the following:
- Functions: attribute_exists | attribute_not_exists | attribute_type | contains | begins_with | size
  These function names are case-sensitive.
- Comparison operators: = | | | = | = | BETWEEN | IN
- Logical operators: AND | OR | NOT

For more information on condition expressions, see Specifying Conditions in the Amazon DynamoDB Developer Guide.

**Note:** ConditionExpression replaces the legacy ConditionalOperator and Expected parameters.
• **ExpressionAttributeNames** *(dict)* – One or more substitution tokens for attribute names in an expression. The following are some use cases for using *ExpressionAttributeNames*:
  - To access an attribute whose name conflicts with a DynamoDB reserved word.
  - To create a placeholder for repeating occurrences of an attribute name in an expression.
  - To prevent special characters in an attribute name from being misinterpreted in an expression.

Use the # character in an expression to dereference an attribute name. For example, consider the following attribute name:

- **Percentile**

The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see **Reserved Words** in the *Amazon DynamoDB Developer Guide*). To work around this, you could specify the following for *ExpressionAttributeNames*:

- `{"#P":"Percentile"}`

You could then use this substitution in an expression, as in this example:

- `#P = :val`

**Note:** Tokens that begin with the : character are *expression attribute values*, which are placeholders for the actual value at runtime.

For more information on expression attribute names, see **Accessing Item Attributes** in the *Amazon DynamoDB Developer Guide*.

- *(string)* –
  - *(string)* –

• **ExpressionAttributeValue** *(dict)* – One or more values that can be substituted in an expression.

Use the : (colon) character in an expression to dereference an attribute value. For example, suppose that you wanted to check whether the value of the **ProductStatus** attribute was one of the following:

- *Available* | *Backordered* | *Discontinued*

You would first need to specify *ExpressionAttributeValue* as follows:

```
{ ":avail":{"S":"Available"}, ":back":{"S":"Backordered"},
":disc":{"S":"Discontinued"} }
```

You could then use these values in an expression, such as this:

```
ProductStatus IN (:avail, :back, :disc)
```

For more information on expression attribute values, see **Specifying Conditions** in the *Amazon DynamoDB Developer Guide*.

Response Structure

- (dict) –
  Represents the output of an UpdateItem operation.
  - Attributes (dict) –
    A map of attribute values as they appeared before the UpdateItem operation. This map only appears if ReturnValues was specified as something other than NONE in the request. Each element represents one attribute.
      - (string) –
        - (dict) –
          Represents the data for an attribute. You can set one, and only one, of the elements.

          Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

          - S (string) –
            A String data type.
          - N (string) –
            A Number data type.
          - B (bytes) –
            A Binary data type.
          - SS (list) –
            A String Set data type.
          - NS (list) –
            A Number Set data type.
          - BS (list) –
            A Binary Set data type.
          - M (dict) –
            A Map of attribute values.
Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L (list)**
  - A List of attribute values.

- **(dict)**
  - Represents the data for an attribute. You can set one, and only one, of the elements.
  
  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL (boolean)**
  - A Null data type.

- **BOOL (boolean)**
  - A Boolean data type.

- **ConsumedCapacity (dict)**
  
  The capacity units consumed by an operation. The data returned includes the total provisioned throughput consumed, along with statistics for the table and any indexes involved in the operation. `ConsumedCapacity` is only returned if the request asked for it. For more information, see [Provisioned Throughput](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/throughput.html) in the *Amazon DynamoDB Developer Guide*.

  - **TableName (string)**
    - The name of the table that was affected by the operation.
  
  - **CapacityUnits (float)**
    - The total number of capacity units consumed by the operation.
  
  - **Table (dict)**
    - The amount of throughput consumed on the table affected by the operation.
      
      - **CapacityUnits (float)**
        - The total number of capacity units consumed on a table or an index.
  
  - **LocalSecondaryIndexes (dict)**
    - The amount of throughput consumed on each local index affected by the operation.
      
      - **(string)**
      - **(dict)**
        - Represents the amount of provisioned throughput capacity consumed on a table or an index.
      
      - **CapacityUnits (float)**
        - The total number of capacity units consumed on a table or an index.
GlobalSecondaryIndexes (dict) –

The amount of throughput consumed on each global index affected by the operation.

- (string) –
  - (dict) –
  Represents the amount of provisioned throughput capacity consumed on a table or an index.

- CapacityUnits (float) –
  The total number of capacity units consumed on a table or an index.

ItemCollectionMetrics (dict) –

Information about item collections, if any, that were affected by the operation. ItemCollectionMetrics is only returned if the request asked for it. If the table does not have any local secondary indexes, this information is not returned in the response.

ItemCollectionKey (dict) –

The hash key value of the item collection. This value is the same as the hash key of the item.

- (string) –
  - (dict) –
  Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- S (string) –
  A String data type.

- N (string) –
  A Number data type.

- B (bytes) –
  A Binary data type.

- SS (list) –
  A String Set data type.

- NS (list) –
  A Number Set data type.

- BS (list) –
  A Binary Set data type.

- M (dict) –
  A Map of attribute values.
Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- `L (list)` – A List of attribute values.
- `dict` – Represents the data for an attribute. You can set one, and only one, of the elements.
  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.
- `NULL (boolean)` – A Null data type.
- `BOOL (boolean)` – A Boolean data type.

* **SizeEstimateRangeGB (list)** –
  An estimate of item collection size, in gigabytes. This value is a two-element array containing a lower bound and an upper bound for the estimate. The estimate includes the size of all the items in the table, plus the size of all attributes projected into all of the local secondary indexes on that table. Use this estimate to measure whether a local secondary index is approaching its size limit.

  The estimate is subject to change over time; therefore, do not rely on the precision or accuracy of the estimate.

- `(float)` –

**update_table(**kwargs**)**

Modifies the provisioned throughput settings, global secondary indexes, or DynamoDB Streams settings for a given table.

You can only perform one of the following operations at once:
- Modify the provisioned throughput settings of the table.
- Enable or disable Streams on the table.
- Remove a global secondary index from the table.
- Create a new global secondary index on the table. Once the index begins backfilling, you can use `UpdateTable` to perform other operations.

`UpdateTable` is an asynchronous operation; while it is executing, the table status changes from **ACTIVE** to **UPDATING**. While it is **UPDATING**, you cannot issue another `UpdateTable` request. When the table returns to the **ACTIVE** state, the `UpdateTable` operation is complete.

**Request Syntax**

```python
response = client.update_table(
    AttributeDefinitions=[
        ]
```
Parameters

- **AttributeDefinitions** *(list)* – An array of attributes that describe the key schema for the table and indexes. If you are adding a new global secondary index to the table, *AttributeDefinitions* must include the key element(s) of the new index.
  - *(dict)* –
    
    Represents an attribute for describing the key schema for the table and indexes.

  - **AttributeName** *(string)* – [REQUIRED]
    
    A name for the attribute.
* **AttributeType** *(string)* – [REQUIRED]
  The data type for the attribute.

* **TableName** *(string)* – [REQUIRED]
  The name of the table to be updated.

* **ProvisionedThroughput** *(dict)* – Represents the provisioned throughput settings for a specified table or index. The settings can be modified using the `UpdateTable` operation.

  For current minimum and maximum provisioned throughput values, see Limits in the *Amazon DynamoDB Developer Guide*.
  
  – **ReadCapacityUnits** *(integer)* – [REQUIRED]
    The maximum number of strongly consistent reads consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see Specifying Read and Write Requirements in the *Amazon DynamoDB Developer Guide*.
  
  – **WriteCapacityUnits** *(integer)* – [REQUIRED]
    The maximum number of writes consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see Specifying Read and Write Requirements in the *Amazon DynamoDB Developer Guide*.

* **GlobalSecondaryIndexUpdates** *(list)* – An array of one or more global secondary indexes for the table. For each index in the array, you can request one action:
  
  – **Create** - add a new global secondary index to the table.
  
  – **Update** - modify the provisioned throughput settings of an existing global secondary index.
  
  – **Delete** - remove a global secondary index from the table.

  For more information, see Managing Global Secondary Indexes in the *Amazon DynamoDB Developer Guide*.

  – *(dict)* –
    Represents one of the following:
    
    * A new global secondary index to be added to an existing table.
    * New provisioned throughput parameters for an existing global secondary index.
    * An existing global secondary index to be removed from an existing table.

    – **Update** *(dict)* –
      The name of an existing global secondary index, along with new provisioned throughput settings to be applied to that index.
      
      – **IndexName** *(string)* – [REQUIRED]
        The name of the global secondary index to be updated.
      
      – **ProvisionedThroughput** *(dict)* – [REQUIRED]
        Represents the provisioned throughput settings for a specified table or index. The settings can be modified using the `UpdateTable` operation.

        For current minimum and maximum provisioned throughput values, see Limits in the *Amazon DynamoDB Developer Guide*.

        – **ReadCapacityUnits** *(integer)* – [REQUIRED]
The maximum number of strongly consistent reads consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see **Specifying Read and Write Requirements** in the *Amazon DynamoDB Developer Guide*.

- **WriteCapacityUnits** (integer) – [REQUIRED]

  The maximum number of writes consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see **Specifying Read and Write Requirements** in the *Amazon DynamoDB Developer Guide*.

* **Create** (dict) –

  The parameters required for creating a global secondary index on an existing table:

  - `IndexName`
  - `KeySchema`
  - `AttributeDefinitions`
  - `Projection`
  - ` ProvisionedThroughput`

  - **IndexName** (string) – [REQUIRED]

    The name of the global secondary index to be created.

  - **KeySchema** (list) – [REQUIRED]

    The key schema for the global secondary index.

  - (dict) –

    Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

    A `KeySchemaElement` represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one `KeySchemaElement`. A hash-and-range type primary key would require one `KeySchemaElement` for the hash attribute, and another `KeySchemaElement` for the range attribute.

  - **AttributeName** (string) – [REQUIRED]

    The name of a key attribute.

  - **KeyType** (string) – [REQUIRED]

    The attribute data, consisting of the data type and the attribute value itself.

  - **Projection** (dict) – [REQUIRED]

    Represents attributes that are copied (projected) from the table into an index. These are in addition to the primary key attributes and index key attributes, which are automatically projected.

  - **ProjectionType** (string) –

    The set of attributes that are projected into the index:

    - **KEYS_ONLY** - Only the index and primary keys are projected into the index.
    - **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in `NonKeyAttributes`.
· **ALL** - All of the table attributes are projected into the index.

· **NonKeyAttributes** *(list)* –

  Represents the non-key attribute names which will be projected into the index.

  For local secondary indexes, the total count of **NonKeyAttributes** summed across all of the local secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

· **NonKeyAttributes** *(string)* –

· **ProvisionedThroughput** *(dict)* – [REQUIRED]

  Represents the provisioned throughput settings for a specified table or index. The settings can be modified using the **UpdateTable** operation.

  For current minimum and maximum provisioned throughput values, see **Limits** in the *Amazon DynamoDB Developer Guide*.

· **ReadCapacityUnits** *(integer)* – [REQUIRED]

  The maximum number of strongly consistent reads consumed per second before DynamoDB returns a **ThrottlingException**. For more information, see **Specifying Read and Write Requirements** in the *Amazon DynamoDB Developer Guide*.

· **WriteCapacityUnits** *(integer)* – [REQUIRED]

  The maximum number of writes consumed per second before DynamoDB returns a **ThrottlingException**. For more information, see **Specifying Read and Write Requirements** in the *Amazon DynamoDB Developer Guide*.

· **Delete** *(dict)* –

  The name of an existing global secondary index to be removed.

· **IndexName** *(string)* – [REQUIRED]

  The name of the global secondary index to be deleted.

· **StreamSpecification** *(dict)* – Represents the DynamoDB Streams configuration for the table.

  **Note:** You will receive a **ResourceInUseException** if you attempt to enable a stream on a table that already has a stream, or if you attempt to disable a stream on a table which does not have a stream.

  · **StreamEnabled** *(boolean)* –

    Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.

  · **StreamViewType** *(string)* –

    The DynamoDB Streams settings for the table. These settings consist of:

    · **StreamEnabled** - Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.
    · **StreamViewType** - When an item in the table is modified, **StreamViewType** determines what information is written to the stream for this table. Valid values for **StreamViewType** are:
**KEYS_ONLY** - Only the key attributes of the modified item are written to the stream.

* **NEW_IMAGE** - The entire item, as it appears after it was modified, is written to the stream.

* **OLD_IMAGE** - The entire item, as it appeared before it was modified, is written to the stream.

* **NEW_AND_OLD_IMAGES** - Both the new and the old item images of the item are written to the stream.

**Return type**  dict

**Returns**

**Response Syntax**

```python
{
   'TableDescription': {
      'AttributeDefinitions': [ {
         'AttributeName': 'string',
         'AttributeType': 'S'|'N'|'B'
      },
   ],
   'TableName': 'string',
   'KeySchema': [ {
         'AttributeName': 'string',
         'KeyType': 'HASH'|'RANGE'
   },
   ],
   'TableStatus': 'CREATING'|'UPDATING'|'DELETING'|'ACTIVE',
   'CreationDateTime': datetime(2015, 1, 1),
   'ProvisionedThroughput': {
         'LastIncreaseDateTime': datetime(2015, 1, 1),
         'LastDecreaseDateTime': datetime(2015, 1, 1),
         'NumberOfDecreasesToday': 123,
         'ReadCapacityUnits': 123,
         'WriteCapacityUnits': 123
   },
   'TableSizeBytes': 123,
   'ItemCount': 123,
   'TableArn': 'string',
   'LocalSecondaryIndexes': [ {
         'IndexName': 'string',

            'AttributeName': 'string',
            'KeyType': 'HASH'|'RANGE'
         },
      ],
      'Projection': { 'ProjectionType': 'ALL'|'KEYS_ONLY'|'INCLUDE',
                     'NonKeyAttributes': [ 'string',
               ]
      },
      'IndexSizeBytes': 123,
      'ItemCount': 123,
      'IndexArn': 'string'
   }
}
```
Response Structure

- (dict) – Represents the output of an UpdateTable operation.
  
  - TableDescription (dict) – Represents the properties of a table.
    
    - AttributeDefinitions (list) – An array of AttributeDefinition objects. Each of these objects describes one attribute in the table and index key schema.
      
      Each AttributeDefinition object in this array is composed of:
      
      - AttributeName - The name of the attribute.
      - AttributeType - The data type for the attribute.
      
      - (dict) – Represents an attribute for describing the key schema for the table and indexes.
· **AttributeName** *(string)* –
  A name for the attribute.
· **AttributeType** *(string)* –
  The data type for the attribute.

* **TableName** *(string)* –
  The name of the table.

* **KeySchema** *(list)* –
  The primary key structure for the table. Each *KeySchemaElement* consists of:
  · **AttributeName** - The name of the attribute.
  · **KeyType** - The key type for the attribute. Can be either HASH or RANGE.

  For more information about primary keys, see Primary Key in the Amazon DynamoDB Developer Guide.

  · *(dict)* –
    Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

    A *KeySchemaElement* represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one *KeySchemaElement*. A hash-and-range type primary key would require one *KeySchemaElement* for the hash attribute, and another *KeySchemaElement* for the range attribute.

  · **AttributeName** *(string)* –
    The name of a key attribute.
  · **KeyType** *(string)* –
    The attribute data, consisting of the data type and the attribute value itself.

* **TableStatus** *(string)* –
  The current state of the table:
  · **CREATING** - The table is being created.
  · **UPDATING** - The table is being updated.
  · **DELETING** - The table is being deleted.
  · **ACTIVE** - The table is ready for use.

* **CreationDateTime** *(datetime)* –
  The date and time when the table was created, in UNIX epoch time format.

* **ProvisionedThroughput** *(dict)* –
  The provisioned throughput settings for the table, consisting of read and write capacity units, along with data about increases and decreases.

  · **LastIncreaseDateTime** *(datetime)* –
    The date and time of the last provisioned throughput increase for this table.
  · **LastDecreaseDateTime** *(datetime)* –
The date and time of the last provisioned throughput decrease for this table.

- **NumberOfDecreasesToday** *(integer)* –

  The number of provisioned throughput decreases for this table during this UTC calendar day. For current maximums on provisioned throughput decreases, see Limits in the Amazon DynamoDB Developer Guide.

- **ReadCapacityUnits** *(integer)* –

  The maximum number of strongly consistent reads consumed per second before DynamoDB returns a ThrottlingException. Eventually consistent reads require less effort than strongly consistent reads, so a setting of 50 ReadCapacityUnits per second provides 100 eventually consistent ReadCapacityUnits per second.

- **WriteCapacityUnits** *(integer)* –

  The maximum number of writes consumed per second before DynamoDB returns a ThrottlingException.

* **TableSizeBytes** *(integer)* –

  The total size of the specified table, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

* **ItemCount** *(integer)* –

  The number of items in the specified table. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

* **TableArn** *(string)* –

  The Amazon Resource Name (ARN) that uniquely identifies the table.

* **LocalSecondaryIndexes** *(list)* –

  Represents one or more local secondary indexes on the table. Each index is scoped to a given hash key value. Tables with one or more local secondary indexes are subject to an item collection size limit, where the amount of data within a given item collection cannot exceed 10 GB. Each element is composed of:

  - **IndexName** - The name of the local secondary index.
  - **KeySchema** - Specifies the complete index key schema. The attribute names in the key schema must be between 1 and 255 characters (inclusive). The key schema must begin with the same hash key attribute as the table.
  - **Projection** - Specifies attributes that are copied (projected) from the table into the index. These are in addition to the primary key attributes and index key attributes, which are automatically projected. Each attribute specification is composed of: * **ProjectionType** - One of the following: * KEYS_ONLY - Only the index and primary keys are projected into the index. * INCLUDE - Only the specified table attributes are projected into the index. The list of projected attributes are in NonKeyAttributes. * ALL - All of the table attributes are projected into the index. * NonKeyAttributes - A list of one or more non-key attribute
names that are projected into the secondary index. The total count of attributes provided in \texttt{NonKeyAttributes}, summed across all of the secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

- \texttt{IndexSizeBytes} - Represents the total size of the index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.
- \texttt{ItemCount} - Represents the number of items in the index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

If the table is in the \texttt{DELETING} state, no information about indexes will be returned.

- \texttt{(dict)} –
  
  Represents the properties of a local secondary index.

- \texttt{IndexName (string)} –
  
  Represents the name of the local secondary index.

- \texttt{KeySchema (list)} –
  
  The complete index key schema, which consists of one or more pairs of attribute names and key types (\texttt{HASH} or \texttt{RANGE}).

- \texttt{(dict)} –
  
  Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

A \texttt{KeySchemaElement} represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one \texttt{KeySchemaElement}. A hash-and-range type primary key would require one \texttt{KeySchemaElement} for the hash attribute, and another \texttt{KeySchemaElement} for the range attribute.

- \texttt{AttributeName (string)} –
  
  The name of a key attribute.

- \texttt{KeyType (string)} –
  
  The attribute data, consisting of the data type and the attribute value itself.

- \texttt{Projection (dict)} –
  
  Represents attributes that are copied (projected) from the table into an index. These are in addition to the primary key attributes and index key attributes, which are automatically projected.

- \texttt{ProjectionType (string)} –
  
  The set of attributes that are projected into the index:
  - \texttt{KEYS_ONLY} - Only the index and primary keys are projected into the index.
  - \texttt{INCLUDE} - Only the specified table attributes are projected into the index. The list of projected attributes are in \texttt{NonKeyAttributes}.
  - \texttt{ALL} - All of the table attributes are projected into the index.
- **NonKeyAttributes (list)** –

Represents the non-key attribute names which will be projected into the index.

For local secondary indexes, the total count of `NonKeyAttributes` summed across all of the local secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

- **(string)** –
- **IndexSizeBytes (integer)** –

The total size of the specified index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **ItemCount (integer)** –

The number of items in the specified index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **IndexArn (string)** –

The Amazon Resource Name (ARN) that uniquely identifies the index.

- **GlobalSecondaryIndexes (list)** –

The global secondary indexes, if any, on the table. Each index is scoped to a given hash key value. Each element is composed of:

  - **Backfilling** - If true, then the index is currently in the backfilling phase. Backfilling occurs only when a new global secondary index is added to the table; it is the process by which DynamoDB populates the new index with data from the table. (This attribute does not appear for indexes that were created during a `CreateTable` operation.)
  - **IndexName** - The name of the global secondary index.
  - **IndexSizeBytes** - The total size of the global secondary index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.
  - **IndexStatus** - The current status of the global secondary index:
    - **CREATING** - The index is being created.
    - **UPDATING** - The index is being updated.
    - **DELETING** - The index is being deleted.
    - **ACTIVE** - The index is ready for use.
  - **ItemCount** - The number of items in the global secondary index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.
  - **KeySchema** - Specifies the complete index key schema. The attribute names in the key schema must be between 1 and 255 characters (inclusive). The key schema must begin with the same hash key attribute as the table.
  - **Projection** - Specifies attributes that are copied (projected) from the table into the index. These are in addition to the primary key attributes and index key attributes, which are automatically projected. Each attribute specification is composed of:
    - **ProjectionType** - One of the following:
      - **KEYS_ONLY** - Only the index and primary keys are projected into the index.
· **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in `NonKeyAttributes`.

· **ALL** - All of the table attributes are projected into the index.

· **NonKeyAttributes** - A list of one or more non-key attribute names that are projected into the secondary index. The total count of attributes provided in `NonKeyAttributes`, summed across all of the secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

· **ProvisionedThroughput** - The provisioned throughput settings for the global secondary index, consisting of read and write capacity units, along with data about increases and decreases.

If the table is in the **DELETING** state, no information about indexes will be returned.

· **(dict)** —

  Represents the properties of a global secondary index.

  · **IndexName** *(string)* —

    The name of the global secondary index.

  · **KeySchema** *(list)* —

    The complete key schema for the global secondary index, consisting of one or more pairs of attribute names and key types (`HASH` or `RANGE`).

  · **(dict)** —

    Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

    A `KeySchemaElement` represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one `KeySchemaElement`. A hash-and-range type primary key would require one `KeySchemaElement` for the hash attribute, and another `KeySchemaElement` for the range attribute.

  · **AttributeName** *(string)* —

    The name of a key attribute.

  · **KeyType** *(string)* —

    The attribute data, consisting of the data type and the attribute value itself.

  · **Projection** *(dict)* —

    Represents attributes that are copied (projected) from the table into an index. These are in addition to the primary key attributes and index key attributes, which are automatically projected.

  · **ProjectionType** *(string)* —

    The set of attributes that are projected into the index:

    · **KEYS_ONLY** - Only the index and primary keys are projected into the index.

    · **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in `NonKeyAttributes`.
Attributes:
- **ALL** - All of the table attributes are projected into the index.
- **NonKeyAttributes (list)** –

  Represents the non-key attribute names which will be projected into the index.

  For local secondary indexes, the total count of **NonKeyAttributes** summed across all of the local secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

- **IndexStatus (string)** –

  The current state of the global secondary index:
  - **CREATING** - The index is being created.
  - **UPDATING** - The index is being updated.
  - **DELETING** - The index is being deleted.
  - **ACTIVE** - The index is ready for use.
  - **Backfilling (boolean)** –

    Indicates whether the index is currently backfilling. *Backfilling* is the process of reading items from the table and determining whether they can be added to the index. (Not all items will qualify: For example, a hash key attribute cannot have any duplicates.) If an item can be added to the index, *DynamoDB* will do so. After all items have been processed, the backfilling operation is complete and **Backfilling** is false.

*Note:* For indexes that were created during a *CreateTable* operation, the **Backfilling** attribute does not appear in the **DescribeTable** output.

- **ProvisionedThroughput (dict)** –

  Represents the provisioned throughput settings for the table, consisting of read and write capacity units, along with data about increases and decreases.

- **LastIncreaseDateTime (datetime)** –

  The date and time of the last provisioned throughput increase for this table.

- **LastDecreaseDateTime (datetime)** –

  The date and time of the last provisioned throughput decrease for this table.

- **NumberOfDecreasesToday (integer)** –

  The number of provisioned throughput decreases for this table during this UTC calendar day. For current maximums on provisioned throughput decreases, see *Limits* in the *Amazon DynamoDB Developer Guide* .

- **ReadCapacityUnits (integer)** –

  The maximum number of strongly consistent reads consumed per second before *DynamoDB* returns a *ThrottlingException* . Eventually consistent reads require less effort than strongly consistent reads, so a setting of 50 *ReadCapacityUnits* per
second provides 100 eventually consistent ReadCapacityUnits per second.

- **WriteCapacityUnits (integer)** –
  
  The maximum number of writes consumed per second before DynamoDB returns a ThrottlingException.

- **IndexSizeBytes (integer)** –
  
  The total size of the specified index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **ItemCount (integer)** –
  
  The number of items in the specified index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **IndexArn (string)** –
  
  The Amazon Resource Name (ARN) that uniquely identifies the index.

* **StreamSpecification (dict)** –

  The current DynamoDB Streams configuration for the table.

  - **StreamEnabled (boolean)** –
    
    Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.

  - **StreamViewType (string)** –
    
    The DynamoDB Streams settings for the table. These settings consist of:
    
    - **StreamEnabled** - Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.
    - **StreamViewType** - When an item in the table is modified, StreamViewType determines what information is written to the stream for this table. Valid values for StreamViewType are:
      * **KEYS_ONLY** - Only the key attributes of the modified item are written to the stream.
      * **NEW_IMAGE** - The entire item, as it appears after it was modified, is written to the stream.
      * **OLD_IMAGE** - The entire item, as it appeared before it was modified, is written to the stream.
      * **NEW_AND_OLD_IMAGES** - Both the new and the old item images of the item are written to the stream.

* **LatestStreamLabel (string)** –

  A timestamp, in ISO 8601 format, for this stream.

  Note that LatestStreamLabel is not a unique identifier for the stream, because it is possible that a stream from another table might have the same timestamp. However, the combination of the following three elements is guaranteed to be unique:
  
  - the AWS customer ID.
  - the table name.
  - the StreamLabel.

* **LatestStreamArn (string)** –

  The Amazon Resource Name (ARN) that uniquely identifies the latest stream for this table.
Paginators

The available paginators are:

- `DynamoDB.Paginator.ListTables`
- `DynamoDB.Paginator.Query`
- `DynamoDB.Paginator.Scan`

class `DynamoDB.Paginator.ListTables`

```
paginator = client.get_paginator('list_tables')
paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `DynamoDB.Client.list_tables()`.

**Request Syntax**

```
response_iterator = paginator.paginate(
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

`PaginationConfig (dict)` – A dictionary that provides parameters to control pagination.

- **MaxItems (integer)** –
  The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.

- **PageSize (integer)** –
  The size of each page.

- **StartingToken (string)** –
  A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type**

dict

**Returns**

**Response Syntax**

```
{
    'TableNames': [
        'string',
    ],
    'NextToken': 'string'
}
```

**Response Structure**

- `(dict)` –
  Represents the output of a `ListTables` operation.
- **TableNames** *(list)* –

The names of the tables associated with the current account at the current endpoint. The maximum size of this array is 100.

If `LastEvaluatedTableName` also appears in the output, you can use this value as the `ExclusiveStartTableName` parameter in a subsequent `ListTables` request and obtain the next page of results.

- **NextToken** *(string)* –

A token to resume pagination.

class DynamoDB.Paginator.Query

```
paginator = client.get_paginator('query')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `DynamoDB.Client.query()`.

**Request Syntax**

```
response_iterator = paginator.paginate(
    TableName='string',
    IndexName='string',
    Select='ALL_ATTRIBUTES'|'ALL_PROJECTED_ATTRIBUTES'|'SPECIFIC_ATTRIBUTES'|'COUNT',
    AttributesToGet=[
        'string',
    ],
    ConsistentRead=True|False,
    KeyConditions={
        'string': {
            'AttributeValueList': [
                {
                    'S': 'string',
                    'N': 'string',
                    'B': b'bytes',
                    'SS': [
                        'string',
                    ],
                    'NS': [
                        'string',
                    ],
                    'BS': [
                        b'bytes',
                    ],
                    'M': {
                        'string': {'... recursive ...'}
                    },
                    'L': {'... recursive ...'},
                    'NULL': True|False,
                    'BOOL': True|False
                }
            ]
        },
        'ComparisonOperator': 'EQ'|'NE'|'IN'|'LE'|'LT'|'GE'|'GT'|'BETWEEN'|'NOT_NULL'|'CONTAINS'|'NOT_CONTAINS'|'BEGINS_WITH'
    }
)
QueryFilter=
    'string': {
        'AttributeValueList': [
            {
                'S': 'string',
                'N': 'string',
                'B': b'bytes',
                'SS': []
            },
            {
                'NS': []
            }
        ],
        'ComparisonOperator': 'EQ'|'NE'|'IN'|'LE'|'LT'|'GE'|'GT'|'BETWEEN'|'NOT_NULL'|'NULL'|'CONTAINS'|'NOT_CONTAINS'|'BEGINS_WITH'
    },
    ConditionalOperator='AND'|'OR',
    ScanIndexForward=True|False,
    ReturnConsumedCapacity='INDEXES'|'TOTAL'|'NONE',
    ProjectionExpression='string',
    FilterExpression='string',
    KeyConditionExpression='string',
    ExpressionAttributeNames=
        'string': 'string'
    },
    ExpressionAttributeValues=
        'string': {
            'S': 'string',
            'N': 'string',
            'B': b'bytes',
            'SS': []
        },
        'NS': []
    }
}
Parameters

- **TableName (string)** – [REQUIRED]

  The name of the table containing the requested items.

- **IndexName (string)** – The name of an index to query. This index can be any local secondary index or global secondary index on the table. Note that if you use the `IndexName` parameter, you must also provide `TableName`.

- **Select (string)** – The attributes to be returned in the result. You can retrieve all item attributes, specific item attributes, the count of matching items, or in the case of an index, some or all of the attributes projected into the index.

  - **ALL_ATTRIBUTES** - Returns all of the item attributes from the specified table or index. If you query a local secondary index, then for each matching item in the index DynamoDB will fetch the entire item from the parent table. If the index is configured to project all item attributes, then all of the data can be obtained from the local secondary index, and no fetching is required.

  - **ALL_PROJECTIONED_ATTRIBUTES** - Allowed only when querying an index. Retrieves all attributes that have been projected into the index. If the index is configured to project all attributes, this return value is equivalent to specifying **ALL_ATTRIBUTES**.

  - **COUNT** - Returns the number of matching items, rather than the matching items themselves.

  - **SPECIFIC_ATTRIBUTES** - Returns only the attributes listed in `AttributesToGet`. This return value is equivalent to specifying `AttributesToGet` without specifying any value for `Select`. If you query a local secondary index and request only attributes that are projected into that index, the operation will read only the index and not the table. If any of the requested attributes are not projected into the local secondary index, DynamoDB will fetch each of these attributes from the parent table. This extra fetching incurs additional throughput cost and latency. If you query a global secondary index, you can only request attributes that are projected into the index. Global secondary index queries cannot fetch attributes from the parent table. If neither `Select` nor `AttributesToGet` are specified, DynamoDB defaults to **ALL_ATTRIBUTES** when accessing a table, and **ALL_PROJECTIONED_ATTRIBUTES** when accessing an index. You cannot use both `Select` and `AttributesToGet` together in a single request, unless the value for `Select` is **SPECIFIC_ATTRIBUTES**. (This usage is equivalent to specifying `AttributesToGet` without any value for `Select`.)

  _Note:_ If you use the `ProjectionExpression` parameter, then the value for `Select` can only be **SPECIFIC_ATTRIBUTES**. Any other value for `Select` will return an error.
• AttributesToGet (list) –

The names of one or more attributes to retrieve. If no attribute names are provided, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

Note that AttributesToGet has no effect on provisioned throughput consumption. DynamoDB determines capacity units consumed based on item size, not on the amount of data that is returned to an application.

You cannot use both AttributesToGet and Select together in a Query request, unless the value for Select is SPECIFIC_ATTRIBUTES. (This usage is equivalent to specifying AttributesToGet without any value for Select.)

If you query a local secondary index and request only attributes that are projected into that index, the operation will read only the index and not the table. If any of the requested attributes are not projected into the local secondary index, DynamoDB will fetch each of these attributes from the parent table. This extra fetching incurs additional throughput cost and latency.

If you query a global secondary index, you can only request attributes that are projected into the index. Global secondary index queries cannot fetch attributes from the parent table.

– (string) –

• ConsistentRead (boolean) – Determines the read consistency model: If set to true, then the operation uses strongly consistent reads; otherwise, the operation uses eventually consistent reads.

Strongly consistent reads are not supported on global secondary indexes. If you query a global secondary index with ConsistentRead set to true, you will receive a ValidationException.

• KeyConditions (dict) –

The selection criteria for the query. For a query on a table, you can have conditions only on the table primary key attributes. You must provide the hash key attribute name and value as an EQ condition. You can optionally provide a second condition, referring to the range key attribute.

Note: If you don’t provide a range key condition, all of the items that match the hash key will be retrieved. If a FilterExpression or QueryFilter is present, it will be applied after the items are retrieved.

For a query on an index, you can have conditions only on the index key attributes. You must provide the index hash attribute name and value as an EQ condition. You can optionally provide a second condition, referring to the index key range attribute.
Each `KeyConditions` element consists of an attribute name to compare, along with the following:

- `AttributeValueList` - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the `ComparisonOperator` being used. For type Number, value comparisons are numeric. String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and a is greater than B. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters). For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- `ComparisonOperator` - A comparator for evaluating attributes, for example, equals, greater than, less than, and so on. For `KeyConditions`, only the following comparison operators are supported: `EQ | LE | LT | GE | GT | BEGINS_WITH | BETWEEN`. The following are descriptions of these comparison operators. * `EQ`: Equal. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.

- `LE`: Less than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- `LT`: Less than. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- `GE`: Greater than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- `GT`: Greater than. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- `BEGINS_WITH`: Checks for a prefix. `AttributeValueList` can contain only one `AttributeValue` of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- `BETWEEN`: Greater than or equal to the first value, and less than or equal to the second value. `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item con-
contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{ "S": "6" }` does not compare to `{ "N": "6" }`. Also, `{ "N": "6" }` does not compare to `{ "NS": [ "6", "2", "1"] }`.

For usage examples of `AttributeValueList` and `ComparisonOperator`, see Legacy Conditional Parameters in the Amazon DynamoDB Developer Guide.

- `(string)` –
  * `(dict)` –
    
    Represents the selection criteria for a `Query` or `Scan` operation:
    
    - For a `Query` operation, `Condition` is used for specifying the `KeyConditions` to use when querying a table or an index. For `KeyConditions`, only the following comparison operators are supported: `EQ` | `LE` | `LT` | `GE` | `GT` | `BEGINS_WITH` | `BETWEEN` `Condition` is also used in a `QueryFilter`, which evaluates the query results and returns only the desired values.
    
    - For a `Scan` operation, `Condition` is used in a `ScanFilter`, which evaluates the scan results and returns only the desired values.

- `AttributeValueList` `(list)` –
  
  One or more values to evaluate against the supplied attribute. The number of values in the list depends on the `ComparisonOperator` being used.

  For type Number, value comparisons are numeric.

  String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, "a" is greater than "A", and "a" is greater than "B". For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters.

  For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- `(dict)` –
  
  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- `S (string)` –
  
  A String data type.

- `N (string)` –
  
  A Number data type.

- `B (bytes)` –
  
  A Binary data type.

- `SS (list)` –
  
  A String Set data type.
· (string) –
  · **NS** (list) –
    A Number Set data type.
· (string) –
  · **BS** (list) –
    A Binary Set data type.
· (bytes) –
  · **M** (dict) –
    A Map of attribute values.
· (string) –
  · (dict) –
    Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

· **L** (list) –
  A List of attribute values.
· (dict) –
    Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

· **NULL** (boolean) –
  A Null data type.
· **BOOL** (boolean) –
  A Boolean data type.
· **ComparisonOperator** (string) – [REQUIRED]
  A comparator for evaluating attributes. For example, equals, greater than, less than, etc.

The following comparison operators are available:

```plaintext
EQ | NE | LE | LT | GE | GT | NOT_NULL
   | NULL | CONTAINS | NOT_CONTAINS | NOT_NULL
BEGIN | WITH | IN | BETWEEN
```

The following are descriptions of each comparison operator.

· **EQ**: Equal. **EQ** is supported for all datatypes, including lists and maps. **AttributeValueList** can contain only one **AttributeValue** element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an **AttributeValue** element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}`
Boto3 Documentation, Release 1.1.4

does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not equal \{"NS": \{"6", "2", "1"\}\}.
- **NE**: Not equal. NE is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not equal \{"NS": \{"6", "2", "1"\}\}.
- **LE**: Less than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not compare to \{"NS": \{"6", "2", "1"\}\}.
- **LT**: Less than. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not compare to \{"NS": \{"6", "2", "1"\}\}.
- **GE**: Greater than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not compare to \{"NS": \{"6", "2", "1"\}\}.
- **GT**: Greater than. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not compare to \{"NS": \{"6", "2", "1"\}\}.
- **NOT_NULL**: The attribute exists. **NOT_NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the existence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NOT_NULL**, the result is a Boolean `true`. This result is because the attribute “a” exists; its data type is not relevant to the **NOT_NULL** comparison operator.
- **NULL**: The attribute does not exist. **NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NULL**, the result is a Boolean `false`. This is because the attribute “a” exists; its data type is not relevant to the **NULL** comparison operator.
- **CONTAINS**: Checks for a subsequence, or value in a set. `AttributeValueList` can contain only one `AttributeValue` element
of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it finds an exact match with any member of the set. CONTAINS is supported for lists: When evaluating "a CONTAINS b", "a" can be a list; however, "b" cannot be a set, a map, or a list.

- NOT_CONTAINS: Checks for absence of a subsequence, or absence of a value in a set. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it does not find an exact match with any member of the set. NOT_CONTAINS is supported for lists: When evaluating "a NOT CONTAINS b", "a" can be a list; however, "b" cannot be a set, a map, or a list.

- BEGINS_WITH: Checks for a prefix. AttributeValueList can contain only one AttributeValue of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- IN: Checks for matching elements within two sets. AttributeValueList can contain one or more AttributeValue elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

- BETWEEN: Greater than or equal to the first value, and less than or equal to the second value. AttributeValueList must contain two AttributeValue elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match.

For usage examples of AttributeValueList and ComparisonOperator, see Legacy Conditional Parameters in the Amazon DynamoDB Developer Guide.

**QueryFilter (dict)** –

**Warning:** This is a legacy parameter, for backward compatibility. New applications should use FilterExpression instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a ValidationException exception.
A condition that evaluates the query results after the items are read and returns only the desired values.

This parameter does not support attributes of type List or Map.

**Note:** A *QueryFilter* is applied after the items have already been read; the process of filtering does not consume any additional read capacity units.

If you provide more than one condition in the *QueryFilter* map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the *ConditionalOperator* parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

Note that *QueryFilter* does not allow key attributes. You cannot define a filter condition on a hash key or range key.

Each *QueryFilter* element consists of an attribute name to compare, along with the following:

- **AttributeValueList** - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the operator specified in *ComparisonOperator*. For type Number, value comparisons are numeric. String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, `a` is greater than `A`, and `a` is greater than `b`. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters). For type Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values. For information on specifying data types in JSON, see [JSON Data Format in the Amazon DynamoDB Developer Guide](http://aws.amazon.com/dre). For complete descriptions of all comparison operators, see the *Condition* data type.

- **ComparisonOperator** - A comparator for evaluating attributes. For example, equals, greater than, less than, etc. The following comparison operators are available: `EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN`. For complete descriptions of all comparison operators, see the *Condition* data type.

- *(string)*

  - *(dict)*

  Represents the selection criteria for a *Query* or *Scan* operation:

  - For a *Query* operation, *Condition* is used for specifying the *KeyConditions* to use when querying a table or an index. For *KeyConditions*, only the following comparison operators are supported: `EQ | LE | LT | GE | GT | BEGINS_WITH | BETWEEN`. *Condition* is also used in a *QueryFilter*, which evaluates the query results and returns only the desired values.

  - For a *Scan* operation, *Condition* is used in a *ScanFilter*, which evaluates the scan results and returns only the desired values.

  - **AttributeValueList** *(list)*

    One or more values to evaluate against the supplied attribute. The number of values in the list depends on the *ComparisonOperator* being used.
For type Number, value comparisons are numeric.

String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, \( a \) is greater than \( A \), and \( a \) is greater than \( B \). For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters.

For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- \( \text{dict} \) –
  
  Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- \( \text{S (string)} \) –
  
  A String data type.

- \( \text{N (string)} \) –
  
  A Number data type.

- \( \text{B (bytes)} \) –
  
  A Binary data type.

- \( \text{SS (list)} \) –
  
  A String Set data type.

- \( \text{L (list)} \) –
  
  A List of attribute values.

- \( \text{M (dict)} \) –
  
  Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- \( \text{M (dict)} \) –
  
  A Map of attribute values.

- \( \text{L (list)} \) –
  
  A List of attribute values.
Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL (boolean)** –

  A Null data type.

- **BOOL (boolean)** –

  A Boolean data type.

- **ComparisonOperator (string)** – [REQUIRED]

  A comparator for evaluating attributes. For example, equals, greater than, less than, etc.

The following comparison operators are available:

```plaintext
EQ | NE | LE | LT | GE | GT | NOT_NULL
| NULL | CONTAINS | NOT_CONTAINS |
| BEGINS_WITH | IN | BETWEEN
```

The following are descriptions of each comparison operator.

- **EQ**: Equal. EQ is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not equal `{"N": "6"}`. Also, `{"N": "6"}` does not equal `{"NS": ["6", "2", "1"]}`.

- **NE**: Not equal. NE is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not equal `{"N": "6"}`. Also, `{"N": "6"}` does not equal `{"NS": ["6", "2", "1"]}`.

- **LE**: Less than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not equal `{"N": "6"}`. Also, `{"N": "6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **LT**: Less than. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not equal `{"N": "6"}`. Also, `{"N": "6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **GE**: Greater than or equal. `AttributeValueList` can contain
only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not equal `{"N": "6"}`. Also, `{"N": "6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

· **GT**: Greater than. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not equal `{"N": "6"}`. Also, `{"N": "6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

· **NOT_NULL**: The attribute exists. **NOT_NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the existence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NOT_NULL**, the result is a Boolean `true`. This result is because the attribute “a” exists; its data type is not relevant to the **NOT_NULL** comparison operator.

· **NULL**: The attribute does not exist. **NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NULL**, the result is a Boolean `false`. This is because the attribute “a” exists; its data type is not relevant to the **NULL** comparison operator.

· **CONTAINS**: Checks for a subsequence, or value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it finds an exact match with any member of the set. CONTAINS is supported for lists: When evaluating "a CONTAINS b", "a" can be a list; however, "b" cannot be a set, a map, or a list.

· **NOT_CONTAINS**: Checks for absence of a subsequence, or absence of a value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it does not find an exact match with any member of the set. NOT_CONTAINS is supported for lists: When evaluating "a NOT CONTAINS b", "a" can be a list; however, "b" cannot be a set, a map, or a list.

· **BEGINS_WITH**: Checks for a prefix. `AttributeValueList` can
contain only one AttributeValue of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- **IN**: Checks for matching elements within two sets. AttributeValueList can contain one or more AttributeValue elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

- **BETWEEN**: Greater than or equal to the first value, and less than or equal to the second value. AttributeValueList must contain two AttributeValue elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, {"S":"6"} does not compare to {"N":"6"} . Also, {"N":"6"} does not compare to {"NS": ["6", "2", "1"]}.

For usage examples of AttributeValueList and ComparisonOperator, see Legacy Conditional Parameters in the Amazon DynamoDB Developer Guide.

- **ConditionalOperator (string)** –

  A logical operator to apply to the conditions in a QueryFilter map:
  - **AND**: If all of the conditions evaluate to true, then the entire map evaluates to true.
  - **OR**: If at least one of the conditions evaluate to true, then the entire map evaluates to true.

  If you omit ConditionalOperator, then AND is the default.

  The operation will succeed only if the entire map evaluates to true.

  **Note**: This parameter does not support attributes of type List or Map.

- **ScanIndexForward (boolean)** – Specifies the order in which to return the query results - either ascending (true) or descending (false).

  Items with the same hash key are stored in sorted order by range key. If the range key data type is Number, the results are stored in numeric order. For type String, the results are returned in order of ASCII character code values. For type Binary, DynamoDB treats each byte of the binary data as unsigned.

  If ScanIndexForward is true, DynamoDB returns the results in order, by range key. This is the default behavior.

  If ScanIndexForward is false, DynamoDB sorts the results in descending order by range key, and then returns the results to the client.

- **ReturnConsumedCapacity (string)** – Determines the level of detail about provisioned throughput consumption that is returned in the response:
  - **INDEXES**: The response includes the aggregate ConsumedCapacity for
the operation, together with ConsumedCapacity for each table and secondary index that was accessed. Note that some operations, such as GetItem and BatchGetItem, do not access any indexes at all. In these cases, specifying INDEXES will only return ConsumedCapacity information for table(s).

- **TOTAL** - The response includes only the aggregate ConsumedCapacity for the operation.
- **NONE** - No ConsumedCapacity details are included in the response.

- **ProjectionExpression** *(string)* – A string that identifies one or more attributes to retrieve from the table. These attributes can include scalars, sets, or elements of a JSON document. The attributes in the expression must be separated by commas.

If no attribute names are specified, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

For more information, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

**Note:** ProjectionExpression replaces the legacy AttributesToGet parameter.

- **FilterExpression** *(string)* – A string that contains conditions that DynamoDB applies after the Query operation, but before the data is returned to you. Items that do not satisfy the FilterExpression criteria are not returned.

**Note:** A FilterExpression is applied after the items have already been read; the process of filtering does not consume any additional read capacity units.

For more information, see Filter Expressions in the Amazon DynamoDB Developer Guide.

**Note:** FilterExpression replaces the legacy QueryFilter and ConditionalOperator parameters.

- **KeyConditionExpression** *(string)* – The condition that specifies the key value(s) for items to be retrieved by the Query action.

The condition must perform an equality test on a single hash key value. The condition can also perform one of several comparison tests on a single range key value. Query can use KeyConditionExpression to retrieve one item with a given hash and range key value, or several items that have the same hash key value but different range key values.

The hash key equality test is required, and must be specified in the following format:

```plaintext
hashAttributeName = :hashval
```

If you also want to provide a range key condition, it must be combined using **AND** with the hash key condition. Following is an example, using the **=** comparison operator for the range key:

```plaintext
hashAttributeName = :hashval AND
rangeAttributeName = :rangeval
```

Valid comparisons for the range key condition are as follows:

- **rangeAttributeName = :rangeval** - true if the range key is equal to :rangeval.
- **rangeAttributeName :rangeval** - true if the range key is less than :rangeval.
- **rangeAttributeName >= :rangeval** - true if the range key is less
than or equal to :rangeval.

- rangeAttributeName ** :rangeval - true if the range key is greater than :rangeval.
- rangeAttributeName = :rangeval - true if the range key is greater than or equal to :rangeval.
- rangeAttributeName BETWEEN :rangeval1 AND :rangeval2 - true if the range key is greater than or equal to :rangeval1, and less than or equal to :rangeval2.
- begins_with { rangeAttributeName , :rangeval } - true if the range key begins with a particular operand. (You cannot use this function with a range key that is of type Number.) Note that the function name begins_with is case-sensitive.

Use the ExpressionAttributeValues parameter to replace tokens such as :hashval and :rangeval with actual values at runtime.

You can optionally use the ExpressionAttributeNames parameter to replace the names of the hash and range attributes with placeholder tokens. This option might be necessary if an attribute name conflicts with a DynamoDB reserved word. For example, the following KeyConditionExpression parameter causes an error because Size is a reserved word:

- Size = :myval

To work around this, define a placeholder (such a #S) to represent the attribute name Size. KeyConditionExpression then is as follows:

- #S = :myval

For a list of reserved words, see Reserved Words in the Amazon DynamoDB Developer Guide.

For more information on ExpressionAttributeNames and ExpressionAttributeValues, see Using Placeholders for Attribute Names and Values in the Amazon DynamoDB Developer Guide.

**Note:** KeyConditionExpression replaces the legacy KeyConditions parameter.

- **ExpressionAttributeNames** *(dict)* – One or more substitution tokens for attribute names in an expression. The following are some use cases for using ExpressionAttributeNames:
  - To access an attribute whose name conflicts with a DynamoDB reserved word.
  - To create a placeholder for repeating occurrences of an attribute name in an expression.
  - To prevent special characters in an attribute name from being misinterpreted in an expression.

Use the # character in an expression to dereference an attribute name. For example, consider the following attribute name:

- Percentile

The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see Reserved Words in the Amazon DynamoDB Developer Guide.) To work around this, you could specify the following for ExpressionAttributeNames:

- { "#P": "Percentile" }

You could then use this substitution in an expression, as in this example:

- #P = :val

**Note:** Tokens that begin with the : character are expression attribute values, which are placeholders for the actual value at runtime.
For more information on expression attribute names, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

- (string) –
  - (string) –
  - (dict) –

• **ExpressionAttributeValue** *(dict)* – One or more values that can be substituted in an expression.

Use the : (colon) character in an expression to dereference an attribute value. For example, suppose that you wanted to check whether the value of the ProductStatus attribute was one of the following:

```
Available | Backordered | Discontinued
```

You would first need to specify ExpressionAttributeValues as follows:

```
{ ":avail":{"S":"Available"}, ":back":{"S":"Backordered"}, ":disc":{"S":"Discontinued"} }
```

You could then use these values in an expression, such as this:

```
ProductStatus IN (:avail, :back, :disc)
```

For more information on expression attribute values, see Specifying Conditions in the Amazon DynamoDB Developer Guide.

- (string) –
  - (dict) –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **S**(string) –
  
  A String data type.

- **N**(string) –
  
  A Number data type.

- **B**(bytes) –
  
  A Binary data type.

- **SS**(list) –
  
  A String Set data type.

- **NS**(list) –
  
  A Number Set data type.

- **BS**(list) –
  
  A Binary Set data type.

- **M**(dict) –
  
  A Map of attribute values.
Represents the data for an attribute. You can set one, and only
one, of the elements.

Each attribute in an item is a name-value pair. An attribute
can be single-valued or multi-valued set. For example, a book
item can have title and authors attributes. Each book has one
title but can have many authors. The multi-valued attribute is
a set; duplicate values are not allowed.

- **L** *(list)* –
  A List of attribute values.
- **(dict)** –
  Represents the data for an attribute. You can set one, and only
  one, of the elements.

Each attribute in an item is a name-value pair. An attribute
can be single-valued or multi-valued set. For example, a book
item can have title and authors attributes. Each book has one
title but can have many authors. The multi-valued attribute is
a set; duplicate values are not allowed.

- **NULL** *(boolean)* –
  A Null data type.
- **BOOL** *(boolean)* –
  A Boolean data type.

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pag-
  ination.
  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available
    is more than the value specified in max-items then a **NextToken** will be
    provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –
    The size of each page.
  - **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the **NextToken**
    from a previous response.

Return type  **dict**

Returns

Response Syntax

```json
{
  'Items': [
    {
      'string': {
        'S': 'string',
        'N': 'string',
        'B': b'bytes',
        'SS': [
          'string',
        ],
        'NS': [
          'string',
        ],
        'BS': [
      
```
Response Structure

- **(dict)** –

  Represents the output of a *Query* operation.

  - **Items (list)** –

    An array of item attributes that match the query criteria. Each element in this array consists of an attribute name and the value for that attribute.

      - **(dict)** –

        - **(string)** –

        - **(dict)** –

        Represents the data for an attribute. You can set one, and only one, of the elements.

        Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

        - **S (string)** –

          A String data type.

        - **N (string)** –

A Number data type.
· **B** *(bytes)*
  A Binary data type.
· **SS** *(list)*
  A String Set data type.
  · *(string)*
  · **NS** *(list)*
  A Number Set data type.
  · *(string)*
  · **BS** *(list)*
  A Binary Set data type.
  · *(bytes)*
  · **M** *(dict)*
  A Map of attribute values.
  · *(string)*
  · *(dict)*
Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.
· **L** *(list)*
  A List of attribute values.
· *(dict)*
  Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.
· **NULL** *(boolean)*
  A Null data type.
· **BOOL** *(boolean)*
  A Boolean data type.

- **Count** *(integer)*
  The number of items in the response.

If you used a `QueryFilter` in the request, then `Count` is the number of items returned after the filter was applied, and `ScannedCount` is the number of matching items before the filter was applied.

If you did not use a filter in the request, then `Count` and `ScannedCount` are the same.
- **ScannedCount** *(integer)*
The number of items evaluated, before any QueryFilter is applied. A high ScannedCount value with few, or no, Count results indicates an inefficient Query operation. For more information, see Count and ScannedCount in the Amazon DynamoDB Developer Guide.

If you did not use a filter in the request, then ScannedCount is the same as Count.

- **ConsumedCapacity (dict)**

  The capacity units consumed by an operation. The data returned includes the total provisioned throughput consumed, along with statistics for the table and any indexes involved in the operation. ConsumedCapacity is only returned if the request asked for it. For more information, see Provisioned Throughput in the Amazon DynamoDB Developer Guide.

  - **TableName (string)**
    
    The name of the table that was affected by the operation.

  - **CapacityUnits (float)**
    
    The total number of capacity units consumed by the operation.

  - **Table (dict)**
    
    The amount of throughput consumed on the table affected by the operation.

    - **CapacityUnits (float)**
      
      The total number of capacity units consumed on a table or an index.

  - **LocalSecondaryIndexes (dict)**

    The amount of throughput consumed on each local index affected by the operation.

    - **(string)**
      
      Represents the amount of provisioned throughput capacity consumed on a table or an index.

    - **(dict)**
      
      The total number of capacity units consumed on a table or an index.

  - **GlobalSecondaryIndexes (dict)**

    The amount of throughput consumed on each global index affected by the operation.

    - **(string)**
      
      Represents the amount of provisioned throughput capacity consumed on a table or an index.

    - **(dict)**
      
      The total number of capacity units consumed on a table or an index.

- **NextToken (string)**

  A token to resume pagination.

```
class DynamoDB.Paginator.Scan
```
paginator = client.get_paginator('scan')

paginate(**kwargs)

Creates an iterator that will paginate through responses from DynamoDB.Client.scan().

Request Syntax

response_iterator = paginator.paginate(
    TableName='string',
    IndexName='string',
    AttributesToGet=[
        'string',
    ],
    Select='ALL_ATTRIBUTES'|'ALL_PROJECTED_ATTRIBUTES'|'SPECIFIC_ATTRIBUTES'|'COUNT',
    ScanFilter={
        'string': {
            'AttributeValueList': [
                {'S': 'string',
                 'N': 'string',
                 'B': b'bytes',
                 'SS': [
                     'string',
                 ],
                 'NS': [
                     'string',
                 ],
                 'BS': [b'bytes',
                ],
                 'M': {
                     'string': {... recursive ...}
                 },
                 'L': [{... recursive ...},
               ],
                'NULL': True|False,
                'BOOL': True|False
            ],
            'ComparisonOperator': 'EQ'|'NE'|'IN'|'LE'|'LT'|'GE'|'GT'|'BETWEEN'|'NOT_NULL'|'NULL'|'CONTAINS'|'NOT_CONTAINS'|'BEGINS_WITH'
        }
    },
    ConditionalOperator='AND'|'OR',
    ReturnConsumedCapacity='INDEXES'|'TOTAL'|'NONE',
    TotalSegments=123,
    Segment=123,
    ProjectionExpression='string',
    FilterExpression='string',
    ExpressionAttributeNames={
        'string': 'string'
    },
    ExpressionAttributeValues={
        'string': {
            'S': 'string',
            'N': 'string',
            'B': b'bytes',
            'SS': [
        }
Boto3 Documentation, Release 1.1.4

Parameters

- **TableName** (string) – [REQUIRED]

  The name of the table containing the requested items; or, if you provide IndexName, the name of the table to which that index belongs.

- **IndexName** (string) – The name of a secondary index to scan. This index can be any local secondary index or global secondary index. Note that if you use the IndexName parameter, you must also provide TableName.

- **AttributesToGet** (list) –

  The names of one or more attributes to retrieve. If no attribute names are provided, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

  Note that AttributesToGet has no effect on provisioned throughput consumption. DynamoDB determines capacity units consumed based on item size, not on the amount of data that is returned to an application.

  - (string)

- **Select** (string) – The attributes to be returned in the result. You can retrieve all item attributes, specific item attributes, or the count of matching items.

  - ALL_ATTRIBUTES - Returns all of the item attributes.
  - COUNT - Returns the number of matching items, rather than the matching items themselves.
  - SPECIFIC_ATTRIBUTES - Returns only the attributes listed in AttributesToGet. This return value is equivalent to specifying AttributesToGet.
Get without specifying any value for Select.

If neither Select nor AttributesToGet are specified, DynamoDB defaults to ALL_ATTRIBUTES. You cannot use both AttributesToGet and Select together in a single request, unless the value for Select is SPECIFIC_ATTRIBUTES. (This usage is equivalent to specifying AttributesToGet without any value for Select.)

• ScanFilter (dict) –

A condition that evaluates the scan results and returns only the desired values.

**Warning:** This is a legacy parameter, for backward compatibility. New applications should use FilterExpression instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a ValidationException exception.

**Note:** This parameter does not support attributes of type List or Map.

If you specify more than one condition in the ScanFilter map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the ConditionalOperator parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

Each ScanFilter element consists of an attribute name to compare, along with the following:

– **AttributeValueList** - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the operator specified in ComparisonOperator. For type Number, value comparisons are numeric. String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and a is greater than B. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters. For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values. For information on specifying data types in JSON, see JSON Data Format in the Amazon DynamoDB Developer Guide.

– **ComparisonOperator** - A comparator for evaluating attributes. For example, equals, greater than, less than, etc. The following comparison operators are available: EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN For complete descriptions of all comparison operators, see Condition.

– (string) –

* (dict) –

Represents the selection criteria for a Query or Scan operation:

• For a Query operation, Condition is used for specifying the KeyConditions to use when querying a table or an index. For KeyConditions, only the following comparison operators are supported: EQ | LE | LT | GE | GT | BEGINS_WITH | BETWEEN Condition is also used in a QueryFilter, which evaluates the query results and returns only the desired values.

• For a Scan operation, Condition is used in a ScanFilter, which evaluates the scan results and returns only the desired values.
· **AttributeValueList** *(list)* –

One or more values to evaluate against the supplied attribute. The number of values in the list depends on the *Comparison-Operator* being used.

For type Number, value comparisons are numeric. String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and a is greater than B. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters).

For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

· **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

· **S** *(string)* –

A String data type.

· **N** *(string)* –

A Number data type.

· **B** *(bytes)* –

A Binary data type.

· **SS** *(list)* –

A String Set data type.

· **(string)** –

· **NS** *(list)* –

A Number Set data type.

· **(string)** –

· **BS** *(list)* –

A Binary Set data type.

· **(bytes)** –

· **M** *(dict)* –

A Map of attribute values.

· **(string)** –

· **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one
title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L (list)**
  A List of attribute values.

- **(dict)**
  Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL (boolean)**
  A Null data type.

- **BOOL (boolean)**
  A Boolean data type.

- **ComparisonOperator (string) – [REQUIRED]**
  A comparator for evaluating attributes. For example, equals, greater than, less than, etc.

The following comparison operators are available:

```
EQ | NE | LE | LT | GE | GT | NOT_NULL
| NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN
```

The following are descriptions of each comparison operator.

- **EQ**: Equal. EQ is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":{"6","2","1"}}`.

- **NE**: Not equal. NE is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":{"6","2","1"}}`.

- **LE**: Less than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":{"6","2","1"}}`.

- **LT**: Less than. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type).
If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not equal `{"N": "6"}`. Also, `{"N": "6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **GE**: Greater than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not equal `{"N": "6"}`. Also, `{"N": "6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **GT**: Greater than. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not equal `{"N": "6"}`. Also, `{"N": "6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **NOT_NULL**: The attribute exists. **NOT_NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the existence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NOT_NULL**, the result is a Boolean `true`. This result is because the attribute “a” exists; its data type is not relevant to the **NOT_NULL** comparison operator.

- **NULL**: The attribute does not exist. **NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NULL**, the result is a Boolean `false`. This is because the attribute “a” exists; its data type is not relevant to the **NULL** comparison operator.

- **CONTAINS**: Checks for a subsequence, or value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it finds an exact match with any member of the set. **CONTAINS** is supported for lists: When evaluating “a CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

- **NOT_CONTAINS**: Checks for absence of a subsequence, or absence of a value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"),
then the operator evaluates to true if it does not find an exact match with any member of the set. NOT_CONTAINS is supported for lists: When evaluating “a NOT CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

· BEGINS_WITH: Checks for a prefix. AttributeValueList can contain only one AttributeValue of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

· IN: Checks for matching elements within two sets. AttributeValueList can contain one or more AttributeValue elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

· BETWEEN: Greater than or equal to the first value, and less than or equal to the second value. AttributeValueList must contain two AttributeValue elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, 

For usage examples of AttributeValueList and ComparisonOperator, see Legacy Conditional Parameters in the Amazon DynamoDB Developer Guide.

· ConditionalOperator (string) –

A logical operator to apply to the conditions in a ScanFilter map:

- AND - If all of the conditions evaluate to true, then the entire map evaluates to true.
- OR - If at least one of the conditions evaluate to true, then the entire map evaluates to true.

If you omit ConditionalOperator, then AND is the default.

The operation will succeed only if the entire map evaluates to true.

Note: This parameter does not support attributes of type List or Map.

· ReturnConsumedCapacity (string) – Determines the level of detail about provisioned throughput consumption that is returned in the response:

- INDEXES - The response includes the aggregate ConsumedCapacity for the operation, together with ConsumedCapacity for each table and secondary index that was accessed. Note that some operations, such as GetItem and BatchGetItem, do not access any indexes at all. In these cases, specifying INDEXES will only return ConsumedCapacity information for table(s).
- **TOTAL** - The response includes only the aggregate ConsumedCapacity for the operation.
- **NONE** - No ConsumedCapacity details are included in the response.

- **TotalSegments (integer)** – For a parallel Scan request, TotalSegments represents the total number of segments into which the Scan operation will be divided. The value of TotalSegments corresponds to the number of application workers that will perform the parallel scan. For example, if you want to use four application threads to scan a table or an index, specify a TotalSegments value of 4.

  The value for TotalSegments must be greater than or equal to 1, and less than or equal to 1000000. If you specify a TotalSegments value of 1, the Scan operation will be sequential rather than parallel.

  If you specify TotalSegments, you must also specify Segment.

- **Segment (integer)** – For a parallel Scan request, Segment identifies an individual segment to be scanned by an application worker.

  Segment IDs are zero-based, so the first segment is always 0. For example, if you want to use four application threads to scan a table or an index, then the first thread specifies a Segment value of 0, the second thread specifies 1, and so on.

  The value of LastEvaluatedKey returned from a parallel Scan request must be used as ExclusiveStartKey with the same segment ID in a subsequent Scan operation.

  The value for Segment must be greater than or equal to 0, and less than the value provided for TotalSegments.

  If you provide Segment, you must also provide TotalSegments.

- **ProjectionExpression (string)** – A string that identifies one or more attributes to retrieve from the specified table or index. These attributes can include scalars, sets, or elements of a JSON document. The attributes in the expression must be separated by commas.

  If no attribute names are specified, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

  For more information, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

  Note: ProjectionExpression replaces the legacy AttributesToGet parameter.

- **FilterExpression (string)** – A string that contains conditions that DynamoDB applies after the Scan operation, but before the data is returned to you. Items that do not satisfy the FilterExpression criteria are not returned.

  Note: A FilterExpression is applied after the items have already been read; the process of filtering does not consume any additional read capacity units.

  For more information, see Filter Expressions in the Amazon DynamoDB Developer Guide.

  Note: FilterExpression replaces the legacy ScanFilter and ConditionalOperator parameters.

- **ExpressionAttributeNames (dict)** – One or more substitution tokens for attribute names in an expression. The following are some use cases for using ExpressionAttributeNames:
– To access an attribute whose name conflicts with a DynamoDB reserved word.
– To create a placeholder for repeating occurrences of an attribute name in an expression.
– To prevent special characters in an attribute name from being misinterpreted in an expression.

Use the # character in an expression to dereference an attribute name. For example, consider the following attribute name:

– Percentile

The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see Reserved Words in the Amazon DynamoDB Developer Guide). To work around this, you could specify the following for ExpressionAttributeNames:

– {"#P":"Percentile"}

You could then use this substitution in an expression, as in this example:

– #:P = :val

**Note:** Tokens that begin with the : character are **expression attribute values**, which are placeholders for the actual value at runtime.

For more information on expression attribute names, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

– (string) –
  * (string) –

**ExpressionAttributeValues (dict)** – One or more values that can be substituted in an expression.

Use the : (colon) character in an expression to dereference an attribute value. For example, suppose that you wanted to check whether the value of the ProductStatus attribute was one of the following:

Available | Backordered | Discontinued

You would first need to specify ExpressionAttributeValues as follows:

{ "avail":{"S":"Available"}, "back":{"S":"Backordered"}, "disc":{"S":"Discontinued"} }

You could then use these values in an expression, such as this:

ProductStatus IN (:avail, :back, :disc)

For more information on expression attribute values, see Specifying Conditions in the Amazon DynamoDB Developer Guide.

– (string) –
  * (dict) –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

– **S (string)** –

A String data type.

– **N (string)** –
A Number data type.

- **B (bytes)** –
  A Binary data type.

- **SS (list)** –
  A String Set data type.
  - **(string)** –
  - **NS (list)** –
    A Number Set data type.
    - **(string)** –
    - **BS (list)** –
      A Binary Set data type.
      - **(bytes)** –
      - **M (dict)** –
        A Map of attribute values.
        - **(string)** –
        - **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L (list)** –
  A List of attribute values.
  - **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL (boolean)** –
  A Null data type.
  - **BOOL (boolean)** –

A Boolean data type.

- **ConsistentRead (boolean)** – A Boolean value that determines the read consistency model during the scan:
  - If **ConsistentRead** is *false*, then *Scan* will use eventually consistent reads. The data returned from *Scan* might not contain the results of other recently completed write operations (PutItem, UpdateItem or DeleteItem). The *Scan* response might include some stale data.
  - If **ConsistentRead** is *true*, then *Scan* will use strongly consistent reads. All of the write operations that completed before the *Scan* began are guaranteed to be contained in the *Scan* response.

The default setting for **ConsistentRead** is *false*, meaning that eventually consistent reads will be used.
Strongly consistent reads are not supported on global secondary indexes. If you scan a global secondary index with `ConsistentRead` set to true, you will receive a `ValidationException`.

- **PaginationConfig** ([dict]) — A dictionary that provides parameters to control pagination.
  - **MaxItems** ([integer]) —
    
The total number of items to return. If the total number of items available is more than the value specified in `max-items` then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize** ([integer]) —
    
The size of each page.
  - **StartingToken** ([string]) —
    
A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** [dict]

**Returns**

**Response Syntax**

```json
{
    'Items': [
        {
            'string': {
                'S': 'string',
                'N': 'string',
                'B': b'bytes',
                'SS': [
                    'string',
                ],
                'NS': [
                    'string',
                ],
                'BS': [
                    b'bytes',
                ],
                'M': {
                    'string': {'... recursive ...'}
                },
                'L': [
                    {'... recursive ...'},
                ],
                'NULL': True|False,
                'BOOL': True|False
            }
        },
    ],
    'Count': 123,
    'ScannedCount': 123,
    'ConsumedCapacity': {
        'TableName': 'string',
        'CapacityUnits': 123.0,
        'Table': {
            'CapacityUnits': 123.0
        },
        'LocalSecondaryIndexes': {
            'string': {
                'string': {
            
```
'CapacityUnits': 123.0
}
}

'GlobalSecondaryIndexes': {
  'string': {
    'CapacityUnits': 123.0
  }
}

'NextToken': 'string'

Response Structure

* (dict) – Represents the output of a Scan operation.
  – Items (list) – An array of item attributes that match the scan criteria. Each element in this array consists of an attribute name and the value for that attribute.
    * (dict) –
      · (string) –
      · (dict) – Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

  · S (string) – A String data type.
  · N (string) – A Number data type.
  · B (bytes) – A Binary data type.
  · SS (list) – A String Set data type.
  · (string) –
  · NS (list) – A Number Set data type.
  · (string) –
  · BS (list) – A Binary Set data type.
  · (bytes) –
  · M (dict) – A Map of attribute values.
    · (string) –
    · (dict) – Represents the data for an attribute. You can set one, and only one, of the elements.
Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L (list)**
  A List of attribute values.

- **(dict)**
  Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL (boolean)**
  A Null data type.

- **BOOL (boolean)**
  A Boolean data type.

- **Count (integer)**
  The number of items in the response.

  If you set ScanFilter in the request, then Count is the number of items returned after the filter was applied, and ScannedCount is the number of matching items before the filter was applied.

  If you did not use a filter in the request, then Count is the same as ScannedCount.

- **ScannedCount (integer)**
  The number of items evaluated, before any ScanFilter is applied. A high ScannedCount value with few, or no, Count results indicates an inefficient Scan operation. For more information, see Count and ScannedCount in the Amazon DynamoDB Developer Guide.

  If you did not use a filter in the request, then ScannedCount is the same as Count.

- **ConsumedCapacity (dict)**
  The capacity units consumed by an operation. The data returned includes the total provisioned throughput consumed, along with statistics for the table and any indexes involved in the operation. ConsumedCapacity is only returned if the request asked for it. For more information, see Provisioned Throughput in the Amazon DynamoDB Developer Guide.

  * **TableName (string)**
    The name of the table that was affected by the operation.

  * **CapacityUnits (float)**
    The total number of capacity units consumed by the operation.

  * **Table (dict)**
    The amount of throughput consumed on the table affected by the operation.
- **CapacityUnits (float)** –
  The total number of capacity units consumed on a table or an index.

- **LocalSecondaryIndexes (dict)** –
  The amount of throughput consumed on each local index affected by the operation.
  - *(string)* –
  - *(dict)* –
    Represents the amount of provisioned throughput capacity consumed on a table or an index.
  - **CapacityUnits (float)** –
    The total number of capacity units consumed on a table or an index.

- **GlobalSecondaryIndexes (dict)** –
  The amount of throughput consumed on each global index affected by the operation.
  - *(string)* –
  - *(dict)* –
    Represents the amount of provisioned throughput capacity consumed on a table or an index.
  - **CapacityUnits (float)** –
    The total number of capacity units consumed on a table or an index.

- **NextToken (string)** –
  A token to resume pagination.

**Waiters**

The available waiters are:

- **DynamoDB.Waiter.TableExists**
- **DynamoDB.Waiter.TableNotExists**

```python
class DynamoDB.Waiter.TableExists

waiter = client.get_waiter('table_exists')

wait(**kwargs)

Polls DynamoDB.Client.describe_table() every 20 seconds until a successful state is reached. An error is returned after 25 failed checks.
```

**Request Syntax**

```python
waiter.wait(
    TableName='string'
)
```

**Parameters**

- **TableName (string)** – [REQUIRED]
  The name of the table to describe.
Returns None

class DynamoDB.Waiter.TableNameExists

waiter = client.get_waiter('table_not_exists')

wait(**kwargs)
    Polls DynamoDB.Client.describe_table() every 20 seconds until a successful state is reached. An error is returned after 25 failed checks.

Request Syntax

waiter.wait(
    TableName='string'
)

Parameters TableName (string) – [REQUIRED]
    The name of the table to describe.

Returns None

Service Resource

class DynamoDB.ServiceResource
    A resource representing Amazon DynamoDB:

    import boto3

    dynamodb = boto3.resource('dynamodb')

These are the resource’s available actions:
    • batch_get_item()
    • batch_write_item()
    • create_table()

These are the resource’s available sub-resources:
    • Table()

These are the resource’s available collections:
    • tables

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

batch_get_item(**kwargs)
    The BatchGetItem operation returns the attributes of one or more items from one or more tables. You identify requested items by primary key.

    A single operation can retrieve up to 16 MB of data, which can contain as many as 100 items. BatchGetItem will return a partial result if the response size limit is exceeded, the table’s provisioned throughput is exceeded, or an internal processing failure occurs. If a partial result is returned, the operation returns a value for UnprocessedKeys. You can use this value to retry the operation starting with the next item to get.

    Warning: If you request more than 100 items BatchGetItem will return a ValidationException with the message “Too many items requested for the BatchGetItem call”. 

976 Chapter 3. API Reference
For example, if you ask to retrieve 100 items, but each individual item is 300 KB in size, the system returns 52 items (so as not to exceed the 16 MB limit). It also returns an appropriate `UnprocessedKeys` value so you can get the next page of results. If desired, your application can include its own logic to assemble the pages of results into one data set.

If none of the items can be processed due to insufficient provisioned throughput on all of the tables in the request, then `BatchGetItem` will return a `ProvisionedThroughputExceededException`. If at least one of the items is successfully processed, then `BatchGetItem` completes successfully, while returning the keys of the unread items in `UnprocessedKeys`.

**Warning:** If DynamoDB returns any unprocessed items, you should retry the batch operation on those items. However, we strongly recommend that you use an exponential backoff algorithm. If you retry the batch operation immediately, the underlying read or write requests can still fail due to throttling on the individual tables. If you delay the batch operation using exponential backoff, the individual requests in the batch are much more likely to succeed. For more information, see Batch Operations and Error Handling in the Amazon DynamoDB Developer Guide.

By default, `BatchGetItem` performs eventually consistent reads on every table in the request. If you want strongly consistent reads instead, you can set `ConsistentRead` to `true` for any or all tables.

In order to minimize response latency, `BatchGetItem` retrieves items in parallel.

When designing your application, keep in mind that DynamoDB does not return attributes in any particular order. To help parse the response by item, include the primary key values for the items in your request in the `AttributesToGet` parameter.

If a requested item does not exist, it is not returned in the result. Requests for nonexistent items consume the minimum read capacity units according to the type of read. For more information, see Capacity Units Calculations in the Amazon DynamoDB Developer Guide.

**Request Syntax**

```python
response = dynamodb.batch_get_item(
    RequestItems={
        'string': {
            'Keys': [
                {'string': 'string'|123|Binary(b'bytes')|True|None|set(['string'])|set([ ]),
            'AttributesToGet': [
                'string',
            ],
            'ConsistentRead': True|False,
            'ProjectionExpression': 'string',
            'ExpressionAttributeNames': {
                'string': 'string'
            }
        }
    },
    ReturnConsumedCapacity='INDEXES'|'TOTAL'|'NONE'
)
```

**Parameters**

- **RequestItems (dict)** – [REQUIRED]
  
  A map of one or more table names and, for each table, a map that describes one or more items to retrieve from that table. Each table name can be used only once.
per BatchGetItem request.

Each element in the map of items to retrieve consists of the following:

- **ConsistentRead** - If True, a strongly consistent read is used; if False (the default), an eventually consistent read is used.
- **ExpressionAttributeNames** - One or more substitution tokens for attribute names in the ProjectionExpression parameter. The following are some use cases for using ExpressionAttributeNames:
  - To access an attribute whose name conflicts with a DynamoDB reserved word.
  - To create a placeholder for repeating occurrences of an attribute name in an expression.
  - To prevent special characters in an attribute name from being misinterpreted in an expression.

Use the # character in an expression to dereference an attribute name. For example, consider the following attribute name:

- **Percentile**

The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see Reserved Words in the Amazon DynamoDB Developer Guide). To work around this, you could specify the following for ExpressionAttributeNames:

- `{"#P":"Percentile"}`

You could then use this substitution in an expression, as in this example:

- `#P = :val`

**Note:** Tokens that begin with the : character are expression attribute values, which are placeholders for the actual value at runtime.

For more information on expression attribute names, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

- **Keys** - An array of primary key attribute values that define specific items in the table. For each primary key, you must provide all of the key attributes. For example, with a hash type primary key, you only need to provide the hash attribute. For a hash-and-range type primary key, you must provide both the hash attribute and the range attribute.

- **ProjectionExpression** - A string that identifies one or more attributes to retrieve from the table. These attributes can include scalars, sets, or elements of a JSON document. The attributes in the expression must be separated by commas. If no attribute names are specified, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result. For more information, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

- **AttributesToGet** - This is a legacy parameter, for backward compatibility. New applications should use ProjectionExpression instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a ValidationException exception. This parameter allows you to retrieve attributes of type List or Map; however, it cannot retrieve individual elements within a List or a Map. The names of one or more attributes to retrieve. If no attribute names are provided, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result. Note that AttributesToGet has no effect on provisioned throughput consumption. DynamoDB determines capacity units consumed based on item size, not on the amount of data that is returned to an application.

- (string) –
*(dict)* –
Represents a set of primary keys and, for each key, the attributes to retrieve from the table.

For each primary key, you must provide *all* of the key attributes. For example, with a hash type primary key, you only need to provide the hash attribute. For a hash-and-range type primary key, you must provide *both* the hash attribute and the range attribute.

- **Keys (list) – [REQUIRED]**
  The primary key attribute values that define the items and the attributes associated with the items.
  - *(dict)* –
    - *(string)* –
    - *(valid DynamoDB type)* – The value of the attribute. The valid value types are listed in the *DynamoDB Reference Guide*.

- **AttributesToGet (list) –**
  One or more attributes to retrieve from the table or index. If no attribute names are specified then all attributes will be returned. If any of the specified attributes are not found, they will not appear in the result.

- **ConsistentRead (boolean) –**
  The consistency of a read operation. If set to *true*, then a strongly consistent read is used; otherwise, an eventually consistent read is used.

- **ProjectionExpression (string) –**
  A string that identifies one or more attributes to retrieve from the table. These attributes can include scalars, sets, or elements of a JSON document. The attributes in the *ProjectionExpression* must be separated by commas.

  If no attribute names are specified, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

  For more information, see *Accessing Item Attributes* in the *Amazon DynamoDB Developer Guide*.

**Note:** *ProjectionExpression* replaces the legacy *AttributesToGet* parameter.

- **ExpressionAttributeNames (dict) –**
  One or more substitution tokens for attribute names in an expression. The following are some use cases for using *ExpressionAttributeNames*:
  - To access an attribute whose name conflicts with a DynamoDB reserved word.
  - To create a placeholder for repeating occurrences of an attribute name in an expression.
  - To prevent special characters in an attribute name from being misinterpreted in an expression.
Use the \# character in an expression to dereference an attribute name. For example, consider the following attribute name:

- Percentile

The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see Reserved Words in the Amazon DynamoDB Developer Guide). To work around this, you could specify the following for ExpressionAttributeNames:

```json
{"#P":"Percentile"}
```

You could then use this substitution in an expression, as in this example:

```json
#P = :val
```

**Note:** Tokens that begin with the : character are expression attribute values, which are placeholders for the actual value at runtime.

For more information on expression attribute names, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

- (string) –
- (string) –

**ReturnConsumedCapacity (string)** – Determines the level of detail about provisioned throughput consumption that is returned in the response:

- INDEXES - The response includes the aggregate ConsumedCapacity for the operation, together with ConsumedCapacity for each table and secondary index that was accessed. Note that some operations, such as GetItem and BatchGetItem, do not access any indexes at all. In these cases, specifying INDEXES will only return ConsumedCapacity information for table(s).

- TOTAL - The response includes only the aggregate ConsumedCapacity for the operation.

- NONE - No ConsumedCapacity details are included in the response.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'Responses': {
        'string': [
            {
                'string': 'string'|123|Binary(b'bytes')|True|None|set(["string"])|set([123])|set([Binary(b'bytes')])|\[]|{}
            },
        ]
    },
    'UnprocessedKeys': {
        'string': {
            'Keys': [
                {
                    'string': 'string'|123|Binary(b'bytes')|True|None|set(["string"])|set([123])|set([Binary(b'bytes')])|\[]|{}
                },
            ],
            'AttributesToGet': [
                'string',
            ],
        },
    },
}
{'ConsistentRead': True|False,
'ProjectionExpression': 'string',
'ExpressionAttributeNames': {
    'string': 'string'
}
},

'ConsumedCapacity': [
    {'TableName': 'string',
    'CapacityUnits': 123.0,
    'Table': {
        'CapacityUnits': 123.0
    },
    'LocalSecondaryIndexes': {
        'string': {
            'CapacityUnits': 123.0
        }
    },
    'GlobalSecondaryIndexes': {
        'string': {
            'CapacityUnits': 123.0
        }
    }
    }
],

Response Structure
• (dict) –

  Represents the output of a BatchGetItem operation.
  
  **Responses (dict)** –

  A map of table name to a list of items. Each object in Responses consists of a table name, along with a map of attribute data consisting of the data type and attribute value.

  * (string) –
    * (list) –
    * (dict) –
    * (string) –
    * (valid DynamoDB type) – - The value of the attribute. The valid value types are listed in the DynamoDB Reference Guide.

  **UnprocessedKeys (dict)** –

  A map of tables and their respective keys that were not processed with the current response. The UnprocessedKeys value is in the same form as RequestItems, so the value can be provided directly to a subsequent BatchGetItem operation. For more information, see RequestItems in the Request Parameters section.

  Each element consists of:

  * Keys - An array of primary key attribute values that define specific items in the table.
  * AttributesToGet - One or more attributes to be retrieved from the table or index. By default, all attributes are returned. If a requested
attribute is not found, it does not appear in the result.

* ConsistentRead - The consistency of a read operation. If set to `true`, then a strongly consistent read is used; otherwise, an eventually consistent read is used.

If there are no unprocessed keys remaining, the response contains an empty `UnprocessedKeys` map.

* (string) –
  · (dict) –
    · Represents a set of primary keys and, for each key, the attributes to retrieve from the table.

    For each primary key, you must provide all of the key attributes. For example, with a hash type primary key, you only need to provide the hash attribute. For a hash-and-range type primary key, you must provide both the hash attribute and the range attribute.

  · Keys (list) –
    · The primary key attribute values that define the items and the attributes associated with the items.

    · (dict) –
      · (string) –
        · (valid DynamoDB type) – The value of the attribute. The valid value types are listed in the *DynamoDB Reference Guide*.

  · AttributesToGet (list) –
    · One or more attributes to retrieve from the table or index. If no attribute names are specified then all attributes will be returned. If any of the specified attributes are not found, they will not appear in the result.

    · (string) –
      · ConsistentRead (boolean) –
        · The consistency of a read operation. If set to `true`, then a strongly consistent read is used; otherwise, an eventually consistent read is used.

    · ProjectionExpression (string) –
      · A string that identifies one or more attributes to retrieve from the table. These attributes can include scalars, sets, or elements of a JSON document. The attributes in the `ProjectionExpression` must be separated by commas.

      If no attribute names are specified, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

      For more information, see [Accessing Item Attributes](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/using-enumerate-items.html) in the *Amazon DynamoDB Developer Guide*.

      **Note:** `ProjectionExpression` replaces the legacy `AttributesToGet` parameter.

  · ExpressionAttributeNames (dict) –
    · One or more substitution tokens for attribute names in an expression. The following are some use cases for using `Expres-
sionAttributeNames:

- To access an attribute whose name conflicts with a DynamoDB reserved word.
- To create a placeholder for repeating occurrences of an attribute name in an expression.
- To prevent special characters in an attribute name from being misinterpreted in an expression.

Use the # character in an expression to dereference an attribute name. For example, consider the following attribute name:

- Percentile

The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see Reserved Words in the Amazon DynamoDB Developer Guide). To work around this, you could specify the following for ExpressionAttributeNames:

- {"#P":"Percentile"}

You could then use this substitution in an expression, as in this example:

- #P = :val

**Note:** Tokens that begin with the : character are expression attribute values, which are placeholders for the actual value at runtime.

For more information on expression attribute names, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

- (string) –
- (string) –

- **ConsumedCapacity (list) –**

The read capacity units consumed by the operation.

Each element consists of:

- **TableName (string)** - The table that consumed the provisioned throughput.
- **CapacityUnits (float)** - The total number of capacity units consumed.

- (dict) –

The capacity units consumed by an operation. The data returned includes the total provisioned throughput consumed, along with statistics for the table and any indexes involved in the operation. ConsumedCapacity is only returned if the request asked for it. For more information, see Provisioned Throughput in the Amazon DynamoDB Developer Guide.

- **TableName (string)** –

  The name of the table that was affected by the operation.

- **CapacityUnits (float)** –

  The total number of capacity units consumed by the operation.

- **Table (dict)** –

  The amount of throughput consumed on the table affected by the operation.

- **CapacityUnits (float)** –
The total number of capacity units consumed on a table or an index.

- **LocalSecondaryIndexes** *(dict)*
  The amount of throughput consumed on each local index affected by the operation.
  - *(string)*
  - *(dict)*

  Represents the amount of provisioned throughput capacity consumed on a table or an index.

- **CapacityUnits** *(float)*
  The total number of capacity units consumed on a table or an index.

- **GlobalSecondaryIndexes** *(dict)*
  The amount of throughput consumed on each global index affected by the operation.
  - *(string)*
  - *(dict)*

  Represents the amount of provisioned throughput capacity consumed on a table or an index.

- **CapacityUnits** *(float)*
  The total number of capacity units consumed on a table or an index.

The overall Boto3 function:

```python
batch_write_item(**kwargs)
```

The `BatchWriteItem` operation puts or deletes multiple items in one or more tables. A single call to `BatchWriteItem` can write up to 16 MB of data, which can comprise as many as 25 put or delete requests. Individual items to be written can be as large as 400 KB.

**Note:** `BatchWriteItem` cannot update items. To update items, use the `UpdateItem` API.

The individual `PutItem` and `DeleteItem` operations specified in `BatchWriteItem` are atomic; however `BatchWriteItem` as a whole is not. If any requested operations fail because the table’s provisioned throughput is exceeded or an internal processing failure occurs, the failed operations are returned in the `UnprocessedItems` response parameter. You can investigate and optionally resend the requests. Typically, you would call `BatchWriteItem` in a loop. Each iteration would check for unprocessed items and submit a new `BatchWriteItem` request with those unprocessed items until all items have been processed.

Note that if none of the items can be processed due to insufficient provisioned throughput on all of the tables in the request, then `BatchWriteItem` will return a `ProvisionedThroughputExceeded` exception.

**Warning:** If DynamoDB returns any unprocessed items, you should retry the batch operation on those items. However, we strongly recommend that you use an exponential backoff algorithm. If you retry the batch operation immediately, the underlying read or write requests can still fail due to throttling on the individual tables. If you delay the batch operation using exponential backoff, the individual requests in the batch are much more likely to succeed.

For more information, see Batch Operations and Error Handling in the Amazon DynamoDB Developer Guide.

With `BatchWriteItem`, you can efficiently write or delete large amounts of data, such as from Amazon Elastic MapReduce (EMR), or copy data from another database into DynamoDB. In order to improve performance with these large-scale operations, `BatchWriteItem` does not behave in the same way as indi-
If you use a programming language that supports concurrency, you can use threads to write items in parallel. Your application must include the necessary logic to manage the threads. With languages that don’t support threading, you must update or delete the specified items one at a time. In both situations, BatchWriteItem provides an alternative where the API performs the specified put and delete operations in parallel, giving you the power of the thread pool approach without having to introduce complexity into your application.

Parallel processing reduces latency, but each specified put and delete request consumes the same number of write capacity units whether it is processed in parallel or not. Delete operations on nonexistent items consume one write capacity unit.

If one or more of the following is true, DynamoDB rejects the entire batch write operation:

- One or more tables specified in the BatchWriteItem request does not exist.
- Primary key attributes specified on an item in the request do not match those in the corresponding table’s primary key schema.
- You try to perform multiple operations on the same item in the same BatchWriteItem request. For example, you cannot put and delete the same item in the same BatchWriteItem request.
- There are more than 25 requests in the batch.
- Any individual item in a batch exceeds 400 KB.
- The total request size exceeds 16 MB.

Request Syntax

```python
response = dynamodb.batch_write_item(
    RequestItems={
        'string': [
            {'PutRequest': {
                'Item': {
                    'string': 'string'|123|Binary(b'bytes')|True|None|set(["string"])|set([123])|set([Binary(b'bytes')])|[]|{}
                }
            },
            'DeleteRequest': {
                'Key': {
                    'string': 'string'|123|Binary(b'bytes')|True|None|set(["string"])|set([123])|set([Binary(b'bytes')])|[]|{}
                }
            }
        ]},
    ReturnConsumedCapacity='INDEXES'|'TOTAL'|'NONE',
    ReturnItemCollectionMetrics='SIZE'|'NONE'
)
```

Parameters

- **RequestItems (dict)** – [REQUIRED]

A map of one or more table names and, for each table, a list of operations to be performed (DeleteRequest or PutRequest). Each element in the map consists of the following:

- **DeleteRequest** - Perform a DeleteItem operation on the specified item. The item to be deleted is identified by a Key subelement:
  - **Key** - A map of primary key attribute values that uniquely identify the item. Each entry in this map consists of an attribute name and an attribute value. For each primary key, you must provide all of the key attributes. For example, with a hash type primary key, you only need to provide the hash attribute. For a
hash-and-range type primary key, you must provide both the hash attribute and the range attribute.

- **PutRequest** - Perform a **PutItem** operation on the specified item. The item to be put is identified by an **Item** subelement. * **Item** - A map of attributes and their values. Each entry in this map consists of an attribute name and an attribute value. Attribute values must not be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests that contain empty values will be rejected with a **ValidationException** exception. If you specify any attributes that are part of an index key, then the data types for those attributes must match those of the schema in the table’s attribute definition.

- **(string)** -
  - *(list)* -
    - *(dict)* -
      Represents an operation to perform - either **DeleteItem** or **PutItem**. You can only request one of these operations, not both, in a single **WriteRequest**. If you do need to perform both of these operations, you will need to provide two separate **WriteRequest** objects.
  
- **PutRequest** *(dict)* -
  
  A request to perform a **PutItem** operation.

- **Item** *(dict)* - [REQUIRED]
  
  A map of attribute name to attribute values, representing the primary key of an item to be processed by **PutItem**. All of the table’s primary key attributes must be specified, and their data types must match those of the table’s key schema. If any attributes are present in the item which are part of an index key schema for the table, their types must match the index key schema.

  - *(string)* -
  
  - *(valid DynamoDB type)* - The value of the attribute. The valid value types are listed in the **DynamoDB Reference Guide**.

- **DeleteRequest** *(dict)* -
  
  A request to perform a **DeleteItem** operation.

- **Key** *(dict)* - [REQUIRED]
  
  A map of attribute name to attribute values, representing the primary key of the item to delete. All of the table’s primary key attributes must be specified, and their data types must match those of the table’s key schema.

  - *(string)* -
  
  - *(valid DynamoDB type)* - The value of the attribute. The valid value types are listed in the **DynamoDB Reference Guide**.

- **ReturnConsumedCapacity** *(string)* - Determines the level of detail about provisioned throughput consumption that is returned in the response:

  - **INDEXES** - The response includes the aggregate **ConsumedCapacity** for the operation, together with **ConsumedCapacity** for each table and secondary index that was accessed. Note that some operations, such as **GetItem** and **BatchGetItem**, do not access any indexes at all. In these cases, specifying **INDEXES** will only return **ConsumedCapacity** informa-
tion for table(s).

- **TOTAL** - The response includes only the aggregate `ConsumedCapacity` for the operation.
- **NONE** - No `ConsumedCapacity` details are included in the response.

- **ReturnItemCollectionMetrics (string)** – Determines whether item collection metrics are returned. If set to `SIZE`, the response includes statistics about item collections, if any, that were modified during the operation are returned in the response. If set to `NONE` (the default), no statistics are returned.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
  'UnprocessedItems': {
    'string': [
      {
        'PutRequest': {
          'Item': {
            'string': 'string'|123|Binary(b'bytes')|True|None|set(['string'])|set([123])|set([Binary(b'bytes')])|[]|{}
          }
        },
        'DeleteRequest': {
          'Key': {
            'string': 'string'|123|Binary(b'bytes')|True|None|set(['string'])|set([123])|set([Binary(b'bytes')])|[]|{}
          }
        }
      }
    ],
    'ItemCollectionMetrics': {
      'string': [
        {
          'ItemCollectionKey': {
            'string': 'string'|123|Binary(b'bytes')|True|None|set(['string'])|set([123])|set([Binary(b'bytes')])|[]|{}
          },
          'SizeEstimateRangeGB': [123.0],
        }
      ],
      'ConsumedCapacity': [
        {
          'TableName': 'string',
          'CapacityUnits': 123.0,
          'Table': {
            'CapacityUnits': 123.0
          },
          'LocalSecondaryIndexes': {
            'string': {
              'CapacityUnits': 123.0
            }
          },
          'GlobalSecondaryIndexes': {
            'string': {
              'CapacityUnits': 123.0
            }
          }
        }
      ]
    }
  }
}
```
Response Structure

- (dict) –

Represents the output of a BatchWriteItem operation.

- UnprocessedItems (dict) –

A map of tables and requests against those tables that were not processed. The UnprocessedItems value is in the same form as RequestItems, so you can provide this value directly to a subsequent BatchGetItem operation. For more information, see RequestItems in the Request Parameters section.

Each UnprocessedItems entry consists of a table name and, for that table, a list of operations to perform (DeleteRequest or PutRequest).

  * DeleteRequest - Perform a DeleteItem operation on the specified item. The item to be deleted is identified by a Key subelement. * Key - A map of primary key attribute values that uniquely identify the item. Each entry in this map consists of an attribute name and an attribute value.

  * PutRequest - Perform a PutItem operation on the specified item. The item to be put is identified by an Item subelement. * Item - A map of attributes and their values. Each entry in this map consists of an attribute name and an attribute value. Attribute values must not be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests that contain empty values will be rejected with a ValidationException exception. If you specify any attributes that are part of an index key, then the data types for those attributes must match those of the schema in the table’s attribute definition.

If there are no unprocessed items remaining, the response contains an empty UnprocessedItems map.

- (string) –

  - (list) –

  - (dict) –

Represents an operation to perform - either DeleteItem or PutItem. You can only request one of these operations, not both, in a single WriteRequest. If you do need to perform both of these operations, you will need to provide two separate WriteRequest objects.

  - PutRequest (dict) –

A request to perform a PutItem operation.

  - Item (dict) –

A map of attribute name to attribute values, representing the primary key of an item to be processed by PutItem. All of the table’s primary key attributes must be specified, and their data types must match those of the table’s key schema. If any attributes are present in the item which are part of an index key schema for the table, their types must match the index key schema.

  - (string) –
· (valid DynamoDB type) – The value of the attribute. The valid value types are listed in the DynamoDB Reference Guide.

· DeleteRequest (dict) –

  A request to perform a DeleteItem operation.

· Key (dict) –

  A map of attribute name to attribute values, representing the primary key of the item to delete. All of the table’s primary key attributes must be specified, and their data types must match those of the table’s key schema.

· (string) –

· (valid DynamoDB type) – The value of the attribute. The valid value types are listed in the DynamoDB Reference Guide.

– ItemCollectionMetrics (dict) –

  A list of tables that were processed by BatchWriteItem and, for each table, information about any item collections that were affected by individual DeleteItem or PutItem operations.

  Each entry consists of the following subelements:

  * ItemCollectionKey - The hash key value of the item collection. This is the same as the hash key of the item.

  * SizeEstimateRange - An estimate of item collection size, expressed in GB. This is a two-element array containing a lower bound and an upper bound for the estimate. The estimate includes the size of all the items in the table, plus the size of all attributes projected into all of the local secondary indexes on the table. Use this estimate to measure whether a local secondary index is approaching its size limit. The estimate is subject to change over time; therefore, do not rely on the precision or accuracy of the estimate.

  * (string) –

  * (list) –

  * (dict) –

    Information about item collections, if any, that were affected by the operation. ItemCollectionMetrics is only returned if the request asked for it. If the table does not have any local secondary indexes, this information is not returned in the response.

  * ItemCollectionKey (dict) –

    The hash key value of the item collection. This value is the same as the hash key of the item.

  * (string) –

  * (valid DynamoDB type) – The value of the attribute. The valid value types are listed in the DynamoDB Reference Guide.

  * SizeEstimateRangeGB (list) –

    An estimate of item collection size, in gigabytes. This value is a two-element array containing a lower bound and an upper bound for the estimate. The estimate includes the size of all the items in the table, plus the size of all attributes projected into all of the local secondary indexes on that table. Use this
estimate to measure whether a local secondary index is approaching its size limit.

The estimate is subject to change over time; therefore, do not rely on the precision or accuracy of the estimate.

- **ConsumedCapacity** *(list)* –

The capacity units consumed by the operation.

Each element consists of:

- **TableName** *(string)* – The name of the table that was affected by the operation.
- **CapacityUnits** *(float)* – The total number of capacity units consumed.

- **(dict)** –

The capacity units consumed by an operation. The data returned includes the total provisioned throughput consumed, along with statistics for the table and any indexes involved in the operation. 

**ConsumedCapacity** is only returned if the request asked for it. For more information, see Provisioned Throughput in the *Amazon DynamoDB Developer Guide*.

- **TableName** *(string)* –

  The name of the table that was affected by the operation.

- **CapacityUnits** *(float)* –

  The total number of capacity units consumed by the operation.

- **Table** *(dict)* –

  The amount of throughput consumed on the table affected by the operation.

- **CapacityUnits** *(float)* –

  The total number of capacity units consumed on a table or an index.

- **LocalSecondaryIndexes** *(dict)* –

  The amount of throughput consumed on each local index affected by the operation.

  - **(string)** –
  - **(dict)** –

Represents the amount of provisioned throughput capacity consumed on a table or an index.

- **CapacityUnits** *(float)* –

  The total number of capacity units consumed on a table or an index.

- **GlobalSecondaryIndexes** *(dict)* –

  The amount of throughput consumed on each global index affected by the operation.

  - **(string)** –
  - **(dict)** –

Represents the amount of provisioned throughput capacity consumed on a table or an index.
The total number of capacity units consumed on a table or an index.

**create_table(**kwargs**)

The `create_table` operation adds a new table to your account. In an AWS account, table names must be unique within each region. That is, you can have two tables with the same name if you create the tables in different regions.

`create_table` is an asynchronous operation. Upon receiving a `create_table` request, DynamoDB immediately returns a response with a `TableStatus` of `CREATING`. After the table is created, DynamoDB sets the `TableStatus` to `ACTIVE`. You can perform read and write operations only on an `ACTIVE` table.

You can optionally define secondary indexes on the new table, as part of the `create_table` operation. If you want to create multiple tables with secondary indexes on them, you must create the tables sequentially. Only one table with secondary indexes can be in the `CREATING` state at any given time.

You can use the `describe_table` API to check the table status.

**Request Syntax**

dynamodb.create_table(
    **kwargs,**
    AttributeDefinitions=[
        {
            'AttributeName': 'string',
            'AttributeType': 'S'|'N'|'B'
        },
    ],
    TableName='string',
    KeySchema=[
        {
            'AttributeName': 'string',
            'KeyType': 'HASH'|'RANGE'
        },
    ],
    LocalSecondaryIndexes=[
        {
            'IndexName': 'string',
            'KeySchema': [
                {
                    'AttributeName': 'string',
                    'KeyType': 'HASH'|'RANGE'
                },
            ],
            'Projection': {
                'ProjectionType': 'ALL'|'KEYS_ONLY'|'INCLUDE',
                'NonKeyAttributes': ['string',
                ]
            }
        },
    ],
    GlobalSecondaryIndexes=[
        {
            'IndexName': 'string',
            'KeySchema': [
                {
                    'AttributeName': 'string',
                    'KeyType': 'HASH'|'RANGE'
                },
            ]
        }
    ]
)
Parameters

- **AttributeDefinitions** *(list) – [REQUIRED]*
  
  An array of attributes that describe the key schema for the table and indexes.
  
  - *(dict) –
    
    Represents an attribute for describing the key schema for the table and indexes.
    
    * **AttributeName (string) – [REQUIRED]**
      
      A name for the attribute.
    
    * **AttributeType (string) – [REQUIRED]**
      
      The data type for the attribute.

- **TableName (string) – [REQUIRED]**
  
  The name of the table to create.

- **KeySchema** *(list) – [REQUIRED]**
  
  Specifies the attributes that make up the primary key for a table or an index. The attributes in **KeySchema** must also be defined in the **AttributeDefinitions** array. For more information, see Data Model in the Amazon DynamoDB Developer Guide.

  Each **KeySchemaElement** in the array is composed of:
  
  - **AttributeName** - The name of this key attribute.
  
  - **KeyType** - Determines whether the key attribute is **HASH** or **RANGE**.

  For a primary key that consists of a hash attribute, you must provide exactly one element with a **KeyType** of **HASH**.

  For a primary key that consists of hash and range attributes, you must provide exactly two elements, in this order: The first element must have a **KeyType** of **HASH**, and the second element must have a **KeyType** of **RANGE**.

  For more information, see Specifying the Primary Key in the Amazon DynamoDB Developer Guide.
  
  - *(dict) –
Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

A KeySchemaElement represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one KeySchemaElement. A hash-and-range type primary key would require one KeySchemaElement for the hash attribute, and another KeySchemaElement for the range attribute.

* AttributeName (string) – [REQUIRED]
  The name of a key attribute.

* KeyType (string) – [REQUIRED]
  The attribute data, consisting of the data type and the attribute value itself.

• LocalSecondaryIndexes (list) – One or more local secondary indexes (the maximum is five) to be created on the table. Each index is scoped to a given hash key value. There is a 10 GB size limit per hash key; otherwise, the size of a local secondary index is unconstrained.

Each local secondary index in the array includes the following:
  – IndexName - The name of the local secondary index. Must be unique only for this table.
  – KeySchema - Specifies the key schema for the local secondary index. The key schema must begin with the same hash key attribute as the table.
  – Projection - Specifies attributes that are copied (projected) from the table into the index. These are in addition to the primary key attributes and index key attributes, which are automatically projected. Each attribute specification is composed of:
    * ProjectionType - One of the following:
      * KEYS_ONLY - Only the index and primary keys are projected into the index.
      * INCLUDE - Only the specified table attributes are projected into the index. The list of projected attributes are in NonKeyAttributes.
      * ALL - All of the table attributes are projected into the index.
    – NonKeyAttributes - A list of one or more non-key attribute names that are projected into the secondary index. The total count of attributes provided in NonKeyAttributes, summed across all of the secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

  – (dict) –
  Represents the properties of a local secondary index.
  * IndexName (string) – [REQUIRED]
    The name of the local secondary index. The name must be unique among all other indexes on this table.
  * KeySchema (list) – [REQUIRED]
    The complete key schema for the local secondary index, consisting of one or more pairs of attribute names and key types (HASH or RANGE).
    – (dict) –
      Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.
A `KeySchemaElement` represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one `KeySchemaElement`. A hash-and-range type primary key would require one `KeySchemaElement` for the hash attribute, and another `KeySchemaElement` for the range attribute.

- **AttributeName (string) – [REQUIRED]**
  The name of a key attribute.

- **KeyType (string) – [REQUIRED]**
  The attribute data, consisting of the data type and the attribute value itself.

* **Projection (dict) – [REQUIRED]**

  Represents attributes that are copied (projected) from the table into an index. These are in addition to the primary key attributes and index key attributes, which are automatically projected.

  - **ProjectionType (string) –**
    The set of attributes that are projected into the index:
    - **KEYS_ONLY** - Only the index and primary keys are projected into the index.
    - **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in NonKeyAttributes.
    - **ALL** - All of the table attributes are projected into the index.

  - **NonKeyAttributes (list) –**
    Represents the non-key attribute names which will be projected into the index.

    For local secondary indexes, the total count of NonKeyAttributes summed across all of the local secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

- **GlobalSecondaryIndexes (list) –** One or more global secondary indexes (the maximum is five) to be created on the table. Each global secondary index in the array includes the following:
  
  - **IndexName** - The name of the global secondary index. Must be unique only for this table.
  - **KeySchema** - Specifies the key schema for the global secondary index.
  - **Projection** - Specifies attributes that are copied (projected) from the table into the index. These are in addition to the primary key attributes and index key attributes, which are automatically projected. Each attribute specification is composed of:
    - **ProjectionType** - One of the following:
      * **KEYS_ONLY** - Only the index and primary keys are projected into the index.
    - **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in NonKeyAttributes.
    - **ALL** - All of the table attributes are projected into the index.
  - **NonKeyAttributes (list) –**
    A list of one or more non-key attribute names that are projected into the secondary index. The total count of attributes provided in NonKeyAttributes, summed across all of the secondary indexes, must not exceed 20. If you project the same attribute into two different indexes,
this counts as two distinct attributes when determining the total.

- `ProvisionedThroughput` - The provisioned throughput settings for the global secondary index, consisting of read and write capacity units.

- `(dict)` –

  Represents the properties of a global secondary index.

  * `IndexName` *(string)* – [REQUIRED]

    The name of the global secondary index. The name must be unique among all other indexes on this table.

  * `KeySchema` *(list)* – [REQUIRED]

    The complete key schema for a global secondary index, which consists of one or more pairs of attribute names and key types (HASH or RANGE).

      * `(dict)` –

        Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

        A `KeySchemaElement` represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one `KeySchemaElement`. A hash-and-range type primary key would require one `KeySchemaElement` for the hash attribute, and another `KeySchemaElement` for the range attribute.

        * `AttributeName` *(string)* – [REQUIRED]

          The name of a key attribute.

        * `KeyType` *(string)* – [REQUIRED]

          The attribute data, consisting of the data type and the attribute value itself.

  * `Projection` *(dict)* – [REQUIRED]

    Represents attributes that are copied (projected) from the table into an index. These are in addition to the primary key attributes and index key attributes, which are automatically projected.

      * `ProjectionType` *(string)* –

        The set of attributes that are projected into the index:

        * `KEYS_ONLY` - Only the index and primary keys are projected into the index.
        * `INCLUDE` - Only the specified table attributes are projected into the index. The list of projected attributes are in `NonKeyAttributes`.
        * `ALL` - All of the table attributes are projected into the index.

      * `NonKeyAttributes` *(list)* –

        Represents the non-key attribute names which will be projected into the index.

        For local secondary indexes, the total count of `NonKeyAttributes` summed across all of the local secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

      * *(string)* –
• **ProvisionedThroughput** *(dict)* – [REQUIRED]

  Represents the provisioned throughput settings for a specified table or index. The settings can be modified using the `UpdateTable` operation.

  For current minimum and maximum provisioned throughput values, see *Limits* in the [Amazon DynamoDB Developer Guide](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/).

  - **ReadCapacityUnits** *(integer)* – [REQUIRED]

    The maximum number of strongly consistent reads consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see Specifying Read and Write Requirements in the [Amazon DynamoDB Developer Guide](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/).

  - **WriteCapacityUnits** *(integer)* – [REQUIRED]

    The maximum number of writes consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see Specifying Read and Write Requirements in the [Amazon DynamoDB Developer Guide](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/).

• **ProvisionedThroughput** *(dict)* – [REQUIRED]

  Represents the provisioned throughput settings for a specified table or index. The settings can be modified using the `UpdateTable` operation.

  For current minimum and maximum provisioned throughput values, see *Limits* in the [Amazon DynamoDB Developer Guide](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/).

  - **ReadCapacityUnits** *(integer)* – [REQUIRED]

    The maximum number of strongly consistent reads consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see Specifying Read and Write Requirements in the [Amazon DynamoDB Developer Guide](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/).

  - **WriteCapacityUnits** *(integer)* – [REQUIRED]

    The maximum number of writes consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see Specifying Read and Write Requirements in the [Amazon DynamoDB Developer Guide](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/).

• **StreamSpecification** *(dict)* – The settings for DynamoDB Streams on the table. These settings consist of:

  - **StreamEnabled** *(boolean)* – Indicates whether Streams is to be enabled (true) or disabled (false).

  - **StreamViewType** *(string)* – When an item in the table is modified, `StreamViewType` determines what information is written to the table’s stream. Valid values for `StreamViewType` are: *

    - `KEYS_ONLY` - Only the key attributes of the modified item are written to the stream.
    - `NEW_IMAGE` - The entire item, as it appears after it was modified, is written to the stream.
    - `OLD_IMAGE` - The entire item, as it appeared before it was modified, is written to the stream.
    - `NEW_AND_OLD_IMAGES` - Both the new and the old item images of the item are written to the stream.

  - **StreamEnabled** *(boolean)* – Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.

  - **StreamViewType** *(string)* –
The DynamoDB Streams settings for the table. These settings consist of:

* **StreamEnabled** - Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.

* **StreamViewType** - When an item in the table is modified, **StreamViewType** determines what information is written to the stream for this table. Valid values for **StreamViewType** are:
  * **KEYS_ONLY** - Only the key attributes of the modified item are written to the stream.
  * **NEW_IMAGE** - The entire item, as it appears after it was modified, is written to the stream.
  * **OLD_IMAGE** - The entire item, as it appeared before it was modified, is written to the stream.
  * **NEW_AND_OLD_IMAGES** - Both the new and the old item images of the item are written to the stream.

**Return type** `dynamodb.Table`

**Returns** Table resource

Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the `Resources Introduction Guide`.

**Table** *(name)*

Creates a Table resource:

```python
table = dynamodb.Table('name')
```

**Parameters**

- `name (string)` – The Table’s name identifier. This must be set.

**Return type** `DynamoDB.Table`

**Returns** A Table resource

Collections

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the `Resources Introduction Guide`.

**tables**

**all()**

Creates an iterable of all Table resources in the collection.

**Request Syntax**

```python
table_iterator = dynamodb.tables.all()
```

**Return type** `list(dynamodb.Table)`

**Returns** A list of Table resources

**filter(**

Creates an iterable of all Table resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
table_iterator = dynamodb.tables.filter(
    ExclusiveStartTableName='string',
    Limit=123
)
```

**Parameters**
• **ExclusiveStartTableName** *(string)* – The first table name that this operation will evaluate. Use the value that was returned for *LastEvaluatedTableName* in a previous operation, so that you can obtain the next page of results.

• **Limit** *(integer)* – A maximum number of table names to return. If this parameter is not specified, the limit is 100.

  Return type: list(dynamodb.Table)
  Returns: A list of Table resources

**limit(****kwargs**)

Creates an iterable up to a specified amount of Table resources in the collection.

**Request Syntax**

```python
table_iterator = dynamodb.tables.limit(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The limit to the number of resources in the iterable.

  Return type: list(dynamodb.Table)
  Returns: A list of Table resources

**pagesize(****kwargs**)

Creates an iterable of all Table resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
table_iterator = dynamodb.tables.page_size(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The number of items returned by each service call

  Return type: list(dynamodb.Table)
  Returns: A list of Table resources

**Table**

class **DynamoDB.Table**(name)

A resource representing an Amazon DynamoDB Table:

```python
import boto3
dynamodb = boto3.resource('dynamodb')
table = dynamodb.Table('name')
```

**Parameters**

- **name** *(string)* – The Table’s name identifier. This must be set.

These are the resource’s available identifiers:

- **name**

These are the resource’s available attributes:

- **attribute_definitions**
- **creation_date_time**
- **global_secondary_indexes**
- **item_count**
- **key_schema**
• latest_stream_arn
• latest_stream_label
• local_secondary_indexes
• provisioned_throughput
• stream_specification
• table_arn
• table_name
• table_size_bytes
• table_status

These are the resource’s available actions:
• batch_writer()
• delete()
• delete_item()
• get_item()
• load()
• put_item()
• query()
• reload()
• scan()
• update()
• update_item()

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

name
(string) The Table’s name identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

attribute_definitions
(list)
An array of AttributeDefinition objects. Each of these objects describes one attribute in the table and index key schema.

Each AttributeDefinition object in this array is composed of:
• AttributeName - The name of the attribute.
• AttributeType - The data type for the attribute.

creation_date_time
(datetime)
The date and time when the table was created, in UNIX epoch time format.

global_secondary_indexes
(list)
The global secondary indexes, if any, on the table. Each index is scoped to a given hash key value. Each element is composed of:
• Backfilling - If true, then the index is currently in the backfilling phase. Backfilling occurs only when a new global secondary index is added to the table; it is the process by which DynamoDB populates the new index with data from the table. (This attribute does not appear for indexes that were created during a CreateTable operation.)
• IndexName - The name of the global secondary index.
• **IndexSizeBytes** - The total size of the global secondary index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

• **IndexStatus** - The current status of the global secondary index: *CREATING* - The index is being created.

• **UPDATING** - The index is being updated.

• **DELETING** - The index is being deleted.

• **ACTIVE** - The index is ready for use.

• **ItemCount** - The number of items in the global secondary index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

• **KeySchema** - Specifies the complete index key schema. The attribute names in the key schema must be between 1 and 255 characters (inclusive). The key schema must begin with the same hash key attribute as the table.

• **Projection** - Specifies attributes that are copied (projected) from the table into the index. These are in addition to the primary key attributes and index key attributes, which are automatically projected. Each attribute specification is composed of: * **ProjectionType** - One of the following:

  * **KEYS_ONLY** - Only the index and primary keys are projected into the index.

  * **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in **NonKeyAttributes**.

  * **ALL** - All of the table attributes are projected into the index.

• **NonKeyAttributes** - A list of one or more non-key attribute names that are projected into the secondary index. The total count of attributes provided in **NonKeyAttributes**, summed across all of the secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

• **ProvisionedThroughput** - The provisioned throughput settings for the global secondary index, consisting of read and write capacity units, along with data about increases and decreases.

If the table is in the **DELETING** state, no information about indexes will be returned.

### item_count

*(integer)*

The number of items in the specified table. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

### key_schema

*(list)*

The primary key structure for the table. Each **KeySchemaElement** consists of:

* **AttributeName** - The name of the attribute.

* **KeyType** - The key type for the attribute. Can be either **HASH** or **RANGE**.

For more information about primary keys, see Primary Key in the Amazon DynamoDB Developer Guide.

### latest_stream_arn

*(string)*

The Amazon Resource Name (ARN) that uniquely identifies the latest stream for this table.

### latest_stream_label

*(string)*

A timestamp, in ISO 8601 format, for this stream.

Note that LatestStreamLabel is not a unique identifier for the stream, because it is possible that a stream from another table might have the same timestamp. However, the combination of the following three elements is guaranteed to be unique:

* the AWS customer ID.

* the table name.

* the StreamLabel.
local_secondary_indexes

(list)

Represents one or more local secondary indexes on the table. Each index is scoped to a given hash key value. Tables with one or more local secondary indexes are subject to an item collection size limit, where the amount of data within a given item collection cannot exceed 10 GB. Each element is composed of:

- **IndexName** - The name of the local secondary index.
- **KeySchema** - Specifies the complete index key schema. The attribute names in the key schema must be between 1 and 255 characters (inclusive). The key schema must begin with the same hash key attribute as the table.
- **Projection** - Specifies attributes that are copied (projected) from the table into the index. These are in addition to the primary key attributes and index key attributes, which are automatically projected. Each attribute specification is composed of:
  - **ProjectionType** - One of the following:
    - **KEYS_ONLY** - Only the index and primary keys are projected into the index.
    - **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in **NonKeyAttributes**.
    - **ALL** - All of the table attributes are projected into the index.
- **NonKeyAttributes** - A list of one or more non-key attribute names that are projected into the secondary index. The total count of attributes provided in **NonKeyAttributes**, summed across all of the secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.
- **IndexSizeBytes** - Represents the total size of the index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.
- **ItemCount** - Represents the number of items in the index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

If the table is in the **DELETING** state, no information about indexes will be returned.

provisioned_throughput

(dict)

The provisioned throughput settings for the table, consisting of read and write capacity units, along with data about increases and decreases.

stream_specification

(dict)

The current DynamoDB Streams configuration for the table.

table_arn

(string)

The Amazon Resource Name (ARN) that uniquely identifies the table.

table_name

(string)

The name of the table.

table_size_bytes

(integer)

The total size of the specified table, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

table_status

(string)

The current state of the table:

- **CREATING** - The table is being created.
- **UPDATING** - The table is being updated.
Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide*.

`batch_writer()`  
Create a batch writer object.

This method creates a context manager for writing objects to Amazon DynamoDB in batch.

The batch writer will automatically handle buffering and sending items in batches. In addition, the batch writer will also automatically handle any unprocessed items and resend them as needed. All you need to do is call `put_item` for any items you want to add, and `delete_item` for any items you want to delete.

Example usage:

```python
with table.batch_writer() as batch:
    for _ in xrange(1000000):
        batch.put_item(Item={'HashKey': '...',
                             'Otherstuff': '...'})
# You can also delete_items in a batch.
batch.delete_item(Key={'HashKey': 'SomeHashKey'})
```

`delete()`  
The `DeleteTable` operation deletes a table and all of its items. After a `DeleteTable` request, the specified table is in the `DELETING` state until DynamoDB completes the deletion. If the table is in the `ACTIVE` state, you can delete it. If a table is in `CREATING` or `UPDATING` states, then DynamoDB returns a `ResourceInUseException`. If the specified table does not exist, DynamoDB returns a `ResourceNotFoundException`. If table is already in the `DELETING` state, no error is returned.

**Note:**  
DynamoDB might continue to accept data read and write operations, such as `GetItem` and `PutItem`, on a table in the `DELETING` state until the table deletion is complete.

When you delete a table, any indexes on that table are also deleted.

If you have DynamoDB Streams enabled on the table, then the corresponding stream on that table goes into the `DISABLED` state, and the stream is automatically deleted after 24 hours.

Use the `DescribeTable` API to check the status of the table.

**Request Syntax**

```python
response = table.delete()
```

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'TableDescription': {

Response Structure

  • (dict) –

    Represents the output of a DeleteTable operation.

    – TableDescription (dict) –

      Represents the properties of a table.

      * AttributeDefinitions (list) –

        An array of AttributeDefinition objects. Each of these objects describes one attribute in the table and index key schema.

        Each AttributeDefinition object in this array is composed of:

          · AttributeName - The name of the attribute.
          · AttributeType - The data type for the attribute.

          • (dict) –

            Represents an attribute for describing the key schema for the table and indexes.

            · AttributeName (string) –

              A name for the attribute.

            · AttributeType (string) –

              The data type for the attribute.

          * TableName (string) –

            The name of the table.

        * KeySchema (list) –

            The primary key structure for the table. Each KeySchemaElement consists of:

            · AttributeName - The name of the attribute.
            · KeyType - The key type for the attribute. Can be either HASH or RANGE.

            For more information about primary keys, see Primary Key in the Amazon DynamoDB Developer Guide.
· (dict) –

Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

A KeySchemaElement represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one KeySchemaElement. A hash-and-range type primary key would require one KeySchemaElement for the hash attribute, and another KeySchemaElement for the range attribute.

· **AttributeName**(string) –

The name of a key attribute.

· **KeyType**(string) –

The attribute data, consisting of the data type and the attribute value itself.

· **TableStatus**(string) –

The current state of the table:

- **CREATING** - The table is being created.
- **UPDATING** - The table is being updated.
- **DELETING** - The table is being deleted.
- **ACTIVE** - The table is ready for use.

· **CreationDateTime**(datetime) –

The date and time when the table was created, in UNIX epoch time format.

· **ProvisionedThroughput**(dict) –

The provisioned throughput settings for the table, consisting of read and write capacity units, along with data about increases and decreases.

- **LastIncreaseDateTime**(datetime) –

The date and time of the last provisioned throughput increase for this table.

- **LastDecreaseDateTime**(datetime) –

The date and time of the last provisioned throughput decrease for this table.

- **NumberOfDecreasesToday**(integer) –

The number of provisioned throughput decreases for this table during this UTC calendar day. For current maximums on provisioned throughput decreases, see Limits in the Amazon DynamoDB Developer Guide.

- **ReadCapacityUnits**(integer) –

The maximum number of strongly consistent reads consumed per second before DynamoDB returns a ThrottlingException. Eventually consistent reads require less effort than strongly consistent reads, so a setting of 50 ReadCapacityUnits per second provides 100 eventually consistent ReadCapacityUnits per second.

- **WriteCapacityUnits**(integer) –
The maximum number of writes consumed per second before DynamoDB returns a `ThrottlingException`.

* **TableSizeBytes** *(integer)* –
  
The total size of the specified table, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

* **ItemCount** *(integer)* –
  
The number of items in the specified table. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

* **TableArn** *(string)* –
  
The Amazon Resource Name (ARN) that uniquely identifies the table.

* **LocalSecondaryIndexes** *(list)* –
  
Represents one or more local secondary indexes on the table. Each index is scoped to a given hash key value. Tables with one or more local secondary indexes are subject to an item collection size limit, where the amount of data within a given item collection cannot exceed 10 GB. Each element is composed of:

  - **IndexName** - The name of the local secondary index.
  - **KeySchema** - Specifies the complete index key schema. The attribute names in the key schema must be between 1 and 255 characters (inclusive). The key schema must begin with the same hash key attribute as the table.
  - **Projection** - Specifies attributes that are copied (projected) from the table into the index. These are in addition to the primary key attributes and index key attributes, which are automatically projected. Each attribute specification is composed of:
    - **ProjectionType** - One of the following: *
      - **KEYS_ONLY** - Only the index and primary keys are projected into the index.
      - **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in `NonKeyAttributes`
      - **ALL** - All of the table attributes are projected into the index.
    - **NonKeyAttributes** - A list of one or more non-key attribute names that are projected into the secondary index. The total count of attributes provided in `NonKeyAttributes`, summed across all of the secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.
    - **IndexSizeBytes** - Represents the total size of the index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.
    - **ItemCount** - Represents the number of items in the index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.
If the table is in the **DELETING** state, no information about indexes will be returned.

- *(dict)* –
  
  Represents the properties of a local secondary index.

- **IndexName** *(string)* –
  
  Represents the name of the local secondary index.

- **KeySchema** *(list)* –
  
  The complete index key schema, which consists of one or more pairs of attribute names and key types (**HASH** or **RANGE**).

- *(dict)* –
  
  Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

  A **KeySchemaElement** represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one **KeySchemaElement**. A hash-and-range type primary key would require one **KeySchemaElement** for the hash attribute, and another **KeySchemaElement** for the range attribute.

- **AttributeName** *(string)* –
  
  The name of a key attribute.

- **KeyType** *(string)* –
  
  The attribute data, consisting of the data type and the attribute value itself.

- **Projection** *(dict)* –
  
  Represents attributes that are copied (projected) from the table into an index. These are in addition to the primary key attributes and index key attributes, which are automatically projected.

- **ProjectionType** *(string)* –
  
  The set of attributes that are projected into the index:

  - **KEYS_ONLY** - Only the index and primary keys are projected into the index.
  - **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in **NonKeyAttributes**.
  - **ALL** - All of the table attributes are projected into the index.

- **NonKeyAttributes** *(list)* –
  
  Represents the non-key attribute names which will be projected into the index.

  For local secondary indexes, the total count of **NonKeyAttributes** summed across all of the local secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.
· **IndexSizeBytes (integer)** –
  The total size of the specified index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

· **ItemCount (integer)** –
  The number of items in the specified index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

· **IndexArn (string)** –
  The Amazon Resource Name (ARN) that uniquely identifies the index.

* **GlobalSecondaryIndexes (list)** –
  The global secondary indexes, if any, on the table. Each index is scoped to a given hash key value. Each element is composed of:
  · **Backfilling** - If true, then the index is currently in the backfilling phase. Backfilling occurs only when a new global secondary index is added to the table; it is the process by which DynamoDB populates the new index with data from the table. (This attribute does not appear for indexes that were created during a `CreateTable` operation.)
  · **IndexName** - The name of the global secondary index.
  · **IndexSizeBytes** - The total size of the global secondary index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.
  · **IndexStatus** - The current status of the global secondary index: * CREATING - The index is being created.
  · **UPDATING** - The index is being updated.
  · **DELETING** - The index is being deleted.
  · **ACTIVE** - The index is ready for use.
  · **ItemCount** - The number of items in the global secondary index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.
  · **KeySchema** - Specifies the complete index key schema. The attribute names in the key schema must be between 1 and 255 characters (inclusive). The key schema must begin with the same hash key attribute as the table.
  · **Projection** - Specifies attributes that are copied (projected) from the table into the index. These are in addition to the primary key attributes and index key attributes, which are automatically projected. Each attribute specification is composed of: * **ProjectionType** - One of the following: * KEYS_ONLY - Only the index and primary keys are projected into the index.
  · **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in `NonKeyAttributes`.
· **ALL** - All of the table attributes are projected into the index.

· **NonKeyAttributes** - A list of one or more non-key attribute names that are projected into the secondary index. The total count of attributes provided in NonKeyAttributes, summed across all of the secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.

· **ProvisionedThroughput** - The provisioned throughput settings for the global secondary index, consisting of read and write capacity units, along with data about increases and decreases.

If the table is in the **DELETING** state, no information about indexes will be returned.

- **(dict)** –

  Represents the properties of a global secondary index.

  · **IndexName** *(string)* –

    The name of the global secondary index.

  · **KeySchema** *(list)* –

    The complete key schema for the global secondary index, consisting of one or more pairs of attribute names and key types *(HASH or RANGE)*.

- **(dict)** –

  Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

  A **KeySchemaElement** represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one **KeySchemaElement**. A hash-and-range type primary key would require one **KeySchemaElement** for the hash attribute, and another **KeySchemaElement** for the range attribute.

  · **AttributeName** *(string)* –

    The name of a key attribute.

  · **KeyType** *(string)* –

    The attribute data, consisting of the data type and the attribute value itself.

  · **Projection** *(dict)* –

    Represents attributes that are copied (projected) from the table into an index. These are in addition to the primary key attributes and index key attributes, which are automatically projected.

  · **ProjectionType** *(string)* –

    The set of attributes that are projected into the index:

    · **KEYS_ONLY** - Only the index and primary keys are projected into the index.
    · **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are
in `NonKeyAttributes`.
- **ALL** - All of the table attributes are projected into the index.
- **NonKeyAttributes** *(list)*
  Represents the non-key attribute names which will be projected into the index.
  For local secondary indexes, the total count of `NonKeyAttributes` summed across all of the local secondary indexes, must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes when determining the total.
- **IndexStatus** *(string)*
  The current state of the global secondary index:
  - **CREATING** - The index is being created.
  - **UPDATING** - The index is being updated.
  - **DELETING** - The index is being deleted.
  - **ACTIVE** - The index is ready for use.
- **Backfilling** *(boolean)*
  Indicates whether the index is currently backfilling. Backfilling is the process of reading items from the table and determining whether they can be added to the index. (Not all items will qualify: For example, a hash key attribute cannot have any duplicates.) If an item can be added to the index, DynamoDB will do so. After all items have been processed, the backfilling operation is complete and `Backfilling` is false.

**Note:** For indexes that were created during a CreateTable operation, the `Backfilling` attribute does not appear in the DescribeTable output.

- **ProvisionedThroughput** *(dict)*
  Represents the provisioned throughput settings for the table, consisting of read and write capacity units, along with data about increases and decreases.
- **LastIncreaseDateTime** *(datetime)*
  The date and time of the last provisioned throughput increase for this table.
- **LastDecreaseDateTime** *(datetime)*
  The date and time of the last provisioned throughput decrease for this table.
- **NumberOfDecreasesToday** *(integer)*
  The number of provisioned throughput decreases for this table during this UTC calendar day. For current maximums on provisioned throughput decreases, see Limits in the Amazon DynamoDB Developer Guide.
- **ReadCapacityUnits** *(integer)*
  The maximum number of strongly consistent reads consumed per second before DynamoDB returns a
Eventually consistent reads require less effort than strongly consistent reads, so a setting of 50 ReadCapacityUnits per second provides 100 eventually consistent ReadCapacityUnits per second.

- **WriteCapacityUnits** (integer) –
  
  The maximum number of writes consumed per second before DynamoDB returns a ThrottlingException.

- **IndexSizeBytes** (integer) –
  
  The total size of the specified index, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **ItemCount** (integer) –
  
  The number of items in the specified index. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value.

- **IndexArn** (string) –
  
  The Amazon Resource Name (ARN) that uniquely identifies the index.

- **StreamSpecification** (dict) –
  
  The current DynamoDB Streams configuration for the table.

  - **StreamEnabled** (boolean) –
    
    Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.

  - **StreamViewType** (string) –
    
    The DynamoDB Streams settings for the table. These settings consist of:

    - StreamEnabled - Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.
    - StreamViewType - When an item in the table is modified, StreamViewType determines what information is written to the stream for this table. Valid values for StreamViewType are: *KEYS_ONLY* - Only the key attributes of the modified item are written to the stream.
    - NEW_IMAGE - The entire item, as it appears after it was modified, is written to the stream.
    - OLD_IMAGE - The entire item, as it appeared before it was modified, is written to the stream.
    - NEW_AND_OLD_IMAGES - Both the new and the old item images of the item are written to the stream.

  - **LatestStreamLabel** (string) –
    
    A timestamp, in ISO 8601 format, for this stream.

  Note that LatestStreamLabel is not a unique identifier for the stream, because it is possible that a stream from another table might have the same timestamp. However, the combination of the following three elements is guaranteed to be unique:

  - the AWS customer ID.
· the table name.
· the StreamLabel.

* LatestStreamArn (string) –

The Amazon Resource Name (ARN) that uniquely identifies the latest stream for this table.

delete_item(**kwargs)

Deletes a single item in a table by primary key. You can perform a conditional delete operation that deletes the item if it exists, or if it has an expected attribute value.

In addition to deleting an item, you can also return the item’s attribute values in the same operation, using the ReturnValues parameter.

Unless you specify conditions, the DeleteItem is an idempotent operation; running it multiple times on the same item or attribute does not result in an error response.

Conditional deletes are useful for deleting items only if specific conditions are met. If those conditions are met, DynamoDB performs the delete. Otherwise, the item is not deleted.

Request Syntax

```python
response = table.delete_item(
    Key={
        'string': 'string'|123|Binary(b'bytes')|True|None|set(['string'])|set([123])|set([Binary(b'bytes')])|[]|{},
    },
    Expected={
        'string': {
            'Value': 'string'|123|Binary(b'bytes')|True|None|set(['string'])|set([123])|set([Binary(b'bytes')])|[]|{},
            'Exists': True|False,
            'ComparisonOperator': 'EQ'|'NE'|'IN'|'LE'|'LT'|'GE'|'GT'|'BETWEEN'|'NOT_NULL'|'NULL'|'CONTAINS'|'NOT_CONTAINS'|'BEGINS_WITH',
            'AttributeValueList': [
                'string'|123|Binary(b'bytes')|True|None|set(['string'])|set([123])|set([Binary(b'bytes')])|[]|{},
            ],
        }
    },
    ConditionalOperator='AND'|'OR',
    ReturnValues='NONE'|'ALL_OLD'|'UPDATED_OLD'|'ALL_NEW'|'UPDATED_NEW',
    ReturnConsumedCapacity='INDEXES'|'TOTAL'|'NONE',
    ReturnItemCollectionMetrics='SIZE'|'NONE',
    ConditionExpression=Attr('myattribute').eq('myvalue'),
    ExpressionAttributeNames={
        'string': 'string'
    },
    ExpressionAttributeValues={
        'string': 'string'|123|Binary(b'bytes')|True|None|set(['string'])|set([123])|set([Binary(b'bytes')])|[]|{},
    }
)
```

Parameters

- **Key (dict) – [REQUIRED]**

A map of attribute names to AttributeValue objects, representing the primary key of the item to delete.

For the primary key, you must provide all of the attributes. For example, with a hash type primary key, you only need to provide the hash attribute. For a hash-and-range type primary key, you must provide both the hash attribute and the range attribute.

- *(string)* –
Boto3 Documentation, Release 1.1.4

- (valid DynamoDB type) - The value of the attribute. The valid value types are listed in the DynamoDB Reference Guide.

* Expected (dict) -

A map of attribute/condition pairs. Expected provides a conditional block for the DeleteItem operation.

Each element of Expected consists of an attribute name, a comparison operator, and one or more values. DynamoDB compares the attribute with the value(s) you supplied, using the comparison operator. For each Expected element, the result of the evaluation is either true or false.

If you specify more than one element in the Expected map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the ConditionalOperator parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

If the Expected map evaluates to true, then the conditional operation succeeds; otherwise, it fails.

Expected contains the following:

- AttributeValueList - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the ComparisonOperator being used. For type Number, value comparisons are numeric. String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and a is greater than B. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters. For type Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- ComparisonOperator - A comparator for evaluating attributes in the AttributeValueList. When performing the comparison, DynamoDB uses strongly consistent reads. The following comparison operators are available: EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN The following are descriptions of each comparison operator. * EQ: Equal. EQ is supported for all datatypes, including lists and maps. AttributeValueList can contain only one AttributeValue element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, {"S":"6"} does not equal {"N":"6"}. Also, {"N":"6"} does not equal {"NS": ["6", "2", "1"]}.

- NE: Not equal. NE is supported for all datatypes, including lists and maps. AttributeValueList can contain only one AttributeValue of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an AttributeValue of a different type than the
one provided in the request, the value does not match. For example, 
{"S":"6"} does not equal{"N":"6"}. Also, {"N":"6"} does not equal{"NS": ["6", "2", "1"]}.
