- **LE**: Less than or equal. *AttributeValueList* can contain only one *AttributeValue* element of type String, Number, or Binary (not a set type). If an item contains an *AttributeValue* element of a different type than the one provided in the request, the value does not match. For example, {"S":"6"} does not equal{"N":"6"}. Also, {"N":"6"} does not compare to{"NS": ["6", "2", "1"]}.

- **LT**: Less than. *AttributeValueList* can contain only one *AttributeValue* of type String, Number, or Binary (not a set type). If an item contains an *AttributeValue* element of a different type than the one provided in the request, the value does not match. For example, {"S":"6"} does not equal{"N":"6"}. Also, {"N":"6"} does not compare to{"NS": ["6", "2", "1"]}.

- **GE**: Greater than or equal. *AttributeValueList* can contain only one *AttributeValue* element of type String, Number, or Binary (not a set type). If an item contains an *AttributeValue* element of a different type than the one provided in the request, the value does not match. For example, {"S":"6"} does not equal{"N":"6"}. Also, {"N":"6"} does not compare to{"NS": ["6", "2", "1"]}.

- **GT**: Greater than. *AttributeValueList* can contain only one *AttributeValue* element of type String, Number, or Binary (not a set type). If an item contains an *AttributeValue* element of a different type than the one provided in the request, the value does not match. For example, {"S":"6"} does not equal{"N":"6"}. Also, {"N":"6"} does not compare to{"NS": ["6", "2", "1"]}.

- **NOT_NULL**: The attribute exists. **NOT_NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the existence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NOT_NULL**, the result is a Boolean true. This result is because the attribute “a” exists; its data type is not relevant to the **NOT_NULL** comparison operator.

- **NULL**: The attribute does not exist. **NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NULL**, the result is a Boolean false. This is because the attribute “a” exists; its data type is not relevant to the **NULL** comparison operator.

- **CONTAINS**: Checks for a subsequence, or value in a set. *AttributeValueList* can contain only one *AttributeValue* element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it finds an exact match with any member of the set. **CONTAINS** is supported for lists: When evaluating “a CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.
- **NOT_CONTAINS**: Checks for absence of a subsequence, or absence of a value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it does not find an exact match with any member of the set. **NOT_CONTAINS** is supported for lists: When evaluating "a NOT CONTAINS b", "a" can be a list; however, "b" cannot be a set, a map, or a list.

- **BEGINS_WITH**: Checks for a prefix. `AttributeValueList` can contain only one `AttributeValue` of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- **IN**: Checks for matching elements within two sets. `AttributeValueList` can contain one or more `AttributeValue` elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

- **BETWEEN**: Greater than or equal to the first value, and less than or equal to the second value. `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not compare to `{"N": "6"}`. Also, `{"N": "6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

For usage examples of `AttributeValueList` and `ComparisonOperator`, see [*Legacy Conditional Parameters*](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/Legacy-Conditional-Parameters.html) in the *Amazon DynamoDB Developer Guide*.

For backward compatibility with previous DynamoDB releases, the following parameters can be used instead of `AttributeValueList` and `ComparisonOperator`:

- **Value** - A value for DynamoDB to compare with an attribute.
- **Exists** - A Boolean value that causes DynamoDB to evaluate the value before attempting the conditional operation: *If* `Exists` is true, DynamoDB will check to see if that attribute value already exists in the table. If it is found, then the condition evaluates to true; otherwise the condition evaluate to false.  
  *If* `Exists` is false, DynamoDB assumes that the attribute value does not exist in the table. If in fact the value does not exist, then the assumption is valid and the condition evaluates to true. If the value is found, despite the assumption that it does not exist, the condition evaluates to false.

Note that the default value for `Exists` is true.

The `Value` and `Exists` parameters are incompatible with `AttributeValueList` and `ComparisonOperator`. Note that if you use both sets of parameters at once, DynamoDB will return a `ValidationException` exception.
Note: This parameter does not support attributes of type List or Map.

- (string) –
  * (dict) –

Represents a condition to be compared with an attribute value. This condition can be used with DeleteItem, PutItem or UpdateItem operations; if the comparison evaluates to true, the operation succeeds; if not, the operation fails. You can use `ExpectedAttributeValue` in one of two different ways:

- Use `AttributeValueList` to specify one or more values to compare against an attribute. Use `ComparisonOperator` to specify how you want to perform the comparison. If the comparison evaluates to true, then the conditional operation succeeds.
- Use `Value` to specify a value that DynamoDB will compare against an attribute. If the values match, then `ExpectedAttributeValue` evaluates to true and the conditional operation succeeds. Optionally, you can also set `Exists` to false, indicating that you do not expect to find the attribute value in the table. In this case, the conditional operation succeeds only if the comparison evaluates to false.

`Value` and `Exists` are incompatible with `AttributeValueList` and `ComparisonOperator`. Note that if you use both sets of parameters at once, DynamoDB will return a `ValidationException` exception.

- `Value (valid DynamoDB type)` – The value of the attribute. The valid value types are listed in the `DynamoDB Reference Guide`.
- `Exists (boolean)` –

Causes DynamoDB to evaluate the value before attempting a conditional operation:

- If `Exists` is `true`, DynamoDB will check to see if that attribute value already exists in the table. If it is found, then the operation succeeds. If it is not found, the operation fails with a `ConditionalCheckFailedException`.
- If `Exists` is `false`, DynamoDB assumes that the attribute value does not exist in the table. If in fact the value does not exist, then the assumption is valid and the operation succeeds. If the value is found, despite the assumption that it does not exist, the operation fails with a `ConditionalCheckFailedException`.

The default setting for `Exists` is `true`. If you supply a `Value` all by itself, DynamoDB assumes the attribute exists: You don’t have to set `Exists` to `true`, because it is implied.

DynamoDB returns a `ValidationException` if:

- `Exists` is `true` but there is no `Value` to check. (You expect a value to exist, but don’t specify what that value is.)
· **Exists** is `false` but you also provide a `Value`. (You cannot expect an attribute to have a value, while also expecting it not to exist.)

· **ComparisonOperator** (string) –

A comparator for evaluating attributes in the `AttributeValueList`. For example, equals, greater than, less than, etc.

The following comparison operators are available:

```plaintext
EQ | NE | LE | LT | GE | GT |
NOT_NULL | NULL | CONTAINS |
NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN
```

The following are descriptions of each comparison operator.

· **EQ**: Equal. `EQ` is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.

· **NE**: Not equal. `NE` is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.

· **LE**: Less than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

· **LT**: Less than. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

· **GE**: Greater than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not
match. For example, \{"S":"6"\} does not equal \{"N":"6"\}. Also, \{"N":"6"\} does not compare to \{"NS":\["6", "2", "1"\]\}.

- **GT**: Greater than. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, \{"S":"6"\} does not equal \{"N":"6"\}. Also, \{"N":"6"\} does not compare to \{"NS":\["6", "2", "1"\]\}.

- **NOT_NULL**: The attribute exists. `NOT_NULL` is supported for all datatypes, including lists and maps. .. note:: This operator tests for the existence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using `NOT_NULL`, the result is a Boolean `true`. This result is because the attribute “a” exists; its data type is not relevant to the `NOT_NULL` comparison operator.

- **NULL**: The attribute does not exist. `NULL` is supported for all datatypes, including lists and maps. .. note:: This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using `NULL`, the result is a Boolean `false`. This is because the attribute “a” exists; its data type is not relevant to the `NULL` comparison operator.

- **CONTAINS**: Checks for a subsequence, or value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it finds an exact match with any member of the set. `CONTAINS` is supported for lists: When evaluating “a CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

- **NOT_CONTAINS**: Checks for absence of a subsequence, or absence of a value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it does not find an exact match with any member of the set. `NOT_CONTAINS` is supported for lists: When evaluating “a NOT CONTAINS b”, “a” can be a list;
however, “b” cannot be a set, a map, or a list.

- **BEGINS WITH**: Checks for a prefix. `AttributeValueList` can contain only one `AttributeValue` of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- **IN**: Checks for matching elements within two sets. `AttributeValueList` can contain one or more `AttributeValue` elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

- **BETWEEN**: Greater than or equal to the first value, and less than or equal to the second value. `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not compare to `{"N": "6"}`. Also, `{"N": "6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **AttributeValueList (list)** –

  One or more values to evaluate against the supplied attribute. The number of values in the list depends on the `ComparisonOperator` being used.

  For type Number, value comparisons are numeric.

  String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and a is greater than B. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters).

  For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

  For information on specifying data types in JSON, see [JSON Data Format](http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/JSON.html) in the *Amazon DynamoDB Developer Guide*.

- **valid DynamoDB type** – The value of the attribute. The valid value types are listed in the *DynamoDB Reference Guide*.

- **ConditionalOperator (string)** –

  A logical operator to apply to the conditions in the *Expected* map:

  - **AND**: All conditions must be true.
  - **OR**: At least one condition must be true.
  - **NOT**: The opposite of the condition must be true.

  **Warning**: This is a legacy parameter, for backward compatibility. New applications should use `ConditionExpression` instead. Do not combine legacy parameters and expression parameters in a single call; otherwise, DynamoDB will return a `ValidationException` exception.
AND - If all of the conditions evaluate to true, then the entire map evaluates to true.

OR - If at least one of the conditions evaluate to true, then the entire map evaluates to true.

If you omit ConditionalOperator, then AND is the default.

The operation will succeed only if the entire map evaluates to true.

**Note:** This parameter does not support attributes of type List or Map.

- **ReturnValues** (string) – Use ReturnValues if you want to get the item attributes as they appeared before they were deleted. For DeleteItem, the valid values are:
  - NONE - If ReturnValues is not specified, or if its value is NONE, then nothing is returned. (This setting is the default for ReturnValues.)
  - ALL_OLD - The content of the old item is returned.

- **ReturnConsumedCapacity** (string) – Determines the level of detail about provisioned throughput consumption that is returned in the response:
  - INDEXES - The response includes the aggregate ConsumedCapacity for the operation, together with ConsumedCapacity for each table and secondary index that was accessed. Note that some operations, such as GetItem and BatchGetItem, do not access any indexes at all. In these cases, specifying INDEXES will only return ConsumedCapacity information for table(s).
  - TOTAL - The response includes only the aggregate ConsumedCapacity for the operation.
  - NONE - No ConsumedCapacity details are included in the response.

- **ReturnItemCollectionMetrics** (string) – Determines whether item collection metrics are returned. If set to SIZE, the response includes statistics about item collections, if any, that were modified during the operation are returned in the response. If set to NONE (the default), no statistics are returned.

- **ConditionExpression** (condition from boto3.dynamodb.conditions Attr method) – The condition(s) an attribute(s) must meet. Valid conditions are listed in the DynamoDB Reference Guide.

- **ExpressionAttributeNames** (dict) – One or more substitution tokens for attribute names in an expression. The following are some use cases for using ExpressionAttributeNames:
  - To access an attribute whose name conflicts with a DynamoDB reserved word.
  - To create a placeholder for repeating occurrences of an attribute name in an expression.
  - To prevent special characters in an attribute name from being misinterpreted in an expression.

Use the # character in an expression to dereference an attribute name. For example, consider the following attribute name:

- **Percentile**

The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see Reserved Words in the Amazon DynamoDB Developer Guide.) To work around this, you could specify the following for ExpressionAttributeNames:

- `{"#P": "Percentile"}`

You could then use this substitution in an expression, as in this example:
Tokens that begin with the : character are expression attribute values, which are placeholders for the actual value at runtime. For more information on expression attribute names, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

• ExpressionAttributeValues (dict) – One or more values that can be substituted in an expression.

Use the : (colon) character in an expression to dereference an attribute value. For example, suppose that you wanted to check whether the value of the ProductStatus attribute was one of the following:

Available | Backordered | Discontinued

You would first need to specify ExpressionAttributeValues as follows:

```{ "avail": { "S": "Available" },
   "back": { "S": "Backordered" },
   "disc": { "S": "Discontinued" } }
```

You could then use these values in an expression, such as this:

```
ProductStatus IN (:avail, :back, :disc)
```

For more information on expression attribute values, see Specifying Conditions in the Amazon DynamoDB Developer Guide.

Response Syntax

```python
def respond(query):
    # Query execution
    response = client.execute_statement(Statement=query)

    # Return response
    return response
```

Returns

dict

3.1. Services
'ItemCollectionMetrics': {
  'ItemCollectionKey': {
    'string': 'string'|123|Binary(b'bytes')|True|None|set(['string'])
  },
  'SizeEstimateRangeGB': [123.0,
}

Response Structure

- (dict) –

  Represents the output of a DeleteItem operation.

  - Attributes (dict) –

    A map of attribute names to AttributeValue objects, representing the item as it appeared before the DeleteItem operation. This map appears in the response only if ReturnValues was specified as ALL_OLD in the request.

    - (string) –

      - (valid DynamoDB type) – - The value of the attribute.
        The valid value types are listed in the DynamoDB Reference Guide.

  - ConsumedCapacity (dict) –

    The capacity units consumed by an operation. The data returned includes the total provisioned throughput consumed, along with statistics for the table and any indexes involved in the operation. ConsumedCapacity is only returned if the request asked for it. For more information, see Provisioned Throughput in the Amazon DynamoDB Developer Guide.

    - TableName (string) –

      The name of the table that was affected by the operation.

    - CapacityUnits (float) –

      The total number of capacity units consumed by the operation.

    - Table (dict) –

      The amount of throughput consumed on the table affected by the operation.

      - CapacityUnits (float) –

        The total number of capacity units consumed on a table or an index.

    - LocalSecondaryIndexes (dict) –

      The amount of throughput consumed on each local index affected by the operation.

      - (string) –

      - (dict) –

        Represents the amount of provisioned throughput capacity consumed on a table or an index.

      - CapacityUnits (float) –
The total number of capacity units consumed on a table or an index.

- **GlobalSecondaryIndexes** *(dict)* –
  The amount of throughput consumed on each global index affected by the operation.
  - *(string)* –
  - *(dict)* –
    Represents the amount of provisioned throughput capacity consumed on a table or an index.
  - **CapacityUnits** *(float)* –
    The total number of capacity units consumed on a table or an index.

- **ItemCollectionMetrics** *(dict)* –
  Information about item collections, if any, that were affected by the operation. *ItemCollectionMetrics* is only returned if the request asked for it. If the table does not have any local secondary indexes, this information is not returned in the response.

Each *ItemCollectionMetrics* element consists of:
- **ItemCollectionKey** *(dict)* - The hash key value of the item collection. This is the same as the hash key of the item.
- **SizeEstimateRange** - An estimate of item collection size, in gigabytes. This value is a two-element array containing a lower bound and an upper bound for the estimate. The estimate includes the size of all the items in the table, plus the size of all attributes projected into all of the local secondary indexes on that table. Use this estimate to measure whether a local secondary index is approaching its size limit. The estimate is subject to change over time; therefore, do not rely on the precision or accuracy of the estimate.

- **ItemCollectionKey** *(dict)* –
  The hash key value of the item collection. This value is the same as the hash key of the item.
  - *(string)* –
  - *(valid DynamoDB type)* – The value of the attribute. The valid value types are listed in the *DynamoDB Reference Guide*.

- **SizeEstimateRangeGB** *(list)* –
  An estimate of item collection size, in gigabytes. This value is a two-element array containing a lower bound and an upper bound for the estimate. The estimate includes the size of all the items in the table, plus the size of all attributes projected into all of the local secondary indexes on that table. Use this estimate to measure whether a local secondary index is approaching its size limit.

  The estimate is subject to change over time; therefore, do not rely on the precision or accuracy of the estimate.

  - *(float)* –

**get_item(****kwargs**)**

The *GetItem* operation returns a set of attributes for the item with the given primary key. If there is
no matching item, `GetItem` does not return any data.

`GetItem` provides an eventually consistent read by default. If your application requires a strongly consistent read, set `ConsistentRead` to `true`. Although a strongly consistent read might take more time than an eventually consistent read, it always returns the last updated value.

**Request Syntax**

```python
response = table.get_item(
    Key={
        'string': 'string'|123|Binary(b'bytes')|True|None|set(["string"])|set([123])|set([Binary(b'bytes')])|[],
    AttributesToGet=[
        'string',
    ],
    ConsistentRead=True|False,
    ReturnConsumedCapacity='INDEXES'|'TOTAL'|'NONE',
    ProjectionExpression='string',
    ExpressionAttributeNames={
        'string': 'string'
    }
)
```

**Parameters**

- **Key (dict) – [REQUIRED]**
  
  A map of attribute names to `AttributeValue` objects, representing the primary key of the item to retrieve.

  For the primary key, you must provide all of the attributes. For example, with a hash type primary key, you only need to provide the hash attribute. For a hash-and-range type primary key, you must provide both the hash attribute and the range attribute.

  - **string**
    
    *(valid DynamoDB type)* — The value of the attribute. The valid value types are listed in the *DynamoDB Reference Guide*.

- **AttributesToGet (list) –**

  The names of one or more attributes to retrieve. If no attribute names are provided, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

  Note that `AttributesToGet` has no effect on provisioned throughput consumption. DynamoDB determines capacity units consumed based on item size, not on the amount of data that is returned to an application.

  - **string**

- **ConsistentRead (boolean) –** Determines the read consistency model: If set to `true`, then the operation uses strongly consistent reads; otherwise, the operation uses eventually consistent reads.

**Warning:** This is a legacy parameter, for backward compatibility. New applications should use `ProjectionExpression` instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a `ValidationException` exception.

This parameter allows you to retrieve attributes of type List or Map; however, it cannot retrieve individual elements within a List or a Map.
• **ReturnConsumedCapacity** (*string*) – Determines the level of detail about provisioned throughput consumption that is returned in the response:
  - **INDEXES** - The response includes the aggregate ConsumedCapacity for the operation, together with ConsumedCapacity for each table and secondary index that was accessed. Note that some operations, such as GetItem and BatchGetItem, do not access any indexes at all. In these cases, specifying INDEXES will only return ConsumedCapacity information for table(s).
  - **TOTAL** - The response includes only the aggregate ConsumedCapacity for the operation.
  - **NONE** - No ConsumedCapacity details are included in the response.

• **ProjectionExpression** (*string*) – A string that identifies one or more attributes to retrieve from the table. These attributes can include scalars, sets, or elements of a JSON document. The attributes in the expression must be separated by commas.

  If no attribute names are specified, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

  For more information, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

  **Note:** ProjectionExpression replaces the legacy AttributesToGet parameter.

• **ExpressionAttributeNames** (*dict*) – One or more substitution tokens for attribute names in an expression. The following are some use cases for using ExpressionAttributeNames:
  - To access an attribute whose name conflicts with a DynamoDB reserved word.
  - To create a placeholder for repeating occurrences of an attribute name in an expression.
  - To prevent special characters in an attribute name from being misinterpreted in an expression.

  Use the # character in an expression to dereference an attribute name. For example, consider the following attribute name:
  - `Percentile`

  The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see Reserved Words in the Amazon DynamoDB Developer Guide). To work around this, you could specify the following for ExpressionAttributeNames:
  - `{"#P":"Percentile"}`

  You could then use this substitution in an expression, as in this example:
  - `#P = :val`

  **Note:** Tokens that begin with the : character are expression attribute values, which are placeholders for the actual value at runtime.

  For more information on expression attribute names, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.
Response Syntax

```json
{
'Item': {
    'string': 'string'|123|Binary(b'bytes')|True|None|set(['string'])|set([123])|set([Binary(b'bytes')])|[[]]|{}
},
'ConsumedCapacity': {
    'TableName': 'string',
    'CapacityUnits': 123.0,
    'Table': {
        'CapacityUnits': 123.0
    },
    'LocalSecondaryIndexes': {
        'string': {
            'CapacityUnits': 123.0
        }
    },
    'GlobalSecondaryIndexes': {
        'string': {
            'CapacityUnits': 123.0
        }
    }
}
}
```

Response Structure

- (dict) – Represents the output of a `GetItem` operation.
  - Item (dict) – A map of attribute names to `AttributeValue` objects, as specified by `AttributesToGet`.
    - (string) – 
      - (valid DynamoDB type) – The value of the attribute. The valid value types are listed in the *DynamoDB Reference Guide*.
  - ConsumedCapacity (dict) – The capacity units consumed by an operation. The data returned includes the total provisioned throughput consumed, along with statistics for the table and any indexes involved in the operation. `ConsumedCapacity` is only returned if the request asked for it. For more information, see Provisioned Throughput in the *Amazon DynamoDB Developer Guide*.
    - TableName (string) – The name of the table that was affected by the operation.
    - CapacityUnits (float) – The total number of capacity units consumed by the operation.
    - Table (dict) – The amount of throughput consumed on the table affected by the operation.
      - CapacityUnits (float) –
The total number of capacity units consumed on a table or an index.

* **LocalSecondaryIndexes** *(dict)* –
  
The amount of throughput consumed on each local index affected by the operation.
  
  · *(string)* –
  
  · *(dict)* –
  
  Represents the amount of provisioned throughput capacity consumed on a table or an index.
  
  · **CapacityUnits** *(float)* –
  
  The total number of capacity units consumed on a table or an index.

* **GlobalSecondaryIndexes** *(dict)* –
  
The amount of throughput consumed on each global index affected by the operation.
  
  · *(string)* –
  
  · *(dict)* –
  
  Represents the amount of provisioned throughput capacity consumed on a table or an index.
  
  · **CapacityUnits** *(float)* –
  
  The total number of capacity units consumed on a table or an index.

### load()

Calls `dynamodb.Client.describe_table()` to update the attributes of the Table resource

#### Request Syntax

`table.load()`

#### Returns

None

### put_item(**kwargs)

Creates a new item, or replaces an old item with a new item. If an item that has the same primary key as the new item already exists in the specified table, the new item completely replaces the existing item. You can perform a conditional put operation (add a new item if one with the specified primary key doesn’t exist), or replace an existing item if it has certain attribute values.

In addition to putting an item, you can also return the item’s attribute values in the same operation, using the `ReturnValues` parameter.

When you add an item, the primary key attribute(s) are the only required attributes. Attribute values cannot be null. String and Binary type attributes must have lengths greater than zero. Set type attributes cannot be empty. Requests with empty values will be rejected with a `ValidationException` exception.

You can request that `PutItem` return either a copy of the original item (before the update) or a copy of the updated item (after the update). For more information, see the `ReturnValues` description below.

**Note:** To prevent a new item from replacing an existing item, use a conditional put operation with `ComparisonOperator` set to `NULL` for the primary key attribute, or attributes.
For more information about using this API, see Working with Items in the Amazon DynamoDB Developer Guide.

**Request Syntax**

```python
response = table.put_item(
    Item={
        'string': 'string'|123|Binary(b'bytes')|True|None|set(["string"])|set([123])|set([Binary(b'bytes')])|{}|[]
    },
    Expected={
        'string': {
            'Value': 'string'|123|Binary(b'bytes')|True|None|set(["string"])|set([123])|set([Binary(b'bytes')])|{}|[]
        },
        'Exists': True|False,
        'ComparisonOperator': 'EQ'|'NE'|'IN'|'LE'|'LT'|'GE'|'GT'|'BETWEEN'|'NOT_NULL'|'NULL'|'CONTAINS'|'NOT_CONTAINS'|'BEGINS_WITH',
        'AttributeValueList': [
            'string'|123|Binary(b'bytes')|True|None|set(["string"])|set([123])|set([Binary(b'bytes')])|{}|[]
        ]
    },
    ReturnValues='NONE'|'ALL_OLD'|'UPDATED_OLD'|'ALL_NEW'|'UPDATED_NEW',
    ReturnConsumedCapacity='INDEXES'|'TOTAL'|'NONE',
    ReturnItemCollectionMetrics='SIZE'|'NONE',
    ConditionalOperator='AND'|'OR',
    ConditionExpression=Attr('myattribute').eq('myvalue'),
    ExpressionAttributeNames={
        'string': 'string'
    },
    ExpressionAttributeValues={
        'string': 'string'|123|Binary(b'bytes')|True|None|set(["string"])|set([123])|set([Binary(b'bytes')])|{}|[]
    }
)
```

**Parameters**

- **Item** *(dict) – [REQUIRED]*

  A map of attribute name/value pairs, one for each attribute. Only the primary key attributes are required; you can optionally provide other attribute name-value pairs for the item.

  You must provide all of the attributes for the primary key. For example, with a hash type primary key, you only need to provide the hash attribute. For a hash-and-range type primary key, you must provide both the hash attribute and the range attribute.

  If you specify any attributes that are part of an index key, then the data types for those attributes must match those of the schema in the table’s attribute definition.

  For more information about primary keys, see Primary Key in the Amazon DynamoDB Developer Guide.

  Each element in the Item map is an AttributeValue object.

  - *(string)* –
    - *(valid DynamoDB type)* – The value of the attribute. The valid value types are listed in the DynamoDB Reference Guide.
• **Expected (dict)** –

A map of attribute/condition pairs. *Expected* provides a conditional block for the *PutItem* operation.

**Note:** This parameter does not support attributes of type List or Map.

Each element of *Expected* consists of an attribute name, a comparison operator, and one or more values. DynamoDB compares the attribute with the value(s) you supplied, using the comparison operator. For each *Expected* element, the result of the evaluation is either true or false.

If you specify more than one element in the *Expected* map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the *ConditionalOperator* parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

If the *Expected* map evaluates to true, then the conditional operation succeeds; otherwise, it fails.

*Expected* contains the following:

- **AttributeValueList** - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the *ComparisonOperator* being used. For type Number, value comparisons are numeric. String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, `a` is greater than `A`, and `a` is greater than `B`. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters). For type Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- **ComparisonOperator** - A comparator for evaluating attributes in the *AttributeValueList*. When performing the comparison, DynamoDB uses strongly consistent reads. The following comparison operators are available: `EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN` The following are descriptions of each comparison operator. *EQ*: Equal. EQ is supported for all datatypes, including lists and maps. *AttributeValueList* can contain only one *AttributeValue* element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an *AttributeValue* element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":{"6","2","1"}}.

- **NE**: Not equal. NE is supported for all datatypes, including lists and maps. *AttributeValueList* can contain only one *AttributeValue* of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an *AttributeValue* of a different type than the one provided in the request, the value does not match. For example,
Boto3 Documentation, Release 1.1.4

–

–

–

–

–

–

1030

{"S":"6"} does not equal {"N":"6"} . Also, {"N":"6"}
does not equal {"NS":["6", "2", "1"]} .
LE : Less than or equal. AttributeValueList can contain only one
AttributeValue element of type String, Number, or Binary (not a set
type). If an item contains an AttributeValue element of a different
type than the one provided in the request, the value does not match.
For example, {"S":"6"} does not equal {"N":"6"} . Also,
{"N":"6"} does not compare to {"NS":["6", "2", "1"]}
.
LT : Less than. AttributeValueList can contain only one AttributeValue of type String, Number, or Binary (not a set type). If an item
contains an AttributeValue element of a different type than the one
provided in the request, the value does not match. For example,
{"S":"6"} does not equal {"N":"6"} . Also, {"N":"6"}
does not compare to {"NS":["6", "2", "1"]} .
GE : Greater than or equal. AttributeValueList can contain only one
AttributeValue element of type String, Number, or Binary (not a set
type). If an item contains an AttributeValue element of a different
type than the one provided in the request, the value does not match.
For example, {"S":"6"} does not equal {"N":"6"} . Also,
{"N":"6"} does not compare to {"NS":["6", "2", "1"]}
.
GT : Greater than. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type).
If an item contains an AttributeValue element of a different type
than the one provided in the request, the value does not match.
For example, {"S":"6"} does not equal {"N":"6"} . Also,
{"N":"6"} does not compare to {"NS":["6", "2", "1"]}
.
NOT_NULL : The attribute exists. NOT_NULL is supported for all
datatypes, including lists and maps. .. note::This operator tests for
the existence of an attribute, not its data type. If the data type of
attribute “a ” is null, and you evaluate it using NOT_NULL , the
result is a Boolean true . This result is because the attribute “a ”
exists; its data type is not relevant to the NOT_NULL comparison
operator.
NULL : The attribute does not exist. NULL is supported for all
datatypes, including lists and maps. .. note::This operator tests for
the nonexistence of an attribute, not its data type. If the data type of
attribute “a ” is null, and you evaluate it using NULL , the result is
a Boolean false . This is because the attribute “a ” exists; its data
type is not relevant to the NULL comparison operator.
CONTAINS : Checks for a subsequence, or value in a set. AttributeValueList can contain only one AttributeValue element of type
String, Number, or Binary (not a set type). If the target attribute of
the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type
Binary, then the operator looks for a subsequence of the target that
matches the input. If the target attribute of the comparison is a set
(“SS ”, “NS ”, or “BS ”), then the operator evaluates to true if it
finds an exact match with any member of the set. CONTAINS is
supported for lists: When evaluating “a CONTAINS b ”, “a ” can
be a list; however, “b ” cannot be a set, a map, or a list.
NOT_CONTAINS : Checks for absence of a subsequence, or ab-

Chapter 3. API Reference


sence of a value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it does not find an exact match with any member of the set. `NOT_CONTAINS` is supported for lists: When evaluating “a NOT CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

- `BEGINS_WITH`: Checks for a prefix. `AttributeValueList` can contain only one `AttributeValue` of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- `IN`: Checks for matching elements within two sets. `AttributeValueList` can contain one or more `AttributeValue` elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

- `BETWEEN`: Greater than or equal to the first value, and less than or equal to the second value. `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, {
  "S": "6"
} does not compare to {
  "N": "6"
}. Also, {
  "N": "6"
} does not compare to {
  "NS": ["6", "2", "1"]
}

For usage examples of `AttributeValueList` and `ComparisonOperator`, see Legacy Conditional Parameters in the Amazon DynamoDB Developer Guide.

For backward compatibility with previous DynamoDB releases, the following parameters can be used instead of `AttributeValueList` and `ComparisonOperator`:

- `Value` - A value for DynamoDB to compare with an attribute.

- `Exists` - A Boolean value that causes DynamoDB to evaluate the value before attempting the conditional operation: * If `Exists` is true, DynamoDB will check to see if that attribute value already exists in the table. If it is found, then the condition evaluates to true; otherwise the condition evaluate to false.

  - If `Exists` is false, DynamoDB assumes that the attribute value does not exist in the table. If in fact the value does not exist, then the assumption is valid and the condition evaluates to true. If the value is found, despite the assumption that it does not exist, the condition evaluates to false.

Note that the default value for `Exists` is true.

The `Value` and `Exists` parameters are incompatible with `AttributeValueList` and `ComparisonOperator`. Note that if you use both sets of parameters at once, DynamoDB will return a `ValidationException` exception.

- (string) –
*(dict)* –

Represents a condition to be compared with an attribute value. This condition can be used with *DeleteItem*, *PutItem* or *UpdateItem* operations; if the comparison evaluates to true, the operation succeeds; if not, the operation fails. You can use *ExpectedAttributeValue* in one of two different ways:

- Use *AttributeValueList* to specify one or more values to compare against an attribute. Use *ComparisonOperator* to specify how you want to perform the comparison. If the comparison evaluates to true, then the conditional operation succeeds.
- Use *Value* to specify a value that DynamoDB will compare against an attribute. If the values match, then *ExpectedAttributeValue* evaluates to true and the conditional operation succeeds. Optionally, you can also set *Exists* to false, indicating that you do not expect to find the attribute value in the table. In this case, the conditional operation succeeds only if the comparison evaluates to false.

*Value* and *Exists* are incompatible with *AttributeValueList* and *ComparisonOperator*. Note that if you use both sets of parameters at once, DynamoDB will return a *ValidationException* exception.

- **Value (valid DynamoDB type)** – The value of the attribute. The valid value types are listed in the *DynamoDB Reference Guide*.
- **Exists (boolean)** –

Causes DynamoDB to evaluate the value before attempting a conditional operation:

- If *Exists* is true, DynamoDB will check to see if that attribute value already exists in the table. If it is found, then the operation succeeds. If it is not found, the operation fails with a *ConditionalCheckFailedException*.
- If *Exists* is false, DynamoDB assumes that the attribute value does not exist in the table. If in fact the value does not exist, then the assumption is valid and the operation succeeds. If the value is found, despite the assumption that it does not exist, the operation fails with a *ConditionalCheckFailedException*.

The default setting for *Exists* is true. If you supply a *Value* all by itself, DynamoDB assumes the attribute exists: You don’t have to set *Exists* to true, because it is implied.

DynamoDB returns a *ValidationException* if:

- *Exists* is true but there is no *Value* to check. (You expect a value to exist, but don’t specify what that value is.)
- *Exists* is false but you also provide a *Value*. (You cannot expect an attribute to have a value, while also expecting it not to exist.)
- **ComparisonOperator (string)** –
A comparator for evaluating attributes in the `AttributeValueList`. For example, equals, greater than, less than, etc.

The following comparison operators are available:

```
EQ | NE | LE | LT | GE | GT |
NOT_NULL | NULL | CONTAINS |
NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN
```

The following are descriptions of each comparison operator.

- **EQ**: Equal. `EQ` is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.

- **NE**: Not equal. `NE` is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.

- **LE**: Less than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **LT**: Less than. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **GE**: Greater than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **GT**: Greater than. `AttributeValueList` can contain only
one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not compare to \{"NS": ["6", "2", "1"]\}.

- **NOT_NULL**: The attribute exists. NOT_NULL is supported for all datatypes, including lists and maps. .. note:: This operator tests for the existence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using NOT_NULL, the result is a Boolean true. This result is because the attribute “a” exists; its data type is not relevant to the NOT_NULL comparison operator.

- **NULL**: The attribute does not exist. NULL is supported for all datatypes, including lists and maps. .. note:: This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using NULL, the result is a Boolean false. This is because the attribute “a” exists; its data type is not relevant to the NULL comparison operator.

- **CONTAINS**: Checks for a subsequence, or value in a set. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set (“SS”, “NS”, or “BS”), then the operator evaluates to true if it finds an exact match with any member of the set. CONTAINS is supported for lists: When evaluating “a CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

- **NOT_CONTAINS**: Checks for absence of a subsequence, or absence of a value in a set. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set (“SS”, “NS”, or “BS”), then the operator evaluates to true if it does not find an exact match with any member of the set. NOT_CONTAINS is supported for lists: When evaluating “a NOT CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

- **BEGINS_WITH**: Checks for a prefix. AttributeValueList can contain only one AttributeValue of type String or Binary (not a Number or a set type). The t-
The get attribute of the comparison must be of type String or Binary (not a Number or a set type).

- **IN**: Checks for matching elements within two sets. `AttributeValueList` can contain one or more `AttributeValue` elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

- **BETWEEN**: Greater than or equal to the first value, and less than or equal to the second value. `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not compare to `{"N": "6"}`. Also, `{"N": "6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **AttributeValueList** (list) – One or more values to evaluate against the supplied attribute. The number of values in the list depends on the `ComparisonOperator` being used.

For type Number, value comparisons are numeric.

String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, 'a' is greater than 'A', and 'a' is greater than 'B'. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters).

For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

For information on specifying data types in JSON, see [JSON Data Format](http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/JSON.html) in the *Amazon DynamoDB Developer Guide*.

- **(valid DynamoDB type)** – The value of the attribute. The valid value types are listed in the *DynamoDB Reference Guide*.

- **ReturnValues** (string) – Use `ReturnValues` if you want to get the item attributes as they appeared before they were updated with the `PutItem` request. For `PutItem`, the valid values are:
  - **NONE** - If `ReturnValues` is not specified, or if its value is **NONE**, then nothing is returned. (This setting is the default for `ReturnValues`.)
  - **ALL_OLD** - If `PutItem` overwrote an attribute name-value pair, then the content of the old item is returned.

  **Note:** Other “Valid Values” are not relevant to `PutItem`.

- **ReturnConsumedCapacity** (string) – Determines the level of detail about provisioned throughput consumption that is returned in the response:
INDEXES - The response includes the aggregate ConsumedCapacity for the operation, together with ConsumedCapacity for each table and secondary index that was accessed. Note that some operations, such as GetItem and BatchGetItem, do not access any indexes at all. In these cases, specifying INDEXES will only return ConsumedCapacity information for table(s).

TOTAL - The response includes only the aggregate ConsumedCapacity for the operation.

NONE - No ConsumedCapacity details are included in the response.

ReturnItemCollectionMetrics (string) – Determines whether item collection metrics are returned. If set to SIZE, the response includes statistics about item collections, if any, that were modified during the operation are returned in the response. If set to NONE (the default), no statistics are returned.

Warning: This is a legacy parameter, for backward compatibility. New applications should use ConditionExpression instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a ValidationException exception.

ConditionalOperator (string) – A logical operator to apply to the conditions in the Expected map:

- AND - If all of the conditions evaluate to true, then the entire map evaluates to true.
- OR - If at least one of the conditions evaluate to true, then the entire map evaluates to true.

If you omit ConditionalOperator, then AND is the default.

The operation will succeed only if the entire map evaluates to true.

Note: This parameter does not support attributes of type List or Map.

ConditionExpression (condition from boto3.dynamodb.conditions.Attr method) – The condition(s) an attribute(s) must meet. Valid conditions are listed in the DynamoDB Reference Guide.

ExpressionAttributeNames (dict) – One or more substitution tokens for attribute names in an expression. The following are some use cases for using ExpressionAttributeNames:

- To access an attribute whose name conflicts with a DynamoDB reserved word.
- To create a placeholder for repeating occurrences of an attribute name in an expression.
- To prevent special characters in an attribute name from being misinterpreted in an expression.

Use the # character in an expression to dereference an attribute name. For example, consider the following attribute name:

Percentile

The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see Reserved Words in the Amazon DynamoDB Developer Guide). To work around this, you could specify the following for ExpressionAttributeNames:

- {"#P":"Percentile"}

You could then use this substitution in an expression, as in this example:
- \#P = :val

**Note:** Tokens that begin with the : character are *expression attribute values*, which are placeholders for the actual value at runtime.

For more information on expression attribute names, see Accessing Item Attributes in the *Amazon DynamoDB Developer Guide*.

- (string) –
  * (string) –

- **ExpressionAttributeValues** (dict) – One or more values that can be substituted in an expression.

Use the : (colon) character in an expression to dereference an attribute value. For example, suppose that you wanted to check whether the value of the *ProductStatus* attribute was one of the following:

Available | Backordered | Discontinued

You would first need to specify *ExpressionAttributeValues* as follows:

```json
{ ":avail":{"S":"Available"},
":back":{"S":"Backordered"},
":disc":{"S":"Discontinued"} }
```

You could then use these values in an expression, such as this:

```python
ProductStatus IN (:avail, :back, :disc)
```

For more information on expression attribute values, see Specifying Conditions in the *Amazon DynamoDB Developer Guide*.

- (string) –
  * (valid DynamoDB type) – The value of the attribute. The valid value types are listed in the *DynamoDB Reference Guide*.

**Response Syntax**

```json
{
  'Attributes': {
    'string': 'string'|123|Binary(b'bytes')|True|None|set(["string"])|set([123])|set([Binary(b'bytes')])|[]|{}
  },
  'ConsumedCapacity': {
    'TableName': 'string',
    'CapacityUnits': 123.0,
    'Table': {
      'CapacityUnits': 123.0
    },
    'LocalSecondaryIndexes': {
      'string': {
        'CapacityUnits': 123.0
      }
    },
    'GlobalSecondaryIndexes': {
      'string': {
        'CapacityUnits': 123.0
      }
    }
  }
}
```

**Returns**

**Response Syntax**

```json
{
  'Attributes': {
    'string': 'string'|123|Binary(b'bytes')|True|None|set(["string"])|set([123])|set([Binary(b'bytes')])|[]|{}
  },
  'ConsumedCapacity': {
    'TableName': 'string',
    'CapacityUnits': 123.0,
    'Table': {
      'CapacityUnits': 123.0
    },
    'LocalSecondaryIndexes': {
      'string': {
        'CapacityUnits': 123.0
      }
    },
    'GlobalSecondaryIndexes': {
      'string': {
        'CapacityUnits': 123.0
      }
    }
  }
}
```
Response Structure

• **(dict)** – 
  Represents the output of a *PutItem* operation.

  - **Attributes (dict)** – 
    The attribute values as they appeared before the *PutItem* operation, but only if *ReturnValues* is specified as *ALL_OLD* in the request. Each element consists of an attribute name and an attribute value.
    
    * (string) – 
      · (valid DynamoDB type) – The value of the attribute. The valid value types are listed in the *DynamoDB Reference Guide*.

  - **ConsumedCapacity (dict)** – 
    The capacity units consumed by an operation. The data returned includes the total provisioned throughput consumed, along with statistics for the table and any indexes involved in the operation. *ConsumedCapacity* is only returned if the request asked for it. For more information, see *Provisioned Throughput* in the *Amazon DynamoDB Developer Guide*.
    
    * TableName (string) – 
      The name of the table that was affected by the operation.
    
    * CapacityUnits (float) – 
      The total number of capacity units consumed by the operation.
    
    * Table (dict) – 
      The amount of throughput consumed on the table affected by the operation.
        
        * CapacityUnits (float) – 
          The total number of capacity units consumed on a table or an index.
    
    * LocalSecondaryIndexes (dict) – 
      The amount of throughput consumed on each local index affected by the operation.
        
        * (string) – 
          · (dict) – 
            Represents the amount of provisioned throughput capacity consumed on a table or an index.
        
        * CapacityUnits (float) – 
          The total number of capacity units consumed on a table or an index.
GlobalSecondaryIndexes (dict) –
The amount of throughput consumed on each global index affected by the operation.
   · (string) –
   · (dict) –
       Represents the amount of provisioned throughput capacity consumed on a table or an index.
   · CapacityUnits (float) –
       The total number of capacity units consumed on a table or an index.

ItemCollectionMetrics (dict) –
Information about item collections, if any, that were affected by the operation. ItemCollectionMetrics is only returned if the request asked for it. If the table does not have any local secondary indexes, this information is not returned in the response.

Each ItemCollectionMetrics element consists of:
   · ItemCollectionKey - The hash key value of the item collection. This is the same as the hash key of the item.
   · SizeEstimateRange - An estimate of item collection size, in gigabytes. This value is a two-element array containing a lower bound and an upper bound for the estimate. The estimate includes the size of all the items in the table, plus the size of all attributes projected into all of the local secondary indexes on that table. Use this estimate to measure whether a local secondary index is approaching its size limit. The estimate is subject to change over time; therefore, do not rely on the precision or accuracy of the estimate.
   · ItemCollectionKey (dict) –
   · (string) –
   · (valid DynamoDB type) – · The value of the attribute.
       The valid value types are listed in the DynamoDB Reference Guide.
   · SizeEstimateRangeGB (list) –
       An estimate of item collection size, in gigabytes. This value is a two-element array containing a lower bound and an upper bound for the estimate. The estimate includes the size of all the items in the table, plus the size of all attributes projected into all of the local secondary indexes on that table. Use this estimate to measure whether a local secondary index is approaching its size limit.
       The estimate is subject to change over time; therefore, do not rely on the precision or accuracy of the estimate.
       · (float) –

query (**kwargs)
A Query operation uses the primary key of a table or a secondary index to directly access items from that table or index.
Use the `KeyConditionExpression` parameter to provide a specific hash key value. The `Query` operation will return all of the items from the table or index with that hash key value. You can optionally narrow the scope of the `Query` operation by specifying a range key value and a comparison operator in `KeyConditionExpression`. You can use the `ScanIndexForward` parameter to get results in forward or reverse order, by range key or by index key.

Queries that do not return results consume the minimum number of read capacity units for that type of read operation.

If the total number of items meeting the query criteria exceeds the result set size limit of 1 MB, the query stops and results are returned to the user with the `LastEvaluatedKey` element to continue the query in a subsequent operation. Unlike a `Scan` operation, a `Query` operation never returns both an empty result set and a `LastEvaluatedKey` value. `LastEvaluatedKey` is only provided if the results exceed 1 MB, or if you have used the `Limit` parameter.

You can query a table, a local secondary index, or a global secondary index. For a query on a table or on a local secondary index, you can set the `ConsistentRead` parameter to `true` and obtain a strongly consistent result. Global secondary indexes support eventually consistent reads only, so do not specify `ConsistentRead` when querying a global secondary index.

**Request Syntax**

```python
response = table.query(
    IndexName='string',
    Select='ALL_ATTRIBUTES'|'ALL_PROJEC TED_ATTRIBUTES'|'SPECIFIC_ATTRIBUTES'|'COUNT',
    AttributesToGet=['string'],
    Limit=123,
    ConsistentRead=True|False,
    KeyConditions={
        'string': {
            'AttributeValueList': [
                'string'|123|Binary(b'by tes')|True|None|set(["string"])|set([123])|set([Binary(b'by tes')])|set([])|set({}),
            ]
            ,
            'ComparisonOperator': 'EQ'|'NE'|'IN'|'LE'|'LT'|'GE'|'GT'|'BETWEEN'|'NOT_NULL'|'NULL'|'CONTAINS'|'NOT_CONTAINS'|'BEGINS WITH'|'NOT NULL',
        }
    ,
    QueryFilter={
        'string': {
            'AttributeValueList': [
                'string'|123|Binary(b'bytes')|True|None|set(["string"])|set([123])|set([Binary(b'bytes')])|set([])|set({}),
            ]
            ,
            'ComparisonOperator': 'EQ'|'NE'|'IN'|'LE'|'LT'|'GE'|'GT'|'BETWEEN'|'NOT_NULL',
        }
    ,
    ConditionalOperator='AND'|'OR',
    ScanIndexForward=True|False,
    ExclusiveStartKey={
        'string': 'string'|123|Binary(b'bytes')|True|None|set(["string"])|set([123])|set([Binary(b'by tes')])|set([])|set({}),
        }
    ,
    ReturnConsumedCapacity='INDEXES'|'TOTAL'|'NONE',
    ProjectionExpression='string',
    FilterExpression=Attr('myattribute').eq('myvalue'),
    KeyConditionExpression=Key('mykey').eq('myvalue'),
    ExpressionAttributeNames={
        'string': 'string'
        },
    ExpressionAttributeValues={
        
```

1040 Chapter 3. API Reference
Parameters

- **IndexName** *(string)* – The name of an index to query. This index can be any local secondary index or global secondary index on the table. Note that if you use the *IndexName* parameter, you must also provide *TableName*.

- **Select** *(string)* – The attributes to be returned in the result. You can retrieve all item attributes, specific item attributes, the count of matching items, or in the case of an index, some or all of the attributes projected into the index.
  - ALL_ATTRIBUTES - Returns all of the item attributes from the specified table or index. If you query a local secondary index, then for each matching item in the index DynamoDB will fetch the entire item from the parent table. If the index is configured to project all item attributes, then all of the data can be obtained from the local secondary index, and no fetching is required.
  - ALL_PROJECTED_ATTRIBUTES - Allowed only when querying an index. Retrieves all attributes that have been projected into the index. If the index is configured to project all attributes, this return value is equivalent to specifying ALL_ATTRIBUTES.
  - COUNT - Returns the number of matching items, rather than the matching items themselves.
  - SPECIFIC_ATTRIBUTES - Returns only the attributes listed in AttributesToGet. This return value is equivalent to specifying AttributesToGet without specifying any value for Select. If you query a local secondary index and request only attributes that are projected into that index, the operation will read only the index and not the table. If any of the requested attributes are not projected into the local secondary index, DynamoDB will fetch each of these attributes from the parent table. This extra fetching incurs additional throughput cost and latency. If you query a global secondary index, you can only request attributes that are projected into the index. Global secondary index queries cannot fetch attributes from the parent table. If neither Select nor AttributesToGet are specified, DynamoDB defaults to ALL_ATTRIBUTES when accessing a table, and ALL_PROJECTED_ATTRIBUTES when accessing an index. You cannot use both Select and AttributesToGet together in a single request, unless the value for Select is SPECIFIC_ATTRIBUTES. (This usage is equivalent to specifying AttributesToGet without any value for Select.)

Note: If you use the ProjectionExpression parameter, then the value for Select can only be SPECIFIC_ATTRIBUTES. Any other value for Select will return an error.

Warning: This is a legacy parameter, for backward compatibility. New applications should use ProjectionExpression instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a ValidationException exception.

- **AttributesToGet** *(list)* –
The names of one or more attributes to retrieve. If no attribute names are provided, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

Note that AttributesToGet has no effect on provisioned throughput consumption. DynamoDB determines capacity units consumed based on item size, not on the amount of data that is returned to an application.

You cannot use both AttributesToGet and Select together in a Query request, unless the value for Select is SPECIFIC_ATTRIBUTES. (This usage is equivalent to specifying AttributesToGet without any value for Select.)

If you query a local secondary index and request only attributes that are projected into that index, the operation will read only the index and not the table. If any of the requested attributes are not projected into the local secondary index, DynamoDB will fetch each of these attributes from the parent table. This extra fetching incurs additional throughput cost and latency.

If you query a global secondary index, you can only request attributes that are projected into the index. Global secondary index queries cannot fetch attributes from the parent table.

- (string) –

  • **Limit** (integer) – The maximum number of items to evaluate (not necessarily the number of matching items). If DynamoDB processes the number of items up to the limit while processing the results, it stops the operation and returns the matching values up to that point, and a key in LastEvaluatedKey to apply in a subsequent operation, so that you can pick up where you left off. Also, if the processed data set size exceeds 1 MB before DynamoDB reaches this limit, it stops the operation and returns the matching values up to the limit, and a key in LastEvaluatedKey to apply in a subsequent operation to continue the operation. For more information, see Query and Scan in the Amazon DynamoDB Developer Guide.

  • **ConsistentRead** (boolean) – Determines the read consistency model: If set to true, then the operation uses strongly consistent reads; otherwise, the operation uses eventually consistent reads.

    Strongly consistent reads are not supported on global secondary indexes. If you query a global secondary index with ConsistentRead set to true, you will receive a ValidationException.

  • **KeyConditions** (dict) –

    The selection criteria for the query. For a query on a table, you can have conditions only on the table primary key attributes. You must provide the hash key attribute name and value as an EQ condition. You can optionally provide a second condition, referring to the range key attribute.

**Warning:** This is a legacy parameter, for backward compatibility. New applications should use KeyConditionExpression instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a ValidationException exception.

**Note:** If you don’t provide a range key condition, all of the items that match the hash key will be retrieved. If a FilterExpression or QueryFilter is present, it will be applied after the items are retrieved.
For a query on an index, you can have conditions only on the index key attributes. You must provide the index hash attribute name and value as an EQ condition. You can optionally provide a second condition, referring to the index key range attribute.

Each KeyConditions element consists of an attribute name to compare, along with the following:

- **AttributeValueList** - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the ComparisonOperator being used. For type Number, value comparisons are numeric. String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and a is greater than B. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters. For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- **ComparisonOperator** - A comparator for evaluating attributes, for example, equals, greater than, less than, and so on. For KeyConditions, only the following comparison operators are supported: EQ | LE | LT | GE | GT | BEGINS_WITH | BETWEEN. The following are descriptions of these comparison operators.

  - **EQ**: Equal. AttributeValueList can contain only one AttributeValue of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one specified in the request, the value does not match. For example, 
    ```
    {"S":"6"} does not equal {"N":"6"}.
    {"N":"6"} does not equal {"NS":["6","2","1"]}.
    ```

  - **LE**: Less than or equal. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, 
    ```
    {"S":"6"} does not equal {"N":"6"}.
    {"N":"6"} does not compare to {"NS":["6","2","1"]}.
    ```

  - **LT**: Less than. AttributeValueList can contain only one AttributeValue of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, 
    ```
    {"S":"6"} does not equal {"N":"6"}.
    {"N":"6"} does not compare to {"NS":["6","2","1"]}.
    ```

  - **GE**: Greater than or equal. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, 
    ```
    {"S":"6"} does not equal {"N":"6"}.
    {"N":"6"} does not compare to {"NS":["6","2","1"]}.
    ```

  - **GT**: Greater than. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, 
    ```
    {"S":"6"} does not equal {"N":"6"}.
    {"N":"6"} does not compare to {"NS":["6","2","1"]}.
    ```
Boto3 Documentation, Release 1.1.4

.
– BEGINS_WITH : Checks for a prefix. AttributeValueList can contain only one AttributeValue of type String or Binary (not a Number
or a set type). The target attribute of the comparison must be of type
String or Binary (not a Number or a set type).
– BETWEEN : Greater than or equal to the first value, and less than
or equal to the second value. AttributeValueList must contain two
AttributeValue elements of the same type, either String, Number, or
Binary (not a set type). A target attribute matches if the target value
is greater than, or equal to, the first element and less than, or equal
to, the second element. If an item contains an AttributeValue element of a different type than the one provided in the request, the
value does not match. For example, {"S":"6"} does not compare to {"N":"6"} . Also, {"N":"6"} does not compare to
{"NS":["6", "2", "1"]}
For usage examples of AttributeValueList and ComparisonOperator , see
Legacy Conditional Parameters in the Amazon DynamoDB Developer
Guide .
– (string) –
* (dict) –
Represents the selection criteria for a Query or Scan operation:
· For a Query operation, Condition is used for specifying
the KeyConditions to use when querying a table or an
index. For KeyConditions , only the following comparison operators are supported: EQ | LE | LT | GE
| GT | BEGINS_WITH | BETWEEN Condition is
also used in a QueryFilter , which evaluates the query
results and returns only the desired values.
· For a Scan operation, Condition is used in a ScanFilter
, which evaluates the scan results and returns only the
desired values.
· AttributeValueList (list) –
One or more values to evaluate against the supplied attribute. The number of values in the list depends on the
ComparisonOperator being used.
For type Number, value comparisons are numeric.
String value comparisons for greater than, equals,
or less than are based on ASCII character code
values. For example, a is greater than A , and a
is greater than B . For a list of code values, see
http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters
.
For Binary, DynamoDB treats each byte of the binary
data as unsigned when it compares binary values.
· (valid DynamoDB type) – - The value of the attribute.
The valid value types are listed in the DynamoDB Reference Guide.
· ComparisonOperator (string) – [REQUIRED]
A comparator for evaluating attributes. For example,

1044

Chapter 3. API Reference


equals, greater than, less than, etc.

The following comparison operators are available:

EQ | NE | LE | LT | GE | GT |
NOT_NULL | NULL | CONTAINS |
NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN

The following are descriptions of each comparison operator.

- **EQ**: Equal. EQ is supported for all datatypes, including lists and maps. AttributeValueList can contain only one AttributeValue element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{ "S": "6" \} does not equal \{ "N": "6" \}. Also, \{ "N": "6" \} does not equal \{ "NS": ["6", "2", "1"] \}.

- **NE**: Not equal. NE is supported for all datatypes, including lists and maps. AttributeValueList can contain only one AttributeValue of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an AttributeValue of a different type than the one provided in the request, the value does not match. For example, \{ "S": "6" \} does not equal \{ "N": "6" \}. Also, \{ "N": "6" \} does not equal \{ "NS": ["6", "2", "1"] \}.

- **LE**: Less than or equal. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{ "S": "6" \} does not equal \{ "N": "6" \}. Also, \{ "N": "6" \} does not compare to \{ "NS": ["6", "2", "1"] \}.

- **LT**: Less than. AttributeValueList can contain only one AttributeValue of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{ "S": "6" \} does not equal \{ "N": "6" \}. Also, \{ "N": "6" \} does not compare to \{ "NS": ["6", "2", "1"] \}.

- **GE**: Greater than or equal. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{ "S": "6" \} does not equal \{ "N": "6" \}. Also, \{ "N": "6" \} does not compare to \{ "NS": ["6", "2", "1"] \}.

- **GT**: Greater than. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an Attribute-
Value element of a different type than the one provided in the request, the value does not match. For example, 
{ "S" : "6" } does not equal { "N" : "6" } . Also, 
{ "N" : "6" } does not compare to { "NS" : [ "6", "2", "1"] } .

- **NOT_NULL**: The attribute exists. NOT_NULL is supported for all datatypes, including lists and maps. ..
ote:: This operator tests for the existence of an attribute, not its data type. If the data type of attribute 
"a " is null, and you evaluate it using NOT_NULL , the result is a Boolean true . This result is because the at-
tribute "a " exists; its data type is not relevant to the NOT_NULL comparison operator.

- **NULL**: The attribute does not exist. NULL is supported for all datatypes, including lists and maps. ..
ote:: This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute 
"a " is null, and you evaluate it using NULL , the result is a Boolean false . This is because the attribute "a " exists; its data type is not relevant to the NULL comparison operator.

- **CONTAINS**: Checks for a subsequence, or value in a set. AttributeValueList can contain only one Attribute-
Value element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS ", "NS ", or "BS "), then the operator evaluates to true if it finds an exact match with any member of the set. CONTAINS is supported for lists: When evaluating "a CONTAINS b ", "a " can be a list; however, "b " cannot be a set, a map, or a list.

- **NOT_CONTAINS**: Checks for absence of a subsequence, or absence of a value in a set. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS ", "NS ", or "BS "), then the operator evaluates to true if it does not find an exact match with any member of the set. NOT_CONTAINS is supported for lists: When evaluating "a NOT CONTAINS b ", "a " can be a list; however, "b " cannot be a set, a map, or a list.

- **BEGINS_WITH**: Checks for a prefix. AttributeValueList can contain only one AttributeValue of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).
IN: Checks for matching elements within two sets. `AttributeValueList` can contain one or more `AttributeValue` elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

BETWEEN: Greater than or equal to the first value, and less than or equal to the second value. `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{ "S": "6" }` does not compare to `{ "N": "6" }`. Also, `{ "N": "6" }` does not compare to `{ "NS": [ "6", "2", "1"] }`

For usage examples of `AttributeValueList` and `ComparisonOperator`, see Legacy Conditional Parameters in the Amazon DynamoDB Developer Guide.

**QueryFilter (dict)** –

A condition that evaluates the query results after the items are read and returns only the desired values.

This parameter does not support attributes of type List or Map.

**Note:** A `QueryFilter` is applied after the items have already been read; the process of filtering does not consume any additional read capacity units.

If you provide more than one condition in the `QueryFilter` map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the `ConditionalOperator` parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

Note that `QueryFilter` does not allow key attributes. You cannot define a filter condition on a hash key or range key.

Each `QueryFilter` element consists of an attribute name to compare, along with the following:

- `AttributeValueList` - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the operator specified in `ComparisonOperator`. For type Number, value comparisons are numeric. String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and a is greater than B. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters).
For type Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values. For information on specifying data types in JSON, see JSON Data Format in the Amazon DynamoDB Developer Guide.

- **ComparisonOperator** - A comparator for evaluating attributes. For example, equals, greater than, less than, etc. The following comparison operators are available: EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN

For complete descriptions of all comparison operators, see the Condition data type.

- (string) –
  - (dict) –

  Represents the selection criteria for a Query or Scan operation:

  - For a Query operation, Condition is used for specifying the KeyConditions to use when querying a table or an index. For KeyConditions, only the following comparison operators are supported: EQ | LE | LT | GE | GT | BEGINs_WITH | BETWEEN

  Condition is also used in a QueryFilter, which evaluates the query results and returns only the desired values.

  - For a Scan operation, Condition is used in a ScanFilter, which evaluates the scan results and returns only the desired values.

- **AttributeValueList** (list) – One or more values to evaluate against the supplied attribute. The number of values in the list depends on the ComparisonOperator being used.

For type Number, value comparisons are numeric.

String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and a is greater than B. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters).

For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- (valid DynamoDB type) – The value of the attribute. The valid value types are listed in the DynamoDB Reference Guide.

- **ComparisonOperator** (string) – [REQUIRED]

  A comparator for evaluating attributes. For example, equals, greater than, less than, etc.

  The following comparison operators are available:

  EQ | NE | LE | LT | GE | GT |
  NOT_NULL | NULL | CONTAINS |
  NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN
The following are descriptions of each comparison operator:

- **EQ**: Equal. EQ is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":["6", "2", "1"]}`.

- **NE**: Not equal. NE is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":["6", "2", "1"]}`.

- **LE**: Less than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- **LT**: Less than. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- **GE**: Greater than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- **GT**: Greater than. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- **NOT_NULL**: The attribute exists. NOT_NULL is supported for all datatypes, including lists and maps. .. note:: This operator tests for the existence of an at-
tribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using `NOT_NULL`, the result is a Boolean `true`. This result is because the attribute “a” exists; its data type is not relevant to the `NOT_NULL` comparison operator.

· **NULL**: The attribute does not exist. `NULL` is supported for all datatypes, including lists and maps. .. note:: This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using `NULL`, the result is a Boolean `false`. This is because the attribute “a” exists; its data type is not relevant to the `NULL` comparison operator.

· **CONTAINS**: Checks for a subsequence, or value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set (“SS”, “NS”, or “BS”), then the operator evaluates to true if it finds an exact match with any member of the set. `CONTAINS` is supported for lists: When evaluating “a CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

· **NOT_CONTAINS**: Checks for absence of a subsequence, or absence of a value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set (“SS”, “NS”, or “BS”), then the operator evaluates to true if it does not find an exact match with any member of the set. `NOT_CONTAINS` is supported for lists: When evaluating “a NOT CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

· **BEGINS_WITH**: Checks for a prefix. `AttributeValueList` can contain only one `AttributeValue` of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

· **IN**: Checks for matching elements within two sets. `AttributeValueList` can contain one or more `AttributeValue` elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

· **BETWEEN**: Greater than or equal to the first value,
and less than or equal to the second value. AttributeValueList must contain two AttributeValue elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, {"S":"6"} does not compare to {"N":"6"}. Also, {"N":"6"} does not compare to {"NS": ["6", "2", "1"]}.

For usage examples of AttributeValueList and ComparisonOperator, see Legacy Conditional Parameters in the Amazon DynamoDB Developer Guide.

• ConditionalOperator (string) –

A logical operator to apply to the conditions in a QueryFilter map:
  – **AND** - If all of the conditions evaluate to true, then the entire map evaluates to true.
  – **OR** - If at least one of the conditions evaluate to true, then the entire map evaluates to true.

If you omit ConditionalOperator, then **AND** is the default.

The operation will succeed only if the entire map evaluates to true.

**Note:** This parameter does not support attributes of type List or Map.

• ScanIndexForward (boolean) – Specifies the order in which to return the query results - either ascending (**true**) or descending (**false**).

Items with the same hash key are stored in sorted order by range key. If the range key data type is Number, the results are stored in numeric order. For type String, the results are returned in order of ASCII character code values. For type Binary, DynamoDB treats each byte of the binary data as unsigned.

If ScanIndexForward is **true**, DynamoDB returns the results in order, by range key. This is the default behavior.

If ScanIndexForward is **false**, DynamoDB sorts the results in descending order by range key, and then returns the results to the client.

• ExclusiveStartKey (dict) – The primary key of the first item that this operation will evaluate. Use the value that was returned for LastEvaluatedKey in the previous operation.

The data type for ExclusiveStartKey must be String, Number or Binary. No set data types are allowed.
  – **(string)** –
    * (valid DynamoDB type) – - The value of the attribute. The valid value types are listed in the DynamoDB Reference Guide.

• ReturnConsumedCapacity (string) – Determines the level of detail about
provisioned throughput consumption that is returned in the response:

- **INDEXES** - The response includes the aggregate ConsumedCapacity for the operation, together with ConsumedCapacity for each table and secondary index that was accessed. Note that some operations, such as GetItem and BatchGetItem, do not access any indexes at all. In these cases, specifying INDEXES will only return ConsumedCapacity information for table(s).
- **TOTAL** - The response includes only the aggregate ConsumedCapacity for the operation.
- **NONE** - No ConsumedCapacity details are included in the response.

- **ProjectionExpression** *(string)* – A string that identifies one or more attributes to retrieve from the table. These attributes can include scalars, sets, or elements of a JSON document. The attributes in the expression must be separated by commas.

If no attribute names are specified, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

For more information, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

**Note:** ProjectionExpression replaces the legacy AttributesToGet parameter.

- **FilterExpression** *(condition from boto3.dynamodb.conditions.Attr method)* – The condition(s) an attribute(s) must meet. Valid conditions are listed in the DynamoDB Reference Guide.
- **KeyConditionExpression** *(condition from boto3.dynamodb.conditions.Key method)* – The condition(s) a key(s) must meet. Valid conditions are listed in the DynamoDB Reference Guide.
- **ExpressionAttributeNames** *(dict)* – One or more substitution tokens for attribute names in an expression. The following are some use cases for using ExpressionAttributeNames:
  - To access an attribute whose name conflicts with a DynamoDB reserved word.
  - To create a placeholder for repeating occurrences of an attribute name in an expression.
  - To prevent special characters in an attribute name from being misinterpreted in an expression.

Use the # character in an expression to dereference an attribute name. For example, consider the following attribute name:

- **Percentile**

The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see Reserved Words in the Amazon DynamoDB Developer Guide.) To work around this, you could specify the following for ExpressionAttributeNames:

- {"#P":"Percentile"}

You could then use this substitution in an expression, as in this example:

- #P = :val

**Note:** Tokens that begin with the : character are expression attribute values, which are placeholders for the actual value at runtime.
For more information on expression attribute names, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

- (string) –
  * (string) –

• ExpressionAttributeValues (dict) – One or more values that can be substituted in an expression.

Use the : (colon) character in an expression to dereference an attribute value. For example, suppose that you wanted to check whether the value of the ProductStatus attribute was one of the following:

Available | Backordered | Discontinued

You would first need to specify ExpressionAttributeValues as follows:

```json
{ "avail" : {"S":"Available"},
  "back" : {"S":"Backordered"},
  "disc" : {"S":"Discontinued"} }
```

You could then use these values in an expression, such as this:

```python
ProductStatus IN (:avail, :back, :disc)
```

For more information on expression attribute values, see Specifying Conditions in the Amazon DynamoDB Developer Guide.

- (string) –
  * (valid DynamoDB type) – The value of the attribute. The valid value types are listed in the DynamoDB Reference Guide.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
  'Items': [
    {
      'string': 'string'|123|Binary(b'bytes')|True|None|set({'string'})
    },
  ],
  'Count': 123,
  'ScannedCount': 123,
  'LastEvaluatedKey': {
    'string': 'string'|123|Binary(b'bytes')|True|None|set({'string'})|set
  },
  'ConsumedCapacity': {
    'TableName': 'string',
    'CapacityUnits': 123.0,
    'Table': {
      'CapacityUnits': 123.0
    },
    'LocalSecondaryIndexes': {
      'string': {
        'CapacityUnits': 123.0
      }
    },
    'GlobalSecondaryIndexes': {
      'string': {
        'CapacityUnits': 123.0
      }
    }
  }
}
```
Response Structure

- **(dict)** – 

  Represents the output of a *Query* operation.

  - **Items (list)** – 

    An array of item attributes that match the query criteria. Each element in this array consists of an attribute name and the value for that attribute.

    - **(dict)** – 
      
      - **(string)** – 
      
      - **(valid DynamoDB type)** – The value of the attribute.

      The valid value types are listed in the *DynamoDB Reference Guide*.

  - **Count (integer)** – 

    The number of items in the response.

    If you used a *QueryFilter* in the request, then *Count* is the number of items returned after the filter was applied, and *ScannedCount* is the number of matching items before the filter was applied.

    If you did not use a filter in the request, then *Count* and *ScannedCount* are the same.

  - **ScannedCount (integer)** – 

    The number of items evaluated, before any *QueryFilter* is applied. A high *ScannedCount* value with few, or no, *Count* results indicates an inefficient *Query* operation. For more information, see Count and ScannedCount in the *Amazon DynamoDB Developer Guide*.

    If you did not use a filter in the request, then *ScannedCount* is the same as *Count*.

  - **LastEvaluatedKey (dict)** – 

    The primary key of the item where the operation stopped, inclusive of the previous result set. Use this value to start a new operation, excluding this value in the new request.

    If *LastEvaluatedKey* is empty, then the “last page” of results has been processed and there is no more data to be retrieved.

    If *LastEvaluatedKey* is not empty, it does not necessarily mean that there is more data in the result set. The only way to know when you have reached the end of the result set is when *LastEvaluatedKey* is empty.

    - **(string)** – 
      
      - **(valid DynamoDB type)** – The value of the attribute.

      The valid value types are listed in the *DynamoDB Reference Guide*.

  - **ConsumedCapacity (dict)** – 

    The capacity units consumed by an operation. The data returned includes the total provisioned throughput consumed, along with statistics for the table and any indexes involved in the operation.
ConsumedCapacity is only returned if the request asked for it. For more information, see Provisioned Throughput in the Amazon DynamoDB Developer Guide.

* **TableName** (string) –
  The name of the table that was affected by the operation.

* **CapacityUnits** (float) –
  The total number of capacity units consumed by the operation.

* **Table** (dict) –
  The amount of throughput consumed on the table affected by the operation.
  - **CapacityUnits** (float) –
    The total number of capacity units consumed on a table or an index.

* **LocalSecondaryIndexes** (dict) –
  The amount of throughput consumed on each local index affected by the operation.
  - *(string)* –
  - *(dict)* –
    Represents the amount of provisioned throughput capacity consumed on a table or an index.
  - **CapacityUnits** (float) –
    The total number of capacity units consumed on a table or an index.

* **GlobalSecondaryIndexes** (dict) –
  The amount of throughput consumed on each global index affected by the operation.
  - *(string)* –
  - *(dict)* –
    Represents the amount of provisioned throughput capacity consumed on a table or an index.
  - **CapacityUnits** (float) –
    The total number of capacity units consumed on a table or an index.

**reload()**
Calls dynamodb.Client.describe_table() to update the attributes of the Table resource

**Request Syntax**

    table.reload()

**Returns** None

**scan(**kwargs**)**
The Scan operation returns one or more items and item attributes by accessing every item in a table or a secondary index. To have DynamoDB return fewer items, you can provide a ScanFilter operation.

If the total number of scanned items exceeds the maximum data set size limit of 1 MB, the scan stops and results are returned to the user as a LastEvaluatedKey value to continue the scan in a
subsequent operation. The results also include the number of items exceeding the limit. A scan can result in no table data meeting the filter criteria.

By default, Scan operations proceed sequentially; however, for faster performance on a large table or secondary index, applications can request a parallel Scan operation by providing the Segment and TotalSegments parameters. For more information, see Parallel Scan in the Amazon DynamoDB Developer Guide.

By default, Scan uses eventually consistent reads when accessing the data in the table or local secondary index. However, you can use strongly consistent reads instead by setting the ConsistentRead parameter to true.

**Request Syntax**

```python
response = table.scan(
    IndexName='string',
    AttributesToGet=['string'],
    Limit=123,
    Select='ALL_ATTRIBUTES'|'ALL_PROJECTED_ATTRIBUTES'|'SPECIFIC_ATTRIBUTES'|'COUNT',
    ScanFilter={
        'string': {
            'AttributeValueList': [
                'string'|123|Binary(b'bytes')|True|None|set(['string'])|set([123])|set([Binary(b'bytes')])|[]|{}
            ],
            'ComparisonOperator': 'EQ'|'NE'|'IN'|'LE'|'LT'|'GE'|'GT'|'BETWEEN'|'NOT_NULL'|'NULL'|'CONTAINS'|'NOT_CONTAINS'|'BEGINS_WITH'
        }
    },
    ConditionalOperator='AND'|'OR',
    ExclusiveStartKey={
        'string': 'string'|123|Binary(b'bytes')|True|None|set(['string'])|set([123])|set([Binary(b'bytes')])|[]|{}
    },
    ReturnConsumedCapacity='INDEXES'|'TOTAL'|'NONE',
    TotalSegments=123,
    Segment=123,
    ProjectionExpression='string',
    FilterExpression=Attr('myattribute').eq('myvalue'),
    ExpressionAttributeNames={
        'string': 'string'
    },
    ExpressionAttributeValues={
        'string': 'string'|123|Binary(b'bytes')|True|None|set(['string'])|set([123])|set([Binary(b'bytes')])|[]|{}
    },
    ConsistentRead=True|False
)
```

**Parameters**

- **IndexName** (*string*) – The name of a secondary index to scan. This index can be any local secondary index or global secondary index. Note that if you use the IndexName parameter, you must also provide TableName.
• **AttributesToGet** *(list)* –

The names of one or more attributes to retrieve. If no attribute names are provided, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

Note that **AttributesToGet** has no effect on provisioned throughput consumption. DynamoDB determines capacity units consumed based on item size, not on the amount of data that is returned to an application.

  - *(string)*

• **Limit** *(integer)* – The maximum number of items to evaluate (not necessarily the number of matching items). If DynamoDB processes the number of items up to the limit while processing the results, it stops the operation and returns the matching values up to that point, and a key in *LastEvaluatedKey* to apply in a subsequent operation, so that you can pick up where you left off. Also, if the processed data set size exceeds 1 MB before DynamoDB reaches this limit, it stops the operation and returns the matching values up to the limit, and a key in *LastEvaluatedKey* to apply in a subsequent operation to continue the operation. For more information, see **Query and Scan** in the Amazon DynamoDB Developer Guide.

• **Select** *(string)* – The attributes to be returned in the result. You can retrieve all item attributes, specific item attributes, or the count of matching items.

  - **ALL_ATTRIBUTES** - Returns all of the item attributes.
  - **COUNT** - Returns the number of matching items, rather than the matching items themselves.
  - **SPECIFIC_ATTRIBUTES** - Returns only the attributes listed in **AttributesToGet**. This return value is equivalent to specifying **AttributesToGet** without specifying any value for **Select**.

If neither **Select** nor **AttributesToGet** are specified, DynamoDB defaults to **ALL_ATTRIBUTES**. You cannot use both **AttributesToGet** and **Select** together in a single request, unless the value for **Select** is **SPECIFIC_ATTRIBUTES**. (This usage is equivalent to specifying **AttributesToGet** without any value for **Select**.)

• **ScanFilter** *(dict)* –

A condition that evaluates the scan results and returns only the desired values.

**Note:** This parameter does not support attributes of type List or Map.

If you specify more than one condition in the **ScanFilter** map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the **ConditionalOperator** parameter to OR the conditions instead. If you do this, then at least one of

---

**Warning:** This is a legacy parameter, for backward compatibility. New applications should use **ProjectionExpression** instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a **ValidationException** exception.

This parameter allows you to retrieve attributes of type List or Map; however, it cannot retrieve individual elements within a List or a Map.
the conditions must evaluate to true, rather than all of them.)

Each ScanFilter element consists of an attribute name to compare, along with the following:

- **AttributeValueList** - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the operator specified in **ComparisonOperator**. For type Number, value comparisons are numeric. String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and a is greater than B. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters). For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values. For information on specifying data types in JSON, see [JSON Data Format](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters) in the Amazon DynamoDB Developer Guide.

- **ComparisonOperator** - A comparator for evaluating attributes. For example, equals, greater than, less than, etc. The following comparison operators are available: EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN For complete descriptions of all comparison operators, see [Condition](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters).

- **(string)**

* (dict) –

Represents the selection criteria for a Query or Scan operation:

- For a Query operation, **Condition** is used for specifying the **KeyConditions** to use when querying a table or an index. For KeyConditions, only the following comparison operators are supported: EQ | LE | LT | GE | GT | BEGINS_WITH | BETWEEN **Condition** is also used in a QueryFilter, which evaluates the query results and returns only the desired values.

- For a Scan operation, **Condition** is used in a ScanFilter, which evaluates the scan results and returns only the desired values.

- **AttributeValueList** (list) –

One or more values to evaluate against the supplied attribute. The number of values in the list depends on the **ComparisonOperator** being used.

For type Number, value comparisons are numeric.

String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and a is greater than B. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters).

For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- (valid DynamoDB type) – The value of the attribute. The valid value types are listed in the [DynamoDB Ref-](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters)
A comparator for evaluating attributes. For example, equals, greater than, less than, etc.

The following comparison operators are available:

- **EQ**: Equal. EQ is supported for all datatypes, including lists and maps. AttributeValueList can contain only one AttributeValue element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not equal \{"NS": ["6", "2", "1"]\}.

- **NE**: Not equal. NE is supported for all datatypes, including lists and maps. AttributeValueList can contain only one AttributeValue of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an AttributeValue of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not equal \{"NS": ["6", "2", "1"]\}.

- **LE**: Less than or equal. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not compare to \{"NS": ["6", "2", "1"]\}.

- **LT**: Less than. AttributeValueList can contain only one AttributeValue of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not compare to \{"NS": ["6", "2", "1"]\}.

- **GE**: Greater than or equal. AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not compare to \{"NS": ["6", "2", "1"]\}.

- **BETWEEN**: AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not compare to \{"NS": ["6", "2", "1"]\}.

- **NOT_NULL**: Not null. NOT_NULL is supported for all datatypes, including lists and maps. AttributeValueList can contain only one AttributeValue element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not equal \{"NS": ["6", "2", "1"]\}.

- **NULL**: Null. NULL is supported for all datatypes, including lists and maps. AttributeValueList can contain only one AttributeValue element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not equal \{"NS": ["6", "2", "1"]\}.

- **CONTAINS**: Contains. CONTAINS is supported for all datatypes, including lists and maps. AttributeValueList can contain only one AttributeValue element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not equal \{"NS": ["6", "2", "1"]\}.

- **NOT_CONTAINS**: Not contains. NOT_CONTAINS is supported for all datatypes, including lists and maps. AttributeValueList can contain only one AttributeValue element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not equal \{"NS": ["6", "2", "1"]\}.

- **BEGINS_WITH**: Begins with. BEGINS_WITH is supported for all datatypes, including lists and maps. AttributeValueList can contain only one AttributeValue element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not equal \{"NS": ["6", "2", "1"]\}.

- **IN**: In. IN is supported for all datatypes, including lists and maps. AttributeValueList can contain only one AttributeValue element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not equal \{"N": "6"\}. Also, \{"N": "6"\} does not equal \{"NS": ["6", "2", "1"]\}.
· **GT**: Greater than. *AttributeValueList* can contain only one *AttributeValue* element of type String, Number, or Binary (not a set type). If an item contains an *AttributeValue* element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not equal `{"N": "6"}`. Also, `{"N": "6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

· **NOT_NULL**: The attribute exists. **NOT_NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the existence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NOT_NULL**, the result is a Boolean **true**. This result is because the attribute “a” exists; its data type is not relevant to the **NOT_NULL** comparison operator.

· **NULL**: The attribute does not exist. **NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NULL**, the result is a Boolean **false**. This is because the attribute “a” exists; its data type is not relevant to the **NULL** comparison operator.

· **CONTAINS**: Checks for a subsequence, or value in a set. *AttributeValueList* can contain only one *AttributeValue* element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it finds an exact match with any member of the set. **CONTAINS** is supported for lists: When evaluating “a CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

· **NOT_CONTAINS**: Checks for absence of a subsequence, or absence of a value in a set. *AttributeValueList* can contain only one *AttributeValue* element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it does not find an exact match with any member of the set. **NOT_CONTAINS** is supported for lists: When evaluating “a NOT CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

· **BEGINS_WITH**: Checks for a prefix. *AttributeValueList* can contain only one *AttributeValue* of type
String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- **IN**: Checks for matching elements within two sets. `AttributeValueList` can contain one or more `AttributeValue` elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

- **BETWEEN**: Greater than or equal to the first value, and less than or equal to the second value. `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not compare to `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6","2","1"]}`.

For usage examples of `AttributeValueList` and `ComparisonOperator`, see Legacy Conditional Parameters in the Amazon DynamoDB Developer Guide.

- **ConditionalOperator (string)** –

A logical operator to apply to the conditions in a `ScanFilter` map:
- **AND** - If all of the conditions evaluate to true, then the entire map evaluates to true.
- **OR** - If at least one of the conditions evaluate to true, then the entire map evaluates to true.

If you omit `ConditionalOperator`, then **AND** is the default.

The operation will succeed only if the entire map evaluates to true.

**Note**: This parameter does not support attributes of type List or Map.

- **ExclusiveStartKey (dict)** – The primary key of the first item that this operation will evaluate. Use the value that was returned for `LastEvaluatedKey` in the previous operation.

The data type for `ExclusiveStartKey` must be String, Number or Binary. No set data types are allowed.

In a parallel scan, a `Scan` request that includes `ExclusiveStartKey` must specify the same segment whose previous `Scan` returned the corresponding value of `LastEvaluatedKey`.

- **(string)** –
  - **(valid DynamoDB type)** - The value of the attribute. The valid value types are listed in the *DynamoDB Reference*. 

**Warning**: This is a legacy parameter, for backward compatibility. New applications should use `FilterExpression` instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a `ValidationException` exception.
• **ReturnConsumedCapacity** *(string)* – Determines the level of detail about provisioned throughput consumption that is returned in the response:
  
  - **INDEXES** - The response includes the aggregate ConsumedCapacity for the operation, together with ConsumedCapacity for each table and secondary index that was accessed. Note that some operations, such as GetItem and BatchGetItem, do not access any indexes at all. In these cases, specifying INDEXES will only return ConsumedCapacity information for table(s).
  
  - **TOTAL** - The response includes only the aggregate ConsumedCapacity for the operation.
  
  - **NONE** - No ConsumedCapacity details are included in the response.

• **TotalSegments** *(integer)* – For a parallel Scan request, TotalSegments represents the total number of segments into which the Scan operation will be divided. The value of TotalSegments corresponds to the number of application workers that will perform the parallel scan. For example, if you want to use four application threads to scan a table or an index, specify a TotalSegments value of 4.

  The value for TotalSegments must be greater than or equal to 1, and less than or equal to 1000000. If you specify a TotalSegments value of 1, the Scan operation will be sequential rather than parallel.

  If you specify TotalSegments, you must also specify Segment.

• **Segment** *(integer)* – For a parallel Scan request, Segment identifies an individual segment to be scanned by an application worker.

  Segment IDs are zero-based, so the first segment is always 0. For example, if you want to use four application threads to scan a table or an index, then the first thread specifies a Segment value of 0, the second thread specifies 1, and so on.

  The value of LastEvaluatedKey returned from a parallel Scan request must be used as ExclusiveStartKey with the same segment ID in a subsequent Scan operation.

  The value for Segment must be greater than or equal to 0, and less than the value provided for TotalSegments.

  If you provide Segment, you must also provide TotalSegments.

• **ProjectionExpression** *(string)* – A string that identifies one or more attributes to retrieve from the specified table or index. These attributes can include scalars, sets, or elements of a JSON document. The attributes in the expression must be separated by commas.

  If no attribute names are specified, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

  For more information, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

  **Note:** ProjectionExpression replaces the legacy AttributesToGet parameter.

• **FilterExpression** *(condition from boto3.dynamodb.conditions.Attr method)* – The condition(s) an attribute(s) must meet. Valid conditions are listed in the DynamoDB Reference Guide.
• **ExpressionAttributeNames** *(dict)* – One or more substitution tokens for attribute names in an expression. The following are some use cases for using `ExpressionAttributeNames`:
  - To access an attribute whose name conflicts with a DynamoDB reserved word.
  - To create a placeholder for repeating occurrences of an attribute name in an expression.
  - To prevent special characters in an attribute name from being misinterpreted in an expression.

Use the `#` character in an expression to dereference an attribute name. For example, consider the following attribute name:

- `Percentile`

The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see Reserved Words in the *Amazon DynamoDB Developer Guide*.) To work around this, you could specify the following for `ExpressionAttributeNames`:

- `{"#P": "Percentile"}`

You could then use this substitution in an expression, as in this example:

- `#P = :val`

**Note:** Tokens that begin with the `:` character are *expression attribute values*, which are placeholders for the actual value at runtime.

For more information on expression attribute names, see Accessing Item Attributes in the *Amazon DynamoDB Developer Guide*.

- *(string)* – *

• **ExpressionAttributeValues** *(dict)* – One or more values that can be substituted in an expression.

Use the `:` (colon) character in an expression to dereference an attribute value. For example, suppose that you wanted to check whether the value of the `ProductStatus` attribute was one of the following:

`Available | Backordered | Discontinued`

You would first need to specify `ExpressionAttributeValues` as follows:

```
{ "avail":{"S":"Available"},
 "back":{"S":"Backordered"},
 "disc":{"S":"Discontinued"} }
```

You could then use these values in an expression, such as this:

```
ProductStatus IN (:avail, :back, :disc)
```

For more information on expression attribute values, see Specifying Conditions in the *Amazon DynamoDB Developer Guide*.

- *(string)* – *

• **ConsistentRead** *(boolean)* – A Boolean value that determines the read consistency model during the scan:

  - If `ConsistentRead` is `false`, then `Scan` will use eventually consistent reads. The data returned from `Scan` might not contain the results...
of other recently completed write operations (PutItem, UpdateItem or DeleteItem). The Scan response might include some stale data.

- If ConsistentRead is true, then Scan will use strongly consistent reads. All of the write operations that completed before the Scan began are guaranteed to be contained in the Scan response.

The default setting for ConsistentRead is false, meaning that eventually consistent reads will be used.

Strongly consistent reads are not supported on global secondary indexes. If you scan a global secondary index with ConsistentRead set to true, you will receive a ValidationException.

Return type dict

Returns

**Response Syntax**

```python
{
    'Items': [
        {
            'string': 'string'|123|Binary(b'bytes')|True|None|set([string])
        },
    ],
    'Count': 123,
    'ScannedCount': 123,
    'LastEvaluatedKey': {
        'string': 'string'|123|Binary(b'bytes')|True|None|set([string])|set()
    },
    'ConsumedCapacity': {
        'TableName': 'string',
        'CapacityUnits': 123.0,
        'Table': {
            'CapacityUnits': 123.0
        },
        'LocalSecondaryIndexes': {
            'string': {
                'CapacityUnits': 123.0
            }
        },
        'GlobalSecondaryIndexes': {
            'string': {
                'CapacityUnits': 123.0
            }
        }
    }
}
```

**Response Structure**

- (dict) – Represents the output of a Scan operation.
  - **Items** (list) – An array of item attributes that match the scan criteria. Each element in this array consists of an attribute name and the value for that attribute.
    - (dict) –
      - (string) –
The valid value types are listed in the *DynamoDB Reference Guide*.

- **Count** (integer)

  The number of items in the response.

  If you set `ScanFilter` in the request, then `Count` is the number of items returned after the filter was applied, and `ScannedCount` is the number of matching items before the filter was applied.

  If you did not use a filter in the request, then `Count` is the same as `ScannedCount`.

- **ScannedCount** (integer)

  The number of items evaluated, before any `ScanFilter` is applied. A high `ScannedCount` value with few, or no, `Count` results indicates an inefficient `Scan` operation. For more information, see *Count and ScannedCount* in the *Amazon DynamoDB Developer Guide*.

  If you did not use a filter in the request, then `ScannedCount` is the same as `Count`.

- **LastEvaluatedKey** (dict)

  The primary key of the item where the operation stopped, inclusive of the previous result set. Use this value to start a new operation, excluding this value in the new request.

  If `LastEvaluatedKey` is empty, then the “last page” of results has been processed and there is no more data to be retrieved.

  If `LastEvaluatedKey` is not empty, it does not necessarily mean that there is more data in the result set. The only way to know when you have reached the end of the result set is when `LastEvaluatedKey` is empty.

  * (string) –

    - **(valid DynamoDB type)** – The value of the attribute.

    The valid value types are listed in the *DynamoDB Reference Guide*.

- **ConsumedCapacity** (dict)

  The capacity units consumed by an operation. The data returned includes the total provisioned throughput consumed, along with statistics for the table and any indexes involved in the operation. `ConsumedCapacity` is only returned if the request asked for it. For more information, see *Provisioned Throughput* in the *Amazon DynamoDB Developer Guide*.

  * **TableName** (string) –

    The name of the table that was affected by the operation.

  * **CapacityUnits** (float) –

    The total number of capacity units consumed by the operation.

  * **Table** (dict) –

    The amount of throughput consumed on the table affected by the operation.

    - **CapacityUnits** (float) –
The total number of capacity units consumed on a table or an index.

- **LocalSecondaryIndexes (dict)** –
  The amount of throughput consumed on each local index affected by the operation.
  - *(string)* –
  - *(dict)* –
    Represents the amount of provisioned throughput capacity consumed on a table or an index.
    - **CapacityUnits (float)** –
      The total number of capacity units consumed on a table or an index.

- **GlobalSecondaryIndexes (dict)** –
  The amount of throughput consumed on each global index affected by the operation.
  - *(string)* –
  - *(dict)* –
    Represents the amount of provisioned throughput capacity consumed on a table or an index.
    - **CapacityUnits (float)** –
      The total number of capacity units consumed on a table or an index.

**update (**kwargs**)**

Modifies the provisioned throughput settings, global secondary indexes, or DynamoDB Streams settings for a given table.

You can only perform one of the following operations at once:
- Modify the provisioned throughput settings of the table.
- Enable or disable Streams on the table.
- Remove a global secondary index from the table.
- Create a new global secondary index on the table. Once the index begins backfilling, you can use `UpdateTable` to perform other operations.

`UpdateTable` is an asynchronous operation; while it is executing, the table status changes from ACTIVE to UPDATING. While it is UPDATING, you cannot issue another `UpdateTable` request. When the table returns to the ACTIVE state, the `UpdateTable` operation is complete.

**Request Syntax**

```python
table = table.update(
    AttributeDefinitions=[
        {
            'AttributeName': 'string',
            'AttributeType': 'S'|'N'|'B'
        },
    ],
    ProvisionedThroughput={
        'ReadCapacityUnits': 123,
        'WriteCapacityUnits': 123
    },
    GlobalSecondaryIndexUpdates=[
        {
            'Update': {
```
Parameters

- **AttributeDefinitions** (list) – An array of attributes that describe the key schema for the table and indexes. If you are adding a new global secondary index to the table, *AttributeDefinitions* must include the key element(s) of the new index.
  - *(dict)* –
    - Represents an attribute for describing the key schema for the table and indexes.
      - **AttributeName** (string) – [REQUIRED]
        - A name for the attribute.
      - **AttributeType** (string) – [REQUIRED]
        - The data type for the attribute.

- **ProvisionedThroughput** (dict) – Represents the provisioned throughput settings for a specified table or index. The settings can be modified using the *UpdateTable* operation.

  For current minimum and maximum provisioned throughput values, see *Limits* in the *Amazon DynamoDB Developer Guide*.  
  - **ReadCapacityUnits** (integer) – [REQUIRED]
The maximum number of strongly consistent reads consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see Specifying Read and Write Requirements in the Amazon DynamoDB Developer Guide.

- **WriteCapacityUnits** (integer) – [REQUIRED]
  
  The maximum number of writes consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see Specifying Read and Write Requirements in the Amazon DynamoDB Developer Guide.

- **GlobalSecondaryIndexUpdates** (list) – An array of one or more global secondary indexes for the table. For each index in the array, you can request one action:
  - **Create** - add a new global secondary index to the table.
  - **Update** - modify the provisioned throughput settings of an existing global secondary index.
  - **Delete** - remove a global secondary index from the table.

For more information, see Managing Global Secondary Indexes in the Amazon DynamoDB Developer Guide.

- **Update**(dict) –

  Represents one of the following:
  - A new global secondary index to be added to an existing table.
  - New provisioned throughput parameters for an existing global secondary index.
  - An existing global secondary index to be removed from an existing table.

- **GlobalSecondaryIndexUpdates** (list) – An array of one or more global secondary indexes for the table. For each index in the array, you can request one action:
  - **Create** - add a new global secondary index to the table.
  - **Update** - modify the provisioned throughput settings of an existing global secondary index.
  - **Delete** - remove a global secondary index from the table.

For more information, see Managing Global Secondary Indexes in the Amazon DynamoDB Developer Guide.

- **Update**(dict) –

  The name of an existing global secondary index, along with new provisioned throughput settings to be applied to that index.

  - **IndexName** (string) – [REQUIRED]
    
    The name of the global secondary index to be updated.

  - **ProvisionedThroughput** (dict) – [REQUIRED]
    
    Represents the provisioned throughput settings for a specified table or index. The settings can be modified using the `UpdateTable` operation.

    For current minimum and maximum provisioned throughput values, see Limits in the Amazon DynamoDB Developer Guide.

  - **ReadCapacityUnits** (integer) – [REQUIRED]
    
    The maximum number of strongly consistent reads consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see Specifying Read and Write Requirements in the Amazon DynamoDB Developer Guide.

  - **WriteCapacityUnits** (integer) – [REQUIRED]
    
    The maximum number of writes consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see Specifying Read and Write Requirements in the Amazon DynamoDB Developer Guide.
Guide.

* Create (dict) –

The parameters required for creating a global secondary index on an existing table:
- IndexName
- KeySchema
- AttributeDefinitions
- Projection
- ProvisionedThroughput

- **IndexName** (string) – [REQUIRED]
  The name of the global secondary index to be created.

- **KeySchema** (list) – [REQUIRED]
  The key schema for the global secondary index.

  - **(dict)** –
    Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

    A KeySchemaElement represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one KeySchemaElement. A hash-and-range type primary key would require one KeySchemaElement for the hash attribute, and another KeySchemaElement for the range attribute.

- **AttributeName** (string) – [REQUIRED]
  The name of a key attribute.

- **KeyType** (string) – [REQUIRED]
  The attribute data, consisting of the data type and the attribute value itself.

- **Projection** (dict) – [REQUIRED]
  Represents attributes that are copied (projected) from the table into an index. These are in addition to the primary key attributes and index key attributes, which are automatically projected.

  - **ProjectionType** (string) –
    The set of attributes that are projected into the index:

    - **KEYS_ONLY** - Only the index and primary keys are projected into the index.
    - **INCLUDE** - Only the specified table attributes are projected into the index. The list of projected attributes are in NonKeyAttributes.
    - **ALL** - All of the table attributes are projected into the index.

- **NonKeyAttributes** (list) –
  Represents the non-key attribute names which will be projected into the index.

For local secondary indexes, the total count of NonKeyAttributes summed across all of the local secondary indexes, must not exceed 20. If you project the same
attribute into two different indexes, this counts as two distinct attributes when determining the total.

- (string) –
- **ProvisionedThroughput** (dict) – [REQUIRED]

  Represents the provisioned throughput settings for a specified table or index. The settings can be modified using the `UpdateTable` operation.

  For current minimum and maximum provisioned throughput values, see [Limits in the Amazon DynamoDB Developer Guide](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/).

- **ReadCapacityUnits** (integer) – [REQUIRED]

  The maximum number of strongly consistent reads consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see [Specifying Read and Write Requirements](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/) in the Amazon DynamoDB Developer Guide.

- **WriteCapacityUnits** (integer) – [REQUIRED]

  The maximum number of writes consumed per second before DynamoDB returns a `ThrottlingException`. For more information, see [Specifying Read and Write Requirements](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/) in the Amazon DynamoDB Developer Guide.

- **Delete** (dict) –

  The name of an existing global secondary index to be removed.

- **IndexName** (string) – [REQUIRED]

  The name of the global secondary index to be deleted.

- **StreamSpecification** (dict) – Represents the DynamoDB Streams configuration for the table.

  - **StreamEnabled** (boolean) –

    Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.

  - **StreamViewType** (string) –

    The DynamoDB Streams settings for the table. These settings consist of:

    - **StreamEnabled** - Indicates whether DynamoDB Streams is enabled (true) or disabled (false) on the table.

    - **StreamViewType** - When an item in the table is modified, `StreamViewType` determines what information is written to the stream for this table. Valid values for `StreamViewType` are:

      - **KEYS_ONLY** - Only the key attributes of the modified item are written to the stream.

      - **NEW_IMAGE** - The entire item, as it appears after it was modified, is written to the stream.
OLD_IMAGE - The entire item, as it appeared before it was modified, is written to the stream.

NEW_AND_OLD_IMAGES - Both the new and the old item images of the item are written to the stream.

Return type  dynamodb.Table
Returns  Table resource

update_item(**kwargs)

Edits an existing item's attributes, or adds a new item to the table if it does not already exist. You can put, delete, or add attribute values. You can also perform a conditional update on an existing item (insert a new attribute name-value pair if it doesn’t exist, or replace an existing name-value pair if it has certain expected attribute values). If conditions are specified and the item does not exist, then the operation fails and a new item is not created.

You can also return the item’s attribute values in the same UpdateItem operation using the ReturnValues parameter.

Request Syntax

```python
response = table.update_item(
    Key={
        'string': 'string'|123|Binary(b'bytes')|True|None|set(['string'])|set([123])|set([Binary(b'bytes')])|
    },
    AttributeUpdates={
        'string': {
            'Value': 'string'|123|Binary(b'bytes')|True|None|set(['string'])|set([123])|set([Binary(b'bytes')])|
            'Action': 'ADD'|'PUT'|'DELETE'
        }
    },
    Expected={
        'string': {
            'Value': 'string'|123|Binary(b'bytes')|True|None|set(['string'])|set([123])|set([Binary(b'bytes')])|
            'Exists': True|False,
            'ComparisonOperator': 'EQ'|'NE'|'IN'|'LE'|'LT'|'GE'|'GT'|'BETWEEN'|'NOT_NULL'|'NULL'|'CONTAINS'|'NOT_CONTAINS'|'BEGINS_WITH',
            'AttributeValueList': [
            'string'|123|Binary(b'bytes')|True|None|set(['string'])|set([123])|set([Binary(b'bytes')])|
            ]
        }
    },
    ConditionalOperator='AND'|'OR',
    ReturnValues='NONE'|'ALL_OLD'|'UPDATED_OLD'|'ALL_NEW'|'UPDATED_NEW',
    ReturnConsumedCapacity='INDEXES'|'TOTAL'|'NONE',
    ReturnItemCollectionMetrics='SIZE'|'NONE',
    UpdateExpression='string',
    ConditionExpression=Attr('myattribute').eq('myvalue'),
    ExpressionAttributeNames={
        'string': 'string'
    },
    ExpressionAttributeValues={
        'string': 'string'|123|Binary(b'bytes')|True|None|set(['string'])|set([123])|set([Binary(b'bytes')])|
    }
)
```

Parameters

- **Key (dict)** – [REQUIRED]

  The primary key of the item to be updated. Each element consists of an attribute name and a value for that attribute.
For the primary key, you must provide all of the attributes. For example, with a hash type primary key, you only need to provide the hash attribute. For a hash-and-range type primary key, you must provide both the hash attribute and the range attribute.

- (string) –

  * (valid DynamoDB type) – - The value of the attribute. The valid value types are listed in the DynamoDB Reference Guide.

- AttributeUpdates (dict) –

The names of attributes to be modified, the action to perform on each, and the new value for each. If you are updating an attribute that is an index key attribute for any indexes on that table, the attribute type must match the index key type defined in the AttributesDefinition of the table description. You can use UpdateItem to update any nonkey attributes.

Attribute values cannot be null. String and Binary type attributes must have lengths greater than zero. Set type attributes must not be empty. Requests with empty values will be rejected with a ValidationException exception.

Each AttributeUpdates element consists of an attribute name to modify, along with the following:

- Value - The new value, if applicable, for this attribute.

- Action - A value that specifies how to perform the update. This action is only valid for an existing attribute whose data type is Number or is a set; do not use ADD for other data types. If an item with the specified primary key is found in the table, the following values perform the following actions:

  - PUT - Adds the specified attribute to the item. If the attribute already exists, it is replaced by the new value.

  - DELETE - Removes the attribute and its value, if no value is specified for DELETE. The data type of the specified value must match the existing value’s data type. If a set of values is specified, then those values are subtracted from the old set. For example, if the attribute value was the set \([a, b, c]\) and the DELETE action specifies \([a, c]\), then the final attribute value is \([b]\). Specifying an empty set is an error.

  - ADD - Adds the specified value to the item, if the attribute does not already exist. If the attribute does exist, then the behavior of ADD depends on the data type of the attribute: * If the existing attribute is a number, and if Value is also a number, then Value is mathematically added to the existing attribute. If Value is a negative number, then it is subtracted from the existing attribute. .. note:: If you use ADD to increment or decrement a number value for an item that doesn’t exist before the update, DynamoDB uses 0 as the initial value. Similarly, if you use ADD for an existing item to increment or decrement an attribute value that doesn’t exist before the update, DynamoDB uses 0 as the initial value. For example, suppose that the item you
want to update doesn’t have an attribute named *itemcount*, but you decide to *ADD* the number 3 to this attribute anyway. DynamoDB will create the *itemcount* attribute, set its initial value to 0, and finally add 3 to it. The result will be a new *itemcount* attribute, with a value of 3.

- If the existing data type is a set, and if *Value* is also a set, then *Value* is appended to the existing set. For example, if the attribute value is the set \([1, 2]\), and the *ADD* action specified \([3]\), then the final attribute value is \([1, 2, 3]\). An error occurs if an *ADD* action is specified for a set attribute and the attribute type specified does not match the existing set type. Both sets must have the same primitive data type. For example, if the existing data type is a set of strings, *Value* must also be a set of strings.

If no item with the specified key is found in the table, the following values perform the following actions:

- **PUT** - Causes DynamoDB to create a new item with the specified primary key, and then adds the attribute.
- **DELETE** - Nothing happens, because attributes cannot be deleted from a nonexistent item. The operation succeeds, but DynamoDB does not create a new item.
- **ADD** - Causes DynamoDB to create an item with the supplied primary key and number (or set of numbers) for the attribute value.

The only data types allowed are Number and Number Set.

If you provide any attributes that are part of an index key, then the data types for those attributes must match those of the schema in the table’s attribute definition.

- *(string)* –
  - *(dict)* –

For the *UpdateItem* operation, represents the attributes to be modified, the action to perform on each, and the new value for each.

**Note:** You cannot use *UpdateItem* to update any primary key attributes. Instead, you will need to delete the item, and then use *PutItem* to create a new item with new attributes.

Attribute values cannot be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests with empty values will be rejected with a *ValidationException* exception.

- **Value** *(valid DynamoDB type)* – The value of the attribute. The valid value types are listed in the *DynamoDB Reference Guide*.
- **Action** *(string)* –

  Specifies how to perform the update. Valid values are *PUT* (default), *DELETE*, and *ADD*. The behavior depends on whether the specified primary key already exists in the table.

  **If an item with the specified *Key* is found in the table:**

  - **PUT** - Adds the specified attribute to the item. If the attribute already exists, it is replaced by the new value.
  - **DELETE** - If no value is specified, the attribute and
its value are removed from the item. The data type of the specified value must match the existing value’s data type. If a set of values is specified, then those values are subtracted from the old set. For example, if the attribute value was the set \([a, b, c]\) and the DELETE action specified \([a, c]\), then the final attribute value would be \([b]\). Specifying an empty set is an error.

- **ADD** - If the attribute does not already exist, then the attribute and its values are added to the item. If the attribute does exist, then the behavior of ADD depends on the data type of the attribute:
  * If the existing attribute is a number, and if Value is also a number, then the Value is mathematically added to the existing attribute. If Value is a negative number, then it is subtracted from the existing attribute.
  * If the existing data type is a set, and if the Value is also a set, then the Value is added to the existing set. (This is a set operation, not mathematical addition.)

For example, suppose that the item you want to update does not yet have an attribute named `itemcount`, but you decide to ADD the number 3 to this attribute anyway, even though it currently does not exist. DynamoDB will create the `itemcount` attribute, set its initial value to 0, and finally add 3 to it. The result will be a new `itemcount` attribute in the item, with a value of 3.

- If the existing data type is a set, and if the Value is also a set, then the Value is added to the existing set. (This is a set operation, not mathematical addition.)

For example, if the attribute value was the set \([1, 2]\), and the ADD action specified \([3]\), then the final attribute value would be \([1, 2, 3]\). An error occurs if an Add action is specified for a set attribute and the attribute type specified does not match the existing set type. Both sets must have the same primitive data type. For example, if the existing data type is a set of strings, the Value must also be a set of strings. The same holds true for number sets and binary sets.

This action is only valid for an existing attribute whose data type is number or is a set. Do not use ADD for any other data types.

If no item with the specified *Key* is found:

- **PUT** - DynamoDB creates a new item with the specified primary key, and then adds the attribute.
- **DELETE** - Nothing happens; there is no attribute to delete.
- **ADD** - DynamoDB creates an item with the supplied primary key and number (or set of numbers) for the attribute value. The only data types allowed are number and number set; no other data types can be specified.
• **Expected** (dict) –

A map of attribute/condition pairs. *Expected* provides a conditional block for the *UpdateItem* operation.

Each element of *Expected* consists of an attribute name, a comparison operator, and one or more values. DynamoDB compares the attribute with the value(s) you supplied, using the comparison operator. For each *Expected* element, the result of the evaluation is either true or false.

If you specify more than one element in the *Expected* map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the *ConditionalOperator* parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

If the *Expected* map evaluates to true, then the conditional operation succeeds; otherwise, it fails.

*Expected* contains the following:

- **AttributeValueList** - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the *ComparisonOperator* being used. For type Number, value comparisons are numeric. String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and a is greater than B. For a list of code values, see [http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters](http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters). For type Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- **ComparisonOperator** - A comparator for evaluating attributes in the *AttributeValueList*. When performing the comparison, DynamoDB uses strongly consistent reads. The following comparison operators are available: EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN The following are descriptions of each comparison operator. *EQ*: Equal. EQ is supported for all datatypes, including lists and maps. *AttributeValueList* can contain only one *AttributeValue* element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an *AttributeValue* element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not equal `{"N": "6"}`. Also, `{"N": "6"}` does not equal `{"NS": ["6", "2", "1"]}`.

- **NE**: Not equal. NE is supported for all datatypes, including lists and maps. *AttributeValueList* can contain only one *AttributeValue* of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an *AttributeValue* of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not equal `{"N": "6"}`. Also, `{"N": "6"}` does not equal `{"NS": ["6", "2", "1"]}`.
- **LE**: Less than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **LT**: Less than. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **GE**: Greater than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **GT**: Greater than. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **NOT_NULL**: The attribute exists. **NOT_NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the existence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NOT_NULL**, the result is a Boolean true. This result is because the attribute “a” exists; its data type is not relevant to the **NOT_NULL** comparison operator.

- **NULL**: The attribute does not exist. **NULL** is supported for all datatypes, including lists and maps. .. note:: This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using **NULL**, the result is a Boolean false. This is because the attribute “a” exists; its data type is not relevant to the **NULL** comparison operator.

- **CONTAINS**: Checks for a subsequence, or value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it finds an exact match with any member of the set. **CONTAINS** is supported for lists: When evaluating “a CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

- **NOT_CONTAINS**: Checks for absence of a subsequence, or absence of a value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type).
If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it does not find an exact match with any member of the set. NOT_CONTAINS is supported for lists: When evaluating "a NOT CONTAINS b", "a" can be a list; however, "b" cannot be a set, a map, or a list.

- BEGINS_WITH: Checks for a prefix. AttributeValueList can contain only one AttributeValue of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- IN: Checks for matching elements within two sets. AttributeValueList can contain one or more AttributeValue elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

- BETWEEN: Greater than or equal to the first value, and less than or equal to the second value. AttributeValueList must contain two AttributeValue elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{"S": "6"\} does not compare to \{"N": "6"\}. Also, \{"N": "6"\} does not compare to \{"NS": ["6", "2", "1"]\}.

For usage examples of AttributeValueList and ComparisonOperator, see Legacy Conditional Parameters in the Amazon DynamoDB Developer Guide.

For backward compatibility with previous DynamoDB releases, the following parameters can be used instead of AttributeValueList and ComparisonOperator:

- Value - A value for DynamoDB to compare with an attribute.
- Exists - A Boolean value that causes DynamoDB to evaluate the value before attempting the conditional operation: * If Exists is true, DynamoDB will check to see if that attribute value already exists in the table. If it is found, then the condition evaluates to true; otherwise the condition evaluate to false.
- If Exists is false, DynamoDB assumes that the attribute value does not exist in the table. If in fact the value does not exist, then the assumption is valid and the condition evaluates to true. If the value is found, despite the assumption that it does not exist, the condition evaluates to false.

Note that the default value for Exists is true.

The Value and Exists parameters are incompatible with AttributeValueList and ComparisonOperator. Note that if you use both sets of parameters at once, DynamoDB will return a ValidationException exception.

Note: This parameter does not support attributes of type List or Map.
- (string) –
  * (dict) –

Represents a condition to be compared with an attribute value. This condition can be used with `DeleteItem`, `PutItem` or `UpdateItem` operations; if the comparison evaluates to true, the operation succeeds; if not, the operation fails. You can use `ExpectedAttributeValue` in one of two different ways:

- Use `AttributeValueList` to specify one or more values to compare against an attribute. Use `ComparisonOperator` to specify how you want to perform the comparison. If the comparison evaluates to true, then the conditional operation succeeds.
- Use `Value` to specify a value that DynamoDB will compare against an attribute. If the values match, then `ExpectedAttributeValue` evaluates to true and the conditional operation succeeds. Optionally, you can also set `Exists` to false, indicating that you do not expect to find the attribute value in the table. In this case, the conditional operation succeeds only if the comparison evaluates to false.

`Value` and `Exists` are incompatible with `AttributeValueList` and `ComparisonOperator`. Note that if you use both sets of parameters at once, DynamoDB will return a `ValidationException` exception.

- `Value (valid DynamoDB type)` – - The value of the attribute. The valid value types are listed in the `DynamoDB Reference Guide`.
- `Exists (boolean)` –

Causes DynamoDB to evaluate the value before attempting a conditional operation:

- If `Exists` is `true`, DynamoDB will check to see if that attribute value already exists in the table. If it is found, then the operation succeeds. If it is not found, the operation fails with a `ConditionalCheckFailedException`.
- If `Exists` is `false`, DynamoDB assumes that the attribute value does not exist in the table. If in fact the value does not exist, then the assumption is valid and the operation succeeds. If the value is found, despite the assumption that it does not exist, the operation fails with a `ConditionalCheckFailedException`.

The default setting for `Exists` is `true`. If you supply a `Value` all by itself, DynamoDB assumes the attribute exists: You don’t have to set `Exists` to `true`, because it is implied.

DynamoDB returns a `ValidationException` if:

- `Exists` is `true` but there is no `Value` to check. (You expect a value to exist, but don’t specify what that value is.)
- `Exists` is `false` but you also provide a `Value`. (You cannot expect an attribute to have a value, while also expecting it not to exist.)
A comparator for evaluating attributes in the `AttributeValueList`. For example, equals, greater than, less than, etc.

The following comparison operators are available:

- **EQ** | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN

The following are descriptions of each comparison operator.

- **EQ** : Equal. `EQ` is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.

- **NE** : Not equal. `NE` is supported for all datatypes, including lists and maps. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.

- **LE** : Less than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **LT** : Less than. `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

- **GE** : Greater than or equal. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.
· GT: Greater than. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not equal `{"N": "6"}`. Also, `{"N": "6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

· NOT_NULL: The attribute exists. `NOT_NULL` is supported for all datatypes, including lists and maps. .. note::This operator tests for the existence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using `NOT_NULL`, the result is a Boolean `true`. This result is because the attribute “a” exists; its data type is not relevant to the `NOT_NULL` comparison operator.

· NULL: The attribute does not exist. `NULL` is supported for all datatypes, including lists and maps. .. note::This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute “a” is null, and you evaluate it using `NULL`, the result is a Boolean `false`. This is because the attribute “a” exists; its data type is not relevant to the `NULL` comparison operator.

· CONTAINS: Checks for a subsequence, or value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set (“SS”, “NS”, or “BS”), then the operator evaluates to true if it finds an exact match with any member of the set. `CONTAINS` is supported for lists: When evaluating “a CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

· NOT_CONTAINS: Checks for absence of a subsequence, or absence of a value in a set. `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set (“SS”, “NS”, or “BS”), then the operator evaluates to true if it does not find an exact match with any member of the set. `NOT_CONTAINS` is supported for lists: When evaluating “a NOT CONTAINS b”, “a” can be a list; however, “b” cannot be a set, a map, or a list.

· BEGINS_WITH: Checks for a prefix. `AttributeValueList` can contain only one `AttributeValue` of type
String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).
· IN: Checks for matching elements within two sets. AttributeValueList can contain one or more AttributeValue elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.
· BETWEEN: Greater than or equal to the first value, and less than or equal to the second value. AttributeValueList must contain two AttributeValue elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{ "S": "6" \} does not compare to \{ "N": "6" \}. Also, \{ "N": "6" \} does not compare to \{ "NS": [ "6", "2", "1" ] \}.
· AttributeValueList (list) – One or more values to evaluate against the supplied attribute. The number of values in the list depends on the ComparisonOperator being used.

For type Number, value comparisons are numeric. String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and a is greater than B. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters.

For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

For information on specifying data types in JSON, see JSON Data Format in the Amazon DynamoDB Developer Guide.

· (valid DynamoDB type) – The value of the attribute. The valid value types are listed in the DynamoDB Reference Guide.

Warning: This is a legacy parameter, for backward compatibility. New applications should use ConditionExpression instead. Do not combine legacy parameters and expression parameters in a single API call; otherwise, DynamoDB will return a ValidationException.

A logical operator to apply to the conditions in the Expected map:
- AND - If all of the conditions evaluate to true, then the entire map evaluates to true.
– OR - If at least one of the conditions evaluate to true, then the entire map evaluates to true.

If you omit ConditionalOperator, then AND is the default.

The operation will succeed only if the entire map evaluates to true.

Note: This parameter does not support attributes of type List or Map.

• **ReturnValues** *(string)* – Use ReturnValues if you want to get the item attributes as they appeared either before or after they were updated. For UpdateItem, the valid values are:
  – NONE - If ReturnValues is not specified, or if its value is NONE, then nothing is returned. (This setting is the default for ReturnValues.)
  – ALL_OLD - If UpdateItem overwrote an attribute name-value pair, then the content of the old item is returned.
  – UPDATED_OLD - The old versions of only the updated attributes are returned.
  – ALL_NEW - All of the attributes of the new version of the item are returned.
  – UPDATED_NEW - The new versions of only the updated attributes are returned.

• **ReturnConsumedCapacity** *(string)* – Determines the level of detail about provisioned throughput consumption that is returned in the response:
  – INDEXES - The response includes the aggregate ConsumedCapacity for the operation, together with ConsumedCapacity for each table and secondary index that was accessed. Note that some operations, such as GetItem and BatchGetItem, do not access any indexes at all. In these cases, specifying INDEXES will only return ConsumedCapacity information for table(s).
  – TOTAL - The response includes only the aggregate ConsumedCapacity for the operation.
  – NONE - No ConsumedCapacity details are included in the response.

• **ReturnItemCollectionMetrics** *(string)* – Determines whether item collection metrics are returned. If set to SIZE, the response includes statistics about item collections, if any, that were modified during the operation are returned in the response. If set to NONE (the default), no statistics are returned.

• **UpdateExpression** *(string)* – An expression that defines one or more attributes to be updated, the action to be performed on them, and new value(s) for them.

The following action values are available for UpdateExpression.
  – SET - Adds one or more attributes and values to an item. If any of these attribute already exist, they are replaced by the new values. You can also use SET to add or subtract from an attribute that is of type Number. For example: SET myNum = myNum + :val

SET supports the following functions: *

if_not_exists (path, operand) - if the item does not contain an attribute at the specified path, then if_not_exists evaluates to operand; otherwise, it evaluates to path. You can use this function to avoid overwriting an attribute that may already be present in the item.

list_append (operand, operand) - evaluates to a list with a new element added to it. You can append the new element to the start or the end of the list by reversing the order of the operands.

These function names are case-sensitive.
- **REMOVE** - Removes one or more attributes from an item.
- **ADD** - Adds the specified value to the item, if the attribute does not already exist. If the attribute does exist, then the behavior of **ADD** depends on the data type of the attribute: * If the existing attribute is a number, and if **Value** is also a number, then **Value** is mathematically added to the existing attribute. If **Value** is a negative number, then it is subtracted from the existing attribute. .. note:: If you use **ADD** to increment or decrement a number value for an item that doesn’t exist before the update, DynamoDB uses 0 as the initial value. Similarly, if you use **ADD** for an existing item to increment or decrement an attribute value that doesn’t exist before the update, DynamoDB uses 0 as the initial value. For example, suppose that the item you want to update doesn’t have an attribute named **itemcount**, but you decide to **ADD** the number 3 to this attribute anyway. DynamoDB will create the **itemcount** attribute, set its initial value to 0, and finally add 3 to it. The result will be a new **itemcount** attribute in the item, with a value of 3.
- If the existing data type is a set and if **Value** is also a set, then **Value** is added to the existing set. For example, if the attribute value is the set [1,2], and the **ADD** action specified [3], then the final attribute value is [1,2,3]. An error occurs if an **ADD** action is specified for a set attribute and the attribute type specified does not match the existing set type. Both sets must have the same primitive data type. For example, if the existing data type is a set of strings, the **Value** must also be a set of strings.

**Warning:** The **ADD** action only supports Number and set data types. In addition, **ADD** can only be used on top-level attributes, not nested attributes.

- **DELETE** - Deletes an element from a set. If a set of values is specified, then those values are subtracted from the old set. For example, if the attribute value was the set [a,b,c] and the **DELETE** action specifies [a,c], then the final attribute value is [b]. Specifying an empty set is an error. .. warning:: The **DELETE** action only supports set data types. In addition, **DELETE** can only be used on top-level attributes, not nested attributes.

You can have many actions in a single expression, such as the following: SET a=:value1, b=:value2 DELETE :value3, :value4, :value5

For more information on update expressions, see Modifying Items and Attributes in the *Amazon DynamoDB Developer Guide*.

**Note:** **UpdateExpression** replaces the legacy **AttributeUpdates** parameter.

- **ConditionExpression** *(condition from boto3.dynamodb.conditions.Attr method)* – The condition(s) an attribute(s) must meet. Valid conditions are listed in the DynamoDB Reference Guide.
- **ExpressionAttributeNames** *(dict)* – One or more substitution tokens for attribute names in an expression. The following are some use cases for using **ExpressionAttributeNames**:
  - To access an attribute whose name conflicts with a DynamoDB reserved word.
  - To create a placeholder for repeating occurrences of an attribute

---

3.1. Services
name in an expression.

– To prevent special characters in an attribute name from being misinterpreted in an expression.

Use the # character in an expression to dereference an attribute name. For example, consider the following attribute name:

– Percentile

The name of this attribute conflicts with a reserved word, so it cannot be used directly in an expression. (For the complete list of reserved words, see Reserved Words in the Amazon DynamoDB Developer Guide). To work around this, you could specify the following for ExpressionAttributeNames:

– {"#P":"Percentile"}

You could then use this substitution in an expression, as in this example:

– #P = :val

**Note:** Tokens that begin with the : character are expression attribute values, which are placeholders for the actual value at runtime.

For more information on expression attribute names, see Accessing Item Attributes in the Amazon DynamoDB Developer Guide.

– (string) –

• ExpressionAttributeValues (dict) – One or more values that can be substituted in an expression.

Use the : (colon) character in an expression to dereference an attribute value. For example, suppose that you wanted to check whether the value of the ProductStatus attribute was one of the following:

Available | Backordered | Discontinued

You would first need to specify ExpressionAttributeValues as follows:

```
{ "avail":{"S":"Available"}, 
"back":{"S":"Backordered"}, 
"disc":{"S":"Discontinued"} }
```

You could then use these values in an expression, such as this:

```
ProductStatus IN (:avail, :back, :disc)
```

For more information on expression attribute values, see Specifying Conditions in the Amazon DynamoDB Developer Guide.

– (string) –

• (valid DynamoDB type) – The value of the attribute. The valid value types are listed in the DynamoDB Reference Guide.

**Return type** dict

**Returns**

**Response Syntax**

```
{
 'Attributes': {
   'string': 'string'|123|Binary(b'bytes')|True|None|set(['string'])|set[123]|set(Binary(b'bytes'))|set[123]|set(Binary(b'bytes'))|{}
 },
 'ConsumedCapacity': {
   'TableName': 'string',}
'CapacityUnits': 123.0,
'Table': {
    'CapacityUnits': 123.0
},
'LocalSecondaryIndexes': {
    'string': {
        'CapacityUnits': 123.0
    }
},
'GlobalSecondaryIndexes': {
    'string': {
        'CapacityUnits': 123.0
    }
}
},
'ItemCollectionMetrics': {
    'ItemCollectionKey': {
        'string': 'string'|123|Binary(b'bytes')|True|None|set([\'string\'])|set([123])|set([Binary(b'bytes')])|
    },
    'SizeEstimateRangeGB': [123.0,
}
]

**Response Structure**

- (dict) – Represents the output of an *UpdateItem* operation.

  - **Attributes (dict) –**
    
    A map of attribute values as they appeared before the *UpdateItem* operation. This map only appears if *ReturnValues* was specified as something other than *NONE* in the request. Each element represents one attribute.

      * (string) –
        
        · (valid *DynamoDB* type) – The value of the attribute. The valid value types are listed in the *DynamoDB Reference Guide*.

      - **ConsumedCapacity (dict) –**

        The capacity units consumed by an operation. The data returned includes the total provisioned throughput consumed, along with statistics for the table and any indexes involved in the operation. *ConsumedCapacity* is only returned if the request asked for it. For more information, see Provisioned Throughput in the *Amazon DynamoDB Developer Guide*.

        * TableName (string) –

            The name of the table that was affected by the operation.

        * CapacityUnits (float) –

            The total number of capacity units consumed by the operation.

        * Table (dict) –

            The amount of throughput consumed on the table affected by the operation.

            · CapacityUnits (float) –
The total number of capacity units consumed on a table or an index.

**LocalSecondaryIndexes (dict)** –

The amount of throughput consumed on each local index affected by the operation.
- *(string)* –
- *(dict)* –

Represents the amount of provisioned throughput capacity consumed on a table or an index.
- **CapacityUnits (float)** –

The total number of capacity units consumed on a table or an index.

**GlobalSecondaryIndexes (dict)** –

The amount of throughput consumed on each global index affected by the operation.
- *(string)* –
- *(dict)* –

Represents the amount of provisioned throughput capacity consumed on a table or an index.
- **CapacityUnits (float)** –

The total number of capacity units consumed on a table or an index.

**ItemCollectionMetrics (dict)** –

Information about item collections, if any, that were affected by the operation. *ItemCollectionMetrics* is only returned if the request asked for it. If the table does not have any local secondary indexes, this information is not returned in the response.

**ItemCollectionKey (dict)** –

The hash key value of the item collection. This value is the same as the hash key of the item.
- *(string)* –
- *(valid DynamoDB type)* – The value of the attribute.

The valid value types are listed in the *DynamoDB Reference Guide*.

**SizeEstimateRangeGB (list)** –

An estimate of item collection size, in gigabytes. This value is a two-element array containing a lower bound and an upper bound for the estimate. The estimate includes the size of all the items in the table, plus the size of all attributes projected into all of the local secondary indexes on that table. Use this estimate to measure whether a local secondary index is approaching its size limit.

The estimate is subject to change over time; therefore, do not rely on the precision or accuracy of the estimate.
- *(float)* –

---

**DynamoDBStreams**
import boto3
client = boto3.client('dynamodbstreams')

These are the available methods:

• can_paginate()
• describe_stream()
• generate_presigned_url()
• get Paginator()
• get_records()
• get_shard_iterator()
• get_waiter()
• list_streams()

can_paginate(operation_name)
Check if an operation can be paginated.

Parameters operation_name (string) – The operation name. This is the same name as
the method name on the client. For example, if the method name is create_foo,
you’d normally invoke the operation as client.create_foo(**kwargs),
if the create_foo operation can be paginated, you can use the call
client.getPaginator("create_foo").

Returns True if the operation can be paginated, False otherwise.

describe_stream(**kwargs)
Returns information about a stream, including the current status of the stream, its Amazon Resource Name
(ARN), the composition of its shards, and its corresponding DynamoDB table.

Note: You can call DescribeStream at a maximum rate of 10 times per second.

Each shard in the stream has a SequenceNumberRange associated with it. If the
SequenceNumberRange has a StartingSequenceNumber but no EndingSequenceNumber,
then the shard is still open (able to receive more stream records). If both StartingSequenceNumber
and EndingSequenceNumber are present, the that shared is closed and can no longer receive more

data.

Request Syntax

response = client.describe_stream(
    StreamArn='string',
    Limit=123,
    ExclusiveStartShardId='string'
)

Parameters
• **StreamArn (string)** – [REQUIRED]
  
The Amazon Resource Name (ARN) for the stream.
• **Limit (integer)** – The maximum number of shard objects to return. The upper limit is 100.
• **ExclusiveStartShardId (string)** – The shard ID of the first item that this operation will evaluate. Use the value that was returned for LastEvaluatedShardId in the previous operation.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'StreamDescription': {
        'StreamArn': 'string',
        'StreamLabel': 'string',
        'StreamStatus': 'ENABLING'|'ENABLED'|'DISABLING'|'DISABLED',
        'StreamViewType': 'NEW_IMAGE'|'OLD_IMAGE'|'NEW_AND_OLD_IMAGES'|'KEYS_ONLY',
        'CreationRequestDateTime': datetime(2015, 1, 1),
        'TableName': 'string',
        'KeySchema': [
            {
                'AttributeName': 'string',
                'KeyType': 'HASH'|'RANGE'
            },
        ],
        'Shards': [
            {
                'ShardId': 'string',
                'SequenceNumberRange': {
                    'StartingSequenceNumber': 'string',
                    'EndingSequenceNumber': 'string'
                },
                'ParentShardId': 'string'
            },
        ],
        'LastEvaluatedShardId': 'string'
    }
}
```

**Response Structure**

• (dict) –

  Represents the output of a **DescribeStream** operation.

  - **StreamDescription (dict)** –

    A complete description of the stream, including its creation date and time, the DynamoDB table associated with the stream, the shard IDs within the stream, and the beginning and ending sequence numbers of stream records within the shards.
    
    * **StreamArn (string)** –
      
The Amazon Resource Name (ARN) for the stream.
    
    * **StreamLabel (string)** –
      
      A timestamp, in ISO 8601 format, for this stream.

      Note that LatestStreamLabel is not a unique identifier for the stream, because it is possible that a stream from another table might have the
same timestamp. However, the combination of the following three elements is guaranteed to be unique:

- the AWS customer ID.
- the table name
- the StreamLabel

* **StreamStatus (string)** –

Indicates the current status of the stream:

- **ENABLING** - Streams is currently being enabled on the DynamoDB table.
- **ENABLING** - the stream is enabled.
- **DISABLED** - Streams is currently being disabled on the DynamoDB table.
- **DISABLED** - the stream is disabled.

* **StreamViewType (string)** –

Indicates the format of the records within this stream:

- **KEYS_ONLY** - only the key attributes of items that were modified in the DynamoDB table.
- **NEW_IMAGE** - entire item from the table, as it appeared after they were modified.
- **OLD_IMAGE** - entire item from the table, as it appeared before they were modified.
- **NEW_AND_OLD_IMAGES** - both the new and the old images of the items from the table.

* **CreationRequestDateTime (datetime)** –

The date and time when the request to create this stream was issued.

* **TableName (string)** –

The DynamoDB table with which the stream is associated.

* **KeySchema (list)** –

The key attribute(s) of the stream’s DynamoDB table.

  - (dict) –

    Represents a single element of a key schema. A key schema specifies the attributes that make up the primary key of a table, or the key attributes of an index.

    A KeySchemaElement represents exactly one attribute of the primary key. For example, a hash type primary key would be represented by one KeySchemaElement. A hash-and-range type primary key would require one KeySchemaElement for the hash attribute, and another KeySchemaElement for the range attribute.

    - **AttributeName (string)** –
      
      The name of a key attribute.
    - **KeyType (string)** –
      
      The attribute data, consisting of the data type and the attribute value itself.

* **Shards (list)** –

The shards that comprise the stream.

  - (dict) –

    A uniquely identified group of stream records within a stream.
- **ShardId** *(string)* –
  The system-generated identifier for this shard.

- **SequenceNumberRange** *(dict)* –
  The range of possible sequence numbers for the shard.

- **StartingSequenceNumber** *(string)* –
  The first sequence number.

- **EndingSequenceNumber** *(string)* –
  The last sequence number.

- **ParentShardId** *(string)* –
  The shard ID of the current shard’s parent.

- **LastEvaluatedShardId** *(string)* –
  The shard ID of the item where the operation stopped, inclusive of the previous result set. Use this value to start a new operation, excluding this value in the new request.

  If `LastEvaluatedShardId` is empty, then the “last page” of results has been processed and there is currently no more data to be retrieved.

  If `LastEvaluatedShardId` is not empty, it does not necessarily mean that there is more data in the result set. The only way to know when you have reached the end of the result set is when `LastEvaluatedShardId` is empty.

---

**generate_presigned_url** *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*
Generate a presigned url given a client, its method, and arguments

**Parameters**

- **ClientMethod** *(string)* – The client method to presign for
- **Params** *(dict)* – The parameters normally passed to `ClientMethod`.
- **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns** The presigned url

**get_paginator**(operation_name)
Create a paginator for an operation.

**Parameters** operation_name *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo")`.

**Raises** OperationNotPageableError Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

**Return type** L{botocore.paginate.Paginator}

**Returns** A paginator object.

**get_records**(**kwargs)**
Retrieves the stream records from a given shard.

Specify a shard iterator using the `ShardIterator` parameter. The shard iterator specifies the position in the shard from which you want to start reading stream records sequentially. If there are no stream records available in the portion of the shard that the iterator points to, `GetRecords` returns an empty list. Note that it might take multiple calls to get to a portion of the shard that contains stream records.
Note: GetRecords can retrieve a maximum of 1 MB of data or 2000 stream records, whichever comes first.

Request Syntax

```python
response = client.get_records(
    ShardIterator='string',
    Limit=123
)
```

Parameters

- **ShardIterator (string)** – [REQUIRED]
  A shard iterator that was retrieved from a previous GetShardIterator operation. This iterator can be used to access the stream records in this shard.
- **Limit (integer)** – The maximum number of records to return from the shard. The upper limit is 1000.

Return type: dict

Returns

Response Syntax

```python
{
    'Records': [
        {
            'eventID': 'string',
            'eventName': 'INSERT'|'MODIFY'|'REMOVE',
            'eventVersion': 'string',
            'eventSource': 'string',
            'awsRegion': 'string',
            'dynamodb': {
                'Keys': {
                    'string': {'... recursive ...'}
                },
                'NewImage': {
                    'string': {'... recursive ...'}
                }
            }
        }
    ]
}
```

3.1. Services
Response Structure

- (dict) – Represents the output of a GetRecords operation.
- **Records** *(list)* –

  The stream records from the shard, which were retrieved using the shard iterator.

* (dict) –

  A description of a unique event within a stream.

  - **eventID** *(string)* –
    
    A globally unique identifier for the event that was recorded in this stream record.

  - **eventName** *(string)* –
    
    The type of data modification that was performed on the DynamoDB table:
    - INSERT - a new item was added to the table.
    - MODIFY - one or more of the item’s attributes were updated.
    - REMOVE - the item was deleted from the table

  - **eventVersion** *(string)* –
    
    The version number of the stream record format. Currently, this is 1.0.

  - **eventSource** *(string)* –
    
    The AWS service from which the stream record originated. For DynamoDB Streams, this is `aws:dynamodb`.

  - **awsRegion** *(string)* –
    
    The region in which the `GetRecords` request was received.

  - **dynamodb** *(dict)* –
    
    The main body of the stream record, containing all of the DynamoDB-specific fields.

  - **Keys** *(dict)* –
    
    The primary key attribute(s) for the DynamoDB item that was modified.

  - (string) –
    
    (dict) –

  Represents the data for an attribute. You can set one, and only one, of the elements.

  Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

  - **S** *(string)* –
    
    A String data type.

  - **N** *(string)* –
    
    A Number data type.

  - **B** *(bytes)* –
    
    A Binary data type.

  - **SS** *(list)* –
    
    A String Set data type.

  - (string) –
- **NS (list)** –
  A Number Set data type.
- **(string)** –
- **BS (list)** –
  A Binary Set data type.
- **(bytes)** –
- **M (dict)** –
  A Map data type.
- **(string)** –
- **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L (list)** –
  A List data type.
- **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL (boolean)** –
  A Null data type.
- **BOOL (boolean)** –
  A Boolean data type.

- **NewImage (dict)** –
  The item in the DynamoDB table as it appeared after it was modified.
- **(string)** –
- **(dict)** –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **S (string)** –
  A String data type.
- **N (string)** –
A Number data type.
- **B (bytes)** –
  A Binary data type.
- **SS (list)** –
  A String Set data type.
  - *(string)* –
  - **NS (list)** –
  A Number Set data type.
  - *(string)* –
  - **BS (list)** –
  A Binary Set data type.
  - *(bytes)* –
  - **M (dict)** –
  A Map data type.
  - *(string)* –
  - *(dict)* –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L (list)** –
  A List data type.
  - *(dict)* –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL (boolean)** –
  A Null data type.
- **BOOL (boolean)** –
  A Boolean data type.
- **OldImage (dict)** –
  The item in the DynamoDB table as it appeared before it was modified.
  - *(string)* –
  - *(dict)* –

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book
item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **S (string)** –
  A String data type.

- **N (string)** –
  A Number data type.

- **B (bytes)** –
  A Binary data type.

- **SS (list)** –
  A String Set data type.

- **(string)** –
  A String data type.

- **NS (list)** –
  A Number Set data type.

- **(string)** –
  A Number data type.

- **BS (list)** –
  A Binary Set data type.

- **M (dict)** –
  A Map data type.

- **(dict)** –
  A Dictionary data type.

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **L (list)** –
  A List data type.

- **(dict)** –
  A Dictionary data type.

Represents the data for an attribute. You can set one, and only one, of the elements.

Each attribute in an item is a name-value pair. An attribute can be single-valued or multi-valued set. For example, a book item can have title and authors attributes. Each book has one title but can have many authors. The multi-valued attribute is a set; duplicate values are not allowed.

- **NULL (boolean)** –
  A Null data type.

- **BOOL (boolean)** –
  A Boolean data type.

- **SequenceNumber (string)** –
  The sequence number of the stream record.
- **SizeBytes** (*integer*) –
  The size of the stream record, in bytes.

- **StreamViewType** (*string*) –
  The type of data from the modified DynamoDB item that was captured in this stream record:
  - **KEYS_ONLY** - only the key attributes of the modified item.
  - **NEW_IMAGE** - the entire item, as it appears after it was modified.
  - **OLD_IMAGE** - the entire item, as it appeared before it was modified.
  - **NEW_AND_OLD_IMAGES** — both the new and the old item images of the item.

- **NextShardIterator** (*string*) –
  The next position in the shard from which to start sequentially reading stream records. If set to `null`, the shard has been closed and the requested iterator will not return any more data.

### `get_shard_iterator(**kwargs)`

Returns a shard iterator. A shard iterator provides information about how to retrieve the stream records from within a shard. Use the shard iterator in a subsequent `GetRecords` request to read the stream records from the shard.

**Note:** A shard iterator expires 15 minutes after it is returned to the requester.

#### Request Syntax

```python
response = client.get_shard_iterator(
    StreamArn='string',
    ShardId='string',
    ShardIteratorType='TRIM_HORIZON'|'LATEST'|'AT_SEQUENCE_NUMBER'|'AFTER_SEQUENCE_NUMBER',
    SequenceNumber='string'
)
```

#### Parameters

- **StreamArn** (*string*) – [REQUIRED]
  The Amazon Resource Name (ARN) for the stream.

- **ShardId** (*string*) – [REQUIRED]
  The identifier of the shard. The iterator will be returned for this shard ID.

- **ShardIteratorType** (*string*) – [REQUIRED]
  Determines how the shard iterator is used to start reading stream records from the shard:
  - **AT_SEQUENCE_NUMBER** - Start reading exactly from the position denoted by a specific sequence number.
  - **AFTER_SEQUENCE_NUMBER** - Start reading right after the position denoted by a specific sequence number.
  - **TRIM_HORIZON** - Start reading at the last (untrimmed) stream record, which is the oldest record in the shard. In DynamoDB Streams, there is a 24 hour limit on data retention. Stream records whose age exceeds this limit are subject to removal (trimming) from the stream.
  - **LATEST** - Start reading just after the most recent stream record in the shard, so that you always read the most recent data in the shard.
• **SequenceNumber** *(string)* – The sequence number of a stream record in the shard from which to start reading.

Return type: **dict**

Returns

Response Syntax

```
{
    'ShardIterator': 'string'
}
```

Response Structure

• *(dict)* –

  Represents the output of a *GetShardIterator* operation.

  – **ShardIterator** *(string)* –

    The position in the shard from which to start reading stream records sequentially. A shard iterator specifies this position using the sequence number of a stream record in a shard.

**get_waiter** *(waiter_name)*

**list_streams** (**kwargs**)

Returns an array of stream ARNs associated with the current account and endpoint. If the **TableName** parameter is present, then *ListStreams* will return only the streams ARNs for that table.

**Note:** You can call *ListStreams* at a maximum rate of 5 times per second.

Request Syntax

```
response = client.list_streams(
    TableName='string',
    Limit=123,
    ExclusiveStartStreamArn='string'
)
```

Parameters

• **TableName** *(string)* – If this parameter is provided, then only the streams associated with this table name are returned.

• **Limit** *(integer)* – The maximum number of streams to return. The upper limit is 100.

• **ExclusiveStartStreamArn** *(string)* – The ARN (Amazon Resource Name) of the first item that this operation will evaluate. Use the value that was returned for **LastEvaluatedStreamArn** in the previous operation.

Return type: **dict**

Returns

Response Syntax

```
{
    'Streams': [
        {
            'StreamArn': 'string',
            'TableName': 'string',
            'StreamLabel': 'string'
        }
    ]
}
```
'LastEvaluatedStreamArn': 'string'
}

Response Structure

- (dict) –

  Represents the output of a ListStreams operation.

  - Streams (list) –

    A list of stream descriptors associated with the current account and endpoint.

    * (dict) –

      Represents all of the data describing a particular stream.

      - StreamArn (string) –

        The Amazon Resource Name (ARN) for the stream.

      - TableName (string) –

        The DynamoDB table with which the stream is associated.

      - StreamLabel (string) –

        A timestamp, in ISO 8601 format, for this stream.

        Note that LatestStreamLabel is not a unique identifier for the stream, because it is possible that a stream from another table might have the same timestamp. However, the combination of the following three elements is guaranteed to be unique:

        - the AWS customer ID.
        - the table name
        - the StreamLabel

    - LastEvaluatedStreamArn (string) –

      The stream ARN of the item where the operation stopped, inclusive of the previous result set. Use this value to start a new operation, excluding this value in the new request.

      If LastEvaluatedStreamArn is empty, then the “last page” of results has been processed and there is no more data to be retrieved.

      If LastEvaluatedStreamArn is not empty, it does not necessarily mean that there is more data in the result set. The only way to know when you have reached the end of the result set is when LastEvaluatedStreamArn is empty.
Client

class EC2.Client
    A low-level client representing Amazon Elastic Compute Cloud (EC2):

    import boto3

    client = boto3.client('ec2')

These are the available methods:

accept_vpc_peering_connection(**kwargs)

Accept a VPC peering connection request. To accept a request, the VPC peering connection must be in the pending-acceptance state, and you must be the owner of the peer VPC. Use the DescribeVpcPeeringConnections request to view your outstanding VPC peering connection requests.

Request Syntax

response = client.accept_vpc_peering_connection(
    DryRun=True|False,
    VpcPeeringConnectionId='string'
)

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **VpcPeeringConnectionId** (string) – The ID of the VPC peering connection.

Return type  dict

Returns

Response Syntax

```python
{
    'VpcPeeringConnection': {
        'AccepterVpcInfo': {
            'CidrBlock': 'string',
            'OwnerId': 'string',
            'VpcId': 'string'
        },
        'ExpirationTime': datetime(2015, 1, 1),
        'RequesterVpcInfo': {
            'CidrBlock': 'string',
            'OwnerId': 'string',
            'VpcId': 'string'
        },
        'Status': {
            'Code': 'initiating-request'|'pending-acceptance'|'active'|'deleted'|'rejected'|'failed'|'expired'|'provisioning'|'deleting',
            'Message': 'string'
        },
        'Tags': [
            {
                'Key': 'string',
                'Value': 'string'
            }
        ],
        'VpcPeeringConnectionId': 'string'
    }
}
```

Response Structure
(dict) –

– **VpcPeeringConnection** (dict) –

Information about the VPC peering connection.

  * **AccepterVpcInfo** (dict) –

    The information of the peer VPC.
    
    - **CidrBlock** (string) –
      
      The CIDR block for the VPC.
    
    - **OwnerId** (string) –
      
      The AWS account ID of the VPC owner.
    
    - **VpcId** (string) –

      The ID of the VPC.

  * **ExpirationTime** (datetime) –

    The time that an unaccepted VPC peering connection will expire.

  * **RequesterVpcInfo** (dict) –

    The information of the requester VPC.
    
    - **CidrBlock** (string) –
      
      The CIDR block for the VPC.
    
    - **OwnerId** (string) –
      
      The AWS account ID of the VPC owner.
    
    - **VpcId** (string) –

      The ID of the VPC.

  * **Status** (dict) –

    The status of the VPC peering connection.
    
    - **Code** (string) –
      
      The status of the VPC peering connection.
    
    - **Message** (string) –

      A message that provides more information about the status, if applicable.

  * **Tags** (list) –

    Any tags assigned to the resource.
    
    - (dict) –

      Describes a tag.
    
    - **Key** (string) –

      The key of the tag.

      Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws`:
    
    - **Value** (string) –

      The value of the tag.

      Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

  * **VpcPeeringConnectionId** (string) –

    The ID of the VPC peering connection.
**allocate_address(**kwargs)**

Acquires an Elastic IP address.

An Elastic IP address is for use either in the EC2-Classic platform or in a VPC. For more information, see Elastic IP Addresses in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = client.allocate_address(
    DryRun=True|False,
    Domain='vpc'|'standard'
)
```

**Parameters**

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **Domain** (*string*) – Set to vpc to allocate the address for use with instances in a VPC.
  
  Default: The address is for use with instances in EC2-Classic.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'PublicIp': 'string',
    'Domain': 'vpc'|'standard',
    'AllocationId': 'string'
}
```

**Response Structure**

- *(dict)* –
  - **PublicIp** (*string*) –
    
    The Elastic IP address.
  - **Domain** (*string*) –
    
    Indicates whether this Elastic IP address is for use with instances in EC2-Classic (standard) or instances in a VPC (vpc).
  - **AllocationId** (*string*) –
    
    [EC2-VPC] The ID that AWS assigns to represent the allocation of the Elastic IP address for use with instances in a VPC.

**assign_private_ip_addresses(**kwargs)**

Assigns one or more secondary private IP addresses to the specified network interface. You can specify one or more specific secondary IP addresses, or you can specify the number of secondary IP addresses to be automatically assigned within the subnet’s CIDR block range. The number of secondary IP addresses that you can assign to an instance varies by instance type. For information about instance types, see Instance Types in the Amazon Elastic Compute Cloud User Guide. For more information about Elastic IP addresses, see Elastic IP Addresses in the Amazon Elastic Compute Cloud User Guide.

AssignPrivateIpAddresses is available only in EC2-VPC.

**Request Syntax**
response = client.assign_private_ip_addresses(
    NetworkInterfaceId='string',
    PrivateIpAddresses=[
        'string',
    ],
    SecondaryPrivateIpAddressCount=123,
    AllowReassignment=True|False
)

Parameters

- **NetworkInterfaceId (string)** – [REQUIRED]
  The ID of the network interface.

- **PrivateIpAddresses (list)** – One or more IP addresses to be assigned as a secondary private IP address to the network interface. You can’t specify this parameter when also specifying a number of secondary IP addresses.

If you don’t specify an IP address, Amazon EC2 automatically selects an IP address within the subnet range.

- **SecondaryPrivateIpAddressCount (integer)** – The number of secondary IP addresses to assign to the network interface. You can’t specify this parameter when also specifying private IP addresses.

- **AllowReassignment (boolean)** – Indicates whether to allow an IP address that is already assigned to another network interface or instance to be reassigned to the specified network interface.

Returns None

associate_address(**kwargs)

Associates an Elastic IP address with an instance or a network interface.

An Elastic IP address is for use in either the EC2-Classic platform or in a VPC. For more information, see Elastic IP Addresses in the Amazon Elastic Compute Cloud User Guide.

[EC2-Classic, VPC in an EC2-VPC-only account] If the Elastic IP address is already associated with a different instance, it is disassociated from that instance and associated with the specified instance.

[VPC in an EC2-Classic account] If you don’t specify a private IP address, the Elastic IP address is associated with the primary IP address. If the Elastic IP address is already associated with a different instance or a network interface, you get an error unless you allow reassociation.

This is an idempotent operation. If you perform the operation more than once, Amazon EC2 doesn’t return an error.

Request Syntax

response = client.associate_address(
    DryRun=True|False,
    InstanceId='string',
    PublicIp='string',
    AllocationId='string',
    NetworkInterfaceId='string',
    PrivateIpAddress='string',
    AllowReassociation=True|False
)

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If
you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **InstanceId** *(string)* – The ID of the instance. This is required for EC2-Classic. For EC2-VPC, you can specify either the instance ID or the network interface ID, but not both. The operation fails if you specify an instance ID unless exactly one network interface is attached.
- **PublicIp** *(string)* – The Elastic IP address. This is required for EC2-Classic.
- **AllocationId** *(string)* – [EC2-VPC] The allocation ID. This is required for EC2-VPC.
- **NetworkInterfaceId** *(string)* – [EC2-VPC] The ID of the network interface. If the instance has more than one network interface, you must specify a network interface ID.
- **PrivaterIpAddress** *(string)* – [EC2-VPC] The primary or secondary private IP address to associate with the Elastic IP address. If no private IP address is specified, the Elastic IP address is associated with the primary private IP address.
- **AllowReassociation** *(boolean)* – [EC2-VPC] Allows an Elastic IP address that is already associated with an instance or network interface to be re-associated with the specified instance or network interface. Otherwise, the operation fails.

Default: `false`

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'AssociationId': 'string'
}
```

**Response Structure**

- *(dict)* –
  - **AssociationId** *(string)* –
    - [EC2-VPC] The ID that represents the association of the Elastic IP address with an instance.

**associate_dhcp_options**(**kwargs**)  
Associates a set of DHCP options (that you’ve previously created) with the specified VPC, or associates no DHCP options with the VPC.

After you associate the options with the VPC, any existing instances and all new instances that you launch in that VPC use the options. You don’t need to restart or relaunch the instances. They automatically pick up the changes within a few hours, depending on how frequently the instance renews its DHCP lease. You can explicitly renew the lease using the operating system on the instance.

For more information, see DHCP Options Sets in the *Amazon Virtual Private Cloud User Guide*.

**Request Syntax**

```python
response = client.associate_dhcp_options(
    DryRun=True|False,
    DhcpOptionsId='string',
    VpcId='string'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If
you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **DhcpOptionsId** *(string) – [REQUIRED]*

  The ID of the DHCP options set, or `default` to associate no DHCP options with the VPC.

- **VpcId** *(string) – [REQUIRED]*

  The ID of the VPC.

Returns None

**associate_route_table(**kwargs**)**

Associates a subnet with a route table. The subnet and route table must be in the same VPC. This association causes traffic originating from the subnet to be routed according to the routes in the route table. The action returns an association ID, which you need in order to disassociate the route table from the subnet later. A route table can be associated with multiple subnets.

For more information about route tables, see Route Tables in the Amazon Virtual Private Cloud User Guide.

Request Syntax

```python
response = client.associate_route_table(
    DryRun=True|False,
    SubnetId='string',
    RouteTableId='string'
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **SubnetId** *(string) – [REQUIRED]*

  The ID of the subnet.

- **RouteTableId** *(string) – [REQUIRED]*

  The ID of the route table.

Returns
dict

Response Syntax

```python
{
    'AssociationId': 'string'
}
```

Response Structure

- *(dict)* –
  - **AssociationId** *(string)* –

    The route table association ID (needed to disassociate the route table).

**attach_classic_link_vpc(**kwargs**)**

Links an EC2-Classic instance to a ClassicLink-enabled VPC through one or more of the VPC’s security groups. You cannot link an EC2-Classic instance to more than one VPC at a time. You can only link an instance that’s in the running state. An instance is automatically unlinked from a VPC when it’s stopped - you can link it to the VPC again when you restart it.
After you’ve linked an instance, you cannot change the VPC security groups that are associated with it. To change the security groups, you must first unlink the instance, and then link it again.

Linking your instance to a VPC is sometimes referred to as attaching your instance.

Request Syntax

```python
response = client.attach_classic_link_vpc(
    DryRun=True|False,
    InstanceId='string',
    VpcId='string',
    Groups=[
        'string',
    ]
)
```

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **InstanceId (string)** – [REQUIRED]
The ID of an EC2-Classic instance to link to the ClassicLink-enabled VPC.
- **VpcId (string)** – [REQUIRED]
The ID of a ClassicLink-enabled VPC.
- **Groups (list)** – [REQUIRED]
The ID of one or more of the VPC’s security groups. You cannot specify security groups from a different VPC.

Return type: dict

Returns

- **Response Syntax**

```python
{
    'Return': True|False
}
```

- **Response Structure**

  - (dict) –
  
    - **Return (boolean)** –
      
      Returns `true` if the request succeeds; otherwise, it returns an error.

**attach_internet_gateway(**kwargs)**

Attaches an Internet gateway to a VPC, enabling connectivity between the Internet and the VPC. For more information about your VPC and Internet gateway, see the Amazon Virtual Private Cloud User Guide.

Request Syntax

```python
response = client.attach_internet_gateway(
    DryRun=True|False,
    InternetGatewayId='string',
    VpcId='string'
)
```

Parameters
• **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

• **InternetGatewayId** (*string*) – [REQUIRED]

  The ID of the Internet gateway.

• **VpcId** (*string*) – [REQUIRED]

  The ID of the VPC.

Returns None

**attach_network_interface(****kwargs**)

Attaches a network interface to an instance.

Request Syntax

```python
response = client.attach_network_interface(
    DryRun=True|False,
    NetworkInterfaceId='string',
    InstanceId='string',
    DeviceIndex=123
)
```

Parameters

• **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

• **NetworkInterfaceId** (*string*) – [REQUIRED]

  The ID of the network interface.

• **InstanceId** (*string*) – [REQUIRED]

  The ID of the instance.

• **DeviceIndex** (*integer*) – [REQUIRED]

  The index of the device for the network interface attachment.

Returns dict

Response Syntax

```python
{
    'AttachmentId': 'string'
}
```

Response Structure

• (**dict**) –

  – **AttachmentId** (*string*) –

    The ID of the network interface attachment.

**attach_volume(****kwargs**)

Attaches an EBS volume to a running or stopped instance and exposes it to the instance with the specified device name.

Encrypted EBS volumes may only be attached to instances that support Amazon EBS encryption. For more information, see Amazon EBS Encryption in the Amazon Elastic Compute Cloud User Guide.
For a list of supported device names, see Attaching an EBS Volume to an Instance. Any device names that aren’t reserved for instance store volumes can be used for EBS volumes. For more information, see Amazon EC2 Instance Store in the Amazon Elastic Compute Cloud User Guide.

If a volume has an AWS Marketplace product code:

- The volume can be attached only to a stopped instance.
- AWS Marketplace product codes are copied from the volume to the instance.
- You must be subscribed to the product.
- The instance type and operating system of the instance must support the product. For example, you can’t detach a volume from a Windows instance and attach it to a Linux instance.

For an overview of the AWS Marketplace, see Introducing AWS Marketplace.

For more information about EBS volumes, see Attaching Amazon EBS Volumes in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = client.attach_volume(
    DryRun=True|False,
    VolumeId='string',
    InstanceId='string',
    Device='string'
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **VolumeId** *(string)* – [REQUIRED]
  
  The ID of the EBS volume. The volume and instance must be within the same Availability Zone.
- **InstanceId** *(string)* – [REQUIRED]
  
  The ID of the instance.
- **Device** *(string)* – [REQUIRED]
  
  The device name to expose to the instance (for example, /dev/sdh or xvdh).

Return type  *dict*

Returns

Response Syntax

```python
{
    'VolumeId': 'string',
    'InstanceId': 'string',
    'Device': 'string',
    'State': 'attaching'|'attached'|'detaching'|'detached',
    'AttachTime': datetime(2015, 1, 1),
    'DeleteOnTermination': True|False
}
```

Response Structure

- *(dict)* –

  Information about the volume attachment.
  - **VolumeId** *(string)* –
    
    The ID of the volume.
- **InstanceId** *(string)* –
  The ID of the instance.
- **Device** *(string)* –
  The device name.
- **State** *(string)* –
  The attachment state of the volume.
- **AttachTime** *(datetime)* –
  The time stamp when the attachment initiated.
- **DeleteOnTermination** *(boolean)* –
  Indicates whether the EBS volume is deleted on instance termination.

**attach_vpn_gateway(****kwargs**
)
Attaches a virtual private gateway to a VPC. For more information, see Adding a Hardware Virtual Private Gateway to Your VPC in the Amazon Virtual Private Cloud User Guide.

**Request Syntax**

```python
response = client.attach_vpn_gateway(
    DryRun=True|False,
    VpnGatewayId='string',
    VpcId='string'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **VpnGatewayId** *(string)* – [REQUIRED]
  The ID of the virtual private gateway.
- **VpcId** *(string)* – [REQUIRED]
  The ID of the VPC.

**Return type**  dict

**Returns**

**Response Syntax**

```python
{
    'VpcAttachment': {
        'VpcId': 'string',
        'State': 'attaching'|'attached'|'detaching'|'detached'
    }
}
```

**Response Structure**

- *(dict)* –
  - **VpcAttachment** *(dict)* –
    Information about the attachment.
  - **VpcId** *(string)* –
    The ID of the VPC.
* State (string) –

The current state of the attachment.

authorize_security_group_egress(**kwargs)

Adds one or more egress rules to a security group for use with a VPC. Specifically, this action permits instances to send traffic to one or more destination CIDR IP address ranges, or to one or more destination security groups for the same VPC.

**Warning:** You can have up to 50 rules per security group (covering both ingress and egress rules).

A security group is for use with instances either in the EC2-Classic platform or in a specific VPC. This action doesn’t apply to security groups for use in EC2-Classic. For more information, see Security Groups for Your VPC in the Amazon Virtual Private Cloud User Guide.

Each rule consists of the protocol (for example, TCP), plus either a CIDR range or a source group. For the TCP and UDP protocols, you must also specify the destination port or port range. For the ICMP protocol, you must also specify the ICMP type and code. You can use -1 for the type or code to mean all types or all codes.

Rule changes are propagated to affected instances as quickly as possible. However, a small delay might occur.

**Request Syntax**

```python
response = client.authorize_security_group_egress(
    DryRun=True|False,
    GroupId='string',
    SourceSecurityGroupName='string',
    SourceSecurityGroupOwnerId='string',
    IpProtocol='string',
    FromPort=123,
    ToPort=123,
    CidrIp='string',
    IpPermissions=[
        {'IpProtocol': 'string',
         'FromPort': 123,
         'ToPort': 123,
         'UserIdGroupPairs': [
             {'UserId': 'string',
              'GroupName': 'string',
              'GroupId': 'string'
             }]
    ]
)
```
Parameters

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **GroupId** (*string*) – [REQUIRED]
  The ID of the security group.
- **SourceSecurityGroupName** (*string*) – The name of a destination security group. To authorize outbound access to a destination security group, we recommend that you use a set of IP permissions instead.
- **SourceSecurityGroupOwnerId** (*string*) – The AWS account number for a destination security group. To authorize outbound access to a destination security group, we recommend that you use a set of IP permissions instead.
- **IpProtocol** (*string*) – The IP protocol name (`tcp`, `udp`, `icmp`) or number (see Protocol Numbers). Use `-1` to specify all.
- **FromPort** (*integer*) – The start of port range for the TCP and UDP protocols, or an ICMP type number. A value of `-1` indicates all ICMP types.
- **ToPort** (*integer*) – The end of port range for the TCP and UDP protocols, or an ICMP code number. A value of `-1` indicates all ICMP codes for the specified ICMP type.
- **CidrIp** (*string*) – The CIDR IP address range. You can’t specify this parameter when specifying a source security group.
- **IpPermissions** (*list*) – A set of IP permissions. You can’t specify a destination security group and a CIDR IP address range.
  - (*dict*) –
    - **IpProtocol** (*string*) –
      - The protocol.
      When you call `DescribeSecurityGroups`, the protocol value returned is the number. Exception: For TCP, UDP, and ICMP, the value returned is the name (for example, `tcp`, `udp`, or `icmp`). For a list of protocol numbers, see Protocol Numbers. (VPC only) When you call `AuthorizeSecurityGroupIngress`, you can use `-1` to specify all.
    - **FromPort** (*integer*) –
      - The start of port range for the TCP and UDP protocols, or an ICMP type number. A value of `-1` indicates all ICMP types.
    - **ToPort** (*integer*) –
      - The end of port range for the TCP and UDP protocols, or an ICMP code. A value of `-1` indicates all ICMP codes for the specified ICMP type.
    - **UserIdGroupPairs** (*list*) –
      - One or more security group and AWS account ID pairs.
        - (*dict*) –
          - **UserId** (*string*) –
            - Describes a security group and AWS account ID pair.

3.1. Services 1115
The ID of an AWS account. EC2-Classic only.

- **GroupName** *(string)*
  
  The name of the security group. In a request, use this parameter for a security group in EC2-Classic or a default VPC only. For a security group in a nondefault VPC, use **GroupId**.

- **GroupId** *(string)*
  
  The ID of the security group.

- **IpRanges** *(list)*
  
  One or more IP ranges.
  
  - *(dict)*
    
    Describes an IP range.
  
  - **CidrIp** *(string)*
    
    The CIDR range. You can either specify a CIDR range or a source security group, not both.

- **PrefixListIds** *(list)*
  
  (Valid for **AuthorizeSecurityGroupEgress** , **RevokeSecurityGroupEgress** and **DescribeSecurityGroups** only) One or more prefix list IDs for an AWS service. In an **AuthorizeSecurityGroupEgress** request, this is the AWS service that you want to access through a VPC endpoint from instances associated with the security group.
  
  - *(dict)*
    
    The ID of the prefix.
  
  - **PrefixListId** *(string)*
    
    The ID of the prefix.

**Returns** None

### authorize_security_group_ingress (**kwargs)**

Adds one or more ingress rules to a security group.

**Warning:** EC2-Classic: You can have up to 100 rules per group.

EC2-VPC: You can have up to 50 rules per group (covering both ingress and egress rules).

Rule changes are propagated to instances within the security group as quickly as possible. However, a small delay might occur.

[EC2-Classic] This action gives one or more CIDR IP address ranges permission to access a security group in your account, or gives one or more security groups (called the source groups) permission to access a security group for your account. A source group can be for your own AWS account, or another.

[EC2-VPC] This action gives one or more CIDR IP address ranges permission to access a security group in your VPC, or gives one or more other security groups (called the source groups) permission to access a security group for your VPC. The security groups must all be for the same VPC.

### Request Syntax

```python
response = client.authorize_security_group_ingress(
    DryRun=True|False,
    GroupName='string',
    GroupId='string',
    SourceSecurityGroupName='string',
    SourceSecurityGroupOwnerId='string',
)```
IpProtocol='string',
FromPort=123,
ToPort=123,
CidrIp='string',
IpPermissions=[
    {
        'IpProtocol': 'string',
        'FromPort': 123,
        'ToPort': 123,
        'UserIdGroupPairs': [
            {
                'UserId': 'string',
                'GroupName': 'string',
                'GroupId': 'string'
            }
        ],
        'IpRanges': [
            {
                'CidrIp': 'string'
            }
        ],
        'PrefixListIds': [
            {
                'PrefixListId': 'string'
            }
        ]
    }
]}

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **GroupName (string)** – [EC2-Classic, default VPC] The name of the security group.
- **GroupId (string)** – The ID of the security group. Required for a nondefault VPC.
- **SourceSecurityGroupName (string)** – [EC2-Classic, default VPC] The name of the source security group. You can’t specify this parameter in combination with the following parameters: the CIDR IP address range, the start of the port range, the IP protocol, and the end of the port range. For EC2-VPC, the source security group must be in the same VPC.
- **SourceSecurityGroupOwnerId (string)** – [EC2-Classic, default VPC] The AWS account number for the source security group. For EC2-VPC, the source security group must be in the same VPC. You can’t specify this parameter in combination with the following parameters: the CIDR IP address range, the IP protocol, the start of the port range, and the end of the port range. Creates rules that grant full ICMP, UDP, and TCP access. To create a rule with a specific IP protocol and port range, use a set of IP permissions instead.
- **IpProtocol (string)** – The IP protocol name (tcp, udp, icmp) or number (see Protocol Numbers). (VPC only) Use -1 to specify all.
- **FromPort (integer)** – The start of port range for the TCP and UDP protocols, or an ICMP type number. For the ICMP type number, use -1 to specify all ICMP types.
• **ToPort** *(integer)* – The end of port range for the TCP and UDP protocols, or an ICMP code number. For the ICMP code number, use −1 to specify all ICMP codes for the ICMP type.

• **CidrIp** *(string)* – The CIDR IP address range. You can’t specify this parameter when specifying a source security group.

• **IpPermissions** *(list)* – A set of IP permissions. Can be used to specify multiple rules in a single command.
  
  - *(dict)* – 
  
  Describes a security group rule.

  * **IpProtocol** *(string)* – 
    
    The protocol.

    When you call DescribeSecurityGroups, the protocol value returned is the number. Exception: For TCP, UDP, and ICMP, the value returned is the name (for example, tcp, udp, or icmp). For a list of protocol numbers, see Protocol Numbers. (VPC only) When you call AuthorizeSecurityGroupIngress, you can use −1 to specify all.

  * **FromPort** *(integer)* – 
    
    The start of port range for the TCP and UDP protocols, or an ICMP type number. A value of −1 indicates all ICMP types.

  * **ToPort** *(integer)* – 
    
    The end of port range for the TCP and UDP protocols, or an ICMP code. A value of −1 indicates all ICMP codes for the specified ICMP type.

  * **UserIdGroupPairs** *(list)* – 
    
    One or more security group and AWS account ID pairs.

    - *(dict)* – 
      
      Describes a security group and AWS account ID pair.

      * **UserId** *(string)* – 
        
        The ID of an AWS account. EC2-Classic only.

      * **GroupName** *(string)* – 
        
        The name of the security group. In a request, use this parameter for a security group in EC2-Classic or a default VPC only. For a security group in a nondefault VPC, use GroupId.

      * **GroupId** *(string)* – 
        
        The ID of the security group.

  * **IpRanges** *(list)* – 
    
    One or more IP ranges.

    - *(dict)* – 
      
      Describes an IP range.

      * **CidrIp** *(string)* – 
        
        The CIDR range. You can either specify a CIDR range or a source security group, not both.

  * **PrefixListIds** *(list)* – 
    
    (Valid for AuthorizeSecurityGroupEgress, RevokeSecurityGroupEgress and DescribeSecurityGroups only) One or more prefix list IDs for an AWS service. In an AuthorizeSecurityGroupEgress request, this is the AWS service that you want to
access through a VPC endpoint from instances associated with the security group.

- **(dict)** –
  - **PrefixListId** *(string)* –
    - The ID of the prefix.

**Returns** None

**bundle_instance(**kwargs)**

Bundles an Amazon instance store-backed Windows instance.

During bundling, only the root device volume (C:) is bundled. Data on other instance store volumes is not preserved.

**Note:** This action is not applicable for Linux/Unix instances or Windows instances that are backed by Amazon EBS.

For more information, see [Creating an Instance Store-Backed Windows AMI](#).

**Request Syntax**

```python
response = client.bundle_instance(
    DryRun=True|False,
    InstanceId='string',
    Storage={
        'S3': {
            'Bucket': 'string',
            'Prefix': 'string',
            'AWSAccessKeyId': 'string',
            'UploadPolicy': b'bytes',
            'UploadPolicySignature': 'string'
        }
    }
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **InstanceId** *(string)* – [REQUIRED]
  - The ID of the instance to bundle.
  - Type: String
  - Default: None
  - Required: Yes

- **Storage** *(dict)* – [REQUIRED]
  - The bucket in which to store the AMI. You can specify a bucket that you already own or a new bucket that Amazon EC2 creates on your behalf. If you specify a bucket that belongs to someone else, Amazon EC2 returns an error.
    - **S3** *(dict)* –
      - An Amazon S3 storage location.
* **Bucket** *(string)* –
  The bucket in which to store the AMI. You can specify a bucket that you already own or a new bucket that Amazon EC2 creates on your behalf. If you specify a bucket that belongs to someone else, Amazon EC2 returns an error.

* **Prefix** *(string)* –
  The beginning of the file name of the AMI.

* **AWSAccessKeyId** *(string)* –
  The access key ID of the owner of the bucket. Before you specify a value for your access key ID, review and follow the guidance in Best Practices for Managing AWS Access Keys.

* **UploadPolicy** *(bytes)* –
  A Base64-encoded Amazon S3 upload policy that gives Amazon EC2 permission to upload items into Amazon S3 on your behalf.

* **UploadPolicySignature** *(string)* –
  The signature of the Base64 encoded JSON document.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'BundleTask': {
        'InstanceId': 'string',
        'BundleId': 'string',
        'State': 'pending'|'waiting-for-shutdown'|'bundling'|'storing'|'cancelling'|'complete'|'failed',
        'StartTime': datetime(2015, 1, 1),
        'UpdateTime': datetime(2015, 1, 1),
        'Storage': {
            'S3': {
                'Bucket': 'string',
                'Prefix': 'string',
                'AWSAccessKeyId': 'string',
                'UploadPolicy': b'bytes',
                'UploadPolicySignature': 'string'
            }
        },
        'Progress': 'string',
        'BundleTaskError': {
            'Code': 'string',
            'Message': 'string'
        }
    }
}
```

**Response Structure**

* *(dict)* –
  - **BundleTask** *(dict)* –
    Information about the bundle task.
    * **InstanceId** *(string)* –
      The ID of the instance associated with this bundle task.
    * **BundleId** *(string)* –
The ID of the bundle task.
* **State** *(string)* –
  The state of the task.
* **StartTime** *(datetime)* –
  The time this task started.
* **UpdateTime** *(datetime)* –
  The time of the most recent update for the task.
* **Storage** *(dict)* –
  The Amazon S3 storage locations.
  · **S3** *(dict)* –
    An Amazon S3 storage location.
  · **Bucket** *(string)* –
    The bucket in which to store the AMI. You can specify a bucket that you already own or a new bucket that Amazon EC2 creates on your behalf. If you specify a bucket that belongs to someone else, Amazon EC2 returns an error.
  · **Prefix** *(string)* –
    The beginning of the file name of the AMI.
  · **AWSAccessKeyId** *(string)* –
    The access key ID of the owner of the bucket. Before you specify a value for your access key ID, review and follow the guidance in Best Practices for Managing AWS Access Keys.
  · **UploadPolicy** *(bytes)* –
    A Base64-encoded Amazon S3 upload policy that gives Amazon EC2 permission to upload items into Amazon S3 on your behalf.
  · **UploadPolicySignature** *(string)* –
    The signature of the Base64 encoded JSON document.
* **Progress** *(string)* –
  The level of task completion, as a percent (for example, 20%).
* **BundleTaskError** *(dict)* –
  If the task fails, a description of the error.
  · **Code** *(string)* –
    The error code.
  · **Message** *(string)* –
    The error message.

**can_paginate**(operation_name)
Check if an operation can be paginated.

**Parameters** operation_name *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

**Returns** True if the operation can be paginated, False otherwise.

**cancel_bundle_task**(**kwargs)
Cancels a bundling operation for an instance store-backed Windows instance.
Request Syntax

```python
response = client.cancel_bundle_task(
    DryRun=True|False,
    BundleId='string'
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **BundleId** *(string)* – [REQUIRED]

  The ID of the bundle task.

Return type  dict

Returns

Response Syntax

```python
{
    'BundleTask': {
        'InstanceId': 'string',
        'BundleId': 'string',
        'State': 'pending'|'waiting-for-shutdown'|'bundling'|'storing'|'cancelling'|'complete'|'failed',
        'StartTime': datetime(2015, 1, 1),
        'UpdateTime': datetime(2015, 1, 1),
        'Storage': {
            'S3': {
                'Bucket': 'string',
                'Prefix': 'string',
                'AWSAccessKeyId': 'string',
                'UploadPolicy': b'bytes',
                'UploadPolicySignature': 'string'
            }
        },
        'Progress': 'string',
        'BundleTaskError': {
            'Code': 'string',
            'Message': 'string'
        }
    }
}
```

Response Structure

- *(dict)* –
  - **BundleTask** *(dict)* –

    Information about the bundle task.

    - **InstanceId** *(string)* –
      The ID of the instance associated with this bundle task.
    - **BundleId** *(string)* –
      The ID of the bundle task.
    - **State** *(string)* –
      The state of the task.
* **StartTime** *(datetime)* –
  The time this task started.
* **UpdateTime** *(datetime)* –
  The time of the most recent update for the task.
* **Storage** *(dict)* –
  The Amazon S3 storage locations.
  - **S3** *(dict)* –
    An Amazon S3 storage location.
  - **Bucket** *(string)* –
    The bucket in which to store the AMI. You can specify a bucket that you already own or a new bucket that Amazon EC2 creates on your behalf. If you specify a bucket that belongs to someone else, Amazon EC2 returns an error.
  - **Prefix** *(string)* –
    The beginning of the file name of the AMI.
  - **AWSAccessKeyId** *(string)* –
    The access key ID of the owner of the bucket. Before you specify a value for your access key ID, review and follow the guidance in Best Practices for Managing AWS Access Keys.
  - **UploadPolicy** *(bytes)* –
    A Base64-encoded Amazon S3 upload policy that gives Amazon EC2 permission to upload items into Amazon S3 on your behalf.
  - **UploadPolicySignature** *(string)* –
    The signature of the Base64 encoded JSON document.
* **Progress** *(string)* –
  The level of task completion, as a percent (for example, 20%).
* **BundleTaskError** *(dict)* –
  If the task fails, a description of the error.
  - **Code** *(string)* –
    The error code.
  - **Message** *(string)* –
    The error message.

**cancel_conversion_task** (**kwargs**)
Cancels an active conversion task. The task can be the import of an instance or volume. The action removes all artifacts of the conversion, including a partially uploaded volume or instance. If the conversion is complete or is in the process of transferring the final disk image, the command fails and returns an exception.

For more information, see Using the Command Line Tools to Import Your Virtual Machine to Amazon EC2 in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = client.cancel_conversion_task(
    DryRun=True|False,
    ConversionTaskId='string',
)```

3.1. Services 1123
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **ConversionTaskId** *(string)* – [REQUIRED]
  
  The ID of the conversion task.
- **ReasonMessage** *(string)* – The reason for canceling the conversion task.

Returns

None

**cancel_export_task(**kwargs**)**

Cancels an active export task. The request removes all artifacts of the export, including any partially-created Amazon S3 objects. If the export task is complete or is in the process of transferring the final disk image, the command fails and returns an error.

Request Syntax

```python
response = client.cancel_export_task(
    ExportTaskId='string'
)
```

**Parameters**

- **ExportTaskId** *(string)* – [REQUIRED]
  
  The ID of the export task. This is the ID returned by `CreateInstanceExportTask`.

Returns

None

**cancel_import_task(**kwargs**)**

Cancels an in-process import virtual machine or import snapshot task.

Request Syntax

```python
response = client.cancel_import_task(
    DryRun=True|False,
    ImportTaskId='string',
    CancelReason='string'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **ImportTaskId** *(string)* – The ID of the import image or import snapshot task to be canceled.
- **CancelReason** *(string)* – The reason for canceling the task.

Return type

*dict*

Returns

**Response Syntax**

```python
{
    'ImportTaskId': 'string',
    'State': 'string',
    ...
}
```
'PreviousState': 'string'
}

Response Structure
• (dict) –
  – ImportTaskId (string) –
    The ID of the task being canceled.
  – State (string) –
    The current state of the task being canceled.
  – PreviousState (string) –
    The current state of the task being canceled.

cancel_reserved_instances_listing(**kwargs)
Cancels the specified Reserved Instance listing in the Reserved Instance Marketplace.

For more information, see Reserved Instance Marketplace in the Amazon Elastic Compute Cloud User Guide.

Request Syntax
response = client.cancel_reserved_instances_listing(
    ReservedInstancesListingId='string'
)

Parameters
ReservedInstancesListingId (string) – [REQUIRED]
  The ID of the Reserved Instance listing.

Return type
dict

Returns

Response Syntax
{
    'ReservedInstancesListings': [
        {
            'ReservedInstancesListingId': 'string',
            'ReservedInstancesId': 'string',
            'CreateDate': datetime(2015, 1, 1),
            'UpdateDate': datetime(2015, 1, 1),
            'Status': 'active'|'pending'|'cancelled'|'closed',
            'StatusMessage': 'string',
            'InstanceCounts': [
                {
                    'State': 'available'|'sold'|'cancelled'|'pending',
                    'InstanceCount': 123
                },
            ],
            'PriceSchedules': [
                {
                    'Term': 123,
                    'Price': 123.0,
                    'CurrencyCode': 'USD',
                    'Active': True|False
                },
            ],
            'Tags': [
            ]
        }
    ]
}
'Key': 'string',
'Value': 'string'
},

'ClientToken': 'string'
}

Response Structure
- (dict) –
  - ReservedInstancesListings (list) –
    The Reserved Instance listing.
    * (dict) –
      Describes a Reserved Instance listing.
      - ReservedInstancesListingId (string) –
        The ID of the Reserved Instance listing.
      - ReservedInstancesId (string) –
        The ID of the Reserved Instance.
      - CreateDate (datetime) –
        The time the listing was created.
      - UpdateDate (datetime) –
        The last modified timestamp of the listing.
      - Status (string) –
        The status of the Reserved Instance listing.
      - StatusMessage (string) –
        The reason for the current status of the Reserved Instance listing. The response can be blank.
      - InstanceCounts (list) –
        The number of instances in this state.
        * (dict) –
          Describes a Reserved Instance listing state.
          - State (string) –
            The states of the listed Reserved Instances.
          - InstanceCount (integer) –
            The number of listed Reserved Instances in the state specified by the state.
          - PriceSchedules (list) –
            The price of the Reserved Instance listing.
            * (dict) –
              Describes the price for a Reserved Instance.
              - Term (integer) –
                The number of months remaining in the reservation. For example, 2 is the second to the last month before the capacity reservation expires.
              - Price (float) –
The fixed price for the term.
- **CurrencyCode** *(string)* –
  The currency for transacting the Reserved Instance resale. At this time, the only supported currency is USD.
- **Active** *(boolean)* –
  The current price schedule, as determined by the term remaining for the Reserved Instance in the listing.

  A specific price schedule is always in effect, but only one price schedule can be active at any time. Take, for example, a Reserved Instance listing that has five months remaining in its term. When you specify price schedules for five months and two months, this means that schedule 1, covering the first three months of the remaining term, will be active during months 5, 4, and 3. Then schedule 2, covering the last two months of the term, will be active for months 2 and 1.
- **Tags** *(list)* –
  Any tags assigned to the resource.
  *(dict)* –
  Describes a tag.
  - **Key** *(string)* –
    The key of the tag.
    Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`
  - **Value** *(string)* –
    The value of the tag.
    Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.
  - **ClientToken** *(string)* –
    A unique, case-sensitive key supplied by the client to ensure that the request is idempotent. For more information, see **Ensuring Idempotency**.

**cancel_spot_fleet_requests(**kwargs**)**
Cancels the specified Spot fleet requests.

**Request Syntax**

```python
response = client.cancel_spot_fleet_requests(
    DryRun=True|False,
    SpotFleetRequestIds=[
        'string',
    ],
    TerminateInstances=True|False
)
```

**Parameters**
- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.
• **SpotFleetRequestIds** *(list)* – [REQUIRED]

The IDs of the Spot fleet requests.
  – *(string)* –

• **TerminateInstances** *(boolean)* – [REQUIRED]

Indicates whether to terminate instances for a Spot fleet request if it is canceled successfully.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
def CancelSpotFleetRequests(SpotFleetRequestIds: list, TerminateInstances: bool):
    return {
        'UnsuccessfulFleetRequests': [
            {'SpotFleetRequestId': 'string',
             'Error': {'Code': 'fleetRequestIdDoesNotExist'|'fleetRequestIdMalformed'|'fleetRequestNotInCancellableState'|'unexpectedError',
                       'Message': 'string'}}
        ],
        'SuccessfulFleetRequests': [
            {'SpotFleetRequestId': 'string',
             'CurrentSpotFleetRequestState': 'submitted'|'active'|'cancelled'|'failed'|'cancelled_running'|'cancelled_terminating',
             'PreviousSpotFleetRequestState': 'submitted'|'active'|'cancelled'|'failed'}
        ]
    }
```

**Response Structure**

• *(dict)* –

Contains the output of CancelSpotFleetRequests.

  – **UnsuccessfulFleetRequests** *(list)* –

  Information about the Spot fleet requests that are not successfully canceled.

    * *(dict)* –

    Describes a Spot fleet request that was not successfully canceled.

      • **SpotFleetRequestId** *(string)* –

          The ID of the Spot fleet request.

      • **Error** *(dict)* –

          The error.

      • **Code** *(string)* –

          The error code.

      • **Message** *(string)* –

          The description for the error code.

  – **SuccessfulFleetRequests** *(list)* –

  Information about the Spot fleet requests that are successfully canceled.

    * *(dict)* –

    Describes a Spot fleet request that was successfully canceled.
· **SpotFleetRequestId** *(string)* – The ID of the Spot fleet request.
· **CurrentSpotFleetRequestState** *(string)* – The current state of the Spot fleet request.
· **PreviousSpotFleetRequestState** *(string)* – The previous state of the Spot fleet request.

**cancel_spot_instance_requests**(**kwargs**)  
Cancels one or more Spot instance requests. Spot instances are instances that Amazon EC2 starts on your behalf when the bid price that you specify exceeds the current Spot price. Amazon EC2 periodically sets the Spot price based on available Spot instance capacity and current Spot instance requests. For more information, see Spot Instance Requests in the *Amazon Elastic Compute Cloud User Guide*.

**Warning:** Canceling a Spot instance request does not terminate running Spot instances associated with the request.

**Request Syntax**

```python
response = client.cancel_spot_instance_requests(
    DryRun=True|False,
    SpotInstanceRequestIds=[
        'string',
    ]
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.
- **SpotInstanceRequestIds** *(list)* – [REQUIRED] One or more Spot instance request IDs.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{}

    'CancelledSpotInstanceRequests': [
        {
            'SpotInstanceRequestId': 'string',
            'State': 'active'|'open'|'closed'|'cancelled'|'completed'
        },
    ]
}
```

**Response Structure**

- *(dict)* – Contains the output of **CancelSpotInstanceRequests**.
  - **CancelledSpotInstanceRequests** *(list)* – One or more Spot instance requests.
* (dict) –

Describes a request to cancel a Spot instance.

- **SpotInstanceRequestId** (string) –
  The ID of the Spot instance request.
- **State** (string) –
  The state of the Spot instance request.

**confirm_product_instance(**kwargs)**

Determines whether a product code is associated with an instance. This action can only be used by the owner of the product code. It is useful when a product code owner needs to verify whether another user’s instance is eligible for support.

### Request Syntax

```python
response = client.confirm_product_instance(
    DryRun=True|False,
    ProductCode='string',
    InstanceId='string'
)
```

### Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **ProductCode** (string) – [REQUIRED]
  The product code. This must be a product code that you own.
- **InstanceId** (string) – [REQUIRED]
  The ID of the instance.

### Return type
dict

### Returns

```
{
    'OwnerId': 'string',
    'Return': True|False
}
```

### Response Structure

- (dict) –
  - **OwnerId** (string) –
    The AWS account ID of the instance owner. This is only present if the product code is attached to the instance.
  - **Return** (boolean) –
    The return value of the request. Returns true if the specified product code is owned by the requester and associated with the specified instance.

**copy_image(**kwargs)**

Initiates the copy of an AMI from the specified source region to the current region. You specify the destination region by using its endpoint when making the request. AMIs that use encrypted EBS snapshots cannot be copied with this method.

For more information, see Copying AMIs in the Amazon Elastic Compute Cloud User Guide.
Request Syntax

```python
response = client.copy_image(
    DryRun=True|False,
    SourceRegion='string',
    SourceImageId='string',
    Name='string',
    Description='string',
    ClientToken='string'
)
```

Parameters

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **SourceRegion** (*string*) – [REQUIRED]
  The name of the region that contains the AMI to copy.
- **SourceImageId** (*string*) – [REQUIRED]
  The ID of the AMI to copy.
- **Name** (*string*) – [REQUIRED]
  The name of the new AMI in the destination region.
- **Description** (*string*) – A description for the new AMI in the destination region.
- **ClientToken** (*string*) – Unique, case-sensitive identifier you provide to ensure idempotency of the request. For more information, see How to Ensure Idempotency in the Amazon Elastic Compute Cloud User Guide.

Return type: `dict`

Returns

Response Syntax

```json
{
    'ImageId': 'string'
}
```

Response Structure

- (dict) –
  - **ImageId** (*string*) –
    The ID of the new AMI.

`copy_snapshot(**kwargs)`

Copies a point-in-time snapshot of an EBS volume and stores it in Amazon S3. You can copy the snapshot within the same region or from one region to another. You can use the snapshot to create EBS volumes or Amazon Machine Images (AMIs). The snapshot is copied to the regional endpoint that you send the HTTP request to.

Copies of encrypted EBS snapshots remain encrypted. Copies of unencrypted snapshots remain unencrypted, unless the `Encrypted` flag is specified during the snapshot copy operation. By default, encrypted snapshot copies use the default AWS Key Management Service (AWS KMS) customer master key (CMK); however, you can specify a non-default CMK with the `KmsKeyId` parameter.

For more information, see Copying an Amazon EBS Snapshot in the Amazon Elastic Compute Cloud User Guide.

Request Syntax
response = client.copy_snapshot(
    DryRun=True|False,
    SourceRegion='string',
    SourceSnapshotId='string',
    Description='string',
    Encrypted=True|False,
    KmsKeyId='string'
)

Parameters

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **SourceRegion** (*string*) – [REQUIRED]

  The ID of the region that contains the snapshot to be copied.

- **SourceSnapshotId** (*string*) – [REQUIRED]

  The ID of the EBS snapshot to copy.

- **Description** (*string*) – A description for the EBS snapshot.

- **DestinationRegion** (*string*) – The destination region to use in the `PresignedUrl` parameter of a snapshot copy operation. This parameter is only valid for specifying the destination region in a `PresignedUrl` parameter, where it is required.

  **Note:** `CopySnapshot` sends the snapshot copy to the regional endpoint that you send the HTTP request to, such as `ec2.us-east-1.amazonaws.com` (in the AWS CLI, this is specified with the `--region` parameter or the default region in your AWS configuration file).

  Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required

- **PresignedUrl** (*string*) – The pre-signed URL that facilitates copying an encrypted snapshot. This parameter is only required when copying an encrypted snapshot with the Amazon EC2 Query API; it is available as an optional parameter in all other cases. The `PresignedUrl` should use the snapshot source endpoint, the `CopySnapshot` action, and include the `SourceRegion`, `SourceSnapshotId`, and `DestinationRegion` parameters. The `PresignedUrl` must be signed using AWS Signature Version 4. Because EBS snapshots are stored in Amazon S3, the signing algorithm for this parameter uses the same logic that is described in [Authenticating Requests by Using Query Parameters (AWS Signature Version 4) in the Amazon Simple Storage Service API Reference](https://docs.aws.amazon.com/AmazonS3/latest/API/auth.html). An invalid or improperly signed `PresignedUrl` will cause the copy operation to fail asynchronously, and the snapshot will move to an error state.

  Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required

- **Encrypted** (*boolean*) – Specifies whether the destination snapshot should be encrypted. There is no way to create an unencrypted snapshot copy from an encrypted snapshot; however, you can encrypt a copy of an unencrypted snapshot with this flag. The default CMK for EBS is used unless a non-default AWS Key Management Service (AWS KMS) CMK is specified with `KmsKeyId`. For more information, see [Amazon EBS Encryption](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/EBSEncryption.html) in the Amazon Elastic Compute Cloud User Guide.

- **KmsKeyId** (*string*) – The full ARN of the AWS Key Management Service
(AWS KMS) CMK to use when creating the snapshot copy. This parameter is only required if you want to use a non-default CMK; if this parameter is not specified, the default CMK for EBS is used. The ARN contains the arn:aws:kms namespace, followed by the region of the CMK, the AWS account ID of the CMK owner, the key namespace, and then the CMK ID. For example, arn:aws:kms:us-east-1:012345678910:key/abcd1234-a123-456a-a12b-a123b4cd56ef. The specified CMK must exist in the region that the snapshot is being copied to. If a KmsKeyId is specified, the Encrypted flag must also be set.

Return type: dict

Response Syntax

```
{
    'SnapshotId': 'string'
}
```

Response Structure

- (dict) –
  - **SnapshotId** (string) –
    The ID of the new snapshot.

create_customer_gateway(**kwargs)

Provides information to AWS about your VPN customer gateway device. The customer gateway is the appliance at your end of the VPN connection. (The device on the AWS side of the VPN connection is the virtual private gateway.) You must provide the Internet-routable IP address of the customer gateway’s external interface. The IP address must be static and can’t be behind a device performing network address translation (NAT).

For devices that use Border Gateway Protocol (BGP), you can also provide the device’s BGP Autonomous System Number (ASN). You can use an existing ASN assigned to your network. If you don’t have an ASN already, you can use a private ASN (in the 64512 - 65534 range).

**Note:** Amazon EC2 supports all 2-byte ASN numbers in the range of 1 - 65534, with the exception of 7224, which is reserved in the us-east-1 region, and 9059, which is reserved in the eu-west-1 region.

For more information about VPN customer gateways, see Adding a Hardware Virtual Private Gateway to Your VPC in the Amazon Virtual Private Cloud User Guide.

**Warning:** You cannot create more than one customer gateway with the same VPN type, IP address, and BGP ASN parameter values. If you run an identical request more than one time, the first request creates the customer gateway, and subsequent requests return information about the existing customer gateway. The subsequent requests do not create new customer gateway resources.

Request Syntax

```
response = client.create_customer_gateway(
    DryRun=True|False,
    Type='ipsec.1',
    PublicIp='string',
    BgpAsn=123
)
```

Parameters
• **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

• **Type (string)** – [REQUIRED]
  
The type of VPN connection that this customer gateway supports (ipsec.1).

• **PublicIp (string)** – [REQUIRED]
  
The Internet-routable IP address for the customer gateway’s outside interface. The address must be static.

• **BgpAsn (integer)** – [REQUIRED]
  
For devices that support BGP, the customer gateway’s BGP ASN.

  Default: 65000

Return type  dict
Returns

Response Syntax

```python
{
    'CustomerGateway': {
        'CustomerGatewayId': 'string',
        'State': 'string',
        'Type': 'string',
        'IpAddress': 'string',
        'BgpAsn': 'string',
        'Tags': [
            {
                'Key': 'string',
                'Value': 'string'
            },
        ],
    }
}
```

Response Structure

• (dict) –

  – **CustomerGateway (dict)** –

  Information about the customer gateway.

  * **CustomerGatewayId (string)** –

    The ID of the customer gateway.

  * **State (string)** –

    The current state of the customer gateway (pending | available | deleting | deleted).

  * **Type (string)** –

    The type of VPN connection the customer gateway supports (ipsec.1).

  * **IpAddress (string)** –

    The Internet-routable IP address of the customer gateway’s outside interface.

  * **BgpAsn (string)** –

    The customer gateway’s Border Gateway Protocol (BGP) Autonomous System Number (ASN).
Tags (list) –

Any tags assigned to the customer gateway.

· (dict) –
  
  Describes a tag.

· Key (string) –
  
  The key of the tag.

  Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with aws:

· Value (string) –
  
  The value of the tag.

  Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

create_dhcp_options (**kwargs)

Creates a set of DHCP options for your VPC. After creating the set, you must associate it with the VPC, causing all existing and new instances that you launch in the VPC to use this set of DHCP options. The following are the individual DHCP options you can specify. For more information about the options, see RFC 2132.

· domain-name-servers - The IP addresses of up to four domain name servers, or AmazonProvidedDNS. The default DHCP option set specifies AmazonProvidedDNS. If specifying more than one domain name server, specify the IP addresses in a single parameter, separated by commas.

· domain-name - If you’re using AmazonProvidedDNS in us-east-1, specify ec2.internal. If you’re using AmazonProvidedDNS in another region, specify region.compute.internal (for example, ap-northeast-1.compute.internal). Otherwise, specify a domain name (for example, MyCompany.com). Important: Some Linux operating systems accept multiple domain names separated by spaces. However, Windows and other Linux operating systems treat the value as a single domain, which results in unexpected behavior. If your DHCP options set is associated with a VPC that has instances with multiple operating systems, specify only one domain name.

· ntp-servers - The IP addresses of up to four Network Time Protocol (NTP) servers.

· netbios-name-servers - The IP addresses of up to four NetBIOS name servers.

· netbios-node-type - The NetBIOS node type (1, 2, 4, or 8). We recommend that you specify 2 (broadcast and multicast are not currently supported). For more information about these node types, see RFC 2132.

Your VPC automatically starts out with a set of DHCP options that includes only a DNS server that we provide (AmazonProvidedDNS). If you create a set of options, and if your VPC has an Internet gateway, make sure to set the domain-name-servers option either to AmazonProvidedDNS or to a domain name server of your choice. For more information about DHCP options, see DHCP Options Sets in the Amazon Virtual Private Cloud User Guide.

Request Syntax

```python
response = client.create_dhcp_options(
    DryRun=True|False,
    DhcpConfigurations=[
        {
            'Key': 'string',
            'Values': ['string',]
        },
    ],
)```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **DhcpConfigurations** *(list)* – [REQUIRED]

  A DHCP configuration option.
  
  - *(dict)* –
    
    - **Key** *(string)* –
    
    - **Values** *(list)* –
      
      - *(string)* –

Return type  dict

Returns

Response Syntax

```
{
  'DhcpOptions': {
    'DhcpOptionsId': 'string',
    'DhcpConfigurations': [
      {
        'Key': 'string',
        'Values': [
          {
            'Value': 'string'
          }]
      },
    ],
    'Tags': [
      {
        'Key': 'string',
        'Value': 'string'
      }
    ]
  }
}
```

Response Structure

- *(dict)* –
  
  - **DhcpOptions** *(dict)* –
    
    A set of DHCP options.
    
    - **DhcpOptionsId** *(string)* –
      
      The ID of the set of DHCP options.
    
    - **DhcpConfigurations** *(list)* –
      
      One or more DHCP options in the set.
      
      - *(dict)* –
        
        Describes a DHCP configuration option.
        
        - **Key** *(string)* –
          
          The name of a DHCP option.
Values (list) –
One or more values for the DHCP option.

(dict) –
The value to use for a resource attribute.

Value (string) –
Valid values are case-sensitive and vary by action.

Tags (list) –
Any tags assigned to the DHCP options set.

(dict) –
Describes a tag.

Key (string) –
The key of the tag.

Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws`.

Value (string) –
The value of the tag.

Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

create_flow_logs(**kwargs)

Creates one or more flow logs to capture IP traffic for a specific network interface, subnet, or VPC. Flow logs are delivered to a specified log group in Amazon CloudWatch Logs. If you specify a VPC or subnet in the request, a log stream is created in CloudWatch Logs for each network interface in the subnet or VPC. Log streams can include information about accepted and rejected traffic to a network interface. You can view the data in your log streams using Amazon CloudWatch Logs.

In your request, you must also specify an IAM role that has permission to publish logs to CloudWatch Logs.

Request Syntax

```python
response = client.create_flow_logs(
    ResourceIds=[
        'string',
    ],
    ResourceType='VPC'|'Subnet'|'NetworkInterface',
    TrafficType='ACCEPT'|'REJECT'|'ALL',
    LogGroupName='string',
    DeliverLogsPermissionArn='string',
    ClientToken='string'
)
```

Parameters

- **ResourceIds (list)** – [REQUIRED]
  One or more subnet, network interface, or VPC IDs.

- **ResourceType (string)** – [REQUIRED]
  The type of resource on which to create the flow log.

- **TrafficType (string)** – [REQUIRED]
  The type of traffic to log.
• **LogGroupName** *(string)* – [REQUIRED]
  
  The name of the CloudWatch log group.

• **DeliverLogsPermissionArn** *(string)* – [REQUIRED]
  
  The ARN for the IAM role that’s used to post flow logs to a CloudWatch Logs log group.

• **ClientToken** *(string)* – Unique, case-sensitive identifier you provide to ensure the idempotency of the request. For more information, see How to Ensure Idempotency.

Return type  dict

Returns

Response Syntax

```
{
    'FlowLogIds': [
        'string',
    ],
    'ClientToken': 'string',
    'Unsuccessful': [
        {
            'ResourceId': 'string',
            'Error': {
                'Code': 'string',
                'Message': 'string'
            }
        },
    ]
}
```

Response Structure

- *(dict)*  
  - **FlowLogIds** *(list)*  
    The IDs of the flow logs.
    
      - *(string)*
  
  - **ClientToken** *(string)*  
    
      Unique, case-sensitive identifier you provide to ensure the idempotency of the request.

  - **Unsuccessful** *(list)*  
    Information about the flow logs that could not be created successfully.
    
      - *(dict)*  
        Information about items that were not successfully processed in a batch call.
        
          - **ResourceId** *(string)*  
            The ID of the resource.
        
          - **Error** *(dict)*  
            Information about the error.
            
              - **Code** *(string)*  
                The error code.
            
              - **Message** *(string)*  
                The error message accompanying the error code.
create_image(**kwargs)

Creates an Amazon EBS-backed AMI from an Amazon EBS-backed instance that is either running or stopped.

If you customized your instance with instance store volumes or EBS volumes in addition to the root device volume, the new AMI contains block device mapping information for those volumes. When you launch an instance from this new AMI, the instance automatically launches with those additional volumes.

For more information, see Creating Amazon EBS-Backed Linux AMIs in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = client.create_image(
    DryRun=True|False,
    InstanceId='string',
    Name='string',
    Description='string',
    NoReboot=True|False,
    BlockDeviceMappings=[
        {
            'VirtualName': 'string',
            'DeviceName': 'string',
            'Ebs': {
                'SnapshotId': 'string',
                'VolumeSize': 123,
                'DeleteOnTermination': True|False,
                'VolumeType': 'standard'|'io1'|'gp2',
                'Iops': 123,
                'Encrypted': True|False
            },
            'NoDevice': 'string'
        },
    ]
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **InstanceId** *(string)* – [REQUIRED]

  The ID of the instance.

- **Name** *(string)* – [REQUIRED]

  A name for the new image.

  Constraints: 3-128 alphanumeric characters, parentheses (()), square brackets ([]), spaces (), periods (.), slashes (/), dashes (-), single quotes ('), at-signs (@), or underscores(_)

- **Description** *(string)* – A description for the new image.

- **NoReboot** *(boolean)* – By default, this parameter is set to `false`, which means Amazon EC2 attempts to shut down the instance cleanly before image creation and then reboots the instance. When the parameter is set to `true`, Amazon EC2 doesn’t shut down the instance before creating the image. When this option is used, file system integrity on the created image can’t be guaranteed.

- **BlockDeviceMappings** *(list)* – Information about one or more block device mappings.
- (dict) –

Describes a block device mapping.

* VirtualName (string) –

The virtual device name (ephemeral N). Instance store volumes are numbered starting from 0. An instance type with 2 available instance store volumes can specify mappings for ephemeral0 and ephemeral1. The number of available instance store volumes depends on the instance type. After you connect to the instance, you must mount the volume.

Constraints: For M3 instances, you must specify instance store volumes in the block device mapping for the instance. When you launch an M3 instance, we ignore any instance store volumes specified in the block device mapping for the AMI.

* DeviceName (string) –

The device name exposed to the instance (for example, /dev/sdh or xvdh).

* Ebs (dict) –

Parameters used to automatically set up EBS volumes when the instance is launched.

  - SnapshotId (string) –
    
The ID of the snapshot.

  - VolumeSize (integer) –
    
The size of the volume, in GiB.
    
    Constraints: 1-1024 for standard volumes, 1-16384 for gp2 volumes, and 4-16384 for io1 volumes. If you specify a snapshot, the volume size must be equal to or larger than the snapshot size.
    
    Default: If you’re creating the volume from a snapshot and don’t specify a volume size, the default is the snapshot size.

  - DeleteOnTermination (boolean) –
    
    Indicates whether the EBS volume is deleted on instance termination.

  - VolumeType (string) –
    
The volume type. gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, and standard for Magnetic volumes.
    
    Default: standard

  - Iops (integer) –
    
The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.
Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.

Condition: This parameter is required for requests to create io1 volumes; it is not used in requests to create standard or gp2 volumes.

- **Encrypted** *(boolean)* – Indicates whether the EBS volume is encrypted. Encrypted Amazon EBS volumes may only be attached to instances that support Amazon EBS encryption.

- **NoDevice** *(string)* – Suppresses the specified device included in the block device mapping of the AMI.

### create_instance_export_task(**kwargs)**

Exports a running or stopped instance to an S3 bucket.

For information about the supported operating systems, image formats, and known limitations for the types of instances you can export, see Exporting EC2 Instances in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```
response = client.create_instance_export_task(
    Description='string',
    InstanceId='string',
    TargetEnvironment='citrix'|'vmware'|'microsoft',
    ExportToS3Task={
        'DiskImageFormat': 'VMDK'|'RAW'|'VHD',
        'ContainerFormat': 'ova',
        'S3Bucket': 'string',
        'S3Prefix': 'string'
    }
)
```

**Parameters**

- **Description** *(string)* – A description for the conversion task or the resource being exported. The maximum length is 255 bytes.

- **InstanceId** *(string)* – [REQUIRED]

  The ID of the instance.

- **TargetEnvironment** *(string)* – The target virtualization environment.

- **ExportToS3Task** *(dict)* – The format and location for an instance export task.
– **DiskImageFormat** *(string)* –
  The format for the exported image.

– **ContainerFormat** *(string)* –
  The container format used to combine disk images with metadata (such as OVF). If absent, only the disk image is exported.

– **S3Bucket** *(string)* –
  The S3 bucket for the destination image. The destination bucket must exist and grant WRITE and READ_ACP permissions to the AWS account `vm-import-export@amazon.com`.

– **S3Prefix** *(string)* –
  The image is written to a single object in the S3 bucket at the S3 key `s3prefix + exportTaskId + '.' + diskImageFormat`.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
 {
   'ExportTask': {
     'ExportTaskId': 'string',
     'Description': 'string',
     'State': 'active'|'cancelling'|'cancelled'|'completed',
     'StatusMessage': 'string',
     'InstanceExportDetails': {
       'InstanceId': 'string',
       'TargetEnvironment': 'citrix'|'vmware'|'microsoft'
     },
     'ExportToS3Task': {
       'DiskImageFormat': 'VMDK'|'RAW'|'VHD',
       'ContainerFormat': 'ova',
       'S3Bucket': 'string',
       'S3Key': 'string'
     }
   }
 }
```

**Response Structure**

• *(dict)* –
  – **ExportTask** *(dict)* –

  Information about the instance export task.
  * **ExportTaskId** *(string)* –
    The ID of the export task.
  * **Description** *(string)* –
    A description of the resource being exported.
  * **State** *(string)* –
    The state of the export task.
  * **StatusMessage** *(string)* –
    The status message related to the export task.
  * **InstanceExportDetails** *(dict)* –
    Information about the instance to export.
- **InstanceId** *(string)* –
  The ID of the resource being exported.
- **TargetEnvironment** *(string)* –
  The target virtualization environment.

* ExportToS3Task *(dict)* –
  Information about the export task.
- **DiskImageFormat** *(string)* –
  The format for the exported image.
- **ContainerFormat** *(string)* –
  The container format used to combine disk images with metadata (such as OVF). If absent, only the disk image is exported.
- **S3Bucket** *(string)* –
  The S3 bucket for the destination image. The destination bucket must exist and grant WRITE and READ_ACP permissions to the AWS account `vm-import-export@amazon.com`.
- **S3Key** *(string)* –
  The encryption key for your S3 bucket.

```python
create_internet_gateway(**kwargs)
```

Creates an Internet gateway for use with a VPC. After creating the Internet gateway, you attach it to a VPC using `AttachInternetGateway`.

For more information about your VPC and Internet gateway, see the Amazon Virtual Private Cloud User Guide.

**Request Syntax**

```python
response = client.create_internet_gateway(
    DryRun=True|False
)
```

**Parameters**
- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'InternetGateway': {
        'InternetGatewayId': 'string',
        'Attachments': [
            {
                'VpcId': 'string',
                'State': 'attaching'|'attached'|'detaching'|'detached'
            },
        ],
        'Tags': [
            {
                'Key': 'string',
```
Response Structure

- (dict) –
  - InternetGateway (dict) –

  Information about the Internet gateway.
  - InternetGatewayId (string) –
    The ID of the Internet gateway.
  - Attachments (list) –
    Any VPCs attached to the Internet gateway.
      - (dict) –
        Describes the attachment of a VPC to an Internet gateway.
        - VpcId (string) –
          The ID of the VPC.
        - State (string) –
          The current state of the attachment.
  - Tags (list) –
    Any tags assigned to the Internet gateway.
      - (dict) –
        Describes a tag.
        - Key (string) –
          The key of the tag.
        - Value (string) –
          The value of the tag.

Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`.
Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

create_key_pair(**kwargs)

Creates a 2048-bit RSA key pair with the specified name. Amazon EC2 stores the public key and displays the private key for you to save to a file. The private key is returned as an unencrypted PEM encoded PKCS#8 private key. If a key with the specified name already exists, Amazon EC2 returns an error.

You can have up to five thousand key pairs per region.

The key pair returned to you is available only in the region in which you create it. To create a key pair that is available in all regions, use ImportKeyPair.

For more information about key pairs, see Key Pairs in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = client.create_key_pair(
    DryRun=True|False,
    KeyName='string'
)
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **KeyName** *(string)* – [REQUIRED]

  A unique name for the key pair.

Constraints: Up to 255 ASCII characters

Return type  dict

Returns

Response Syntax

```python
{
    'KeyName': 'string',
    'KeyFingerprint': 'string',
    'KeyMaterial': 'string'
}
```

Response Structure

- *(dict)* – Information about the key pair.
  - **KeyName** *(string)* – The name of the key pair.
  - **KeyFingerprint** *(string)* – The SHA-1 digest of the DER encoded private key.
  - **KeyMaterial** *(string)* – An unencrypted PEM encoded RSA private key.

`create_network_acl(**kwargs)`

Creates a network ACL in a VPC. Network ACLs provide an optional layer of security (in addition to security groups) for the instances in your VPC.

For more information about network ACLs, see Network ACLs in the Amazon Virtual Private Cloud User Guide.

Request Syntax

```python
response = client.create_network_acl(
    DryRun=True|False,
    VpcId='string'
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **VpcId** *(string)* – [REQUIRED]

  The ID of the VPC.

Return type  dict

Returns

Response Syntax
{  
    'NetworkAcl': {
        'NetworkAclId': 'string',
        'VpcId': 'string',
        'IsDefault': True|False,
        'Entries': [
            {
                'RuleNumber': 123,
                'Protocol': 'string',
                'RuleAction': 'allow'|'deny',
                'Egress': True|False,
                'CidrBlock': 'string',
                'IcmpTypeCode': {
                    'Type': 123,
                    'Code': 123
                },
                'PortRange': {
                    'From': 123,
                    'To': 123
                }
            },
        ],
        'Associations': [
            {
                'NetworkAclAssociationId': 'string',
                'NetworkAclId': 'string',
                'SubnetId': 'string'
            },
        ],
        'Tags': [
            {
                'Key': 'string',
                'Value': 'string'
            }
        ]
    }
}

Response Structure

- (dict) –
  - NetworkAcl (dict) –

  Information about the network ACL.
  - NetworkAclId (string) –
    The ID of the network ACL.
  - VpcId (string) –
    The ID of the VPC for the network ACL.
  - IsDefault (boolean) –
    Indicates whether this is the default network ACL for the VPC.
  - Entries (list) –
    One or more entries (rules) in the network ACL.
      - (dict) –
        Describes an entry in a network ACL.
        - RuleNumber (integer) –
The rule number for the entry. ACL entries are processed in ascending order by rule number.

- **Protocol (string)** –

  The protocol. A value of -1 means all protocols.

- **RuleAction (string)** –

  Indicates whether to allow or deny the traffic that matches the rule.

- **Egress (boolean)** –

  Indicates whether the rule is an egress rule (applied to traffic leaving the subnet).

- **CidrBlock (string)** –

  The network range to allow or deny, in CIDR notation.

- **IcmpTypeCode (dict)** –

  ICMP protocol: The ICMP type and code.

  - **Type (integer)** –

    The ICMP code. A value of -1 means all codes for the specified ICMP type.

  - **Code (integer)** –

    The ICMP type. A value of -1 means all types.

- **PortRange (dict)** –

  TCP or UDP protocols: The range of ports the rule applies to.

  - **From (integer)** –

    The first port in the range.

  - **To (integer)** –

    The last port in the range.

- **Associations (list)** –

  Any associations between the network ACL and one or more subnets.

  - (dict) –

    Describes an association between a network ACL and a subnet.

  - **NetworkAclAssociationId (string)** –

    The ID of the association between a network ACL and a subnet.

  - **NetworkAclId (string)** –

    The ID of the network ACL.

  - **SubnetId (string)** –

    The ID of the subnet.

- **Tags (list)** –

  Any tags assigned to the network ACL.

  - (dict) –

    Describes a tag.

  - **Key (string)** –

    The key of the tag.
Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`.

- **Value (string)** –

  The value of the tag.

Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

create_network_acl_entry (**kwargs)**

Creates an entry (a rule) in a network ACL with the specified rule number. Each network ACL has a set of numbered ingress rules and a separate set of numbered egress rules. When determining whether a packet should be allowed in or out of a subnet associated with the ACL, we process the entries in the ACL according to the rule numbers, in ascending order. Each network ACL has a set of ingress rules and a separate set of egress rules.

We recommend that you leave room between the rule numbers (for example, 100, 110, 120, ...), and not number them one right after the other (for example, 101, 102, 103, ...). This makes it easier to add a rule between existing ones without having to renumber the rules.

After you add an entry, you can’t modify it; you must either replace it, or create an entry and delete the old one.

For more information about network ACLs, see Network ACLs in the Amazon Virtual Private Cloud User Guide.

**Request Syntax**

```python
response = client.create_network_acl_entry(
    DryRun=True|False,
    NetworkAclId='string',
    RuleNumber=123,
    Protocol='string',
    RuleAction='allow'|'deny',
    Egress=True|False,
    CidrBlock='string',
    IcmpTypeCode={
        'Type': 123,
        'Code': 123
    },
    PortRange={
        'From': 123,
        'To': 123
    }
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **NetworkAclId (string)** – [REQUIRED]  
  The ID of the network ACL.

- **RuleNumber (integer)** – [REQUIRED]  
  The rule number for the entry (for example, 100). ACL entries are processed in ascending order by rule number.

  Constraints: Positive integer from 1 to 32766
- **Protocol** *(string)* – [REQUIRED]
  The protocol. A value of -1 means all protocols.

- **RuleAction** *(string)* – [REQUIRED]
  Indicates whether to allow or deny the traffic that matches the rule.

- **Egress** *(boolean)* – [REQUIRED]
  Indicates whether this is an egress rule (rule is applied to traffic leaving the subnet).

- **CidrBlock** *(string)* – [REQUIRED]
  The network range to allow or deny, in CIDR notation (for example 172.16.0.0/24).

- **IcmpTypeCode** *(dict)* – ICMP protocol: The ICMP type and code. Required if specifying ICMP for the protocol.
  - **Type** *(integer)* –
    The ICMP code. A value of -1 means all codes for the specified ICMP type.
  - **Code** *(integer)* –
    The ICMP type. A value of -1 means all types.

- **PortRange** *(dict)* – TCP or UDP protocols: The range of ports the rule applies to.
  - **From** *(integer)* –
    The first port in the range.
  - **To** *(integer)* –
    The last port in the range.

**Returns** None

```python
create_network_interface(**kwargs)
```

Creates a network interface in the specified subnet.

For more information about network interfaces, see Elastic Network Interfaces in the *Amazon Elastic Compute Cloud User Guide*.

**Request Syntax**

```python
response = client.create_network_interface(
    SubnetId='string',
    Description='string',
    PrivateIpAddress='string',
    Groups=[
        'string',
    ],
    PrivateIpAddresses=[
        {
            'PrivateIpAddress': 'string',
            'Primary': True|False
        },
    ],
    SecondaryPrivateIpAddressCount=123,
    DryRun=True|False
)
```

**Parameters**

- **SubnetId** *(string)* – [REQUIRED]
The ID of the subnet to associate with the network interface.

- **Description** *(string)* – A description for the network interface.
- **PrivateIpAddress** *(string)* – The primary private IP address of the network interface. If you don’t specify an IP address, Amazon EC2 selects one for you from the subnet range. If you specify an IP address, you cannot indicate any IP addresses specified in `privateIpAddresses` as primary (only one IP address can be designated as primary).
- **Groups** *(list)* – The IDs of one or more security groups.
- **PrivateIpAddresses** *(list)* – One or more private IP addresses.

  Describes a secondary private IP address for a network interface.

  - **PrivateIpAddress** *(string)* – [REQUIRED]
    The private IP addresses.
  - **Primary** *(boolean)* –
    Indicates whether the private IP address is the primary private IP address. Only one IP address can be designated as primary.

- **SecondaryPrivateIpAddressCount** *(integer)* – The number of secondary private IP addresses to assign to a network interface. When you specify a number of secondary IP addresses, Amazon EC2 selects these IP addresses within the subnet range. You can’t specify this option and specify more than one private IP address using `privateIpAddresses`.

The number of IP addresses you can assign to a network interface varies by instance type. For more information, see Private IP Addresses Per ENI Per Instance Type in the *Amazon Elastic Compute Cloud User Guide*.

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'NetworkInterface': {
        'NetworkInterfaceId': 'string',
        'SubnetId': 'string',
        'VpcId': 'string',
        'AvailabilityZone': 'string',
        'Description': 'string',
        'OwnerId': 'string',
        'RequesterId': 'string',
        'RequesterManaged': True|False,
        'Status': 'available'|'attaching'|'in-use'|'detaching',
        'MacAddress': 'string',
        'PrivateIpAddress': 'string',
        'PrivateDnsName': 'string',
        'SourceDestCheck': True|False,
        'Groups': [  
            {
                'GroupName': 'string',
                'GroupId': 'string'
            },
        ]
    }
}
```
Response Structure

* (dict) –

  - NetworkInterface (dict) –

    Information about the network interface.

    * NetworkInterfaceId (string) –
      The ID of the network interface.
    
    * SubnetId (string) –
      The ID of the subnet.
    
    * VpcId (string) –
      The ID of the VPC.
    
    * AvailabilityZone (string) –
      The Availability Zone.
    
    * Description (string) –
      A description.
* **OwnerId** *(string)* –
  The AWS account ID of the owner of the network interface.

* **RequesterId** *(string)* –
  The ID of the entity that launched the instance on your behalf (for example, AWS Management Console or Auto Scaling).

* **RequesterManaged** *(boolean)* –
  Indicates whether the network interface is being managed by AWS.

* **Status** *(string)* –
  The status of the network interface.

* **MacAddress** *(string)* –
  The MAC address.

* **PrivateIpAddress** *(string)* –
  The IP address of the network interface within the subnet.

* **PrivateDnsName** *(string)* –
  The private DNS name.

* **SourceDestCheck** *(boolean)* –
  Indicates whether traffic to or from the instance is validated.

* **Groups** *(list)* –
  Any security groups for the network interface.
    - *(dict)* –
      Describes a security group.
      - **GroupName** *(string)* –
        The name of the security group.
      - **GroupId** *(string)* –
        The ID of the security group.

* **Attachment** *(dict)* –
  The network interface attachment.
    - **AttachmentId** *(string)* –
      The ID of the network interface attachment.
    - **InstanceId** *(string)* –
      The ID of the instance.
    - **InstanceOwnerId** *(string)* –
      The AWS account ID of the owner of the instance.
    - **DeviceIndex** *(integer)* –
      The device index of the network interface attachment on the instance.
    - **Status** *(string)* –
      The attachment state.
    - **AttachTime** *(datetime)* –
      The timestamp indicating when the attachment initiated.
    - **DeleteOnTermination** *(boolean)* –
      Indicates whether the network interface is deleted when the instance is terminated.
* **Association** (*dict*) –

The association information for an Elastic IP associated with the network interface.

- **PublicIp** (*string*) –
  The address of the Elastic IP address bound to the network interface.

- **PublicDnsName** (*string*) –
  The public DNS name.

- **IpOwnerId** (*string*) –
  The ID of the Elastic IP address owner.

- **AllocationId** (*string*) –
  The allocation ID.

- **AssociationId** (*string*) –
  The association ID.

* **TagSet** (*list*) –

Any tags assigned to the network interface.

- (*dict*) –
  Describes a tag.

- **Key** (*string*) –
  The key of the tag.

  Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`

- **Value** (*string*) –
  The value of the tag.

  Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

* **PrivateIpAddresses** (*list*) –

The private IP addresses associated with the network interface.

- (*dict*) –
  Describes the private IP address of a network interface.

- **PrivateIpAddress** (*string*) –
  The private IP address.

- **PrivateDnsName** (*string*) –
  The private DNS name.

- **Primary** (*boolean*) –
  Indicates whether this IP address is the primary private IP address of the network interface.

- **Association** (*dict*) –
  The association information for an Elastic IP address associated with the network interface.

- **PublicIp** (*string*) –
  The address of the Elastic IP address bound to the network interface.
- PublicDnsName (string) –
  The public DNS name.
- IpOwnerId (string) –
  The ID of the Elastic IP address owner.
- AllocationId (string) –
  The allocation ID.
- AssociationId (string) –
  The association ID.

**create_placement_group** (**kwargs**)  
Creates a placement group that you launch cluster instances into. You must give the group a name that’s unique within the scope of your account.

For more information about placement groups and cluster instances, see Cluster Instances in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = client.create_placement_group(
    DryRun=True|False,
    GroupName='string',
    Strategy='cluster'
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **GroupName (string)** – [REQUIRED]
  A name for the placement group.
  Constraints: Up to 255 ASCII characters
- **Strategy (string)** – [REQUIRED]
  The placement strategy.

**Returns**
None

**create_reserved_instances_listing** (**kwargs**)  
Creates a listing for Amazon EC2 Reserved Instances to be sold in the Reserved Instance Marketplace. You can submit one Reserved Instance listing at a time. To get a list of your Reserved Instances, you can use the DescribeReservedInstances operation.

The Reserved Instance Marketplace matches sellers who want to resell Reserved Instance capacity that they no longer need with buyers who want to purchase additional capacity. Reserved Instances bought and sold through the Reserved Instance Marketplace work like any other Reserved Instances.

To sell your Reserved Instances, you must first register as a seller in the Reserved Instance Marketplace. After completing the registration process, you can create a Reserved Instance Marketplace listing of some or all of your Reserved Instances, and specify the upfront price to receive for them. Your Reserved Instance listings then become available for purchase. To view the details of your Reserved Instance listing, you can use the DescribeReservedInstancesListings operation.

For more information, see Reserved Instance Marketplace in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
```
response = client.create_reserved_instances_listing(
    ReservedInstancesId='string',
    InstanceCount=123,
    PriceSchedules=[
        {
            'Term': 123,
            'Price': 123.0,
            'CurrencyCode': 'USD'
        },
    ],
    ClientToken='string'
)

Parameters

- **ReservedInstancesId** *(string)* – [REQUIRED]
  The ID of the active Reserved Instance.

- **InstanceCount** *(integer)* – [REQUIRED]
  The number of instances that are a part of a Reserved Instance account to be listed in the Reserved Instance Marketplace. This number should be less than or equal to the instance count associated with the Reserved Instance ID specified in this call.

- **PriceSchedules** *(list)* – [REQUIRED]
  A list specifying the price of the Reserved Instance for each month remaining in the Reserved Instance term.
  
  - *(dict)* –
    Describes the price for a Reserved Instance.
    
    - **Term** *(integer)* –
      The number of months remaining in the reservation. For example, 2 is the second to the last month before the capacity reservation expires.
    
    - **Price** *(float)* –
      The fixed price for the term.
    
    - **CurrencyCode** *(string)* –
      The currency for transacting the Reserved Instance resale. At this time, the only supported currency is USD.

- **ClientToken** *(string)* – [REQUIRED]
  Unique, case-sensitive identifier you provide to ensure idempotency of your listings. This helps avoid duplicate listings. For more information, see Ensuring Idempotency.

Return type  **dict**

Returns

Response Syntax

```python
{
    'ReservedInstancesListings': [
        {
            'ReservedInstancesListingId': 'string',
            'ReservedInstancesId': 'string',
            'CreateDate': datetime(2015, 1, 1),
            'UpdateDate': datetime(2015, 1, 1),
        },
    ]
}
```
Response Structure

- (dict) –
  - ReservedInstancesListings (list) –
    Information about the Reserved Instances listing.
      * (dict) –
        Describes a Reserved Instance listing.
          - ReservedInstancesListingId (string) –
            The ID of the Reserved Instance listing.
          - ReservedInstancesId (string) –
            The ID of the Reserved Instance.
          - CreateDate (datetime) –
            The time the listing was created.
          - UpdateDate (datetime) –
            The last modified timestamp of the listing.
          - Status (string) –
            The status of the Reserved Instance listing.
          - StatusMessage (string) –
            The reason for the current status of the Reserved Instance listing. The response can be blank.
          - InstanceCounts (list) –
            The number of instances in this state.
      (dict) –
        Describes a Reserved Instance listing state.
- **State** (*string*) –
  The states of the listed Reserved Instances.
- **InstanceCount** (*integer*) –
  The number of listed Reserved Instances in the state specified by the `state`.
- **PriceSchedules** (*list*) –
  The price of the Reserved Instance listing.
- **Term** (*integer*) –
  The number of months remaining in the reservation. For example, 2 is the second to the last month before the capacity reservation expires.
- **Price** (*float*) –
  The fixed price for the term.
- **CurrencyCode** (*string*) –
  The currency for transacting the Reserved Instance resale. At this time, the only supported currency is USD.
- **Active** (*boolean*) –
  The current price schedule, as determined by the term remaining for the Reserved Instance in the listing.
  A specific price schedule is always in effect, but only one price schedule can be active at any time. Take, for example, a Reserved Instance listing that has five months remaining in its term. When you specify price schedules for five months and two months, this means that schedule 1, covering the first three months of the remaining term, will be active during months 5, 4, and 3. Then schedule 2, covering the last two months of the term, will be active for months 2 and 1.
- **Tags** (*list*) –
  Any tags assigned to the resource.
- **Key** (*string*) –
  The key of the tag.
  Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws`.
- **Value** (*string*) –
  The value of the tag.
  Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.
- **ClientToken** (*string*) –
  A unique, case-sensitive key supplied by the client to ensure that the request is idempotent. For more information, see **Ensuring Idempotency**.
create_route(**kwargs)

Creates a route in a route table within a VPC.

You must specify one of the following targets: Internet gateway or virtual private gateway, NAT instance, VPC peering connection, or network interface.

When determining how to route traffic, we use the route with the most specific match. For example, let’s say the traffic is destined for 192.0.2.3, and the route table includes the following two routes:

• 192.0.2.0/24 (goes to some target A)
• 192.0.2.0/28 (goes to some target B)

Both routes apply to the traffic destined for 192.0.2.3. However, the second route in the list covers a smaller number of IP addresses and is therefore more specific, so we use that route to determine where to target the traffic.

For more information about route tables, see Route Tables in the Amazon Virtual Private Cloud User Guide.

Request Syntax

response = client.create_route(
    DryRun=True|False,
    RouteTableId='string',
    DestinationCidrBlock='string',
    GatewayId='string',
    InstanceId='string',
    NetworkInterfaceId='string',
    VpcPeeringConnectionId='string'
)

Parameters

• DryRun (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
• RouteTableId (string) – [REQUIRED]

The ID of the route table for the route.
• DestinationCidrBlock (string) – [REQUIRED]

The CIDR address block used for the destination match. Routing decisions are based on the most specific match.
• GatewayId (string) – The ID of an Internet gateway or virtual private gateway attached to your VPC.
• InstanceId (string) – The ID of a NAT instance in your VPC. The operation fails if you specify an instance ID unless exactly one network interface is attached.
• NetworkInterfaceId (string) – The ID of a network interface.
• VpcPeeringConnectionId (string) – The ID of a VPC peering connection.

Return type dict

Returns

Response Syntax

{

    'Return': True|False

}

Response Structure

• (dict) –
create_route_table(**kwargs)

Creates a route table for the specified VPC. After you create a route table, you can add routes and associate the table with a subnet.

For more information about route tables, see Route Tables in the Amazon Virtual Private Cloud User Guide.

Request Syntax

```python
response = client.create_route_table(
    DryRun=True|False,
    VpcId='string'
)
```

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **VpcId (string)** – [REQUIRED]

The ID of the VPC.

Return type  dict

Returns

Response Syntax

```json
{
    'RouteTable': {
        'RouteTableId': 'string',
        'VpcId': 'string',
    'Routes': [
    
        'DestinationCidrBlock': 'string',
        'DestinationPrefixListId': 'string',
        'GatewayId': 'string',
        'InstanceId': 'string',
        'InstanceOwnerId': 'string',
        'NetworkInterfaceId': 'string',
        'VpcPeeringConnectionId': 'string',
        'State': 'active'|'blackhole',
        'Origin': 'CreateRouteTable'|'CreateRoute'|'EnableVgwRoutePropagation',
    
    },
    'Associations': [
    
        'RouteTableAssociationId': 'string',
        'RouteTableId': 'string',
        'SubnetId': 'string',
        'Main': True|False
    
    ],
    'Tags': [
    
        'Key': 'string',
```
Response Structure

- **(dict)** –
  - **RouteTable** *(dict)* –
    
    Information about the route table.
    
    - **RouteTableId** *(string)* –
      
      The ID of the route table.
    
    - **VpcId** *(string)* –
      
      The ID of the VPC.
    
    - **Routes** *(list)* –
      
      The routes in the route table.
      
      - *(dict)* –
        
        Describes a route in a route table.
        
        - **DestinationCidrBlock** *(string)* –
          
          The CIDR block used for the destination match.
        
        - **DestinationPrefixListId** *(string)* –
          
          The prefix of the AWS service.
        
        - **GatewayId** *(string)* –
          
          The ID of a gateway attached to your VPC.
        
        - **InstanceId** *(string)* –
          
          The ID of a NAT instance in your VPC.
        
        - **InstanceOwnerId** *(string)* –
          
          The AWS account ID of the owner of the instance.
        
        - **NetworkInterfaceId** *(string)* –
          
          The ID of the network interface.
        
        - **VpcPeeringConnectionId** *(string)* –
          
          The ID of the VPC peering connection.
        
        - **State** *(string)* –
          
          The state of the route. The blackhole state indicates that the route’s target isn’t available (for example, the specified gateway isn’t attached to the VPC, or the specified NAT instance has been terminated).
        
        - **Origin** *(string)* –
          
          Describes how the route was created.
        
        - **CreateRouteTable** indicates that route was automatically created when the route table was created.
· **CreateRoute** indicates that the route was manually added to the route table.
· **EnableVgwRoutePropagation** indicates that the route was propagated by route propagation.

**Associations** (list) –

The associations between the route table and one or more subnets.

· (dict) –
  · Describes an association between a route table and a subnet.
    · **RouteTableAssociationId** (string) –
      · The ID of the association between a route table and a subnet.
    · **RouteTableId** (string) –
      · The ID of the route table.
    · **SubnetId** (string) –
      · The ID of the subnet. A subnet ID is not returned for an implicit association.
    · **Main** (boolean) –
      · Indicates whether this is the main route table.

**Tags** (list) –

Any tags assigned to the route table.

· (dict) –
  · Describes a tag.
    · **Key** (string) –
      · The key of the tag.
      Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws`:
    · **Value** (string) –
      · The value of the tag.
      Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

**PropagatingVgws** (list) –

Any virtual private gateway (VGW) propagating routes.

· (dict) –
  · Describes a virtual private gateway propagating route.
    · **GatewayId** (string) –
      · The ID of the virtual private gateway (VGW).

**create_security_group** (**kwargs)**

Creates a security group.

A security group is for use with instances either in the EC2-Classic platform or in a specific VPC. For more information, see Amazon EC2 Security Groups in the Amazon Elastic Compute Cloud User Guide and Security Groups for Your VPC in the Amazon Virtual Private Cloud User Guide.

**Warning:** EC2-Classic: You can have up to 500 security groups.
EC2-VPC: You can create up to 100 security groups per VPC.
When you create a security group, you specify a friendly name of your choice. You can have a security group for use in EC2-Classic with the same name as a security group for use in a VPC. However, you can’t have two security groups for use in EC2-Classic with the same name or two security groups for use in a VPC with the same name.

You have a default security group for use in EC2-Classic and a default security group for use in your VPC. If you don’t specify a security group when you launch an instance, the instance is launched into the appropriate default security group. A default security group includes a default rule that grants instances unrestricted network access to each other.

You can add or remove rules from your security groups using AuthorizeSecurityGroupIngress, AuthorizeSecurityGroupEgress, RevokeSecurityGroupIngress, and RevokeSecurityGroupEgress.

Request Syntax

```python
response = client.create_security_group(
    DryRun=True|False,
    GroupName='string',
    Description='string',
    VpcId='string'
)
```

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **GroupName** (string) – [REQUIRED]

  The name of the security group.

  Constraints: Up to 255 characters in length

  Constraints for EC2-Classic: ASCII characters

  Constraints for EC2-VPC: a-z, A-Z, 0-9, spaces, and .-:/()#,@\[+=;{}!$*#

- **Description** (string) – [REQUIRED]

  A description for the security group. This is informational only.

  Constraints: Up to 255 characters in length

  Constraints for EC2-Classic: ASCII characters

  Constraints for EC2-VPC: a-z, A-Z, 0-9, spaces, and .-:/()#,@\[+=;{}!$*#

- **VpcId** (string) – [EC2-VPC] The ID of the VPC. Required for EC2-VPC.

Return type  dict

Returns

Response Syntax

```python
{
    'GroupId': 'string'
}
```

Response Structure

- (dict) –
  - **GroupId** (string) –

    The ID of the security group.
create_snapshot(**kwargs)

Creates a snapshot of an EBS volume and stores it in Amazon S3. You can use snapshots for backups, to make copies of EBS volumes, and to save data before shutting down an instance.

When a snapshot is created, any AWS Marketplace product codes that are associated with the source volume are propagated to the snapshot.

You can take a snapshot of an attached volume that is in use. However, snapshots only capture data that has been written to your EBS volume at the time the snapshot command is issued; this may exclude any data that has been cached by any applications or the operating system. If you can pause any file systems on the volume long enough to take a snapshot, your snapshot should be complete. However, if you cannot pause all file writes to the volume, you should unmount the volume from within the instance, issue the snapshot command, and then remount the volume to ensure a consistent and complete snapshot. You may remount and use your volume while the snapshot status is pending.

To create a snapshot for EBS volumes that serve as root devices, you should stop the instance before taking the snapshot.

Snapshots that are taken from encrypted volumes are automatically encrypted. Volumes that are created from encrypted snapshots are also automatically encrypted. Your encrypted volumes and any associated snapshots always remain protected.

For more information, see Amazon Elastic Block Store and Amazon EBS Encryption in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

response = client.create_snapshot(
    DryRun=True|False,
    VolumeId='string',
    Description='string'
)

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **VolumeId (string)** – [REQUIRED]
  The ID of the EBS volume.
- **Description (string)** – A description for the snapshot.

Return type  dict

Returns

Response Syntax

```python
{
    'SnapshotId': 'string',
    'VolumeId': 'string',
    'State': 'pending'|'completed'|'error',
    'StateMessage': 'string',
    'StartTime': datetime(2015, 1, 1),
    'Progress': 'string',
    'OwnerId': 'string',
    'Description': 'string',
    'VolumeSize': 123,
    'OwnerAlias': 'string',
    'Tags': [
```
{
  'Key': 'string',
  'Value': 'string'
},

'
Encrypted': True|False,
'KmsKeyId': 'string',
'DataEncryptionKeyId': 'string'
}

Response Structure

- (dict) –

  Information about the snapshot.
  - SnapshotId (string) –
    
    The ID of the snapshot. Each snapshot receives a unique identifier when it is created.
  - VolumeId (string) –
    
    The ID of the volume that was used to create the snapshot.
  - State (string) –
    
    The snapshot state.
  - StateMessage (string) –
    
    Encrypted Amazon EBS snapshots are copied asynchronously. If a snapshot copy operation fails (for example, if the proper AWS Key Management Service (AWS KMS) permissions are not obtained) this field displays error state details to help you diagnose why the error occurred. This parameter is only returned by the DescribeSnapshots API operation.
  - StartTime (datetime) –
    
    The time stamp when the snapshot was initiated.
  - Progress (string) –
    
    The progress of the snapshot, as a percentage.
  - OwnerId (string) –
    
    The AWS account ID of the EBS snapshot owner.
  - Description (string) –
    
    The description for the snapshot.
  - VolumeSize (integer) –
    
    The size of the volume, in GiB.
  - OwnerAlias (string) –
    
    The AWS account alias (for example, amazon, self) or AWS account ID that owns the snapshot.
  - Tags (list) –
    
    Any tags assigned to the snapshot.
    * (dict) –

    Describes a tag.
        - Key (string) –

        The key of the tag.

    Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with aws:
· **Value** *(string)* –
  The value of the tag.

  Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

- **Encrypted** *(boolean)* –
  Indicates whether the snapshot is encrypted.

- **KmsKeyId** *(string)* –
  The full ARN of the AWS Key Management Service (AWS KMS) customer master key (CMK) that was used to protect the volume encryption key for the parent volume.

- **DataEncryptionKeyId** *(string)* –
  The data encryption key identifier for the snapshot. This value is a unique identifier that corresponds to the data encryption key that was used to encrypt the original volume or snapshot copy. Because data encryption keys are inherited by volumes created from snapshots, and vice versa, if snapshots share the same data encryption key identifier, then they belong to the same volume/snapshot lineage. This parameter is only returned by the DescribeSnapshots API operation.

**create_spot_datafeed_subscription** (**kwargs**)  
Creates a data feed for Spot instances, enabling you to view Spot instance usage logs. You can create one data feed per AWS account. For more information, see Spot Instance Data Feed in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```
response = client.create_spot_datafeed_subscription(
    DryRun=True|False,
    Bucket='string',
    Prefix='string'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **Bucket** *(string)* – [REQUIRED]
  The Amazon S3 bucket in which to store the Spot instance data feed.

- **Prefix** *(string)* – A prefix for the data feed file names.

**Return type**  dict

**Returns**

**Response Syntax**

```
{
    'SpotDatafeedSubscription': {
        'OwnerId': 'string',
        'Bucket': 'string',
        'Prefix': 'string',
        'State': 'Active'|'Inactive',
        'Fault': {
            'Code': 'string',
        }
    }
}
```
Response Structure

- **(dict)** –
  Contains the output of CreateSpotDatafeedSubscription.

  - **SpotDatafeedSubscription (dict)** –
    The Spot instance data feed subscription.
    - **OwnerId (string)** –
      The AWS account ID of the account.
    - **Bucket (string)** –
      The Amazon S3 bucket where the Spot instance data feed is located.
    - **Prefix (string)** –
      The prefix that is prepended to data feed files.
    - **State (string)** –
      The state of the Spot instance data feed subscription.
    - **Fault (dict)** –
      The fault codes for the Spot instance request, if any.
      - **Code (string)** –
        The reason code for the Spot instance state change.
      - **Message (string)** –
        The message for the Spot instance state change.

**create_subnet(**kwargs)**

Creates a subnet in an existing VPC.

When you create each subnet, you provide the VPC ID and the CIDR block you want for the subnet. After you create a subnet, you can’t change its CIDR block. The subnet’s CIDR block can be the same as the VPC’s CIDR block (assuming you want only a single subnet in the VPC), or a subset of the VPC’s CIDR block. If you create more than one subnet in a VPC, the subnets’ CIDR blocks must not overlap. The smallest subnet (and VPC) you can create uses a /28 netmask (16 IP addresses), and the largest uses a /16 netmask (65,536 IP addresses).

**Warning:** AWS reserves both the first four and the last IP address in each subnet’s CIDR block. They’re not available for use.

If you add more than one subnet to a VPC, they’re set up in a star topology with a logical router in the middle.

If you launch an instance in a VPC using an Amazon EBS-backed AMI, the IP address doesn’t change if you stop and restart the instance (unlike a similar instance launched outside a VPC, which gets a new IP address when restarted). It’s therefore possible to have a subnet with no running instances (they’re all stopped), but no remaining IP addresses available.

For more information about subnets, see Your VPC and Subnets in the Amazon Virtual Private Cloud User Guide.

**Request Syntax**
response = client.create_subnet(
    DryRun=True|False,
    VpcId='string',
    CidrBlock='string',
    AvailabilityZone='string'
)

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **VpcId** (string) – [REQUIRED]
  The ID of the VPC.
- **CidrBlock** (string) – [REQUIRED]
  The network range for the subnet, in CIDR notation. For example, 10.0.0.0/24.
- **AvailabilityZone** (string) – The Availability Zone for the subnet.
  Default: Amazon EC2 selects one for you (recommended).

Return type  dict

Returns

Response Syntax

```{ 'Subnet': { 'SubnetId': 'string', 'State': 'pending'|'available', 'VpcId': 'string', 'CidrBlock': 'string', 'AvailableIpAddressCount': 123, 'AvailabilityZone': 'string', 'DefaultForAz': True|False, 'MapPublicIpOnLaunch': True|False, 'Tags': [ { 'Key': 'string', 'Value': 'string' } ] } }```

Response Structure

- (dict) –
  - **Subnet** (dict) –
    Information about the subnet.
    - **SubnetId** (string) –
      The ID of the subnet.
    - **State** (string) –
      The current state of the subnet.
    - **VpcId** (string) –
The ID of the VPC the subnet is in.

- **CidrBlock** *(string)* –
  
The CIDR block assigned to the subnet.

- **AvailableIpAddressCount** *(integer)* –
  
The number of unused IP addresses in the subnet. Note that the IP addresses for any stopped instances are considered unavailable.

- **AvailabilityZone** *(string)* –
  
The Availability Zone of the subnet.

- **DefaultForAz** *(boolean)* –
  
Indicates whether this is the default subnet for the Availability Zone.

- **MapPublicIpOnLaunch** *(boolean)* –
  
Indicates whether instances launched in this subnet receive a public IP address.

- **Tags** *(list)* –
  
Any tags assigned to the subnet.
  
  - *(dict)* –
    
Describes a tag.
  
  - **Key** *(string)* –
    
The key of the tag.

Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`.

  - **Value** *(string)* –
    
The value of the tag.

Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

---

**create_tags(** **kwargs**)**

Adds or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each resource can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys must be unique per resource.

For more information about tags, see Tagging Your Resources in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = client.create_tags(
    DryRun=True|False,
    Resources=['string'],
    Tags=[
        {'Key': 'string',
         'Value': 'string'},
    ],
)
```

**Parameters**
• **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is *DryRunOperation*. Otherwise, it is *UnauthorizedOperation*.

• **Resources** *(list)* – *[REQUIRED]*
  The IDs of one or more resources to tag. For example, ami-1a2b3c4d.
  - *(string)* –

• **Tags** *(list)* – *[REQUIRED]*
  One or more tags. The *value* parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.
  - *(dict)* –
    Describes a tag.
    * **Key** *(string)* –
      The key of the tag.
      Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with *aws:*
    * **Value** *(string)* –
      The value of the tag.
      Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

**Returns** None

**create_volume(***kwargs**)**

Creates an EBS volume that can be attached to an instance in the same Availability Zone. The volume is created in the regional endpoint that you send the HTTP request to. For more information see *Regions and Endpoints*.

You can create a new empty volume or restore a volume from an EBS snapshot. Any AWS Marketplace product codes from the snapshot are propagated to the volume.

You can create encrypted volumes with the *Encrypted* parameter. Encrypted volumes may only be attached to instances that support Amazon EBS encryption. Volumes that are created from encrypted snapshots are also automatically encrypted. For more information, see *Amazon EBS Encryption* in the *Amazon Elastic Compute Cloud User Guide*.

For more information, see *Creating or Restoring an Amazon EBS Volume* in the *Amazon Elastic Compute Cloud User Guide*.

**Request Syntax**

```python
response = client.create_volume(
    DryRun=True|False,
    Size=123,
    SnapshotId='string',
    AvailabilityZone='string',
    VolumeType='standard'|'io1'|'gp2',
    Iops=123,
    Encrypted=True|False,
    KmsKeyId='string'
)
```

**Parameters**
• **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

• **Size** *(integer)* – The size of the volume, in GiBs.

  Constraints: 1-1024 for **standard** volumes, 1-16384 for **gp2** volumes, and 4-16384 for **io1** volumes. If you specify a snapshot, the volume size must be equal to or larger than the snapshot size.

  Default: If you’re creating the volume from a snapshot and don’t specify a volume size, the default is the snapshot size.

• **SnapshotId** *(string)* – The snapshot from which to create the volume.

• **AvailabilityZone** *(string)* – **[REQUIRED]**

  The Availability Zone in which to create the volume. Use DescribeAvailabilityZones to list the Availability Zones that are currently available to you.

• **VolumeType** *(string)* – The volume type. This can be **gp2** for General Purpose (SSD) volumes, **io1** for Provisioned IOPS (SSD) volumes, or **standard** for Magnetic volumes.

  Default: **standard**

• **Iops** *(integer)* – Only valid for Provisioned IOPS (SSD) volumes. The number of I/O operations per second (IOPS) to provision for the volume, with a maximum ratio of 30 IOPS/GiB.

  Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes

• **Encrypted** *(boolean)* – Specifies whether the volume should be encrypted. Encrypted Amazon EBS volumes may only be attached to instances that support Amazon EBS encryption. Volumes that are created from encrypted snapshots are automatically encrypted. There is no way to create an encrypted volume from an unencrypted snapshot or vice versa. If your AMI uses encrypted volumes, you can only launch it on supported instance types. For more information, see Amazon EBS Encryption in the Amazon Elastic Compute Cloud User Guide.

• **KmsKeyId** *(string)* – The full ARN of the AWS Key Management Service (AWS KMS) customer master key (CMK) to use when creating the encrypted volume. This parameter is only required if you want to use a non-default CMK; if this parameter is not specified, the default CMK for EBS is used. The ARN contains the `arn:aws:kms` namespace, followed by the region of the CMK, the AWS account ID of the CMK owner, the `key` namespace, and then the CMK ID. For example, `arn:aws:kms:us-east-1:012345678901:key/abcd1234-a123-456a-a12b-a123b4cd56ef`. If a KmsKeyId is specified, the Encrypted flag must also be set.

**Return type** dict

**Returns**

**Response Syntax**

```
{
    'VolumeId': 'string',
    'Size': 123,
    'SnapshotId': 'string',
    'AvailabilityZone': 'string',
    'State': 'creating'|'available'|'in-use'|'deleting'|'deleted'|'error',
    'CreateTime': datetime(2015, 1, 1),
    'Attachments': [ ]
}
```

```json
{
    'VolumeId': 'string',
    'InstanceId': 'string',
    'Device': 'string',
    'State': 'attaching'|'attached'|'detaching'|'detached',
    'AttachTime': datetime(2015, 1, 1),
    'DeleteOnTermination': True|False,
    'Tags': [
        {
            'Key': 'string',
            'Value': 'string'
        }
    ],
    'VolumeType': 'standard'|'io1'|'gp2',
    'Iops': 123,
    'Encrypted': True|False,
    'KmsKeyId': 'string'
}
```

**Response Structure**

- **(dict)** – Information about the volume.
  - **VolumeId (string)** – The ID of the volume.
  - **Size (integer)** – The size of the volume, in GiBs.
  - **SnapshotId (string)** – The snapshot from which the volume was created, if applicable.
  - **AvailabilityZone (string)** – The Availability Zone for the volume.
  - **State (string)** – The volume state.
  - **CreateTime (datetime)** – The time stamp when volume creation was initiated.
  - **Attachments (list)** – Information about the volume attachments.
    - *(dict)* – Describes volume attachment details.
      - **VolumeId (string)** – The ID of the volume.
      - **InstanceId (string)** – The ID of the instance.
      - **Device (string)** – The device name.
      - **State (string)** – The attachment state of the volume.

---

3.1. Services 1171
• **AttachTime** *(datetime)* —
  The time stamp when the attachment initiated.

• **DeleteOnTermination** *(boolean)* —
  Indicates whether the EBS volume is deleted on instance termination.

• **Tags** *(list)* —
  Any tags assigned to the volume.

  • **dict** —
    Describes a tag.

    • **Key** *(string)* —
      The key of the tag.

      Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`.

    • **Value** *(string)* —
      The value of the tag.

      Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

• **VolumeType** *(string)* —
  The volume type. This can be `gp2` for General Purpose (SSD) volumes, `io1` for Provisioned IOPS (SSD) volumes, or `standard` for Magnetic volumes.

• **Iops** *(integer)* —
  The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.

  Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.

  Condition: This parameter is required for requests to create `io1` volumes; it is not used in requests to create `standard` or `gp2` volumes.

• **Encrypted** *(boolean)* —
  Indicates whether the volume will be encrypted.

• **KmsKeyId** *(string)* —
  The full ARN of the AWS Key Management Service (AWS KMS) customer master key (CMK) that was used to protect the volume encryption key for the volume.

**create_vpc(****kwargs***)

Creates a VPC with the specified CIDR block.

The smallest VPC you can create uses a /28 netmask (16 IP addresses), and the largest uses a /16 netmask (65,536 IP addresses). To help you decide how big to make your VPC, see Your VPC and Subnets in the Amazon Virtual Private Cloud User Guide.
By default, each instance you launch in the VPC has the default DHCP options, which includes only a
default DNS server that we provide (AmazonProvidedDNS). For more information about DHCP options,
see DHCP Options Sets in the Amazon Virtual Private Cloud User Guide.

**Request Syntax**

```python
response = client.create_vpc(
    DryRun=True|False,
    CidrBlock='string',
    InstanceTenancy='default'|'dedicated'
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the
  action, without actually making the request, and provides an error response. If
  you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **CidrBlock (string)** – [REQUIRED]
The network range for the VPC, in CIDR notation. For example, 10.0.0.0/16.
- **InstanceTenancy (string)** – The supported tenancy options for instances
  launched into the VPC. A value of default means that instances can be
  launched with any tenancy; a value of dedicated means all instances launched
  into the VPC are launched as dedicated tenancy instances regardless of the ten-
  ancy assigned to the instance at launch. Dedicated tenancy instances run on
  single-tenant hardware.

  Default: default

**Return type** dict

**Returns**

- **Response Syntax**

  ```
  { 'Vpc': { 
    'VpcId': 'string',
    'State': 'pending'|'available',
    'CidrBlock': 'string',
    'DhcpOptionsId': 'string',
    'Tags': [  
      { 'Key': 'string',
        'Value': 'string'  
      },
      'InstanceTenancy': 'default'|'dedicated',
      'IsDefault': True|False
    }
  }
  }
  ```

- **Response Structure**

  - *(dict)* –
    - **Vpc (dict)** –
      Information about the VPC.
      - **VpcId (string)** –
        The ID of the VPC.
* State (string) –  
The current state of the VPC.
* CidrBlock (string) –  
The CIDR block for the VPC.
* DhcpOptionsId (string) –  
The ID of the set of DHCP options you’ve associated with the VPC 
(or default if the default options are associated with the VPC).
* Tags (list) –  
Any tags assigned to the VPC.
  · (dict) –  
    Describes a tag.
  · Key (string) –  
    The key of the tag.
    Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with aws:
  · Value (string) –  
    The value of the tag.
    Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.
* InstanceTenancy (string) –  
The allowed tenancy of instances launched into the VPC.
* IsDefault (boolean) –  
Indicates whether the VPC is the default VPC.

create_vpc_endpoint (**kwargs)

Creates a VPC endpoint for a specified AWS service. An endpoint enables you to create a private connection between your VPC and another AWS service in your account. You can specify an endpoint policy to attach to the endpoint that will control access to the service from your VPC. You can also specify the VPC route tables that use the endpoint.

Currently, only endpoints to Amazon S3 are supported.

Request Syntax

```python
response = client.create_vpc_endpoint(
    DryRun=True|False,
    VpcId='string',
    ServiceName='string',
    PolicyDocument='string',
    RouteTableIds=['string',
                   'string',
                   ],
    ClientToken='string'
)
```

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
• **VpcId** *(string)* – [REQUIRED]

The ID of the VPC in which the endpoint will be used.

• **ServiceName** *(string)* – [REQUIRED]

The AWS service name, in the form `com.amazonaws.*region*.*service*`. To get a list of available services, use the DescribeVpcEndpointServices request.

• **PolicyDocument** *(string)* – A policy to attach to the endpoint that controls access to the service. The policy must be in valid JSON format. If this parameter is not specified, we attach a default policy that allows full access to the service.

• **RouteTableIds** *(list)* – One or more route table IDs.

  – *(string)*

• **ClientToken** *(string)* – Unique, case-sensitive identifier you provide to ensure the idempotency of the request. For more information, see How to Ensure Idempotency .

Return type  `dict`

Returns

**Response Syntax**

```python
{
    'VpcEndpoint': {
        'VpcEndpointId': 'string',
        'VpcId': 'string',
        'ServiceName': 'string',
        'State': 'Pending'|'Available'|'Deleting'|'Deleted',
        'PolicyDocument': 'string',
        'RouteTableIds': [
            'string',
        ],
        'CreationTimestamp': datetime(2015, 1, 1)
    },
    'ClientToken': 'string'
}
```

**Response Structure**

• *(dict)* –

  – **VpcEndpoint** *(dict)* –

    Information about the endpoint.

    • **VpcEndpointId** *(string)* –

        The ID of the VPC endpoint.

    • **VpcId** *(string)* –

        The ID of the VPC to which the endpoint is associated.

    • **ServiceName** *(string)* –

        The name of the AWS service to which the endpoint is associated.

    • **State** *(string)* –

        The state of the VPC endpoint.

    • **PolicyDocument** *(string)* –

        The policy document associated with the endpoint.

    • **RouteTableIds** *(list)* –

        One or more route tables associated with the endpoint.

        – *(string)* –
* CreationTimestamp (datetime) –
  The date and time the VPC endpoint was created.

- ClientToken (string) –
  Unique, case-sensitive identifier you provide to ensure the idempotency of the request.

create_vpc_peering_connection(**kwargs)
Requests a VPC peering connection between two VPCs: a requester VPC that you own and a peer VPC
with which to create the connection. The peer VPC can belong to another AWS account. The requester
VPC and peer VPC cannot have overlapping CIDR blocks.

The owner of the peer VPC must accept the peering request to activate the peering connection. The VPC
peering connection request expires after 7 days, after which it cannot be accepted or rejected.

A CreateVpcPeeringConnection request between VPCs with overlapping CIDR blocks results in
the VPC peering connection having a status of failed.

Request Syntax

```python
response = client.create_vpc_peering_connection(
    DryRun=True|False,
    VpcId='string',
    PeerVpcId='string',
    PeerOwnerId='string'
)
```

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the
  action, without actually making the request, and provides an error response. If
  you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **VpcId (string)** – The ID of the requester VPC.

- **PeerVpcId (string)** – The ID of the VPC with which you are creating the VPC
  peering connection.

- **PeerOwnerId (string)** – The AWS account ID of the owner of the peer VPC.
  Default: Your AWS account ID

Return type: dict

Returns

Response Syntax

```python
{
    'VpcPeeringConnection': {
        'AccepterVpcInfo': {
            'CidrBlock': 'string',
            'OwnerId': 'string',
            'VpcId': 'string'
        },
        'ExpirationTime': datetime(2015, 1, 1),
        'RequesterVpcInfo': {
            'CidrBlock': 'string',
            'OwnerId': 'string',
            'VpcId': 'string'
        },
        'Status': {
            'Code': 'initiating-request'|'pending-acceptance'|'active'|'deleted'|'failed'|'expired'|'provisioning'|'deleting',
```
Response Structure

- **VpcPeeringConnection** *(dict)* – Information about the VPC peering connection.
  
  * **AccepterVpcInfo** *(dict)* –
    
    The information of the peer VPC.
    
    - **CidrBlock** *(string)* – The CIDR block for the VPC.
    - **OwnerId** *(string)* – The AWS account ID of the VPC owner.
    - **VpcId** *(string)* – The ID of the VPC.
  
  * **ExpirationTime** *(datetime)* – The time that an unaccepted VPC peering connection will expire.
  
  * **RequesterVpcInfo** *(dict)* –
    
    The information of the requester VPC.
    
    - **CidrBlock** *(string)* – The CIDR block for the VPC.
    - **OwnerId** *(string)* – The AWS account ID of the VPC owner.
    - **VpcId** *(string)* – The ID of the VPC.
  
  * **Status** *(dict)* –
    
    The status of the VPC peering connection.
    
    - **Code** *(string)* – The status of the VPC peering connection.
    - **Message** *(string)* – A message that provides more information about the status, if applicable.
  
  * **Tags** *(list)* – Any tags assigned to the resource.
    
    - *(dict)* –
      
      Describes a tag.
      
    - **Key** *(string)* – The key of the tag.
Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`

- **Value (string)** –
  The value of the tag.
  
Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

* **VpcPeeringConnectionId (string)** –
  The ID of the VPC peering connection.

### create_vpn_connection(**kwargs)

Creates a VPN connection between an existing virtual private gateway and a VPN customer gateway. The only supported connection type is `ipsec.1`.

The response includes information that you need to give to your network administrator to configure your customer gateway.

**Warning:** We strongly recommend that you use HTTPS when calling this operation because the response contains sensitive cryptographic information for configuring your customer gateway.

If you decide to shut down your VPN connection for any reason and later create a new VPN connection, you must reconfigure your customer gateway with the new information returned from this call.

For more information about VPN connections, see Adding a Hardware Virtual Private Gateway to Your VPC in the *Amazon Virtual Private Cloud User Guide*.

**Request Syntax**

```python
response = client.create_vpn_connection(
    DryRun=True|False,
    Type='string',
    CustomerGatewayId='string',
    VpnGatewayId='string',
    Options={
        'StaticRoutesOnly': True|False
    }
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **Type (string)** – [REQUIRED]
  The type of VPN connection (`ipsec.1`).

- **CustomerGatewayId (string)** – [REQUIRED]
  The ID of the customer gateway.

- **VpnGatewayId (string)** – [REQUIRED]
  The ID of the virtual private gateway.

- **Options (dict)** – Indicates whether the VPN connection requires static routes. If you are creating a VPN connection for a device that does not support BGP, you must specify `true`.
  
Default: `false`
- **StaticRoutesOnly** *(boolean)* –
  Indicates whether the VPN connection uses static routes only. Static routes must be used for devices that don’t support BGP.

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'VpnConnection': {
        'VpnConnectionId': 'string',
        'State': 'pending'|'available'|'deleting'|'deleted',
        'CustomerGatewayConfiguration': 'string',
        'Type': 'ipsec.1',
        'CustomerGatewayId': 'string',
        'VpnGatewayId': 'string',
        'Tags': [
            {
                'Key': 'string',
                'Value': 'string'
            }
        ],
        'VgwTelemetry': [
            {
                'OutsideIpAddress': 'string',
                'Status': 'UP'|'DOWN',
                'LastStatusChange': datetime(2015, 1, 1),
                'StatusMessage': 'string',
                'AcceptedRouteCount': 123
            }
        ],
        'Options': {
            'StaticRoutesOnly': True|False
        },
        'Routes': [
            {
                'DestinationCidrBlock': 'string',
                'Source': 'Static',
                'State': 'pending'|'available'|'deleting'|'deleted'
            }
        ]
    }
}
```

**Response Structure**

- *(dict)* –
  - **VpnConnection** *(dict)* –
    Information about the VPN connection.
    - **VpnConnectionId** *(string)* –
      The ID of the VPN connection.
    - **State** *(string)* –
      The current state of the VPN connection.
    - **CustomerGatewayConfiguration** *(string)* –
      The configuration information for the VPN connection’s customer gateway (in the native XML format). This element is always present
in the CreateVpnConnection response; however, it’s present in the DescribeVpnConnections response only if the VPN connection is in the pending or available state.

* **Type (string)** –
  The type of VPN connection.

* **CustomerGatewayId (string)** –
  The ID of the customer gateway at your end of the VPN connection.

* **VpnGatewayId (string)** –
  The ID of the virtual private gateway at the AWS side of the VPN connection.

* **Tags (list)** –
  Any tags assigned to the VPN connection.
  · (dict) –
    Describes a tag.
  · **Key (string)** –
    The key of the tag.
    Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`
  · **Value (string)** –
    The value of the tag.
    Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

* **VgwTelemetry (list)** –
  Information about the VPN tunnel.
  · (dict) –
    Describes telemetry for a VPN tunnel.
  · **OutsideIpAddress (string)** –
    The Internet-routable IP address of the virtual private gateway’s outside interface.
  · **Status (string)** –
    The status of the VPN tunnel.
  · **LastStatusChange (datetime)** –
    The date and time of the last change in status.
  · **StatusMessage (string)** –
    If an error occurs, a description of the error.
  · **AcceptedRouteCount (integer)** –
    The number of accepted routes.

* **Options (dict)** –
  The VPN connection options.
  · **StaticRoutesOnly (boolean)** –
    Indicates whether the VPN connection uses static routes only. Static routes must be used for devices that don’t support BGP.

* **Routes (list)** –
  The static routes associated with the VPN connection.
create_vpn_connection_route(**kwargs)

Creates a static route associated with a VPN connection between an existing virtual private gateway and a VPN customer gateway. The static route allows traffic to be routed from the virtual private gateway to the VPN customer gateway.

For more information about VPN connections, see Adding a Hardware Virtual Private Gateway to Your VPC in the Amazon Virtual Private Cloud User Guide.

Request Syntax

response = client.create_vpn_connection_route(
    VpnConnectionId='string',
    DestinationCidrBlock='string'
)

Parameters

- **VpnConnectionId (string)** – [REQUIRED]
  The ID of the VPN connection.

- **DestinationCidrBlock (string)** – [REQUIRED]
  The CIDR block associated with the local subnet of the customer network.

Returns

None

create_vpn_gateway(**kwargs)

Creates a virtual private gateway. A virtual private gateway is the endpoint on the VPC side of your VPN connection. You can create a virtual private gateway before creating the VPC itself.

For more information about virtual private gateways, see Adding a Hardware Virtual Private Gateway to Your VPC in the Amazon Virtual Private Cloud User Guide.

Request Syntax

response = client.create_vpn_gateway(
    DryRun=True|False,
    Type='ipsec.1',
    AvailabilityZone='string'
)

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **Type (string)** – [REQUIRED]
  The type of VPN connection this virtual private gateway supports.
- **AvailabilityZone** *(string)* - The Availability Zone for the virtual private gateway.

**Return type** `dict`

**Returns**

**Response Syntax**

```
{
    'VpnGateway': {
        'VpnGatewayId': 'string',
        'State': 'pending'|'available'|'deleting'|'deleted',
        'Type': 'ipsec.1',
        'AvailabilityZone': 'string',
        'VpcAttachments': [
            {
                'VpcId': 'string',
                'State': 'attaching'|'attached'|'detaching'|'detached'
            },
        ],
        'Tags': [
            {
                'Key': 'string',
                'Value': 'string'
            }
        ]
    }
}
```

**Response Structure**

- *(dict)* –
  - **VpnGateway** *(dict)* –
    - Information about the virtual private gateway.
      - **VpnGatewayId** *(string)* –
        - The ID of the virtual private gateway.
      - **State** *(string)* –
        - The current state of the virtual private gateway.
      - **Type** *(string)* –
        - The type of VPN connection the virtual private gateway supports.
      - **AvailabilityZone** *(string)* –
        - The Availability Zone where the virtual private gateway was created.
      - **VpcAttachments** *(list)* –
        - Any VPCs attached to the virtual private gateway.
          - *(dict)* –
            - Describes an attachment between a virtual private gateway and a VPC.
          - **VpcId** *(string)* –
            - The ID of the VPC.
          - **State** *(string)* –
            - The current state of the attachment.
      - **Tags** *(list)* –
        - Any tags assigned to the virtual private gateway.
· *(dict)* –
  Describes a tag.
  · **Key** *(string)* –
    The key of the tag.
    Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`
  · **Value** *(string)* –
    The value of the tag.
    Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

delete_customer_gateway(**kwargs)**

Deletes the specified customer gateway. You must delete the VPN connection before you can delete the customer gateway.

**Request Syntax**

```python
response = client.delete_customer_gateway(
    DryRun=True|False,
    CustomerGatewayId='string'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **CustomerGatewayId** *(string)* – [REQUIRED]
  The ID of the customer gateway.

**Returns** None

delete_dhcp_options(**kwargs)**

Deletes the specified set of DHCP options. You must disassociate the set of DHCP options before you can delete it. You can disassociate the set of DHCP options by associating either a new set of options or the default set of options with the VPC.

**Request Syntax**

```python
response = client.delete_dhcp_options(
    DryRun=True|False,
    DhcpOptionsId='string'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **DhcpOptionsId** *(string)* – [REQUIRED]
  The ID of the DHCP options set.

**Returns** None
**delete_flow_logs(**kwargs)

Deletes one or more flow logs.

**Request Syntax**

```python
response = client.delete_flow_logs(
    FlowLogIds=[
        'string',
    ],
)
```

**Parameters**

**FlowLogIds** *(list)* – [REQUIRED]

One or more flow log IDs.

**Return type**

**dict**

**Returns**

**Response Syntax**

```
{
    'Unsuccessful': [
        {
            'ResourceId': 'string',
            'Error': {
                'Code': 'string',
                'Message': 'string'
            }
        },
    ],
}
```

**Response Structure**

* (dict) –
  - **Unsuccessful** *(list)* –
    Information about the flow logs that could not be deleted successfully.
    * (dict) –
      Information about items that were not successfully processed in a batch call.
      - **ResourceId** *(string)* –
        The ID of the resource.
      - **Error** *(dict)* –
        Information about the error.
      - **Code** *(string)* –
        The error code.
      - **Message** *(string)* –
        The error message accompanying the error code.

**delete_internet_gateway(**kwargs)

Deletes the specified Internet gateway. You must detach the Internet gateway from the VPC before you can delete it.

**Request Syntax**

```python
```
response = client.delete_internet_gateway(
    DryRun=True|False,
    InternetGatewayId='string'
)

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.
- **InternetGatewayId (string)** – [REQUIRED]

The ID of the Internet gateway.

Returns None

delete_key_pair(**kwargs)**

Deletes the specified key pair, by removing the public key from Amazon EC2.

Request Syntax

response = client.delete_key_pair(
    DryRun=True|False,
    KeyName='string'
)

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.
- **KeyName (string)** – [REQUIRED]

The name of the key pair.

Returns None

delete_network_acl(**kwargs)**

Deletes the specified network ACL. You can’t delete the ACL if it’s associated with any subnets. You can’t delete the default network ACL.

Request Syntax

response = client.delete_network_acl(
    DryRun=True|False,
    NetworkAclId='string'
)

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.
- **NetworkAclId (string)** – [REQUIRED]

The ID of the network ACL.

Returns None

delete_network_acl_entry(**kwargs)**

Deletes the specified ingress or egress entry (rule) from the specified network ACL.
Request Syntax

```python
response = client.delete_network_acl_entry(
    DryRun=True|False,
    NetworkAclId='string',
    RuleNumber=123,
    Egress=True|False
)
```

Parameters

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **NetworkAclId** (*string*) – [REQUIRED]
  The ID of the network ACL.
- **RuleNumber** (*integer*) – [REQUIRED]
  The rule number of the entry to delete.
- **Egress** (*boolean*) – [REQUIRED]
  Indicates whether the rule is an egress rule.

Returns None

`delete_network_interface(**kwargs)`

Deletes the specified network interface. You must detach the network interface before you can delete it.

Request Syntax

```python
response = client.delete_network_interface(
    DryRun=True|False,
    NetworkInterfaceId='string'
)
```

Parameters

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **NetworkInterfaceId** (*string*) – [REQUIRED]
  The ID of the network interface.

Returns None

`delete_placement_group(**kwargs)`

Deletes the specified placement group. You must terminate all instances in the placement group before you can delete the placement group. For more information about placement groups and cluster instances, see Cluster Instances in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = client.delete_placement_group(
    DryRun=True|False,
    GroupName='string'
)
```

Parameters
• **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

• **GroupName** *(string)* – [REQUIRED]
The name of the placement group.

```python
def delete_route(**kwargs)
    Deletes the specified route from the specified route table.

    Request Syntax

    response = client.delete_route(
        DryRun=True|False,
        RouteTableId='string',
        DestinationCidrBlock='string'
    )
```

**Parameters**

• **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

• **RouteTableId** *(string)* – [REQUIRED]
The ID of the route table.

• **DestinationCidrBlock** *(string)* – [REQUIRED]
The CIDR range for the route. The value you specify must match the CIDR for the route exactly.

**Returns** None

```python
def delete_route_table(**kwargs)
    Deletes the specified route table. You must disassociate the route table from any subnets before you can delete it. You can’t delete the main route table.

    Request Syntax

    response = client.delete_route_table(
        DryRun=True|False,
        RouteTableId='string'
    )
```

**Parameters**

• **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

• **RouteTableId** *(string)* – [REQUIRED]
The ID of the route table.

**Returns** None

```python
def delete_security_group(**kwargs)
    Deletes a security group.
```

3.1. Services
If you attempt to delete a security group that is associated with an instance, or is referenced by another security group, the operation fails with InvalidGroup.InUse in EC2-Classic or DependencyViolation in EC2-VPC.

Request Syntax

```python
response = client.delete_security_group(
    DryRun=True|False,
    GroupName='string',
    GroupId='string'
)
```

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **GroupName (string)** – [EC2-Classic, default VPC] The name of the security group. You can specify either the security group name or the security group ID.
- **GroupId (string)** – The ID of the security group. Required for a nondefault VPC.

Returns None

delete_snapshot(**kwargs)

Deletes the specified snapshot.

When you make periodic snapshots of a volume, the snapshots are incremental, and only the blocks on the device that have changed since your last snapshot are saved in the new snapshot. When you delete a snapshot, only the data not needed for any other snapshot is removed. So regardless of which prior snapshots have been deleted, all active snapshots will have access to all the information needed to restore the volume.

You cannot delete a snapshot of the root device of an EBS volume used by a registered AMI. You must first de-register the AMI before you can delete the snapshot.

For more information, see Deleting an Amazon EBS Snapshot in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = client.delete_snapshot(
    DryRun=True|False,
    SnapshotId='string'
)
```

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **SnapshotId (string)** – [REQUIRED] The ID of the EBS snapshot.

Returns None

delete_spot_datafeed_subscription(**kwargs)

Deletes the data feed for Spot instances.

Request Syntax
response = client.delete_spot_datafeed_subscription(
    DryRun=True|False
)

**Parameters**

**DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Returns**

None

### delete_subnet(**kwargs**)

Deletes the specified subnet. You must terminate all running instances in the subnet before you can delete the subnet.

**Request Syntax**

```python
response = client.delete_subnet(
    DryRun=True|False,
    SubnetId='string'
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **SubnetId (string)** – [REQUIRED]
  
  The ID of the subnet.

**Returns**

None

### delete_tags(**kwargs**)

Deletes the specified set of tags from the specified set of resources. This call is designed to follow a DescribeTags request.

For more information about tags, see Tagging Your Resources in the *Amazon Elastic Compute Cloud User Guide*.

**Request Syntax**

```python
response = client.delete_tags(
    DryRun=True|False,
    Resources=['string',
              'string'],
    Tags=[
          {'Key': 'string',
           'Value': 'string'},
          ...
    ]
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
• **Resources** *(list)* – [REQUIRED]

The ID of the resource. For example, ami-1a2b3c4d. You can specify more than one resource ID.
- *(string)* –

• **Tags** *(list)* – One or more tags to delete. If you omit the `value` parameter, we delete the tag regardless of its value. If you specify this parameter with an empty string as the value, we delete the key only if its value is an empty string.
- *(dict)* –

  Describes a tag.
  * **Key** *(string)* –
    - The key of the tag.
  * **Value** *(string)* –
    - The value of the tag.

Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`.

Returns None

delete_volume(**kwargs)**

Deletes the specified EBS volume. The volume must be in the available state (not attached to an instance).

**Note:** The volume may remain in the deleting state for several minutes.

For more information, see Deleting an Amazon EBS Volume in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = client.delete_volume(
    DryRun=True|False,
    VolumeId='string'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **VolumeId** *(string)* – [REQUIRED]
  - The ID of the volume.

Returns None

delete_vpc(**kwargs)**

Deletes the specified VPC. You must detach or delete all gateways and resources that are associated with the VPC before you can delete it. For example, you must terminate all instances running in the VPC, delete all security groups associated with the VPC (except the default one), delete all route tables associated with the VPC (except the default one), and so on.

Request Syntax
response = client.delete_vpc(
    DryRun=True|False,
    VpcId='string'
)

Parameters

• **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

• **VpcId (string)** – [REQUIRED]

The ID of the VPC.

Returns None

delete_vpc_endpoints(**kwargs)**

Deletes one or more specified VPC endpoints. Deleting the endpoint also deletes the endpoint routes in the route tables that were associated with the endpoint.

Request Syntax

response = client.delete_vpc_endpoints(
    DryRun=True|False,
    VpcEndpointIds=[
        'string',
    ]
)

Parameters

• **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

• **VpcEndpointIds (list)** – [REQUIRED]

One or more endpoint IDs.

- (string) –

Return type dict

Returns

Response Syntax

```python
{
    'Unsuccessful': [
        {
            'ResourceId': 'string',
            'Error': {
                'Code': 'string',
                'Message': 'string'
            }
        }
    ]
}
```

Response Structure

• (dict) –
**Unsuccessful** *(list)* —

Information about the endpoints that were not successfully deleted.

* *(dict)* —

Information about items that were not successfully processed in a batch call.

- **ResourceId** *(string)* —
  The ID of the resource.

- **Error** *(dict)* —
  Information about the error.

  - **Code** *(string)* —
    The error code.

  - **Message** *(string)* —
    The error message accompanying the error code.

**delete_vpc_peering_connection** (**kwargs**)

Deletes a VPC peering connection. Either the owner of the requester VPC or the owner of the peer VPC can delete the VPC peering connection if it’s in the **active** state. The owner of the requester VPC can delete a VPC peering connection in the **pending-acceptance** state.

**Request Syntax**

```python
response = client.delete_vpc_peering_connection(
    DryRun=True|False,
    VpcPeeringConnectionId='string'
)
```

**Parameters**

- **DryRun** *(boolean)* — Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **VpcPeeringConnectionId** *(string)* — [REQUIRED]
  The ID of the VPC peering connection.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'Return': True|False
}
```

**Response Structure**

- *(dict)* —
  - **Return** *(boolean)* —
    Returns **true** if the request succeeds; otherwise, it returns an error.

**delete_vpn_connection** (**kwargs**)

Deletes the specified VPN connection.

If you’re deleting the VPC and its associated components, we recommend that you detach the virtual private gateway from the VPC and delete the VPC before deleting the VPN connection. If you believe that the tunnel credentials for your VPN connection have been compromised, you can delete the VPN connection.
connection and create a new one that has new keys, without needing to delete the VPC or virtual private gateway. If you create a new VPN connection, you must reconfigure the customer gateway using the new configuration information returned with the new VPN connection ID.

**Request Syntax**

```python
response = client.delete_vpn_connection(
    DryRun=True|False,
    VpnConnectionId='string'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **VpnConnectionId** *(string)* – [REQUIRED]

  The ID of the VPN connection.

**Returns** None

**delete_vpn_connection_route(**kwargs)**

Deletes the specified static route associated with a VPN connection between an existing virtual private gateway and a VPN customer gateway. The static route allows traffic to be routed from the virtual private gateway to the VPN customer gateway.

**Request Syntax**

```python
response = client.delete_vpn_connection_route(
    VpnConnectionId='string',
    DestinationCidrBlock='string'
)
```

**Parameters**

- **VpnConnectionId** *(string)* – [REQUIRED]

  The ID of the VPN connection.
- **DestinationCidrBlock** *(string)* – [REQUIRED]

  The CIDR block associated with the local subnet of the customer network.

**Returns** None

**delete_vpn_gateway(**kwargs)**

Deletes the specified virtual private gateway. We recommend that before you delete a virtual private gateway, you detach it from the VPC and delete the VPN connection. Note that you don’t need to delete the virtual private gateway if you plan to delete and recreate the VPN connection between your VPC and your network.

**Request Syntax**

```python
response = client.delete_vpn_gateway(
    DryRun=True|False,
    VpnGatewayId='string'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If
you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **VpnGatewayId (string)** – [REQUIRED]

  The ID of the virtual private gateway.

**Returns** None

deregister_image(**kwargs)

Deregisters the specified AMI. After you deregister an AMI, it can’t be used to launch new instances. This command does not delete the AMI.

**Request Syntax**

```python
response = client.deregister_image(
    DryRun=True|False,
    ImageId='string'
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **ImageId (string)** – [REQUIRED]

  The ID of the AMI.

**Returns** None

describe_account_attributes(**kwargs)

Describes attributes of your AWS account. The following are the supported account attributes:

- **supported-platforms**: Indicates whether your account can launch instances into EC2-Classic and EC2-VPC, or only into EC2-VPC.
- **default-vpc**: The ID of the default VPC for your account, or none.
- **max-instances**: The maximum number of On-Demand instances that you can run.
- **vpc-max-security-groups-per-interface**: The maximum number of security groups that you can assign to a network interface.
- **max-elastic-ips**: The maximum number of Elastic IP addresses that you can allocate for use with EC2-Classic.
- **vpc-max-elastic-ips**: The maximum number of Elastic IP addresses that you can allocate for use with EC2-VPC.

**Request Syntax**

```python
response = client.describe_account_attributes(
    DryRun=True|False,
    AttributeNames=[
        'supported-platforms', 'default-vpc',
    ]
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **AttributeNames (list)** – One or more account attribute names.

  - **(string)** –

**Return type** dict
Returns

Response Syntax

```python
{
    'AccountAttributes': [
        {
            'AttributeName': 'string',
            'AttributeValues': [
                {
                    'AttributeValue': 'string'
                }
            ]
        }
    ]
}
```

Response Structure

* (dict) –
  - **AccountAttributes** (list) –
    Information about one or more account attributes.
    * (dict) –
      - **AttributeName** (string) –
        The name of the account attribute.
      - **AttributeValues** (list) –
        One or more values for the account attribute.
        * (dict) –
          - **AttributeValue** (string) –
            The value of the attribute.

**describe_addresses(**kwargs)**

Describes one or more of your Elastic IP addresses.

An Elastic IP address is for use in either the EC2-Classic platform or in a VPC. For more information, see Elastic IP Addresses in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = client.describe_addresses(
    DryRun=True|False,
    PublicIps=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ]
        },
    ],
    AllocationIds=[
        'string',
    ]
)
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **PublicIps** *(list)* – [EC2-Classic] One or more Elastic IP addresses.
  Default: Describes all your Elastic IP addresses.

- **Filters** *(list)* – One or more filters. Filter names and values are case-sensitive.
  - `allocation-id` - [EC2-VPC] The allocation ID for the address.
  - `association-id` - [EC2-VPC] The association ID for the address.
  - `domain` - Indicates whether the address is for use in EC2-Classic (`standard`) or in a VPC (`vpc`).
  - `instance-id` - The ID of the instance the address is associated with, if any.
  - `network-interface-id` - [EC2-VPC] The ID of the network interface that the address is associated with, if any.
  - `network-interface-owner-id` - The AWS account ID of the owner.
  - `private-ip-address` - [EC2-VPC] The private IP address associated with the Elastic IP address.
  - `public-ip` - The Elastic IP address.

- **AllocationIds** *(list)* – [EC2-VPC] One or more allocation IDs.
  Default: Describes all your Elastic IP addresses.

Return type  ```dict```

Returns

**Response Syntax**

```json
{
    'Addresses': [
        {
            'InstanceId': 'string',
            'PublicIp': 'string',
            'AllocationId': 'string',
            'AssociationId': 'string',
            'Domain': 'vpc'! 'standard',
            'NetworkInterfaceId': 'string',
            'NetworkInterfaceOwnerId': 'string',
        },
    ]
}
```
Response Structure

* (dict) –
  - Addresses (list) –

Information about one or more Elastic IP addresses.

* (dict) –

Describes an Elastic IP address.

  - InstanceId (string) –
    The ID of the instance that the address is associated with (if any).
  - PublicIp (string) –
    The Elastic IP address.
  - AllocationId (string) –
    The ID representing the allocation of the address for use with EC2-VPC.
  - AssociationId (string) –
    The ID representing the association of the address with an instance in a VPC.
  - Domain (string) –
    Indicates whether this Elastic IP address is for use with instances in EC2-Classic (standard) or instances in a VPC (vpc).
  - NetworkInterfaceId (string) –
    The ID of the network interface.
  - NetworkInterfaceOwnerId (string) –
    The ID of the AWS account that owns the network interface.
  - PrivateIpAddress (string) –
    The private IP address associated with the Elastic IP address.

**Glossary**

- **PrivateIpAddress**: string

**Usage: deslape_availability_zones(**kwargs)***

Describes one or more of the Availability Zones that are available to you. The results include zones only for the region you’re currently using. If there is an event impacting an Availability Zone, you can use this request to view the state and any provided message for that Availability Zone.

For more information, see Regions and Availability Zones in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = client.describe_availability_zones(
    DryRun=True|False,
    ZoneNames=[
        'string',
    ],
    Filters=[
        
        'Name': 'string',
    ]
)```
'Values': [  
'dictionary'
],
  ]
}]

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **ZoneNames** *(list)* – The names of one or more Availability Zones.
  - *(string)* –

- **Filters** *(list)* – One or more filters.
  - **message** - Information about the Availability Zone.
  - **region-name** - The name of the region for the Availability Zone (for example, us-east-1).
  - **state** - The state of the Availability Zone (available | impaired | unavailable).
  - **zone-name** - The name of the Availability Zone (for example, us-east-1a).

  - *(dictionary)* –

  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  - **Name** *(string)* –

    The name of the filter. Filter names are case-sensitive.

  - **Values** *(list)* –

    One or more filter values. Filter values are case-sensitive.

    - *(string)* –

Return type: dict

Returns

**Response Syntax**

```
{
'AvailabilityZones': [
{
'ZoneName': 'string',
'State': 'available',
'RegionName': 'string',
'Messages': [
{
'Message': 'string'
},
]
},
]
}
```

**Response Structure**

- *(dictionary)* –
– **AvailabilityZones** *(list)* –  
  Information about one or more Availability Zones.  
  * *(dict)* –  
    Describes an Availability Zone.  
      · **ZoneName** *(string)* –  
        The name of the Availability Zone.  
      · **State** *(string)* –  
        The state of the Availability Zone *(available|impaired |unavailable)*.  
      · **RegionName** *(string)* –  
        The name of the region.  
      · **Messages** *(list)* –  
        Any messages about the Availability Zone.  
          *(dict)* –  
            Describes a message about an Availability Zone.  
              · **Message** *(string)* –  
                The message about the Availability Zone.

**describe_bundle_tasks** (**kwargs)**  
Describes one or more of your bundling tasks.

**Note:** Completed bundle tasks are listed for only a limited time. If your bundle task is no longer in the list, you can still register an AMI from it. Just use `RegisterImage` with the Amazon S3 bucket name and image manifest name you provided to the bundle task.

---

**Request Syntax**

```python
response = client.describe_bundle_tasks(  
    DryRun=True|False,  
    BundleIds=[  
        'string',  
    ],  
    Filters=[  
        {  
            'Name': 'string',  
            'Values': [  
                'string',  
            ],  
        },  
    ]
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **BundleIds** *(list)* – One or more bundle task IDs.  
  Default: Describes all your bundle tasks.  
  * *(string)* –  
  · **Filters** *(list)* – One or more filters.
- `bundle-id` - The ID of the bundle task.
- `error-code` - If the task failed, the error code returned.
- `error-message` - If the task failed, the error message returned.
- `instance-id` - The ID of the instance.
- `progress` - The level of task completion, as a percentage (for example, 20%).
- `s3-bucket` - The Amazon S3 bucket to store the AMI.
- `s3-prefix` - The beginning of the AMI name.
- `start-time` - The time the task started (for example, 2013-09-15T17:15:20.000Z).
- `state` - The state of the task (`pending`|`waiting-for-shutdown`|`bundling`|`storing`|`cancelling`|`complete`|`failed`).
- `update-time` - The time of the most recent update for the task.

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* **Name** *(string)*
  The name of the filter. Filter names are case-sensitive.

* **Values** *(list)*
  One or more filter values. Filter values are case-sensitive.

  * **(string)**

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
'BundleTasks': [
{
'InstanceId': 'string',
'BundleId': 'string',
'State': 'pending'|'waiting-for-shutdown'|'bundling'|'storing'|'cancelling'|'complete'|'failed',
'StartTime': datetime(2015, 1, 1),
'UpdateTime': datetime(2015, 1, 1),
'Storage': {
'S3': {
'Bucket': 'string',
'Prefix': 'string',
'AWSAccessKeyId': 'string',
'UploadPolicy': 'bytes',
'UploadPolicySignature': 'string'
}
},
'Progress': 'string',
'BundleTaskError': {
'Code': 'string',
'Message': 'string'
}
}]
}
```

**Response Structure**

* **(dict)**
- **BundleTasks** *(list)* –

  Information about one or more bundle tasks.
  * *(dict)* –

  Describes a bundle task.
  - **InstanceId** *(string)* –
    
    The ID of the instance associated with this bundle task.
  - **BundleId** *(string)* –
    
    The ID of the bundle task.
  - **State** *(string)* –
    
    The state of the task.
  - **StartTime** *(datetime)* –
    
    The time this task started.
  - **UpdateTime** *(datetime)* –
    
    The time of the most recent update for the task.
  - **Storage** *(dict)* –
    
    The Amazon S3 storage locations.
    - **S3** *(dict)* –
      
      An Amazon S3 storage location.
      - **Bucket** *(string)* –
        
        The bucket in which to store the AMI. You can specify a bucket that you already own or a new bucket that Amazon EC2 creates on your behalf. If you specify a bucket that belongs to someone else, Amazon EC2 returns an error.
      - **Prefix** *(string)* –
        
        The beginning of the file name of the AMI.
      - **AWSAccessKeyId** *(string)* –
        
        The access key ID of the owner of the bucket. Before you specify a value for your access key ID, review and follow the guidance in Best Practices for Managing AWS Access Keys.
      - **UploadPolicy** *(bytes)* –
        
        A Base64-encoded Amazon S3 upload policy that gives Amazon EC2 permission to upload items into Amazon S3 on your behalf.
      - **UploadPolicySignature** *(string)* –
        
        The signature of the Base64 encoded JSON document.
  - **Progress** *(string)* –
    
    The level of task completion, as a percent (for example, 20%).
  - **BundleTaskError** *(dict)* –
    
    If the task fails, a description of the error.
    - **Code** *(string)* –
      
      The error code.
    - **Message** *(string)* –
      
      The error message.
describe_classic_link_instances(**kwargs)

Describes one or more of your linked EC2-Classic instances. This request only returns information about EC2-Classic instances linked to a VPC through ClassicLink; you cannot use this request to return information about other instances.

Request Syntax

```python
response = client.describe_classic_link_instances(
    DryRun=True|False,
    InstanceIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ],
    NextToken='string',
    MaxResults=123
)
```

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **InstanceIds (list)** – One or more instance IDs. Must be instances linked to a VPC through ClassicLink.
  - (string)
- **Filters (list)** – One or more filters.
  - group-id - The ID of a VPC security group that’s associated with the instance.
  - instance-id - The ID of the instance.
  - tag :key =*value* - The key/value combination of a tag assigned to the resource.
  - tag-key - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key =*value* filter.
  - tag-value - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
  - vpc-id - The ID of the VPC that the instance is linked to.
  - (dict)

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

- **Name (string)** –
  - The name of the filter. Filter names are case-sensitive.
- **Values (list)** –
One or more filter values. Filter values are case-sensitive.

- (string) –
- **NextToken** (string) – The token to retrieve the next page of results.
- **MaxResults** (integer) – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned `NextToken` value. This value can be between 5 and 1000; if `MaxResults` is given a value larger than 1000, only 1000 results are returned. You cannot specify this parameter and the instance IDs parameter in the same request.

Constraint: If the value is greater than 1000, we return only 1000 items.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Instances': [
        {
            'InstanceId': 'string',
            'VpcId': 'string',
            'Groups': [
                {
                    'GroupName': 'string',
                    'GroupId': 'string'
                },
            ],
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                },
            ],
            'NextToken': 'string'
        }
    ]
}
```

**Response Structure**

- (dict) –
  - **Instances** (list) –
    
    Information about one or more linked EC2-Classic instances.
    
    * (dict) –

    Describes a linked EC2-Classic instance.

    - **InstanceId** (string) –
      
      The ID of the instance.
    - **VpcId** (string) –
      
      The ID of the VPC.
    - **Groups** (list) –
      
      A list of security groups.
    - (dict) –

      Describes a security group.
    - **GroupName** (string) –

3.1. Services
The name of the security group.
· **GroupId** *(string)* –
  The ID of the security group.
· **Tags** *(list)* –
  Any tags assigned to the instance.
  · *(dict)* –
    Describes a tag.
  · **Key** *(string)* –
    The key of the tag.
  Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`.
  · **Value** *(string)* –
    The value of the tag.
  Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.
· **NextToken** *(string)* –
  The token to use to retrieve the next page of results. This value is null when there are no more results to return.

describe_conversion_tasks(**kwargs)
Describes one or more of your conversion tasks. For more information, see Using the Command Line Tools to Import Your Virtual Machine to Amazon EC2 in the *Amazon Elastic Compute Cloud User Guide*.

Request Syntax
```python
response = client.describe_conversion_tasks(
    DryRun=True|False,
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ],
    ConversionTaskIds=[
        'string',
    ]
)
```

Parameters
- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **Filters** *(list)* – One or more filters.
  · *(dict)* –
    A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
Name (string) – The name of the filter. Filter names are case-sensitive.

Values (list) – One or more filter values. Filter values are case-sensitive.

- (string) –

ConversionTaskIds (list) – One or more conversion task IDs.

Returns

Response Syntax

```
{
    'ConversionTasks': [
        {
            'ConversionTaskId': 'string',
            'ExpirationTime': 'string',
            'ImportInstance': {
                'Volumes': [
                    {
                        'BytesConverted': 123,
                        'AvailabilityZone': 'string',
                        'Image': {
                            'Format': 'VMDK'|'RAW'|'VHD',
                            'Size': 123,
                            'ImportManifestUrl': 'string',
                            'Checksum': 'string'
                        },
                        'Volume': {
                            'Size': 123,
                            'Id': 'string'
                        },
                        'Status': 'string',
                        'StatusMessage': 'string',
                        'Description': 'string'
                    }
                ],
                'InstanceId': 'string',
                'Platform': 'Windows',
                'Description': 'string'
            },
            'ImportVolume': {
                'BytesConverted': 123,
                'AvailabilityZone': 'string',
                'Description': 'string',
                'Image': {
                    'Format': 'VMDK'|'RAW'|'VHD',
                    'Size': 123,
                    'ImportManifestUrl': 'string',
                    'Checksum': 'string'
                },
                'Volume': {
                    'Size': 123,
                    'Id': 'string'
                }
            }
        },
        {
            'InstanceIds': 'string',
            'Platform': 'Windows',
            'Description': 'string'
        },
        {
            'ImportVolume': {
                'BytesConverted': 123,
                'AvailabilityZone': 'string',
                'Description': 'string',
                'Image': {
                    'Format': 'VMDK'|'RAW'|'VHD',
                    'Size': 123,
                    'ImportManifestUrl': 'string',
                    'Checksum': 'string'
                },
                'Volume': {
                    'Size': 123,
                    'Id': 'string'
                }
            }
        }
    ],
    'State': 'active'|'cancelling'|'cancelled'|'completed',
```

3.1. Services 1205
Response Structure

- **(dict) –**
  - **ConversionTasks (list) –**
    
    Information about the conversion tasks.
    
    * **(dict) –**
      
      Describes a conversion task.
      
      - **ConversionTaskId (string) –**
        
        The ID of the conversion task.
      
      - **ExpirationTime (string) –**
        
        The time when the task expires. If the upload isn’t complete before the expiration time, we automatically cancel the task.
      
      - **ImportInstance (dict) –**
        
        If the task is for importing an instance, this contains information about the import instance task.
      
      - **Volumes (list) –**
        
        One or more volumes.
      
      - **(dict) –**
        
        Describes an import volume task.
      
      - **BytesConverted (integer) –**
        
        The number of bytes converted so far.
      
      - **AvailabilityZone (string) –**
        
        The Availability Zone where the resulting instance will reside.
      
      - **Image (dict) –**
        
        The image.
      
      - **Format (string) –**
        
        The disk image format.
      
      - **Size (integer) –**
        
        The size of the disk image, in GiB.
      
      - **ImportManifestUrl (string) –**
        
        A presigned URL for the import manifest stored in Amazon S3. For information about creating a presigned URL for an Amazon S3 object, read the “Query String Request Authentication Alternative” section of the Authenticating REST Requests topic in the Amazon Simple Storage Service Developer Guide .
      
      - **Checksum (string) –**
<table>

</table>

The checksum computed for the disk image.

- Volume (dict) –
  - The volume.
- Size (integer) –
  - The size of the volume, in GiB.
- Id (string) –
  - The volume identifier.
- Status (string) –
  - The status of the import of this particular disk image.
- StatusMessage (string) –
  - The status information or errors related to the disk image.
- Description (string) –
  - A description of the task.
- InstanceId (string) –
  - The ID of the instance.
- Platform (string) –
  - The instance operating system.
- Description (string) –
  - A description of the task.
- ImportVolume (dict) –
  - If the task is for importing a volume, this contains information about the import volume task.
- BytesConverted (integer) –
  - The number of bytes converted so far.
- AvailabilityZone (string) –
  - The Availability Zone where the resulting volume will reside.
- Description (string) –
  - The description you provided when starting the import volume task.
- Image (dict) –
  - The image.
- Format (string) –
  - The disk image format.
- Size (integer) –
  - The size of the disk image, in GiB.
- ImportManifestUrl (string) –
  - A presigned URL for the import manifest stored in Amazon S3. For information about creating a presigned URL for an Amazon S3 object, read the “Query String Request Authentication Alternative” section of the Authenticating REST Requests topic in the Amazon Simple Storage Service Developer Guide.
- Checksum (string) –
  - The checksum computed for the disk image.
describe_customer_gateways(**kwargs)

Describes one or more of your VPN customer gateways.

For more information about VPN customer gateways, see Adding a Hardware Virtual Private Gateway to Your VPC in the Amazon Virtual Private Cloud User Guide.

Request Syntax

def response = client.describe_customer_gateways(
    DryRun=True|False,
    CustomerGatewayIds=[
        'string',
    ],
    Filters=[
        
            'Name': 'string',
            'Values': [ 
                'string',
            ]
    ]
)

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
• **CustomerGatewayIds** *(list)* – One or more customer gateway IDs.

  Default: Describes all your customer gateways.

  – *(string)*

• **Filters** *(list)* – One or more filters.

  – customer-gateway-id - The ID of the customer gateway.
  – ip-address - The IP address of the customer gateway's Internet-routable external interface.
  – state - The state of the customer gateway *(pending|available|deleting|deleted)*.
  – type - The type of customer gateway. Currently, the only supported type is ipsec.1.
  – tag :key =*value* - The key/value combination of a tag assigned to the resource.
  – tag-key - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key =*value* filter.
  – tag-value - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.

  – *(dict)*

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  * **Name** *(string)* –

    The name of the filter. Filter names are case-sensitive.

  * **Values** *(list)* –

    One or more filter values. Filter values are case-sensitive.

  – *(string)*

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
  'CustomerGateways': [
    {
      'CustomerGatewayId': 'string',
      'State': 'string',
      'Type': 'string',
      'IpAddress': 'string',
      'BgpAsn': 'string',
      'Tags': [
        {
          'Key': 'string',
          'Value': 'string'
        }
      ]
    }
  ]
}
```
Response Structure

- (dict) –
  - CustomerGateways (list) –
    Information about one or more customer gateways.
    - (dict) –
      Describes a customer gateway.
      - CustomerGatewayId (string) –
        The ID of the customer gateway.
      - State (string) –
        The current state of the customer gateway (pending | available | deleting | deleted).
      - Type (string) –
        The type of VPN connection the customer gateway supports (ipsec.1).
      - IpAddress (string) –
        The Internet-routable IP address of the customer gateway’s outside interface.
      - BgpAsn (string) –
        The customer gateway’s Border Gateway Protocol (BGP) Autonomous System Number (ASN).
      - Tags (list) –
        Any tags assigned to the customer gateway.
        - (dict) –
          Describes a tag.
          - Key (string) –
            The key of the tag.
          - Value (string) –
            The value of the tag.

Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with **aws**: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

**describe_dhcp_options (**kwargs**)

Describes one or more of your DHCP options sets.

For more information about DHCP options sets, see DHCP Options Sets in the Amazon Virtual Private Cloud User Guide.

Request Syntax

```python
response = client.describe_dhcp_options(
    DryRun=True|False,
    DhcpOptionsIds=[
        'string',
    ],
```
Filters=
{
    'Name': 'string',
    'Values': [
        'string',
    ],
},
}

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **DhcpOptionsIds** *(list)* – The IDs of one or more DHCP options sets.

  Default: Describes all your DHCP options sets.

- **Filters** *(list)* – One or more filters.

  - `dhcp-options-id` - The ID of a set of DHCP options.
  - `key` - The key for one of the options (for example, `domain-name`).
  - `value` - The value for one of the options.
  - `tag: key =*value*` - The key/value combination of a tag assigned to the resource.
  - `tag-key` - The key of a tag assigned to the resource. This filter is independent of the `tag-value` filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag: key =*value*` filter.
  - `tag-value` - The value of a tag assigned to the resource. This filter is independent of the `tag-key` filter.

- *(dict)* – A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  - **Name** *(string)* – The name of the filter. Filter names are case-sensitive.
  - **Values** *(list)* – One or more filter values. Filter values are case-sensitive.

Return type *dict*

Returns

Response Syntax

```json
{
    'DhcpOptions': [
        {
            'DhcpOptionsId': 'string',
            'DhcpConfigurations': [
                {
                    'Key': 'string',
                }
            ]
        }
    ]
}
```
'Values': [
    {
      'Value': 'string'
    },
  ],
],
'Tags': [
  {
    'Key': 'string',
    'Value': 'string'
  },
],

Response Structure
• (dict) –
  – DhcpOptions (list) –
    Information about one or more DHCP options sets.
    • (dict) –
      Describes a set of DHCP options.
      • DhcpOptionsId (string) –
        The ID of the set of DHCP options.
      • DhcpConfigurations (list) –
        One or more DHCP options in the set.
        • (dict) –
          Describes a DHCP configuration option.
          • Key (string) –
            The name of a DHCP option.
          • Values (list) –
            One or more values for the DHCP option.
            • (dict) –
              The value to use for a resource attribute.
              • Value (string) –
                Valid values are case-sensitive and vary by action.
              • Tags (list) –
                Any tags assigned to the DHCP options set.
                • (dict) –
                  Describes a tag.
                  • Key (string) –
                    The key of the tag.
                    Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with aws:
                  • Value (string) –
                    The value of the tag.
describe_export_tasks(**kwargs)

Describes one or more of your export tasks.

Request Syntax

```
response = client.describe_export_tasks(
    ExportTaskIds=[
        'string',
    ]
)
```

Parameters

- **ExportTaskIds** (list) – One or more export task IDs.
  - *(string)* –

Return type

- **dict** –

Returns

Response Syntax

```
{
    'ExportTasks': [
        {
            'ExportTaskId': 'string',
            'Description': 'string',
            'State': 'active'|'cancelling'|'cancelled'|'completed',
            'StatusMessage': 'string',
            'InstanceExportDetails': {
                'InstanceId': 'string',
                'TargetEnvironment': 'citrix'|'vmware'|'microsoft'
            },
            'ExportToS3Task': {
                'DiskImageFormat': 'VMDK'|'RAW'|'VHD',
                'ContainerFormat': 'ova',
                'S3Bucket': 'string',
                'S3Key': 'string'
            }
        }]
}
```

Response Structure

- *(dict)* –
  - **ExportTasks** (list) – Information about the export tasks.
    - *(dict)* – Describes an instance export task.
      - **ExportTaskId** *(string)* – The ID of the export task.
      - **Description** *(string)* – A description of the resource being exported.
      - **State** *(string)* – The state of the export task.

Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.
· **StatusMessage** *(string)* –
  The status message related to the export task.

· **InstanceExportDetails** *(dict)* –
  Information about the instance to export.

· **InstanceId** *(string)* –
  The ID of the resource being exported.

· **TargetEnvironment** *(string)* –
  The target virtualization environment.

· **ExportToS3Task** *(dict)* –
  Information about the export task.

· **DiskImageFormat** *(string)* –
  The format for the exported image.

· **ContainerFormat** *(string)* –
  The container format used to combine disk images with metadata (such as OVF). If absent, only the disk image is exported.

· **S3Bucket** *(string)* –
  The S3 bucket for the destination image. The destination bucket must exist and grant WRITE and READ_ACP permissions to the AWS account `vm-import-export@amazon.com`.

· **S3Key** *(string)* –
  The encryption key for your S3 bucket.

describe_flow_logs(**kwargs)**

Describes one or more flow logs. To view the information in your flow logs (the log streams for the network interfaces), you must use the CloudWatch Logs console or the CloudWatch Logs API.

**Request Syntax**

```python
response = client.describe_flow_logs(
    FlowLogIds=['string'],
    Filter=[
        {'Name': 'string',
         'Values': ['string',
                    'string']},
    ],
    NextToken='string',
    MaxResults=123
)
```

**Parameters**

- **FlowLogIds** *(list)* – One or more flow log IDs.
  - *(string)* –

- **Filter** *(list)* – One or more filters.
  - `deliver-log-status` - The status of the logs delivery *(SUCCESS | FAILED)*.
  - `flow-log-id` - The ID of the flow log.
– log-group-name - The name of the log group.
– resource-id - The ID of the VPC, subnet, or network interface.
– traffic-type - The type of traffic (ACCEPT|REJECT|ALL)
– (dict) –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  * Name (string) –
    The name of the filter. Filter names are case-sensitive.
  * Values (list) –
    One or more filter values. Filter values are case-sensitive.
  * NextToken (string) – The token to retrieve the next page of results.
  * MaxResults (integer) – The maximum number of results to return for the request in a single page. The remaining results can be seen by sending another request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. You cannot specify this parameter and the flow log IDs parameter in the same request.

Return type  dict
Returns

Response Syntax

```python
{
    'FlowLogs': [
        {
            'CreationTime': datetime(2015, 1, 1),
            'FlowLogId': 'string',
            'FlowLogStatus': 'string',
            'ResourceId': 'string',
            'TrafficType': 'ACCEPT'|'REJECT'|'ALL',
            'LogGroupName': 'string',
            'DeliverLogsStatus': 'string',
            'DeliverLogsErrorMessage': 'string',
            'DeliverLogsPermissionArn': 'string'
        },
        ...
    ],
    'NextToken': 'string'
}
```

Response Structure

• (dict) –
  – FlowLogs (list) –
    Information about the flow logs.
    * (dict) –
      Describes a flow log.
      • CreationTime (datetime) –
        The date and time the flow log was created.
      • FlowLogId (string) –
        The flow log ID.
- **FlowLogStatus** *(string)* –
  The status of the flow log *(ACTIVE)*.
- **ResourceId** *(string)* –
  The ID of the resource on which the flow log was created.
- **TrafficType** *(string)* –
  The type of traffic captured for the flow log.
- **LogGroupName** *(string)* –
  The name of the flow log group.
- **DeliverLogsStatus** *(string)* –
  The status of the logs delivery *(SUCCESS | FAILED)*.
- **DeliverLogsErrorMessage** *(string)* –
  Information about the error that occurred. *Rate limited* indicates that CloudWatch logs throttling has been applied for one or more network interfaces. *Access error* indicates that the IAM role associated with the flow log does not have sufficient permissions to publish to CloudWatch Logs. *Unknown error* indicates an internal error.
- **DeliverLogsPermissionArn** *(string)* –
  The ARN of the IAM role that posts logs to CloudWatch Logs.

  - **NextToken** *(string)* –
    The token to use to retrieve the next page of results. This value is *null* when there are no more results to return.

`describe_image_attribute(**kwargs)`

Describes the specified attribute of the specified AMI. You can specify only one attribute at a time.

**Request Syntax**

```python
response = client.describe_image_attribute(
    DryRun=True|False,
    ImageId='string',
    Attribute='description'|'kernel'|'ramdisk'|'launchPermission'|'productCodes'|'blockDeviceMapping'|'sriovNetSupport'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **ImageId** *(string)* – [REQUIRED]
  The ID of the AMI.
- **Attribute** *(string)* – [REQUIRED]
  The AMI attribute.

Note: Depending on your account privileges, the `blockDeviceMapping` attribute may return a `Client.AuthFailure` error. If this happens, use `DescribeImages` to get information about the block device mapping for the AMI.

**Return type**  `dict`
Returns

Response Syntax

```json
{
   'ImageId': 'string',
   'LaunchPermissions': [
      {
         'UserId': 'string',
         'Group': 'all'
      },
   ],
   'ProductCodes': [
      {
         'ProductCodeId': 'string',
         'ProductCodeType': 'devpay'|'marketplace'
      },
   ],
   'KernelId': {
      'Value': 'string'
   },
   'RamdiskId': {
      'Value': 'string'
   },
   'Description': {
      'Value': 'string'
   },
   'SriovNetSupport': {
      'Value': 'string'
   },
   'BlockDeviceMappings': [
      {
         'VirtualName': 'string',
         'DeviceName': 'string',
         'Ebs': {
            'SnapshotId': 'string',
            'VolumeSize': 123,
            'DeleteOnTermination': True|False,
            'VolumeType': 'standard'|'io1'|'gp2',
            'Iops': 123,
            'Encrypted': True|False
         },
         'NoDevice': 'string'
      },
   ]
}
```

Response Structure

- *(dict)* – Information about the image attribute.
  - **ImageId** *(string)* – The ID of the AMI.
  - **LaunchPermissions** *(list)* – One or more launch permissions.
    * *(dict)* – Describes a launch permission.
- **UserId** *(string)* –
The AWS account ID.
- **Group** *(string)* –
The name of the group.

- **ProductCodes** *(list)* –
One or more product codes.
  *
  *(dict)* –
  Describes a product code.
    - **ProductCodeId** *(string)* –
The product code.
    - **ProductCodeType** *(string)* –
The type of product code.

- **KernelId** *(dict)* –
The kernel ID.
  *
  **Value** *(string)* –
  Valid values are case-sensitive and vary by action.

- **RamdiskId** *(dict)* –
The RAM disk ID.
  *
  **Value** *(string)* –
  Valid values are case-sensitive and vary by action.

- **Description** *(dict)* –
A description for the AMI.
  *
  **Value** *(string)* –
  Valid values are case-sensitive and vary by action.

- **SriovNetSupport** *(dict)* –
The value to use for a resource attribute.
  *
  **Value** *(string)* –
  Valid values are case-sensitive and vary by action.

- **BlockDeviceMappings** *(list)* –
One or more block device mapping entries.
  *
  *(dict)* –
  Describes a block device mapping.
    - **VirtualName** *(string)* –
The virtual device name *(ephemeral N)*. Instance store volumes are numbered starting from 0. An instance type with 2 available instance store volumes can specify mappings for *ephemeral0* and *ephemeral1*. The number of available instance store volumes depends on the instance type. After you connect to the instance, you must mount the volume.

Constraints: For M3 instances, you must specify instance store volumes in the block device mapping for the instance. When you launch an M3 instance, we ignore any instance store volumes specified in the block device mapping for the AMI.
- **DeviceName** *(string)* –
  The device name exposed to the instance (for example, `/dev/sdh` or `xvdh`).

- **Ebs** *(dict)* –
  Parameters used to automatically set up EBS volumes when the instance is launched.

- **SnapshotId** *(string)* –
  The ID of the snapshot.

- **VolumeSize** *(integer)* –
  The size of the volume, in GiB.

  Constraints: 1-1024 for standard volumes, 1-16384 for gp2 volumes, and 4-16384 for io1 volumes. If you specify a snapshot, the volume size must be equal to or larger than the snapshot size.

  Default: If you’re creating the volume from a snapshot and don’t specify a volume size, the default is the snapshot size.

- **DeleteOnTermination** *(boolean)* –
  Indicates whether the EBS volume is deleted on instance termination.

- **VolumeType** *(string)* –
  The volume type. gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, and standard for Magnetic volumes.

  Default: standard

- **Iops** *(integer)* –
  The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.

  Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.

  Condition: This parameter is required for requests to create io1 volumes; it is not used in requests to create standard or gp2 volumes.

- **Encrypted** *(boolean)* –
  Indicates whether the EBS volume is encrypted. Encrypted Amazon EBS volumes may only be attached to instances that support Amazon EBS encryption.

- **NoDevice** *(string)* –
  Suppresses the specified device included in the block device mapping of the AMI.
**describe_images**(**kwargs**)  
Describes one or more of the images (AMIs, AKIs, and ARIs) available to you. Images available to you include public images, private images that you own, and private images owned by other AWS accounts but for which you have explicit launch permissions.

Note: Deregistered images are included in the returned results for an unspecified interval after deregistration.

### Request Syntax

```python
response = client.describe_images(
    DryRun=True|False,
    ImageIds=['string'],
    Owners=['string'],
    ExecutableUsers=['string'],
    Filters=[
        {'Name': 'string', 'Values': ['string']}
    ]
)
```

### Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **ImageIds** *(list)* – One or more image IDs.  
Default: Describes all images available to you.

- **Owners** *(list)* – Filters the images by the owner. Specify an AWS account ID, `amazon` (owner is Amazon), `aws-marketplace` (owner is AWS Marketplace), `self` (owner is the sender of the request). Omitting this option returns all images for which you have launch permissions, regardless of ownership.

- **ExecutableUsers** *(list)* – Scopes the images by users with explicit launch permissions. Specify an AWS account ID, `self` (the sender of the request), or `all` (public AMIs).

- **Filters** *(list)* – One or more filters.

  - **architecture** - The image architecture (`i386`|`x86_64`).
  - **block-device-mapping.delete-on-termination** - A Boolean value that indicates whether the Amazon EBS volume is deleted on instance termination.
  - **block-device-mapping.device-name** - The device name for the EBS volume (for example, `/dev/sdh`).
- block-device-mapping.snapshot-id - The ID of the snapshot used for the EBS volume.
- block-device-mapping.volume-size - The volume size of the EBS volume, in GiB.
- block-device-mapping.volume-type - The volume type of the EBS volume (gp2 | standard | io1).
- description - The description of the image (provided during image creation).
- hypervisor - The hypervisor type (ovm | xen).
- image-id - The ID of the image.
- image-type - The image type (machine | kernel | ramdisk).
- is-public - A Boolean that indicates whether the image is public.
- kernel-id - The kernel ID.
- manifest-location - The location of the image manifest.
- name - The name of the AMI (provided during image creation).
- owner-alias - The AWS account alias (for example, amazon).
- owner-id - The AWS account ID of the image owner.
- platform - The platform. To only list Windows-based AMIs, use windows.
- product-code - The product code.
- product-code.type - The type of the product code (devpay | marketplace).
- ramdisk-id - The RAM disk ID.
- root-device-name - The name of the root device volume (for example, /dev/sdal).
- root-device-type - The type of the root device volume (ebs | instance-store).
- state - The state of the image (available | pending | failed).
- state-reason-code - The reason code for the state change.
- state-reason-message - The message for the state change.
- tag :key =*value* - The key/value combination of a tag assigned to the resource.
- tag-key - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter "tag-key=Purpose" and the filter "tag-value=X", you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key =*value* filter.
- tag-value - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- virtualization-type - The virtualization type (paravirtual | hvm).

(dict) –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* Name (string) –
    The name of the filter. Filter names are case-sensitive.

* Values (list) –
    One or more filter values. Filter values are case-sensitive.

    · (string) –
Returns

Response Syntax

```json
{
    'Images': [
        {
            'ImageId': 'string',

}```
Response Structure

* (dict) –
  – Images (list) –

Information about one or more images.

* (dict) –

Describes an image.

  · **ImageId (string)** –
    The ID of the AMI.
  · **ImageLocation (string)** –
    The location of the AMI.
  · **State (string)** –
    The current state of the AMI. If the state is available, the image is successfully registered and can be used to launch an instance.
  · **OwnerId (string)** –
    The AWS account ID of the image owner.
  · **CreationDate (string)** –
    The date and time the image was created.
  · **Public (boolean)** –
    Indicates whether the image has public launch permissions. The value is true if this image has public launch permissions or false if it has only implicit and explicit launch permissions.
  · **ProductCodes (list)** –
    Any product codes associated with the AMI.

* (dict) –

Describes a product code.

  · **ProductCodeId (string)** –
    The product code.
  · **ProductCodeType (string)** –
    The type of product code.
  · **Architecture (string)** –
    The architecture of the image.
  · **ImageType (string)** –
    The type of image.
  · **KernelId (string)** –
    The kernel associated with the image, if any. Only applicable for machine images.
  · **RamdiskId (string)** –
    The RAM disk associated with the image, if any. Only applicable for machine images.
• **Platform** *(string)* –
  The value is `Windows` for Windows AMIs; otherwise blank.

• **SriovNetSupport** *(string)* –
  Specifies whether enhanced networking is enabled.

• **StateReason** *(dict)* –
  The reason for the state change.

• **Code** *(string)* –
  The reason code for the state change.

• **Message** *(string)* –
  The message for the state change.

• **Server.SpotInstanceTermination** : A Spot Instance was terminated due to an increase in the market price.

• **Server.InternalError** : An internal error occurred during instance launch, resulting in termination.

• **Server.InsufficientInstanceCapacity** : There was insufficient instance capacity to satisfy the launch request.

• **Client.InternalError** : A client error caused the instance to terminate on launch.

• **Client.InstanceInitiatedShutdown** : The instance was shut down using the `shutdown -h` command from the instance.

• **Client.UserInitiatedShutdown** : The instance was shut down using the Amazon EC2 API.

• **Client.VolumeLimitExceeded** : The volume limit was exceeded.

• **Client.InvalidSnapshot.NotFound** : The specified snapshot was not found.

• **ImageOwnerAlias** *(string)* –
  The AWS account alias (for example, `amazon`, `self`) or the AWS account ID of the AMI owner.

• **Name** *(string)* –
  The name of the AMI that was provided during image creation.

• **Description** *(string)* –
  The description of the AMI that was provided during image creation.

• **RootDeviceType** *(string)* –
  The type of root device used by the AMI. The AMI can use an EBS volume or an instance store volume.

• **RootDeviceName** *(string)* –
  The device name of the root device (for example, `/dev/sdal` or `/dev/xvda`).

• **BlockDeviceMappings** *(list)* –
  Any block device mapping entries.

• *(dict)* –
  Describes a block device mapping.
- **VirtualName** *(string)* –
  The virtual device name *(ephemeral N)*. Instance store volumes are numbered starting from 0. An instance type with 2 available instance store volumes can specify mappings for *ephemeral0* and *ephemeral1* . The number of available instance store volumes depends on the instance type. After you connect to the instance, you must mount the volume.

  Constraints: For M3 instances, you must specify instance store volumes in the block device mapping for the instance. When you launch an M3 instance, we ignore any instance store volumes specified in the block device mapping for the AMI.

- **DeviceName** *(string)* –
  The device name exposed to the instance (for example, /dev/sdh or xvdh ).

- **Ebs** *(dict)* –
  Parameters used to automatically set up EBS volumes when the instance is launched.

- **SnapshotId** *(string)* –
  The ID of the snapshot.

- **VolumeSize** *(integer)* –
  The size of the volume, in GiB.

  Constraints: 1-1024 for standard volumes, 1-16384 for gp2 volumes, and 4-16384 for io1 volumes. If you specify a snapshot, the volume size must be equal to or larger than the snapshot size.

  Default: If you're creating the volume from a snapshot and don't specify a volume size, the default is the snapshot size.

- **DeleteOnTermination** *(boolean)* –
  Indicates whether the EBS volume is deleted on instance termination.

- **VolumeType** *(string)* –
  The volume type. gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, and standard for Magnetic volumes.

  Default: standard

- **Iops** *(integer)* –
  The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.

  Constraint: Range is 100 to 20000 for Provisioned IOPS.
(SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.

Condition: This parameter is required for requests to create io1 volumes; it is not used in requests to create standard or gp2 volumes.

- **Encrypted (boolean)** –
  
  Indicates whether the EBS volume is encrypted. Encrypted Amazon EBS volumes may only be attached to instances that support Amazon EBS encryption.

- **NoDevice (string)** –
  
  Suppresses the specified device included in the block device mapping of the AMI.

- **VirtualizationType (string)** –
  
  The type of virtualization of the AMI.

- **Tags (list)** –
  
  Any tags assigned to the image.

- **Key (string)** –
  
  The key of the tag.

Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`

- **Value (string)** –
  
  The value of the tag.

Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

- **Hypervisor (string)** –
  
  The hypervisor type of the image.

**describe_import_image_tasks(****kwargs**

Displays details about an import virtual machine or import snapshot tasks that are already created.

**Request Syntax**

```python
response = client.describe_import_image_tasks(
    DryRun=True|False,
    ImportTaskIds=['string'],
    NextToken='string',
    MaxResults=123,
    Filters=[
        {'Name': 'string',
         'Values': ['string',
                    ]},
    ]
)
```

1226 Chapter 3. API Reference
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **ImportTaskIds** *(list)* – A list of import image task IDs.

- **NextToken** *(string)* – A token that indicates the next page of results.

- **MaxResults** *(integer)* – The maximum number of results to return in a single request.

- **Filters** *(list)* – One or more filters.

  - *(dict)* –

    A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

    - **Name** *(string)* –

      The name of the filter. Filter names are case-sensitive.

    - **Values** *(list)* –

      One or more filter values. Filter values are case-sensitive.

    - *(string)* –

Return type **dict**

Returns

Response Syntax

```python
{
    'ImportImageTasks': [  
        {
            'ImportTaskId': 'string',  
            'Architecture': 'string',  
            'LicenseType': 'string',  
            'Platform': 'string',  
            'Hypervisor': 'string',  
            'Description': 'string',  
            'SnapshotDetails': [  
                {
                    'DiskImageSize': 123.0,  
                    'Description': 'string',  
                    'Format': 'string',  
                    'Url': 'string',  
                    'UserBucket': {  
                        'S3Bucket': 'string',  
                        'S3Key': 'string'
                    },  
                    'DeviceName': 'string',  
                    'SnapshotId': 'string',  
                    'Progress': 'string',  
                    'StatusMessage': 'string',  
                    'Status': 'string'
                },  
                {
                    'DiskImageSize': 123.0,  
                    'Description': 'string',  
                    'Format': 'string',  
                    'Url': 'string',  
                    'UserBucket': {  
                        'S3Bucket': 'string',  
                        'S3Key': 'string'
                    },  
                    'DeviceName': 'string',  
                    'SnapshotId': 'string',  
                    'Progress': 'string',  
                    'StatusMessage': 'string',  
                    'Status': 'string'
                }
            ],  
            'ImageId': 'string',  
            'Progress': 'string',  
            'StatusMessage': 'string',  
            'Status': 'string'
        }
    ]
}
```
Response Structure

- **ImportImageTasks** (list)
  
  A list of zero or more import image tasks that are currently active or were completed or canceled in the previous 7 days.

  - (dict)
    
    Describes an import image task.
    
    - **ImportTaskId** (string)
      
      The ID of the import image task.
    
    - **Architecture** (string)
      
      The architecture of the virtual machine.
      
      Valid values: `i386` | `x86_64`
    
    - **LicenseType** (string)
      
      The license type of the virtual machine.
    
    - **Platform** (string)
      
      The description string for the import image task.
    
    - **Hypervisor** (string)
      
      The target hypervisor for the import task.
      
      Valid values: `xen`
    
    - **Description** (string)
      
      A description of the import task.
    
    - **SnapshotDetails** (list)
      
      Information about the snapshots.
      
      - (dict)
        
        Describes the snapshot created from the imported disk.
        
        - **DiskImageSize** (float)
          
          The size of the disk in the snapshot, in GiB.
        
        - **Description** (string)
          
          A description for the snapshot.
        
        - **Format** (string)
          
          The format of the disk image from which the snapshot is created.
        
        - **Url** (string)
          
          The URL used to access the disk image.
        
        - **UserBucket** (dict)
          
          Describes the S3 bucket for the disk image.
        
        - **S3Bucket** (string)
          
          The S3 bucket from which the disk image was created.
· **S3Key** *(string)* – 
The key from which the disk image was created.
· **DeviceName** *(string)* – 
The block device mapping for the snapshot.
· **SnapshotId** *(string)* – 
The snapshot ID of the disk being imported.
· **Progress** *(string)* – 
The percentage of progress for the task.
· **StatusMessage** *(string)* – 
A detailed status message for the snapshot creation.
· **Status** *(string)* – 
A brief status of the snapshot creation.
· **ImageId** *(string)* – 
The ID of the Amazon Machine Image (AMI) of the imported virtual machine.
· **Progress** *(string)* – 
The percentage of progress of the import image task.
· **StatusMessage** *(string)* – 
A descriptive status message for the import image task.
· **Status** *(string)* – 
A brief status for the import image task.

– **NextToken** *(string)* – 
The token to use to get the next page of results. This value is null when there are no more results to return.

describe_import_snapshot_tasks(**kwargs)**

Describes your import snapshot tasks.

**Request Syntax**

```python
response = client.describe_import_snapshot_tasks(
    DryRun=True|False,
    ImportTaskIds=[
        'string',
    ],
    NextToken='string',
    MaxResults=123,
    Filters=[
        {'Name': 'string',
         'Values': [
             'string',
         ]},
    ]
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If
you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **ImportTaskIds** *(list)* – A list of import snapshot task IDs.
  - *(string)*
- **NextToken** *(string)* – A token that indicates the next page of results.
- **MaxResults** *(integer)* – The maximum number of results to return in a single request.
- **Filters** *(list)* – One or more filters.
  - *(dict)* –
    - **Name** *(string)*
      - The name of the filter. Filter names are case-sensitive.
    - **Values** *(list)* –
      - *(string)*

**Return type** **dict**

**Returns**

**Response Syntax**

```json
{
    'ImportSnapshotTasks': [
        {
            'ImportTaskId': 'string',
            'SnapshotTaskDetail': {
                'DiskImageSize': 123.0,
                'Description': 'string',
                'Format': 'string',
                'Url': 'string',
                'UserBucket': {
                    'S3Bucket': 'string',
                    'S3Key': 'string'
                },
                'SnapshotId': 'string',
                'Progress': 'string',
                'StatusMessage': 'string',
                'Status': 'string'
            },
            'Description': 'string'
        },
        {
            'ImportTaskId': 'string',
            'SnapshotTaskDetail': {
                'DiskImageSize': 123.0,
                'Description': 'string',
                'Format': 'string',
                'Url': 'string',
                'UserBucket': {
                    'S3Bucket': 'string',
                    'S3Key': 'string'
                },
                'SnapshotId': 'string',
                'Progress': 'string',
                'StatusMessage': 'string',
                'Status': 'string'
            },
            'Description': 'string'
        }
    ],
    'NextToken': 'string'
}
```

**Response Structure**

- *(dict)* –
  - **ImportSnapshotTasks** *(list)* –
    - A list of zero or more import snapshot tasks that are currently active or were completed or canceled in the previous 7 days.
      - *(dict)* –
        - Describes an import snapshot task.
· **ImportTaskId** *(string)* –
  The ID of the import snapshot task.

· **SnapshotTaskDetail** *(dict)* –
  Describes an import snapshot task.

· **DiskImageSize** *(float)* –
  The size of the disk in the snapshot, in GiB.

· **Description** *(string)* –
  The description of the snapshot.

· **Format** *(string)* –
  The format of the disk image from which the snapshot is created.

· **Url** *(string)* –
  The URL of the disk image from which the snapshot is created.

· **UserBucket** *(dict)* –
  The S3 bucket for the disk image.

· **S3Bucket** *(string)* –
  The S3 bucket from which the disk image was created.

· **S3Key** *(string)* –
  The key from which the disk image was created.

· **SnapshotId** *(string)* –
  The snapshot ID of the disk being imported.

· **Progress** *(string)* –
  The percentage of completion for the import snapshot task.

· **StatusMessage** *(string)* –
  A detailed status message for the import snapshot task.

· **Status** *(string)* –
  A brief status for the import snapshot task.

· **Description** *(string)* –
  A description of the import snapshot task.

· **NextToken** *(string)* –
  The token to use to get the next page of results. This value is null when there are no more results to return.

**describe_instance_attribute(**kwargs)**

Describes the specified attribute of the specified instance. You can specify only one attribute at a time. Valid attribute values are: `instanceType` | `kernel` | `ramdisk` | `userData` | `disableApiTermination` | `instanceInitiatedShutdownBehavior` | `rootDeviceName` | `blockDeviceMapping` | `productCodes` | `sourceDestCheck` | `groupSet` | `ebsOptimized` | `sriovNetSupport`

**Request Syntax**

```python
response = client.describe_instance_attribute(
    DryRun=True|False,
    InstanceId='string',
)```

3.1. Services
Attribute='instanceType'|'kernel'|'ramdisk'|'userData'|'disableApiTermination'|'instanceInitiatedShutdownBehavior'|'rootDeviceName'|'blockDeviceMapping'|'productCodes'|'sourceDestCheck'|'groupSet'|'ebsOptimized'|'sriovNetSupport}

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **InstanceId** *(string)* – [REQUIRED]
  
  The ID of the instance.
- **Attribute** *(string)* – [REQUIRED]
  
  The instance attribute.

Return type  dict

Returns

Response Syntax

```
{
    'InstanceId': 'string',
    'InstanceType': {
        'Value': 'string'
    },
    'KernelId': {
        'Value': 'string'
    },
    'RamdiskId': {
        'Value': 'string'
    },
    'UserData': {
        'Value': 'string'
    },
    'DisableApiTermination': {
        'Value': True|False
    },
    'InstanceInitiatedShutdownBehavior': {
        'Value': 'string'
    },
    'RootDeviceName': {
        'Value': 'string'
    },
    'BlockDeviceMappings': [
        {
            'DeviceName': 'string',
            'Ebs': {
                'VolumeId': 'string',
                'Status': 'attaching'|'attached'|'detaching'|'detached',
                'AttachTime': datetime(2015, 1, 1),
                'DeleteOnTermination': True|False
            }
        },
    ],
    'ProductCodes': [
        {
            'ProductCodeId': 'string',
            'ProductCodeType': 'devpay'|'marketplace'
        },
    ]
}
```
EbsOptimized': {
    'Value': True|False
},
'SriovNetSupport': {
    'Value': 'string'
},
'SourceDestCheck': {
    'Value': True|False
},
'Groups': [
    {
        'GroupName': 'string',
        'GroupId': 'string'
    }
]
}

Response Structure

• (dict) –

Information about the instance attribute.
  – InstanceId (string) –
    The ID of the instance.
  – InstanceType (dict) –
    The instance type.
    * Value (string) –
      Valid values are case-sensitive and vary by action.
  – KernelId (dict) –
    The kernel ID.
    * Value (string) –
      Valid values are case-sensitive and vary by action.
  – RamdiskId (dict) –
    The RAM disk ID.
    * Value (string) –
      Valid values are case-sensitive and vary by action.
  – UserData (dict) –
    The Base64-encoded MIME user data.
    * Value (string) –
      Valid values are case-sensitive and vary by action.
  – DisableApiTermination (dict) –
    If the value is true, you can’t terminate the instance through the Amazon
    EC2 console, CLI, or API; otherwise, you can.
    * Value (boolean) –
      Valid values are true or false.
  – InstanceInitiatedShutdownBehavior (dict) –
    Indicates whether an instance stops or terminates when you initiate shut-
    down from the instance (using the operating system command for system
    shutdown).
* **Value** *(string)* –
  Valid values are case-sensitive and vary by action.

- **RootDeviceName** *(dict)* –
  The name of the root device (for example, /dev/sdal or /dev/xvda).
  * **Value** *(string)* –
    Valid values are case-sensitive and vary by action.

- **BlockDeviceMappings** *(list)* –
  The block device mapping of the instance.
  * *(dict)* –
    Describes a block device mapping.
    - **DeviceName** *(string)* –
      The device name exposed to the instance (for example, /dev/sdh or xvdh).
    - **Ebs** *(dict)* –
      Parameters used to automatically set up EBS volumes when
      the instance is launched.
      - **VolumeId** *(string)* –
        The ID of the EBS volume.
      - **Status** *(string)* –
        The attachment state.
      - **AttachTime** *(datetime)* –
        The time stamp when the attachment initiated.
      - **DeleteOnTermination** *(boolean)* –
        Indicates whether the volume is deleted on instance termination.

- **ProductCodes** *(list)* –
  A list of product codes.
  * *(dict)* –
    Describes a product code.
    - **ProductCodeId** *(string)* –
      The product code.
    - **ProductCodeType** *(string)* –
      The type of product code.

- **EbsOptimized** *(dict)* –
  Indicates whether the instance is optimized for EBS I/O.
  * **Value** *(boolean)* –
    Valid values are true or false.

- **SriovNetSupport** *(dict)* –
  The value to use for a resource attribute.
  * **Value** *(string)* –
    Valid values are case-sensitive and vary by action.
– **SourceDestCheck** *(dict)*

Indicates whether source/destination checking is enabled. A value of `true` means checking is enabled, and `false` means checking is disabled. This value must be `false` for a NAT instance to perform NAT.

* **Value** *(boolean)*

Valid values are `true` or `false`.

– **Groups** *(list)*

The security groups associated with the instance.

* *(dict)*

Describes a security group.

· **GroupName** *(string)*

The name of the security group.

· **GroupId** *(string)*

The ID of the security group.

**describe_instance_status** *(**kwargs)*

Describes the status of one or more instances.

Instance status includes the following components:

- **Status checks** - Amazon EC2 performs status checks on running EC2 instances to identify hardware and software issues. For more information, see Status Checks for Your Instances and Troubleshooting Instances with Failed Status Checks in the *Amazon Elastic Compute Cloud User Guide*.

- **Scheduled events** - Amazon EC2 can schedule events (such as reboot, stop, or terminate) for your instances related to hardware issues, software updates, or system maintenance. For more information, see Scheduled Events for Your Instances in the *Amazon Elastic Compute Cloud User Guide*.

- **Instance state** - You can manage your instances from the moment you launch them through their termination. For more information, see Instance Lifecycle in the *Amazon Elastic Compute Cloud User Guide*.

**Request Syntax**

```python
response = client.describe_instance_status(
    DryRun=True|False,
    InstanceIds=['string'],
    Filters=[
        {'Name': 'string',
         'Values': ['string'],
        },
    ],
    NextToken='string',
    MaxResults=123,
    IncludeAllInstances=True|False
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If
you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **InstanceIds (list)** – One or more instance IDs.

  Default: Describes all your instances.

  Constraints: Maximum 100 explicitly specified instance IDs.

  - (string)

- **Filters (list)** – One or more filters.

  - availability-zone - The Availability Zone of the instance.
  - event.code - The code for the scheduled event (instance-reboot | system-reboot | system-maintenance | instance-retirement | instance-stop).
  - event.description - A description of the event.
  - event.not-after - The latest end time for the scheduled event (for example, 2014-09-15T17:15:20.000Z).
  - event.not-before - The earliest start time for the scheduled event (for example, 2014-09-15T17:15:20.000Z).
  - instance-state-code - The code for the instance state, as a 16-bit unsigned integer. The high byte is an opaque internal value and should be ignored. The low byte is set based on the state represented. The valid values are 0 (pending), 16 (running), 32 (shutting-down), 48 (terminated), 64 (stopping), and 80 (stopped).
  - instance-state-name - The state of the instance (pending | running | shutting-down | terminated | stopping | stopped).
  - instance-status.reachability - Filters on instance status where the name is reachability (passed | failed | initializing | insufficient-data).
  - instance-status.status - The status of the instance (ok | impaired | initializing | insufficient-data | not-applicable).
  - system-status.reachability - Filters on system status where the name is reachability (passed | failed | initializing | insufficient-data).
  - system-status.status - The system status of the instance (ok | impaired | initializing | insufficient-data | not-applicable).

- (dict)

  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  - **Name (string)** –

    The name of the filter. Filter names are case-sensitive.

  - **Values (list)** –

    One or more filter values. Filter values are case-sensitive.

  - (string)

- **NextToken (string)** – The token to retrieve the next page of results.

- **MaxResults (integer)** – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. You cannot specify this parameter and the instance
IDs parameter in the same request.

- **IncludeAllInstances (boolean)** – When `true`, includes the health status for all instances. When `false`, includes the health status for running instances only.

  Default: `false`

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
  'InstanceStatuses': [
    {
      'InstanceId': 'string',
      'AvailabilityZone': 'string',
      'Events': [
        {

            'ImpairedSince': datetime(2015, 1, 1)
          }
        ]
      }
    }
  ],
  'NextToken': 'string'
}
```

**Response Structure**

- `(dict)` –
  - **InstanceStatuses (list)** –
    - One or more instance status descriptions.

**3.1. Services**
Describes the status of an instance.

- **InstanceId** (string) –
  The ID of the instance.

- **AvailabilityZone** (string) –
  The Availability Zone of the instance.

- **Events** (list) –
  Any scheduled events associated with the instance.
  
  - **dict** –
    Describes a scheduled event for an instance.

  - **Code** (string) –
    The event code.

  - **Description** (string) –
    A description of the event.

After a scheduled event is completed, it can still be described for up to a week. If the event has been completed, this description starts with the following text: [Completed].

- **NotBefore** (datetime) –
  The earliest scheduled start time for the event.

- **NotAfter** (datetime) –
  The latest scheduled end time for the event.

- **InstanceState** (dict) –
  The intended state of the instance. DescribeInstanceStatus requires that an instance be in the running state.

  - **Code** (integer) –
    The low byte represents the state. The high byte is an opaque internal value and should be ignored.
    - 0: pending
    - 16: running
    - 32: shutting-down
    - 48: terminated
    - 64: stopping
    - 80: stopped

  - **Name** (string) –
    The current state of the instance.

- **SystemStatus** (dict) –
  Reports impaired functionality that stems from issues related to the systems that support an instance, such as hardware failures and network connectivity problems.

  - **Status** (string) –
    The status.

- **Details** (list) –
  The system instance health or application instance health.

  - **dict** –
    Describes the instance status.

  - **Name** (string) –
The type of instance status.

- **Status** *(string)* –

  The status.

- **ImpairedSince** *(datetime)* –

  The time when a status check failed. For an instance that was launched and impaired, this is the time when the instance was launched.

- **InstanceStatus** *(dict)* –

  Reports impaired functionality that stems from issues internal to the instance, such as impaired reachability.

  - **Status** *(string)* –

    The status.

  - **Details** *(list)* –

    The system instance health or application instance health.

      - *(dict)* –

        Describes the instance status.

      - **Name** *(string)* –

        The type of instance status.

      - **Status** *(string)* –

        The status.

      - **ImpairedSince** *(datetime)* –

        The time when a status check failed. For an instance that was launched and impaired, this is the time when the instance was launched.

- **NextToken** *(string)* –

  The token to use to retrieve the next page of results. This value is null when there are no more results to return.

**describe_instances(** **kwargs**)**

Describes one or more of your instances.

If you specify one or more instance IDs, Amazon EC2 returns information for those instances. If you do not specify instance IDs, Amazon EC2 returns information for all relevant instances. If you specify an instance ID that is not valid, an error is returned. If you specify an instance that you do not own, it is not included in the returned results.

Recently terminated instances might appear in the returned results. This interval is usually less than one hour.

**Request Syntax**

```python
response = client.describe_instances(
    DryRun=True|False,
    InstanceIds=[
        'string',
    ],
    Filters=[
        {  
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ],
)
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **InstanceIds** *(list)* – One or more instance IDs.

Default: Describes all your instances.

- *(string)*

- **Filters** *(list)* – One or more filters.
  - **architecture** - The instance architecture (i386|x86_64).
  - **availability-zone** - The Availability Zone of the instance.
  - **block-device-mapping.attach-time** - The attach time for an EBS volume mapped to the instance, for example, 2010-09-15T17:15:20.000Z.
  - **block-device-mapping.delete-on-termination** - A Boolean that indicates whether the EBS volume is deleted on instance termination.
  - **block-device-mapping.device-name** - The device name for the EBS volume (for example, /dev/sdh or xvdh).
  - **block-device-mapping.status** - The status for the EBS volume (attaching|attached|detaching|detached).
  - **block-device-mapping.volume-id** - The volume ID of the EBS volume.
  - **client-token** - The idempotency token you provided when you launched the instance.
  - **dns-name** - The public DNS name of the instance.
  - **group-id** - The ID of the security group for the instance. EC2-Classic only.
  - **group-name** - The name of the security group for the instance. EC2-Classic only.
  - **hypervisor** - The hypervisor type of the instance (ovm|xen).
  - **iam-instance-profile.arn** - The instance profile associated with the instance. Specified as an ARN.
  - **image-id** - The ID of the image used to launch the instance.
  - **instance-id** - The ID of the instance.
  - **instance-lifecycle** - Indicates whether this is a Spot Instance (spot).
  - **instance-state-code** - The state of the instance, as a 16-bit unsigned integer. The high byte is an opaque internal value and should be ignored. The low byte is set based on the state represented. The valid values are: 0 (pending), 16 (running), 32 (shutting-down), 48 (terminated), 64 (stopping), and 80 (stopped).
  - **instance-state-name** - The state of the instance (pending|running|shutting-down|terminated|stopping|stopped).
  - **instance-type** - The type of instance (for example, t2.micro).
  - **instance.group-id** - The ID of the security group for the instance.
- **instance.group-name** - The name of the security group for the instance.
- **ip-address** - The public IP address of the instance.
- **kernel-id** - The kernel ID.
- **key-name** - The name of the key pair used when the instance was launched.
- **launch-index** - When launching multiple instances, this is the index for the instance in the launch group (for example, 0, 1, 2, and so on).
- **launch-time** - The time when the instance was launched.
- **monitoring-state** - Indicates whether monitoring is enabled for the instance (disabled | enabled).
- **owner-id** - The AWS account ID of the instance owner.
- **placement-group-name** - The name of the placement group for the instance.
- **platform** - The platform. Use windows if you have Windows instances; otherwise, leave blank.
- **private-dns-name** - The private DNS name of the instance.
- **private-ip-address** - The private IP address of the instance.
- **product-code** - The product code associated with the AMI used to launch the instance.
- **product-code.type** - The type of product code (devpay | marketplace).
- **ramdisk-id** - The RAM disk ID.
- **reason** - The reason for the current state of the instance (for example, shows “User Initiated [date]” when you stop or terminate the instance). Similar to the state-reason-code filter.
- **requester-id** - The ID of the entity that launched the instance on your behalf (for example, AWS Management Console, Auto Scaling, and so on).
- **reservation-id** - The ID of the instance’s reservation. A reservation ID is created any time you launch an instance. A reservation ID has a one-to-one relationship with an instance launch request, but can be associated with more than one instance if you launch multiple instances using the same launch request. For example, if you launch one instance, you’ll get one reservation ID. If you launch ten instances using the same launch request, you’ll also get one reservation ID.
- **root-device-name** - The name of the root device for the instance (for example, /dev/sda1 or /dev/xvda).
- **root-device-type** - The type of root device that the instance uses (ebs | instance-store).
- **source-dest-check** - Indicates whether the instance performs source/destination checking. A value of true means that checking is enabled, and false means checking is disabled. The value must be false for the instance to perform network address translation (NAT) in your VPC.
- **spot-instance-request-id** - The ID of the Spot Instance request.
- **state-reason-code** - The reason code for the state change.
- **state-reason-message** - A message that describes the state change.
- **subnet-id** - The ID of the subnet for the instance.
- **tag :key ="value"** - The key/value combination of a tag assigned to the resource, where tag :key is the tag’s key.
- **tag-key** - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources as-
signed both the tag key Purpose (regardless of what the tag’s value is), and
the tag value X (regardless of what the tag’s key is). If you want to list
only resources where Purpose is X, see the tag key=’value’ filter.

- **tag-value** - The value of a tag assigned to the resource. This filter is
  independent of the tag-key filter.
- **tenancy** - The tenancy of an instance (dedicated|default).
- **virtualization-type** - The virtualization type of the instance
  (paravirtual|hvm).
- **vpc-id** - The ID of the VPC that the instance is running in.
- **network-interface.description** - The description of the network
  interface.
- **network-interface.subnet-id** - The ID of the subnet for the
  network interface.
- **network-interface.vpc-id** - The ID of the VPC for the network
  interface.
- **network-interface.network-interface.id** - The ID of the
  network interface.
- **network-interface.owner-id** - The ID of the owner of the network
  interface.
- **network-interface.availability-zone** - The Availability Zone for the
  network interface.
- **network-interface.requester-id** - The requester ID for the network
  interface.
- **network-interface.requester-managed** - Indicates whether
  the network interface is being managed by AWS.
- **network-interface.status** - The status of the network interface
  (available|in-use).
- **network-interface.mac-address** - The MAC address of the network
  interface.
- **network-interface-private-dns-name** - The private DNS name of the
  network interface.
- **network-interface.source-dest-check** - Whether the network
  interface performs source/destination checking. A value of true
  means checking is enabled, and false means checking is disabled. The
  value must be false for the network interface to perform network address
  translation (NAT) in your VPC.
- **network-interface.group-id** - The ID of a security group associated
  with the network interface.
- **network-interface.group-name** - The name of a security group
  associated with the network interface.
- **network-interface.attachment.attachment-id** - The ID
  of the interface attachment.
- **network-interface.attachment.instance-id** - The ID of
  the instance to which the network interface is attached.
- **network-interface.attachment.instance-owner-id** - The owner ID of
  the instance to which the network interface is attached.
- **network-interface.addresses.private-ip-address** - The
  private IP address associated with the network interface.
- **network-interface.attachment.device-index** - The device
  index to which the network interface is attached.
- **network-interface.attachment.status** - The status of the
  attachment (attaching|attached|detaching|detached).
- **network-interface.attachment.attach-time** - The time
  that the network interface was attached to an instance.
- `network-interface.attachment.delete-on-termination` - Specifies whether the attachment is deleted when an instance is terminated.
- `network-interface.addresses.primary` - Specifies whether the IP address of the network interface is the primary private IP address.
- `network-interface.addresses.association.public-ip` - The ID of the association of an Elastic IP address with a network interface.
- `network-interface.addresses.association.ip-owner-id` - The owner ID of the private IP address associated with the network interface.
- `association.public-ip` - The address of the Elastic IP address bound to the network interface.
- `association.ip-owner-id` - The owner of the Elastic IP address associated with the network interface.
- `association.allocation-id` - The allocation ID returned when you allocated the Elastic IP address for your network interface.
- `association.association-id` - The association ID returned when the network interface was associated with an IP address.

- *(dict)* –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* **Name (string)** – The name of the filter. Filter names are case-sensitive.

* **Values (list)** – One or more filter values. Filter values are case-sensitive.

- *(string)* –

- **NextToken (string)** – The token to request the next page of results.
- **MaxResults (integer)** – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned `NextToken` value. This value can be between 5 and 1000; if `MaxResults` is given a value larger than 1000, only 1000 results are returned. You cannot specify this parameter and the instance IDs parameter in the same request.

**Return type** dict

**Returns**

**Response Syntax**

```json

Response Structure

- (dict) –
  - Reservations (list) –
    One or more reservations.
      * (dict) –
        Describes a reservation.
          - ReservationId (string) –
            The ID of the reservation.
          - OwnerId (string) –
            The ID of the AWS account that owns the reservation.
          - RequesterId (string) –
            The ID of the requester that launched the instances on your behalf (for example, AWS Management Console or Auto Scaling).
          - Groups (list) –
            One or more security groups.
              * (dict) –
                Describes a security group.
                  - GroupName (string) –
                    The name of the security group.
                  - GroupId (string) –
                    The ID of the security group.
          - Instances (list) –
            One or more instances.
              * (dict) –
                Describes an instance.
                  - InstanceId (string) –
                    The ID of the instance.
                  - ImageId (string) –
                    The ID of the AMI used to launch the instance.
                  - State (dict) –
                    The current state of the instance.
                  - Code (integer) –
                    The low byte represents the state. The high byte is an opaque internal value and should be ignored.
- **Name** *(string)* –
  The current state of the instance.

- **PrivateDnsName** *(string)* –
  The private DNS name assigned to the instance. This DNS name can only be used inside the Amazon EC2 network. This name is not available until the instance enters the **running** state.

- **PublicDnsName** *(string)* –
  The public DNS name assigned to the instance. This name is not available until the instance enters the **running** state.

- **StateTransitionReason** *(string)* –
  The reason for the most recent state transition. This might be an empty string.

- **KeyName** *(string)* –
  The name of the key pair, if this instance was launched with an associated key pair.

- **AmiLaunchIndex** *(integer)* –
  The AMI launch index, which can be used to find this instance in the launch group.

- **ProductCodes** *(list)* –
  The product codes attached to this instance.

  - *(dict)* –
    Describes a product code.

    - **ProductCodeId** *(string)* –
      The product code.

    - **ProductCodeType** *(string)* –
      The type of product code.

    - **InstanceType** *(string)* –
      The instance type.

    - **LaunchTime** *(datetime)* –
      The time the instance was launched.

- **Placement** *(dict)* –
  The location where the instance launched.

  - **AvailabilityZone** *(string)* –
    The Availability Zone of the instance.

  - **GroupName** *(string)* –
    The name of the placement group the instance is in (for cluster compute instances).

  - **Tenancy** *(string)* –
The tenancy of the instance (if the instance is running in a VPC). An instance with a tenancy of dedicated runs on single-tenant hardware.

- **KernelId** *(string)* —
  The kernel associated with this instance.

- **RamdiskId** *(string)* —
  The RAM disk associated with this instance.

- **Platform** *(string)* —
  The value is `Windows` for Windows instances; otherwise blank.

- **Monitoring** *(dict)* —
  The monitoring information for the instance.

- **State** *(string)* —
  Indicates whether monitoring is enabled for the instance.

- **SubnetId** *(string)* —
  The ID of the subnet in which the instance is running.

- **VpcId** *(string)* —
  The ID of the VPC in which the instance is running.

- **PrivateIpAddress** *(string)* —
  The private IP address assigned to the instance.

- **PublicIpAddress** *(string)* —
  The public IP address assigned to the instance.

- **StateReason** *(dict)* —
  The reason for the most recent state transition.

- **Code** *(string)* —
  The reason code for the state change.

- **Message** *(string)* —
  The message for the state change.

- **Server.SpotInstanceTermination** : A Spot Instance was terminated due to an increase in the market price.

- **Server.InternalError** : An internal error occurred during instance launch, resulting in termination.

- **Server.InsufficientInstanceCapacity** : There was insufficient instance capacity to satisfy the launch request.

- **Client.InternalError** : A client error caused the instance to terminate on launch.

- **Client.InstanceInitiatedShutdown** : The instance was shut down using the `shutdown -h` command from the instance.

- **Client.UserInitiatedShutdown** : The instance was shut down using the Amazon EC2 API.

- **Client.VolumeLimitExceeded** : The volume limit was exceeded.

- **Client.InvalidSnapshot.NotFound** : The specified snapshot was not found.

- **Architecture** *(string)* —
The architecture of the image.

- **RootDeviceType** *(string)*
  - The root device type used by the AMI. The AMI can use an EBS volume or an instance store volume.

- **RootDeviceName** *(string)*
  - The root device name (for example, `/dev/sdal` or `/dev/xvda`).

- **BlockDeviceMappings** *(list)*
  - Any block device mapping entries for the instance.
    - *(dict)*
      - Describes a block device mapping.

- **DeviceName** *(string)*
  - The device name exposed to the instance (for example, `/dev/sdh` or `xvdh`).

- **Ebs** *(dict)*
  - Parameters used to automatically set up EBS volumes when the instance is launched.
    - **VolumeId** *(string)*
      - The ID of the EBS volume.
    - **Status** *(string)*
      - The attachment state.
    - **AttachTime** *(datetime)*
      - The time stamp when the attachment initiated.

- **DeleteOnTermination** *(boolean)*
  - Indicates whether the volume is deleted on instance termination.

- **VirtualizationType** *(string)*
  - The virtualization type of the instance.

- **InstanceLifecycle** *(string)*
  - Indicates whether this is a Spot Instance.

- **SpotInstanceRequestId** *(string)*
  - The ID of the Spot Instance request.

- **ClientToken** *(string)*
  - The idempotency token you provided when you launched the instance.

- **Tags** *(list)*
  - Any tags assigned to the instance.
    - *(dict)*
      - Describes a tag.

- **Key** *(string)*
  - The key of the tag.

Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`
· **Value (string)** –
  The value of the tag.
  Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

· **SecurityGroups (list)** –
  One or more security groups for the instance.
  · (dict) –
    Describes a security group.
    · **GroupName (string)** –
      The name of the security group.
    · **GroupId (string)** –
      The ID of the security group.
    · **SourceDestCheck (boolean)** –
      Specifies whether to enable an instance launched in a VPC to perform NAT. This controls whether source/destination checking is enabled on the instance. A value of true means checking is enabled, and false means checking is disabled. The value must be false for the instance to perform NAT. For more information, see NAT Instances in the Amazon Virtual Private Cloud User Guide.
    · **Hypervisor (string)** –
      The hypervisor type of the instance.

· **NetworkInterfaces (list)** –
  [EC2-VPC] One or more network interfaces for the instance.
  · (dict) –
    Describes a network interface.
    · **NetworkInterfaceId (string)** –
      The ID of the network interface.
    · **SubnetId (string)** –
      The ID of the subnet.
    · **VpcId (string)** –
      The ID of the VPC.
    · **Description (string)** –
      The description.
    · **OwnerId (string)** –
      The ID of the AWS account that created the network interface.
    · **Status (string)** –
      The status of the network interface.
    · **MacAddress (string)** –
      The MAC address.
    · **PrivateIpAddress (string)** –
      The IP address of the network interface within the subnet.
    · **PrivateDnsName (string)** –
      The private DNS name.
· **SourceDestCheck** *(boolean)* –
  Indicates whether to validate network traffic to or from this
  network interface.
· **Groups** *(list)* –
  One or more security groups.
  *(dict)* –
  Describes a security group.
· **GroupName** *(string)* –
  The name of the security group.
· **GroupId** *(string)* –
  The ID of the security group.
· **Attachment** *(dict)* –
  The network interface attachment.
  · **AttachmentId** *(string)* –
    The ID of the network interface attachment.
  · **DeviceIndex** *(integer)* –
    The index of the device on the instance for the network inter-
    face attachment.
  · **Status** *(string)* –
    The attachment state.
  · **AttachTime** *(datetime)* –
    The time stamp when the attachment initiated.
· **DeleteOnTermination** *(boolean)* –
  Indicates whether the network interface is deleted when the
  instance is terminated.
· **Association** *(dict)* –
  The association information for an Elastic IP associated with
  the network interface.
· **PublicIp** *(string)* –
  The public IP address or Elastic IP address bound to the net-
  work interface.
· **PublicDnsName** *(string)* –
  The public DNS name.
· **IpOwnerId** *(string)* –
  The ID of the owner of the Elastic IP address.
· **PrivateIpAddresses** *(list)* –
  The private IP addresses associated with the network inter-
  face.
  *(dict)* –
  Describes a private IP address.
· **PrivateIpAddress** *(string)* –
  The private IP address of the network interface.
· **PrivateDnsName** *(string)* –
  The private DNS name.
- **Primary** (boolean) –
  Indicates whether this IP address is the primary private IP address of the network interface.

- **Association** (dict) –
  The association information for an Elastic IP address for the network interface.

- **PublicIp** (string) –
  The public IP address or Elastic IP address bound to the network interface.

- **PublicDnsName** (string) –
  The public DNS name.

- **IpOwnerId** (string) –
  The ID of the owner of the Elastic IP address.

- **IamInstanceProfile** (dict) –
  The IAM instance profile associated with the instance.

- **Arn** (string) –
  The Amazon Resource Name (ARN) of the instance profile.

- **Id** (string) –
  The ID of the instance profile.

- **EbsOptimized** (boolean) –
  Indicates whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal I/O performance. This optimization isn’t available with all instance types. Additional usage charges apply when using an EBS Optimized instance.

- **SriovNetSupport** (string) –
  Specifies whether enhanced networking is enabled.

- **NextToken** (string) –
  The token to use to retrieve the next page of results. This value is **null** when there are no more results to return.

**describe_internet_gateways(****kwargs)**

Describes one or more of your Internet gateways.

**Request Syntax**

```python
response = client.describe_internet_gateways(
    DryRun=True|False,
    InternetGatewayIds=['string'],
    Filters=[
        'Name': 'string',
        'Values': ['string'],
    ],
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is *DryRunOperation*. Otherwise, it is *UnauthorizedOperation*.

- **InternetGatewayIds** *(list)* – One or more Internet gateway IDs.
  
  Default: Describes all your Internet gateways.

  - *(string)* –

- **Filters** *(list)* – One or more filters.
  - *attachment.state* - The current state of the attachment between the gateway and the VPC *(available)*. Present only if a VPC is attached.
  - *attachment.vpc-id* - The ID of an attached VPC.
  - *internet-gateway-id* - The ID of the Internet gateway.
  - *tag: key =*value* - The key/value combination of a tag assigned to the resource.
  - *tag-key* - The key of a tag assigned to the resource. This filter is independent of the *tag-value* filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the *tag: key =*value* filter.
  - *tag-value* - The value of a tag assigned to the resource. This filter is independent of the *tag-key* filter.

- *(dict)* –
  
  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  * **Name** *(string)* –
    
    The name of the filter. Filter names are case-sensitive.

  * **Values** *(list)* –
    
    One or more filter values. Filter values are case-sensitive.

    - *(string)* –

Returns

**Response Syntax**

```json
{
    'InternetGateways': [
        {
            'InternetGatewayId': 'string',
            'Attachments': [
                {
                    'VpcId': 'string',
                    'State': 'attaching'|'attached'|'detaching'|'detached'
                }
            ],
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                }
            ]
        }
    ]
}
```

3.1. Services 1253
Response Structure

- (dict) –
  - InternetGateways (list) –
    Information about one or more Internet gateways.
    - (dict) –
      Describes an Internet gateway.
      - InternetGatewayId (string) –
        The ID of the Internet gateway.
      - Attachments (list) –
        Any VPCs attached to the Internet gateway.
      - (dict) –
        Describes the attachment of a VPC to an Internet gateway.
        - VpcId (string) –
          The ID of the VPC.
        - State (string) –
          The current state of the attachment.
      - Tags (list) –
        Any tags assigned to the Internet gateway.
      - (dict) –
        Describes a tag.
        - Key (string) –
          The key of the tag.
        - Value (string) –
          The value of the tag.

Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws`.

Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

describe_key_pairs(**kwargs)

Describes one or more of your key pairs.

For more information about key pairs, see Key Pairs in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = client.describe_key_pairs(
    DryRun=True|False,
    KeyNames=[
        'string',
    ],
    Filters=[
        'Value': 'string'
    ],
)
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **KeyNames** *(list)* – One or more key pair names.
  Default: Describes all your key pairs.
  - *(string)*

- **Filters** *(list)* – One or more filters.
  - **fingerprint** - The fingerprint of the key pair.
  - **key-name** - The name of the key pair.
  - *(dict)*

  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  - **Name** *(string)* – The name of the filter. Filter names are case-sensitive.
  - **Values** *(list)* – One or more filter values. Filter values are case-sensitive.
    - *(string)*

**Return type** *dict*

**Returns**

**Response Syntax**

```
{
    'KeyPairs': [
        {
            'KeyName': 'string',
            'KeyFingerprint': 'string'
        },
    ]
}
```

**Response Structure**

- *(dict)*
  - **KeyPairs** *(list)*
    Information about one or more key pairs.
    - *(dict)*
      Describes a key pair.
      - **KeyName** *(string)* – The name of the key pair.
KeyFingerprint (string) –

If you used CreateKeyPair to create the key pair, this is the SHA-1 digest of the DER encoded private key. If you used ImportKeyPair to provide AWS the public key, this is the MD5 public key fingerprint as specified in section 4 of RFC4716.

describe_moving_addresses(**kwargs)

Describes your Elastic IP addresses that are being moved to the EC2-VPC platform, or that are being restored to the EC2-Classic platform. This request does not return information about any other Elastic IP addresses in your account.

Request Syntax

response = client.describe_moving_addresses(
    DryRun=True|False,
    PublicIps=['string'],
    NextToken='string',
    Filters=[
        {'Name': 'string',
         'Values': ['string'],
        },
    ],
    MaxResults=123
)

Parameters

* **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

* **PublicIps** (list) – One or more Elastic IP addresses.
  – (string) –

* **NextToken** (string) – The token to use to retrieve the next page of results.

* **Filters** (list) – One or more filters.
  – moving-status - The status of the Elastic IP address (MovingToVpc | RestoringToClassic).
  – (dict) –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  * **Name** (string) –

    The name of the filter. Filter names are case-sensitive.

  * **Values** (list) –

    One or more filter values. Filter values are case-sensitive.

  – (string) –

* **MaxResults** (integer) – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned NextToken value. This value can be
between 5 and 1000; if MaxResults is given a value outside of this range, an error is returned.

Default: If no value is provided, the default is 1000.

Returns:
- **Return type**: dict
- **Response Syntax**

```py
{
   'MovingAddressStatuses': [
       {
           'PublicIp': 'string',
           'MoveStatus': 'movingToVpc'|'restoringToClassic'
       },
   ],
   'NextToken': 'string'
}
```

**Response Structure**
- **(dict)**
  - **MovingAddressStatuses** (list)
    - The status for each Elastic IP address.
      - **(dict)**
        - **PublicIp** (string)
          - The Elastic IP address.
        - **MoveStatus** (string)
          - The status of the Elastic IP address that’s being moved to the EC2-VPC platform, or restored to the EC2-Classic platform.
  - **NextToken** (string)
    - The token to use to retrieve the next page of results. This value is null when there are no more results to return.

**describe_network_acls(**kwargs)**
Describes one or more of your network ACLs.

For more information about network ACLs, see Network ACLs in the Amazon Virtual Private Cloud User Guide.

**Request Syntax**

```py
response = client.describe_network_acls(
   DryRun=True|False,
   NetworkAclIds=[
       'string',
   ],
   Filters=[
       {
           'Name': 'string',
           'Values': [ 'string',
       ]
   ]
)
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **NetworkAclIds** *(list)* – One or more network ACL IDs.

  Default: Describes all your network ACLs.

  - *(string)* –

- **Filters** *(list)* – One or more filters.

  - `association.association-id` - The ID of an association ID for the ACL.
  - `association.network-acl-id` - The ID of the network ACL involved in the association.
  - `association.subnet-id` - The ID of the subnet involved in the association.
  - `default` - Indicates whether the ACL is the default network ACL for the VPC.
  - `entry.cidr` - The CIDR range specified in the entry.
  - `entry.egress` - Indicates whether the entry applies to egress traffic.
  - `entry.icmp.code` - The ICMP code specified in the entry, if any.
  - `entry.icmp.type` - The ICMP type specified in the entry, if any.
  - `entry.port-range.from` - The start of the port range specified in the entry.
  - `entry.port-range.to` - The end of the port range specified in the entry.
  - `entry.protocol` - The protocol specified in the entry (tcp | udp | icmp or a protocol number).
  - `entry.rule-action` - Allows or denies the matching traffic (allow | deny).
  - `entry.rule-number` - The number of an entry (in other words, rule) in the ACL’s set of entries.
  - `network-acl-id` - The ID of the network ACL.
  - `tag :key =*value*` - The key/value combination of a tag assigned to the resource.
  - `tag-key` - The key of a tag assigned to the resource. This filter is independent of the **tag-value** filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the **tag :key =*value* filter.
  - `tag-value` - The value of a tag assigned to the resource. This filter is independent of the **tag-key** filter.
  - `vpc-id` - The ID of the VPC for the network ACL.

- *(dict)* –

  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  * **Name** *(string)* –

    The name of the filter. Filter names are case-sensitive.

  * **Values** *(list)* –
One or more filter values. Filter values are case-sensitive.

Return type  dict

Returns

Response Syntax

```python
{
    'NetworkAcls': [
        {
            'NetworkAclId': 'string',
            'VpcId': 'string',
            'IsDefault': True|False,
            'Entries': [
                {
                    'RuleNumber': 123,
                    'Protocol': 'string',
                    'RuleAction': 'allow'|'deny',
                    'Egress': True|False,
                    'CidrBlock': 'string',
                    'IcmpTypeCode': {
                        'Type': 123,
                        'Code': 123
                    },
                    'PortRange': {
                        'From': 123,
                        'To': 123
                    }
                }
            ],
            'Associations': [
                {
                    'NetworkAclAssociationId': 'string',
                    'NetworkAclId': 'string',
                    'SubnetId': 'string'
                }
            ],
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                }
            ]
        }
    ],
    'NetworkAcls': [
        {
            'NetworkAclId': 'string',
            'VpcId': 'string',
            'IsDefault': True|False,
            'Entries': [
                {
                    'RuleNumber': 123,
                    'Protocol': 'string',
                    'RuleAction': 'allow'|'deny',
                    'Egress': True|False,
                    'CidrBlock': 'string',
                    'IcmpTypeCode': {
                        'Type': 123,
                        'Code': 123
                    },
                    'PortRange': {
                        'From': 123,
                        'To': 123
                    }
                }
            ],
            'Associations': [
                {
                    'NetworkAclAssociationId': 'string',
                    'NetworkAclId': 'string',
                    'SubnetId': 'string'
                }
            ],
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                }
            ]
        }
    ]
}
```

Response Structure

* (dict) –
  * NetworkAcls (list) –
    Information about one or more network ACLs.
  * (dict) –
    Describes a network ACL.
    * NetworkAclId (string) –
      The ID of the network ACL.
    * VpcId (string) –
The ID of the VPC for the network ACL.

- **IsDefault** *(boolean)* –
  Indicates whether this is the default network ACL for the VPC.

- **Entries** *(list)* –
  One or more entries (rules) in the network ACL.

  - *(dict)* –
    Describes an entry in a network ACL.

    - **RuleNumber** *(integer)* –
      The rule number for the entry. ACL entries are processed in ascending order by rule number.

    - **Protocol** *(string)* –
      The protocol. A value of -1 means all protocols.

    - **RuleAction** *(string)* –
      Indicates whether to allow or deny the traffic that matches the rule.

    - **Egress** *(boolean)* –
      Indicates whether the rule is an egress rule (applied to traffic leaving the subnet).

    - **CidrBlock** *(string)* –
      The network range to allow or deny, in CIDR notation.

    - **IcmpTypeCode** *(dict)* –
      ICMP protocol: The ICMP type and code.

      - **Type** *(integer)* –
        The ICMP code. A value of -1 means all codes for the specified ICMP type.

      - **Code** *(integer)* –
        The ICMP type. A value of -1 means all types.

    - **PortRange** *(dict)* –
      TCP or UDP protocols: The range of ports the rule applies to.

      - **From** *(integer)* –
        The first port in the range.

      - **To** *(integer)* –
        The last port in the range.

    - **Associations** *(list)* –
      Any associations between the network ACL and one or more subnets

      - *(dict)* –
        Describes an association between a network ACL and a subnet.

      - **NetworkAclAssociationId** *(string)* –
        The ID of the association between a network ACL and a subnet.

      - **NetworkAclId** *(string)* –
        The ID of the network ACL.
- SubnetId (string)
  The ID of the subnet.
- Tags (list)
  Any tags assigned to the network ACL.
  (dict)
  Describes a tag.
- Key (string)
  The key of the tag.

Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with aws:
- Value (string)
  The value of the tag.

Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

**describe_network_interface_attribute(****kwargs**

Describes a network interface attribute. You can specify only one attribute at a time.

**Request Syntax**

```python
response = client.describe_network_interface_attribute(
    DryRun=True|False,
    NetworkInterfaceId='string',
    Attribute='description'|'groupSet'|'sourceDestCheck'|'attachment'
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **NetworkInterfaceId (string)** – [REQUIRED]
  The ID of the network interface.
- **Attribute (string)** – The attribute of the network interface.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'NetworkInterfaceId': 'string',
    'Description': {
        'Value': 'string'
    },
    'SourceDestCheck': {
        'Value': True|False
    },
    'Groups': [
        {
            'GroupName': 'string',
            'GroupId': 'string'
        },
    ],
}
```
'Attachment': {
    'AttachmentId': 'string',
    'InstanceId': 'string',
    'InstanceOwnerId': 'string',
    'DeviceIndex': 123,
    'Status': 'attaching'|'attached'|'detaching'|'detached',
    'AttachTime': datetime(2015, 1, 1),
    'DeleteOnTermination': True|False
}

Response Structure
• (dict) –
  – NetworkInterfaceId (string) –
    The ID of the network interface.
  – Description (dict) –
    The description of the network interface.
    * Value (string) –
      Valid values are case-sensitive and vary by action.
  – SourceDestCheck (dict) –
    Indicates whether source/destination checking is enabled.
    * Value (boolean) –
      Valid values are true or false.
  – Groups (list) –
    The security groups associated with the network interface.
    * (dict) –
      Describes a security group.
      · GroupName (string) –
        The name of the security group.
      · GroupId (string) –
        The ID of the security group.
  – Attachment (dict) –
    The attachment (if any) of the network interface.
    * AttachmentId (string) –
      The ID of the network interface attachment.
    * InstanceId (string) –
      The ID of the instance.
    * InstanceOwnerId (string) –
      The AWS account ID of the owner of the instance.
    * DeviceIndex (integer) –
      The device index of the network interface attachment on the in-
      stance.
    * Status (string) –
      The attachment state.
    * AttachTime (datetime) –
      The timestamp indicating when the attachment initiated.
DeleteOnTermination (boolean) –
Indicates whether the network interface is deleted when the instance is terminated.

describe_network_interfaces(**kwargs)
Describes one or more of your network interfaces.

Request Syntax

```python
response = client.describe_network_interfaces(
    DryRun=True|False,
    NetworkInterfaceIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ]
        },
    ]
)
```

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **NetworkInterfaceIds** (list) – One or more network interface IDs.
  Default: Describes all your network interfaces.
- **Filters** (list) – One or more filters.
  - addresses.private-ip-address - The private IP addresses associated with the network interface.
  - addresses.primary - Whether the private IP address is the primary IP address associated with the network interface.
  - addresses.association.public-ip - The association ID returned when the network interface was associated with the Elastic IP address.
  - addresses.association.owner-id - The owner ID of the addresses associated with the network interface.
  - association.association-id - The association ID returned when the network interface was associated with an IP address.
  - association.allocation-id - The allocation ID returned when you allocated the Elastic IP address for your network interface.
  - association.ip-owner-id - The owner of the Elastic IP address associated with the network interface.
  - association.public-ip - The address of the Elastic IP address bound to the network interface.
  - association.public-dns-name - The public DNS name for the network interface.
  - attachment.attachment-id - The ID of the interface attachment.
  - attachment.instance-id - The ID of the instance to which the network interface is attached.
- attachment.instance-owner-id - The owner ID of the instance to which the network interface is attached.
- attachment.device-index - The device index to which the network interface is attached.
- attachment.status - The status of the attachment (attaching | attached | detaching | detached).
- attachment.attach.time - The time that the network interface was attached to an instance.
- attachment.delete-on-termination - Indicates whether the attachment is deleted when an instance is terminated.
- availability-zone - The Availability Zone of the network interface.
- description - The description of the network interface.
- group-id - The ID of a security group associated with the network interface.
- group-name - The name of a security group associated with the network interface.
- mac-address - The MAC address of the network interface.
- network-interface-id - The ID of the network interface.
- owner-id - The AWS account ID of the network interface owner.
- private-ip-address - The private IP address or addresses of the network interface.
- private-dns-name - The private DNS name of the network interface.
- requester-id - The ID of the entity that launched the instance on your behalf (for example, AWS Management Console, Auto Scaling, and so on).
- requester-managed - Indicates whether the network interface is being managed by an AWS service (for example, AWS Management Console, Auto Scaling, and so on).
- source-desk-check - Indicates whether the network interface performs source/destination checking. A value of true means checking is enabled, and false means checking is disabled. The value must be false for the network interface to perform Network Address Translation (NAT) in your VPC.
- status - The status of the network interface. If the network interface is not attached to an instance, the status is available; if a network interface is attached to an instance the status is in-use.
- subnet-id - The ID of the subnet for the network interface.
- tag :key=*value* - The key/value combination of a tag assigned to the resource.
- tag-key - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter "tag-key=Purpose" and the filter "tag-value=X", you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key=*value* filter.
- tag-value - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- vpc-id - The ID of the VPC for the network interface.

(dict) –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* Name (string) –
The name of the filter. Filter names are case-sensitive.

* Values (list) –

One or more filter values. Filter values are case-sensitive.

Returns

- `dict`

Response Syntax

```
{
    'NetworkInterfaces': [
        {
            'NetworkInterfaceId': 'string',
            'SubnetId': 'string',
            'VpcId': 'string',
            'AvailabilityZone': 'string',
            'Description': 'string',
            'OwnerId': 'string',
            'RequesterId': 'string',
            'RequesterManaged': True|False,
            'Status': 'available'|'attaching'|'in-use'|'detaching',
            'MacAddress': 'string',
            'PrivateIpAddress': 'string',
            'PrivateDnsName': 'string',
            'SourceDestCheck': True|False,
            'Groups': [
                {
                    'GroupName': 'string',
                    'GroupId': 'string'
                }
            ],
            'Attachment': {
                'AttachmentId': 'string',
                'InstanceId': 'string',
                'InstanceOwnerId': 'string',
                'DeviceIndex': 123,
                'Status': 'attaching'|'attached'|'detaching'|'detached',
                'AttachTime': datetime(2015, 1, 1),
                'DeleteOnTermination': True|False
            },
            'Association': {
                'PublicIp': 'string',
                'PublicDnsName': 'string',
                'IpOwnerId': 'string',
                'AllocationId': 'string',
                'AssociationId': 'string'
            },
            'TagSet': [
                {
                    'Key': 'string',
                    'Value': 'string'
                }
            ],
            'PrivateIpAddresses': [
                {
                    'PrivateIpAddress': 'string',
                    'PrivateDnsName': 'string',
                    'Primary': True|False,
                }
            ]
        }
    ]
}```
Response Structure

- (dict) –
  - NetworkInterfaces (list) –
    Information about one or more network interfaces.
    - (dict) –
      Describes a network interface.
      - NetworkInterfaceId (string) –
        The ID of the network interface.
      - SubnetId (string) –
        The ID of the subnet.
      - VpcId (string) –
        The ID of the VPC.
      - AvailabilityZone (string) –
        The Availability Zone.
      - Description (string) –
        A description.
      - OwnerId (string) –
        The AWS account ID of the owner of the network interface.
      - RequesterId (string) –
        The ID of the entity that launched the instance on your behalf (for example, AWS Management Console or Auto Scaling).
      - RequesterManaged (boolean) –
        Indicates whether the network interface is being managed by AWS.
      - Status (string) –
        The status of the network interface.
      - MacAddress (string) –
        The MAC address.
      - PrivateIpAddress (string) –
        The IP address of the network interface within the subnet.
      - PrivateDnsName (string) –
        The private DNS name.
      - SourceDestCheck (boolean) –
        Indicates whether traffic to or from the instance is validated.
- **Groups** *(list)* –
  Any security groups for the network interface.
- **(dict)** –
  Describes a security group.
- **GroupName** *(string)* –
  The name of the security group.
- **GroupId** *(string)* –
  The ID of the security group.
- **Attachment** *(dict)* –
  The network interface attachment.
- **AttachmentId** *(string)* –
  The ID of the network interface attachment.
- **InstanceId** *(string)* –
  The ID of the instance.
- **InstanceOwnerId** *(string)* –
  The AWS account ID of the owner of the instance.
- **DeviceIndex** *(integer)* –
  The device index of the network interface attachment on the instance.
- **Status** *(string)* –
  The attachment state.
- **AttachTime** *(datetime)* –
  The timestamp indicating when the attachment initiated.
- **DeleteOnTermination** *(boolean)* –
  Indicates whether the network interface is deleted when the instance is terminated.
- **Association** *(dict)* –
  The association information for an Elastic IP associated with the network interface.
- **PublicIp** *(string)* –
  The address of the Elastic IP address bound to the network interface.
- **PublicDnsName** *(string)* –
  The public DNS name.
- **IpOwnerId** *(string)* –
  The ID of the Elastic IP address owner.
- **AllocationId** *(string)* –
  The allocation ID.
- **AssociationId** *(string)* –
  The association ID.
- **TagSet** *(list)* –
  Any tags assigned to the network interface.
- **(dict)** –
  Describes a tag.
Key (string) –
The key of the tag.

Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with aws:

Value (string) –
The value of the tag.

Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

PrivateIpAddresses (list) –
The private IP addresses associated with the network interface.

• (dict) –
  Describes the private IP address of a network interface.
  • PrivateIpAddress (string) –
    The private IP address.
  • PrivateDnsName (string) –
    The private DNS name.
  • Primary (boolean) –
    Indicates whether this IP address is the primary private IP address of the network interface.
  • Association (dict) –
    The association information for an Elastic IP address associated with the network interface.
  • PublicIp (string) –
    The address of the Elastic IP address bound to the network interface.
  • PublicDnsName (string) –
    The public DNS name.
  • IpOwnerId (string) –
    The ID of the Elastic IP address owner.
  • AllocationId (string) –
    The allocation ID.
  • AssociationId (string) –
    The association ID.

describe_placement_groups (**kwargs)
Describes one or more of your placement groups. For more information about placement groups and cluster instances, see Cluster Instances in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

response = client.describe_placement_groups(
    DryRun=True|False,
    GroupNames=[
        'string',
    ],
    Filters=[
    ]
)
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **GroupNames** *(list)* – One or more placement group names.
  
  Default: Describes all your placement groups, or only those otherwise specified.
  
  - *(string)* –

- **Filters** *(list)* – One or more filters.
  
  - **group-name** *(string)* – The name of the placement group.
  
  - **state** *(string)* – The state of the placement group (`pending`|`available`|`deleting`|`deleted`).
  
  - **strategy** *(string)* – The strategy of the placement group (`cluster`).

  - *(dict)* –

  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  * **Name** *(string)* –

    The name of the filter. Filter names are case-sensitive.

  * **Values** *(list)* –

    One or more filter values. Filter values are case-sensitive.

      - *(string)* –

Return type  *dict*

Returns

Response Syntax

```
{
    'PlacementGroups': [
        {
            'GroupName': 'string',
            'Strategy': 'cluster',
            'State': 'pending'|'available'|'deleting'|'deleted'
        },
        ...
    ]
}
```

Response Structure

- *(dict)* –

  - **PlacementGroups** *(list)* –

    One or more placement groups.

      - *(dict)* –

        Describes a placement group.
· **GroupName** *(string)* –
  The name of the placement group.
· **Strategy** *(string)* –
  The placement strategy.
· **State** *(string)* –
  The state of the placement group.

describe_prefix_lists(**kwargs)**

Describes available AWS services in a prefix list format, which includes the prefix list name and prefix list ID of the service and the IP address range for the service. A prefix list ID is required for creating an outbound security group rule that allows traffic from a VPC to access an AWS service through a VPC endpoint.

**Request Syntax**

```python
response = client.describe_prefix_lists(
    DryRun=True|False,
    PrefixListIds=['string'],
    Filters=[
        {'Name': 'string',
         'Values': ['string'],
        },
    ],
    MaxResults=123,
    NextToken='string'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.
- **PrefixListIds** *(list)* – One or more prefix list IDs.
  - *(string)* –
- **Filters** *(list)* – One or more filters.
  - **prefix-list-id**: The ID of a prefix list.
  - **prefix-list-name**: The name of a prefix list.
  - *(dict)* –
    A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
    - **Name** *(string)* –
      The name of the filter. Filter names are case-sensitive.
    - **Values** *(list)* –
      One or more filter values. Filter values are case-sensitive.
• **MaxResults** *(integer)* – The maximum number of items to return for this request. The request returns a token that you can specify in a subsequent call to get the next set of results.

  Constraint: If the value specified is greater than 1000, we return only 1000 items.

• **NextToken** *(string)* – The token for the next set of items to return. (You received this token from a prior call.)

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'PrefixLists': [
        {
            'PrefixListId': 'string',
            'PrefixListName': 'string',
            'Cidrs': [
                'string',
            ],
        },
    ],
    'NextToken': 'string'
}
```

**Response Structure**

• *(dict)* –
  - **PrefixLists** *(list)* –
    All available prefix lists.
    * *(dict)* –
      Describes prefixes for AWS services.
      - **PrefixListId** *(string)* –
        The ID of the prefix.
      - **PrefixListName** *(string)* –
        The name of the prefix.
      - **Cidrs** *(list)* –
        The IP address range of the AWS service.
      - *(string)* –
    - **NextToken** *(string)* –
      The token to use when requesting the next set of items. If there are no additional items to return, the string is empty.

**describe_regions(****kwargs**)**

Describes one or more regions that are currently available to you.

For a list of the regions supported by Amazon EC2, see Regions and Endpoints.

**Request Syntax**

```python
response = client.describe_regions(
    DryRun=True|False,
    RegionNames=[
        'string',
    ],
    Filters=[
```
Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **RegionNames** (list) – The names of one or more regions.
  - (string)

- **Filters** (list) – One or more filters.
  - endpoint - The endpoint of the region (for example, `ec2.us-east-1.amazonaws.com`).
  - region-name - The name of the region (for example, `us-east-1`).
  - (dict)

  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  - **Name** (string) –
    The name of the filter. Filter names are case-sensitive.

  - **Values** (list) –
    One or more filter values. Filter values are case-sensitive.

Return type dict

Returns

Response Syntax

```json
{
    'Regions': [
        {
            'RegionName': 'string',
            'Endpoint': 'string'
        },
    ]
}
```

Response Structure

- (dict) –
  - **Regions** (list) –
    Information about one or more regions.
    - (dict) –
      Describes a region.
      - **RegionName** (string) –
        The name of the region.
**Endpoint** *(string)* —  
The region service endpoint.

**describe_reserved_instances** (**kwargs**)
Describes one or more of the Reserved Instances that you purchased.

For more information about Reserved Instances, see Reserved Instances in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = client.describe_reserved_instances(
    DryRun=True|False,
    ReservedInstancesIds=[
        'string',
    ],
    Filters=[
        {'Name': 'string',
         'Values': [
             'string',
         ]}
    ],
    OfferingType='Heavy Utilization'|'Medium Utilization'|'Light Utilization'|'No Upfront'|'Partial Upfront'|'All Upfront'
)
```

**Parameters**

- **DryRun** *(boolean)* — Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **ReservedInstancesIds** *(list)* — One or more Reserved Instance IDs.
  
  Default: Describes all your Reserved Instances, or only those otherwise specified.

  - *(string)*

- **Filters** *(list)* — One or more filters.
  
  - **availability-zone** - The Availability Zone where the Reserved Instance can be used.
  
  - **duration** - The duration of the Reserved Instance (one year or three years), in seconds (31536000|94608000).
  
  - **end** - The time when the Reserved Instance expires (for example, 2015-08-07T11:54:42.00Z).
  
  - **fixed-price** - The purchase price of the Reserved Instance (for example, 9800.0).
  
  - **instance-type** - The instance type on which the Reserved Instance can be used.
  
  - **product-description** - The Reserved Instance product platform description. Instances that include (Amazon VPC) in the product platform description will only be displayed to EC2-Classic account holders and are for use with Amazon VPC. (Linux/UNIX | Linux/UNIX (Amazon VPC) | SUSE Linux | SUSE Linux (Amazon VPC) | Red Hat Enterprise Linux | Red Hat Enterprise Linux (Amazon VPC) | Windows | Windows (Amazon VPC) | Windows with SQL Server Standard | Windows with SQL Server Standard (Amazon VPC) | Windows with SQL Server Standard (Amazon VPC))
Web | Windows with SQL Server Web (Amazon VPC) |
Windows with SQL Server Enterprise | Windows with SQL Server Enterprise (Amazon VPC).

- `reserved-instances-id` - The ID of the Reserved Instance.
- `start` - The time at which the Reserved Instance purchase request was placed (for example, 2014-08-07T11:54:42.000Z).
- `state` - The state of the Reserved Instance (payment-pending | active | payment-failed | retired).
- `tag: key=value` - The key/value combination of a tag assigned to the resource.
- `tag: key` - The key of a tag assigned to the resource. This filter is independent of the `tag: value` filter. For example, if you use both the filter "tag: key=Purpose" and the filter "tag: value=X", you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag: key=value` filter.
- `tag: value` - The value of a tag assigned to the resource. This filter is independent of the `tag: key` filter.
- `usage-price` - The usage price of the Reserved Instance, per hour (for example, 0.84).

- `(dict)` –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

- **Name** *(string)* –
  The name of the filter. Filter names are case-sensitive.
- **Values** *(list)* –
  One or more filter values. Filter values are case-sensitive.
- **OfferingType** *(string)* – The Reserved Instance offering type. If you are using tools that predate the 2011-11-01 API version, you only have access to the Medium Utilization Reserved Instance offering type.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'ReservedInstances': [
        {
            'ReservedInstancesId': 'string',
            'InstanceType': 't1.micro'|'ml.small'|'ml.medium'|'ml.large'|'ml.xlarge',
            'AvailabilityZone': 'string',
            'Start': datetime(2015, 1, 1),
            'End': datetime(2015, 1, 1),
            'Duration': 123,
            'UsagePrice': ...,
            'FixedPrice': ...,
            'InstanceCount': 123,
            'ProductDescription': 'Linux/UNIX'|'Linux/UNIX (Amazon VPC)'|'Windows'
            'State': 'payment-pending'|'active'|'payment-failed'|'retired',
            'Tags': [
                {
                ...
```
'Key': 'string',
  'Value': 'string'
},
'
',
'InstanceTenancy': 'default'|'dedicated',
'CurrencyCode': 'USD',

'RecurringCharges': [ 
    { 
      'Frequency': 'Hourly',
      'Amount': 123.0
    },
  ],
}
]
}
}

Response Structure

• (dict) –
  – ReservedInstances (list) –
    A list of Reserved Instances.
      • (dict) –
        Describes a Reserved Instance.
          • ReservedInstancesId (string) –
            The ID of the Reserved Instance.
          • InstanceType (string) –
            The instance type on which the Reserved Instance can be used.
          • AvailabilityZone (string) –
            The Availability Zone in which the Reserved Instance can be used.
          • Start (datetime) –
            The date and time the Reserved Instance started.
          • End (datetime) –
            The time when the Reserved Instance expires.
          • Duration (integer) –
            The duration of the Reserved Instance, in seconds.
          • UsagePrice (float) –
            The usage price of the Reserved Instance, per hour.
          • FixedPrice (float) –
            The purchase price of the Reserved Instance.
          • InstanceCount (integer) –
            The number of Reserved Instances purchased.
          • ProductDescription (string) –
            The Reserved Instance product platform description.
          • State (string) –
            The state of the Reserved Instance purchase.
          • Tags (list) –
Any tags assigned to the resource.

- **(dict)** –
  Describes a tag.
  - **Key (string)** –
    The key of the tag.
    Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws`.
  - **Value (string)** –
    The value of the tag.
    Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

- **InstanceTenancy (string)** –
  The tenancy of the reserved instance.

- **CurrencyCode (string)** –
  The currency of the Reserved Instance. It's specified using ISO 4217 standard currency codes. At this time, the only supported currency is USD.

- **OfferingType (string)** –
  The Reserved Instance offering type.

- **RecurringCharges (list)** –
  The recurring charge tag assigned to the resource.
  - **(dict)** –
    Describes a recurring charge.
    - **Frequency (string)** –
      The frequency of the recurring charge.
    - **Amount (float)** –
      The amount of the recurring charge.

**describe_reserved_instances_listings(**kwargs)**

Describes your account’s Reserved Instance listings in the Reserved Instance Marketplace.

The Reserved Instance Marketplace matches sellers who want to resell Reserved Instance capacity that they no longer need with buyers who want to purchase additional capacity. Reserved Instances bought and sold through the Reserved Instance Marketplace work like any other Reserved Instances.

As a seller, you choose to list some or all of your Reserved Instances, and you specify the upfront price to receive for them. Your Reserved Instances are then listed in the Reserved Instance Marketplace and are available for purchase.

As a buyer, you specify the configuration of the Reserved Instance to purchase, and the Marketplace matches what you’re searching for with what’s available. The Marketplace first sells the lowest priced Reserved Instances to you, and continues to sell available Reserved Instance listings to you until your demand is met. You are charged based on the total price of all of the listings that you purchase.

For more information, see Reserved Instance Marketplace in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**
response = client.describe_reserved_instances_listings(
    ReservedInstancesId='string',
    ReservedInstancesListingId='string',
    Filters=[
        {
            'Name': 'string',
            'Values': [ 'string',
            ]
        },
    ]
)

Parameters

- **ReservedInstancesId** *(string)* – One or more Reserved Instance IDs.
- **ReservedInstancesListingId** *(string)* – One or more Reserved Instance Listing IDs.
- **Filters** *(list)* – One or more filters.
  - reserved-instances-id - The ID of the Reserved Instances.
  - reserved-instances-listing-id - The ID of the Reserved Instances listing.
  - status - The status of the Reserved Instance listing (pending | active|cancelled|closed).
  - status-message - The reason for the status.
- *(dict)* –
  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  * **Name** *(string)* –
    The name of the filter. Filter names are case-sensitive.
  * **Values** *(list)* –
    One or more filter values. Filter values are case-sensitive.
- *(string)* –

Return type **dict**

Returns

**Response Syntax**

```python
{
    'ReservedInstancesListings': [
        {
            'ReservedInstancesListingId': 'string',
            'ReservedInstancesId': 'string',
            'CreateDate': datetime(2015, 1, 1),
            'UpdateDate': datetime(2015, 1, 1),
            'Status': 'active'|'pending'|'cancelled'|'closed',
            'StatusMessage': 'string',
            'InstanceCounts': [
                {
                    'State': 'available'|'sold'|'cancelled'|'pending',
                    'InstanceCount': 123
                }
            ],
            'PriceSchedules': [
        }
    ]
}
```
Response Structure

* (dict) –

- **ReservedInstancesListings (list)** –

  Information about the Reserved Instance listing.

  * (dict) –

  Describes a Reserved Instance listing.

  - **ReservedInstancesListingId (string)** –

    The ID of the Reserved Instance listing.

  - **ReservedInstancesId (string)** –

    The ID of the Reserved Instance.

  - **CreateDate (datetime)** –

    The time the listing was created.

  - **UpdateDate (datetime)** –

    The last modified timestamp of the listing.

  - **Status (string)** –

    The status of the Reserved Instance listing.

  - **StatusMessage (string)** –

    The reason for the current status of the Reserved Instance listing. The response can be blank.

  - **InstanceCounts (list)** –

    The number of instances in this state.

    * (dict) –

    Describes a Reserved Instance listing state.

    - **State (string)** –

      The states of the listed Reserved Instances.

    - **InstanceCount (integer)** –

      The number of listed Reserved Instances in the state specified by the **state**.

    - **PriceSchedules (list)** –

      The price of the Reserved Instance listing.
(dict) –
Describes the price for a Reserved Instance.

Term (integer) –
The number of months remaining in the reservation. For example, 2 is the second to the last month before the capacity reservation expires.

Price (float) –
The fixed price for the term.

CurrencyCode (string) –
The currency for transacting the Reserved Instance resale. At this time, the only supported currency is USD.

Active (boolean) –
The current price schedule, as determined by the term remaining for the Reserved Instance in the listing.

A specific price schedule is always in effect, but only one price schedule can be active at any time. Take, for example, a Reserved Instance listing that has five months remaining in its term. When you specify price schedules for five months and two months, this means that schedule 1, covering the first three months of the remaining term, will be active during months 5, 4, and 3. Then schedule 2, covering the last two months of the term, will be active for months 2 and 1.

Tags (list) –
Any tags assigned to the resource.

(dict) –
Describes a tag.

Key (string) –
The key of the tag.

Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with aws:

Value (string) –
The value of the tag.

Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

ClientToken (string) –
A unique, case-sensitive key supplied by the client to ensure that the request is idempotent. For more information, see Ensuring Idempotency.

**describe_reserved_instances_modifications (**kwargs)
Describes the modifications made to your Reserved Instances. If no parameter is specified, information about all your Reserved Instances modification requests is returned. If a modification ID is specified, only information about the specific modification is returned.

For more information, see Modifying Reserved Instances in the Amazon Elastic Compute Cloud User Guide.

Request Syntax
response = client.describe_reserved_instances_modifications(
    ReservedInstancesModificationIds=[
        'string',
    ],
    NextToken='string',
    Filters=[
        {'Name': 'string',
         'Values': [
             'string',
         ]},
    ],
)

Parameters

- **ReservedInstancesModificationIds (list)** – IDs for the submitted modification request.
  - *(string)* –
- **NextToken (string)** – The token to retrieve the next page of results.
- **Filters (list)** – One or more filters.
  - client-token - The idempotency token for the modification request.
  - create-date - The time when the modification request was created.
  - effective-date - The time when the modification becomes effective.
  - modification-result.reserved-instances-id - The ID for the Reserved Instances created as part of the modification request. This ID is only available when the status of the modification is fulfilled.
  - modification-result.target-configuration.availability-zone - The Availability Zone for the new Reserved Instances.
  - modification-result.target-configuration.instance-count - The number of new Reserved Instances.
  - modification-result.target-configuration.instance-type - The instance type of the new Reserved Instances.
  - modification-result.target-configuration.platform - The network platform of the new Reserved Instances (EC2-Classic | EC2-VPC).
  - reserved-instances-id - The ID of the Reserved Instances modified.
  - reserved-instances-modification-id - The ID of the modification request.
  - status - The status of the Reserved Instances modification request (processing|fulfilled|failed).
  - status-message - The reason for the status.
  - update-date - The time when the modification request was last updated.
  - *(dict)* –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

- **Name (string)** –
  - The name of the filter. Filter names are case-sensitive.
- **Values (list)** –
One or more filter values. Filter values are case-sensitive.

Return type:  
- `dict`

Returns:

**Response Syntax**

```plaintext
{
    'ReservedInstancesModifications': [
        {
            'ReservedInstancesModificationId': 'string',
            'ReservedInstancesIds': [{
                'ReservedInstancesId': 'string'
            }],
        },
        'ModificationResults': [
            {
                'ReservedInstancesId': 'string',
                'TargetConfiguration': {
                    'AvailabilityZone': 'string',
                    'Platform': 'string',
                    'InstanceCount': 123,
                    'InstanceType': 't1.micro'|'ml.small'|'ml.medium'|'ml.large'|...
                }
            }
        ],
        'CreateDate': datetime(2015, 1, 1),
        'UpdateDate': datetime(2015, 1, 1),
        'EffectiveDate': datetime(2015, 1, 1),
        'Status': 'string',
        'StatusMessage': 'string',
        'ClientToken': 'string'
    },
    'NextToken': 'string'
}
```

**Response Structure**

- `(dict)` –
  - `ReservedInstancesModifications (list)` –
    The Reserved Instance modification information.
    - `(dict)` –
      Describes a Reserved Instance modification.
      - `ReservedInstancesModificationId (string)` –
        A unique ID for the Reserved Instance modification.
      - `ReservedInstancesIds (list)` –
        The IDs of one or more Reserved Instances.
      - `(dict)` –
        Describes the ID of a Reserved Instance.
      - `ReservedInstancesId (string)` –
        The ID of the Reserved Instance.
      - `ModificationResults (list)` –
Contains target configurations along with their corresponding new Reserved Instance IDs.

- (dict)
  - **ReservedInstancesId** *(string)*
    The ID for the Reserved Instances that were created as part of the modification request. This field is only available when the modification is fulfilled.
  - **TargetConfiguration** *(dict)*
    The target Reserved Instances configurations supplied as part of the modification request.
  - **AvailabilityZone** *(string)*
    The Availability Zone for the modified Reserved Instances.
  - **Platform** *(string)*
    The network platform of the modified Reserved Instances, which is either EC2-Classic or EC2-VPC.
  - **InstanceCount** *(integer)*
    The number of modified Reserved Instances.
  - **InstanceType** *(string)*
    The instance type for the modified Reserved Instances.
  - **CreateDate** *(datetime)*
    The time when the modification request was created.
  - **UpdateDate** *(datetime)*
    The time when the modification request was last updated.
  - **EffectiveDate** *(datetime)*
    The time for the modification to become effective.
  - **Status** *(string)*
    The status of the Reserved Instances modification request.
  - **StatusMessage** *(string)*
    The reason for the status.
  - **ClientToken** *(string)*
    A unique, case-sensitive key supplied by the client to ensure that the request is idempotent. For more information, see En-\text{suring Idempotency}.
  - **NextToken** *(string)*
    The token to use to retrieve the next page of results. This value is \text{null} when there are no more results to return.

\text{\textbf{describeReservedInstancesOfferings}} (**kwargs)

Describes Reserved Instance offerings that are available for purchase. With Reserved Instances, you purchase the right to launch instances for a period of time. During that time period, you do not receive insufficient capacity errors, and you pay a lower usage rate than the rate charged for On-Demand instances for the actual time used.

For more information, see Reserved Instance Marketplace in the Amazon Elastic Compute Cloud User Guide.

\text{Request Syntax}
response = client.describe_reserved_instances_offerings(
    DryRun=True|False,
    ReservedInstancesOfferingIds=[
        'string',
    ],
    InstanceType='t1.micro'|'m1.small'|'m1.medium'|'m1.large'|'m1.xlarge'|'m3.medium'|'m3.large'|'m3.xlarge'|'m3.2xlarge'|'m4.large'|'m4.xlarge'|'m4.2xlarge'|'m4.4xlarge'|'m4.8xlarge'|'r3.large'|'r3.xlarge'|'r3.2xlarge'|'r3.4xlarge'|'r3.8xlarge'|'d2.xlarge'|'d2.2xlarge'|'d2.4xlarge'|'d2.8xlarge',
    AvailabilityZone='string',
    ProductDescription='Linux/UNIX'|'Linux/UNIX (Amazon VPC)'|'Windows'|'Windows (Amazon VPC)',
    Filters=[
        {
            'Name': 'string',
            'Values': [ 
                'string',
            ],
        },
    ],
    InstanceTenancy='default'|'dedicated',
    OfferingType='Heavy Utilization'|'Medium Utilization'|'Light Utilization'|'No Upfront'|'Partial Upfront'|'All Upfront',
    NextToken='string',
    MaxResults=123,
    IncludeMarketplace=True|False,
    MinDuration=123,
    MaxDuration=123,
    MaxInstanceCount=123
)

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **ReservedInstancesOfferingIds** *(list)* – One or more Reserved Instances offering IDs.
  - *(string)*
- **InstanceType** *(string)* – The instance type on which the Reserved Instance can be used. For more information, see Instance Types in the Amazon Elastic Compute Cloud User Guide.
- **AvailabilityZone** *(string)* – The Availability Zone in which the Reserved Instance can be used.
- **ProductDescription** *(string)* – The Reserved Instance product platform description. Instances that include (Amazon VPC) in the description are for use with Amazon VPC.
- **Filters** *(list)* – One or more filters.
  - availability-zone - The Availability Zone where the Reserved Instance can be used.
  - duration - The duration of the Reserved Instance (for example, one year or three years), in seconds (31536000 | 94608000).
  - fixed-price - The purchase price of the Reserved Instance (for example, 9800.0).
  - instance-type - The instance type on which the Reserved Instance can be used.
  - marketplace - Set to true to show only Reserved Instance Marketplace offerings. When this filter is not used, which is the default behavior, all offerings from AWS and Reserved Instance Marketplace are listed.
  - product-description - The Reserved Instance product platform
description. Instances that include (Amazon VPC) in the product platform description will only be displayed to EC2-Classic account holders and are for use with Amazon VPC. (Linux/UNIX | Linux/UNIX (Amazon VPC) | SUSE Linux | SUSE Linux (Amazon VPC) | Red Hat Enterprise Linux | Red Hat Enterprise Linux (Amazon VPC) | Windows | Windows (Amazon VPC) | Windows with SQL Server Standard | Windows with SQL Server Standard (Amazon VPC) | Windows with SQL Server Web | Windows with SQL Server Web (Amazon VPC) | Windows with SQL Server Enterprise | Windows with SQL Server Enterprise (Amazon VPC) )

- reserved-instances-offering-id - The Reserved Instances offering ID.
- usage-price - The usage price of the Reserved Instance, per hour (for example, 0.84).

- (dict)

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* Name (string) –
  The name of the filter. Filter names are case-sensitive.

* Values (list) –
  One or more filter values. Filter values are case-sensitive.
  
  - (string) –
    
  • InstanceTenancy (string) – The tenancy of the Reserved Instance offering. A Reserved Instance with dedicated tenancy runs on single-tenant hardware and can only be launched within a VPC.

Default: default

• OfferingType (string) – The Reserved Instance offering type. If you are using tools that predate the 2011-11-01 API version, you only have access to the Medium Utilization Reserved Instance offering type.

• NextToken (string) – The token to retrieve the next page of results.

• MaxResults (integer) – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned NextToken value. The maximum is 100.

Default: 100

• IncludeMarketplace (boolean) – Include Marketplace offerings in the response.

• MinDuration (integer) – The minimum duration (in seconds) to filter when searching for offerings.

Default: 2592000 (1 month)

• MaxDuration (integer) – The maximum duration (in seconds) to filter when searching for offerings.

Default: 94608000 (3 years)

• MaxInstanceCount (integer) – The maximum number of instances to filter when searching for offerings.

Default: 20

Return type dict

Returns
Response Syntax

```json

               'Amount': 123.0
            },
            ...
         ],
         'Marketplace': True|False,
         'PricingDetails': [
            {
               'Price': 123.0,
               'Count': 123
            },
            ...
         ],
         'NextToken': 'string'
      }
   ]
}
```

Response Structure

- *(dict)* –
  - **ReservedInstancesOfferings** *(list)* –
    A list of Reserved Instances offerings.
    - *(dict)* –
      Describes a Reserved Instance offering.
      - **ReservedInstancesOfferingId** *(string)* –
        The ID of the Reserved Instance offering.
      - **InstanceType** *(string)* –
        The instance type on which the Reserved Instance can be used.
      - **AvailabilityZone** *(string)* –
        The Availability Zone in which the Reserved Instance can be used.
      - **Duration** *(integer)* –
        The duration of the Reserved Instance, in seconds.
      - **UsagePrice** *(float)* –
        The usage price of the Reserved Instance, per hour.
      - **FixedPrice** *(float)* –
The purchase price of the Reserved Instance.

- **ProductDescription** *(string)* –
  The Reserved Instance product platform description.

- **InstanceTenancy** *(string)* –
  The tenancy of the reserved instance.

- **CurrencyCode** *(string)* –
  The currency of the Reserved Instance offering you are purchasing. It’s specified using ISO 4217 standard currency codes. At this time, the only supported currency is **USD**.

- **OfferingType** *(string)* –
  The Reserved Instance offering type.

- **RecurringCharges** *(list)* –
  The recurring charge tag assigned to the resource.
  · *(dict)* –
    Describes a recurring charge.
  · **Frequency** *(string)* –
    The frequency of the recurring charge.
  · **Amount** *(float)* –
    The amount of the recurring charge.

- **Marketplace** *(boolean)* –
  Indicates whether the offering is available through the Reserved Instance Marketplace (resale) or AWS. If it’s a Reserved Instance Marketplace offering, this is **true**.

- **PricingDetails** *(list)* –
  The pricing details of the Reserved Instance offering.
  · *(dict)* –
    Describes a Reserved Instance offering.
  · **Price** *(float)* –
    The price per instance.
  · **Count** *(integer)* –
    The number of instances available for the price.

- **NextToken** *(string)* –
  The token to use to retrieve the next page of results. This value is **null** when there are no more results to return.

**describe_route_tables** (**kwargs**)

Describes one or more of your route tables.

Each subnet in your VPC must be associated with a route table. If a subnet is not explicitly associated with any route table, it is implicitly associated with the main route table. This command does not return the subnet ID for implicit associations.

For more information about route tables, see Route Tables in the Amazon Virtual Private Cloud User Guide.

**Request Syntax**
response = client.describe_route_tables(
    DryRun=True|False,
    RouteTableIds=[
        'string',
    ],
    Filters=[
        
            'Name': 'string',
            'Values': [ 
                'string',
            ],
    ],
)

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **RouteTableIds** *(list)* – One or more route table IDs.
  
  Default: Describes all your route tables.
  
  - *(string)* –

- **Filters** *(list)* – One or more filters.
  
  - `association.route-table-association-id` - The ID of an association ID for the route table.
  
  - `association.route-table-id` - The ID of the route table involved in the association.
  
  - `association.subnet-id` - The ID of the subnet involved in the association.
  
  - `association.main` - Indicates whether the route table is the main route table for the VPC.
  
  - `route-table-id` - The ID of the route table.
  
  - `route.destination-cidr-block` - The CIDR range specified in a route in the table.
  
  - `route.destination-prefix-list-id` - The ID (prefix) of the AWS service specified in a route in the table.
  
  - `route.gateway-id` - The ID of a gateway specified in a route in the table.
  
  - `route.instance-id` - The ID of an instance specified in a route in the table.
  
  - `route.origin` - Describes how the route was created. `CreateRouteTable` indicates that the route was automatically created when the route table was created; `CreateRoute` indicates that the route was manually added to the route table; `EnableVgwRoutePropagation` indicates that the route was propagated by route propagation.
  
  - `route.state` - The state of a route in the route table (active | blackhole). The blackhole state indicates that the route’s target isn’t available (for example, the specified gateway isn’t attached to the VPC, the specified NAT instance has been terminated, and so on).
  
  - `route.vpc-peering-connection-id` - The ID of a VPC peering connection specified in a route in the table.
  
  - `tag :key ="value"` - The key/value combination of a tag assigned to the
– **tag-key** - The key of a tag assigned to the resource. This filter is independent of the **tag-value** filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the **tag :key =*value* filter.

– **tag-value** - The value of a tag assigned to the resource. This filter is independent of the **tag-key** filter.

– **vpc-id** - The ID of the VPC for the route table.

– (dict) –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* Name *(string)* –

The name of the filter. Filter names are case-sensitive.

* Values *(list)* –

One or more filter values. Filter values are case-sensitive.

* (string)* –

**Return type** dict

**Returns**

**Response Syntax**

```json
{
  'RouteTables': [
    {
      'RouteTableId': 'string',
      'VpcId': 'string',
      'Routes': [
        {
          'DestinationCidrBlock': 'string',
          'DestinationPrefixListId': 'string',
          'GatewayId': 'string',
          'InstanceId': 'string',
          'InstanceOwnerId': 'string',
          'NetworkInterfaceId': 'string',
          'VpcPeeringConnectionId': 'string',
          'State': 'active'|'blackhole',
          'Origin': 'CreateRouteTable'|'CreateRoute'|'EnableVgwRoutePropagation',
        },

        },
      ],
      'Tags': [
        {
          'Key': 'string',
          'Value': 'string'
        }
      ]
    }
  ]
}
```
Response Structure

- (dict) –
  - RouteTables (list) –
    Information about one or more route tables.
    * (dict) –
      Describes a route table.
      - RouteTableId (string) –
        The ID of the route table.
      - VpcId (string) –
        The ID of the VPC.
      - Routes (list) –
        The routes in the route table.
        * (dict) –
          Describes a route in a route table.
          - DestinationCidrBlock (string) –
            The CIDR block used for the destination match.
          - DestinationPrefixListId (string) –
            The prefix of the AWS service.
          - GatewayId (string) –
            The ID of a gateway attached to your VPC.
          - InstanceId (string) –
            The ID of a NAT instance in your VPC.
          - InstanceOwnerId (string) –
            The AWS account ID of the owner of the instance.
          - NetworkInterfaceId (string) –
            The ID of the network interface.
          - VpcPeeringConnectionId (string) –
            The ID of the VPC peering connection.
          - State (string) –
            The state of the route. The `blackhole` state indicates that the route’s target isn’t available (for example, the specified gateway isn’t attached to the VPC, or the specified NAT instance has been terminated).
          - Origin (string) –
            Describes how the route was created.
          - CreateRouteTable indicates that route was automatically created when the route table was created.
· **CreateRoute** indicates that the route was manually added to the route table.
· **EnableVgwRoutePropagation** indicates that the route was propagated by route propagation.

· **Associations** *(list)* –
  The associations between the route table and one or more subnets.
· *(dict)* –
  Describes an association between a route table and a subnet.
· **RouteTableAssociationId** *(string)* –
  The ID of the association between a route table and a subnet.
· **RouteTableId** *(string)* –
  The ID of the route table.
· **SubnetId** *(string)* –
  The ID of the subnet. A subnet ID is not returned for an implicit association.
· **Main** *(boolean)* –
  Indicates whether this is the main route table.
· **Tags** *(list)* –
  Any tags assigned to the route table.
· *(dict)* –
  Describes a tag.
· **Key** *(string)* –
  The key of the tag.
  Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws`:
· **Value** *(string)* –
  The value of the tag.
  Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.
· **PropagatingVgws** *(list)* –
  Any virtual private gateway (VGW) propagating routes.
· *(dict)* –
  Describes a virtual private gateway propagating route.
· **GatewayId** *(string)* –
  The ID of the virtual private gateway (VGW).

**describe_security_groups** (**kwargs**)
Describes one or more of your security groups.

A security group is for use with instances either in the EC2-Classic platform or in a specific VPC. For more information, see Amazon EC2 Security Groups in the *Amazon Elastic Compute Cloud User Guide* and Security Groups for Your VPC in the *Amazon Virtual Private Cloud User Guide*.

**Request Syntax**
response = client.describe_security_groups(
    DryRun=True|False,
    GroupNames=[
        'string',
    ],
    GroupIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ]
        },
    ],
)

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **GroupNames** *(list)* – [EC2-Classic and default VPC only] One or more security group names. You can specify either the security group name or the security group ID. For security groups in a nondefault VPC, use the group-name filter to describe security groups by name.

  Default: Describes all your security groups.
  - *(string)* –

- **GroupIds** *(list)* – One or more security group IDs. Required for security groups in a nondefault VPC.

  Default: Describes all your security groups.
  - *(string)* –

- **Filters** *(list)* – One or more filters. If using multiple filters for rules, the results include security groups for which any combination of rules - not necessarily a single rule - match all filters.

  - description - The description of the security group.
  - egress.ip-permission.prefix-list-id - The ID (prefix) of the AWS service to which the security group allows access.
  - group-id - The ID of the security group.
  - group-name - The name of the security group.
  - ip-permission.cidr - A CIDR range that has been granted permission.
  - ip-permission.from-port - The start of port range for the TCP and UDP protocols, or an ICMP type number.
  - ip-permission.group-id - The ID of a security group that has been granted permission.
  - ip-permission.group-name - The name of a security group that has been granted permission.
  - ip-permission.protocol - The IP protocol for the permission (tcp|udp|icmp or a protocol number).
  - ip-permission.to-port - The end of port range for the TCP and UDP protocols, or an ICMP code.
  - ip-permission.user-id - The ID of an AWS account that has been
granted permission.
- owner-id - The AWS account ID of the owner of the security group.
- tag-key - The key of a tag assigned to the security group.
- tag-value - The value of a tag assigned to the security group.
- vpc-id - The ID of the VPC specified when the security group was created.

- (dict) –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* Name (string) –

The name of the filter. Filter names are case-sensitive.

* Values (list) –

One or more filter values. Filter values are case-sensitive.

  - (string) –

Response Syntax

```
{
  'SecurityGroups': [
  {
    'OwnerId': 'string',
    'GroupName': 'string',
    'GroupId': 'string',
    'Description': 'string',
    'IpPermissions': [
      {
        'IpProtocol': 'string',

        'ToPort': 123,
        'UserIdGroupPairs': [
          {
            'UserId': 'string',
            'GroupName': 'string',
            'GroupId': 'string'
          },
        ],
        'IpRanges': [
          {
            'CidrIp': 'string'
          },
        ],
        'PrefixListIds': [
          {
            'PrefixListId': 'string'
          },
        ],
      }
    ],
    'IpPermissionsEgress': [
      {
        'IpProtocol': 'string',
        'FromPort': 123,
```
{'ToPort': 123,
'UserIdGroupPairs': [
{
  'UserId': 'string',
  'GroupName': 'string',
  'GroupId': 'string'
},
],
'IpRanges': [
{
  'CidrIp': 'string'
},
],
'PrefixListIds': [
{
  'PrefixListId': 'string'
}
],
],
],
'VpcId': 'string',
'Tags': [
{
  'Key': 'string',
  'Value': 'string'
}
],
}

Response Structure

* (dict) –
  – SecurityGroups (list) –

Information about one or more security groups.

* (dict) –

Describes a security group

  - **OwnerId** (string) –

    The AWS account ID of the owner of the security group.

  - **GroupName** (string) –

    The name of the security group.

  - **GroupId** (string) –

    The ID of the security group.

  - **Description** (string) –

    A description of the security group.

  - **IpPermissions** (list) –

    One or more inbound rules associated with the security group.

    * (dict) –

      Describes a security group rule.

      - **IpProtocol** (string) –

        The protocol.
When you call DescribeSecurityGroups, the protocol value returned is the number. Exception: For TCP, UDP, and ICMP, the value returned is the name (for example, tcp, udp, or icmp). For a list of protocol numbers, see Protocol Numbers. (VPC only) When you call AuthorizeSecurityGroupIngress, you can use -1 to specify all.

- **FromPort** (integer)
  The start of port range for the TCP and UDP protocols, or an ICMP type number. A value of -1 indicates all ICMP types.

- **ToPort** (integer)
  The end of port range for the TCP and UDP protocols, or an ICMP code. A value of -1 indicates all ICMP codes for the specified ICMP type.

- **UserIdGroupPairs** (list)
  One or more security group and AWS account ID pairs.

  - (dict)
    Describes a security group and AWS account ID pair.

    - **UserId** (string)
      The ID of an AWS account. EC2-Classic only.

    - **GroupName** (string)
      The name of the security group. In a request, use this parameter for a security group in EC2-Classic or a default VPC only. For a security group in a nondefault VPC, use GroupId.

    - **GroupId** (string)
      The ID of the security group.

    - **IpRanges** (list)
      One or more IP ranges.

      - (dict)
        Describes an IP range.

      - **CidrIp** (string)
        The CIDR range. You can either specify a CIDR range or a source security group, not both.

    - **PrefixListIds** (list)
      (Valid for AuthorizeSecurityGroupEgress, RevokeSecurityGroupEgress and DescribeSecurityGroups only) One or more prefix list IDs for an AWS service. In an AuthorizeSecurityGroupEgress request, this is the AWS service that you want to access through a VPC endpoint from instances associated with the security group.

      - (dict)
        The ID of the prefix.

    - **PrefixListId** (string)
      The ID of the prefix.

- **IpPermissionsEgress** (list)
  [EC2-VPC] One or more outbound rules associated with the security group.
(dict) –
Describes a security group rule.

IpProtocol (string) –
The protocol.

When you call DescribeSecurityGroups, the protocol value returned is the number. Exception: For TCP, UDP, and ICMP, the value returned is the name (for example, tcp, udp, or icmp). For a list of protocol numbers, see Protocol Numbers. (VPC only) When you call AuthorizeSecurityGroupIngress, you can use -1 to specify all.

FromPort (integer) –
The start of port range for the TCP and UDP protocols, or an ICMP type number. A value of -1 indicates all ICMP types.

ToPort (integer) –
The end of port range for the TCP and UDP protocols, or an ICMP code. A value of -1 indicates all ICMP codes for the specified ICMP type.

UserIdGroupPairs (list) –
One or more security group and AWS account ID pairs.

(dict) –
Describes a security group and AWS account ID pair.

UserId (string) –
The ID of an AWS account. EC2-Classic only.

GroupName (string) –
The name of the security group. In a request, use this parameter for a security group in EC2-Classic or a default VPC only. For a security group in a nondefault VPC, use GroupId.

GroupId (string) –
The ID of the security group.

IpRanges (list) –
One or more IP ranges.

(dict) –
Describes an IP range.

CidrIp (string) –
The CIDR range. You can either specify a CIDR range or a source security group, not both.

PrefixListIds (list) –
(Valid for AuthorizeSecurityGroupEgress, RevokeSecurityGroupEgress and DescribeSecurityGroups only) One or more prefix list IDs for an AWS service. In an AuthorizeSecurityGroupEgress request, this is the AWS service that you want to access through a VPC endpoint from instances associated with the security group.

(dict) –
The ID of the prefix.
- **PrefixListId** *(string)* –
  The ID of the prefix.
- **VpcId** *(string)* –
  [EC2-VPC] The ID of the VPC for the security group.
- **Tags** *(list)* –
  Any tags assigned to the security group.
  - *(dict)* –
    Describes a tag.
  - **Key** *(string)* –
    The key of the tag.
    Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`.
  - **Value** *(string)* –
    The value of the tag.
    Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

**describe_snapshot_attribute(****kwargs**

Describes the specified attribute of the specified snapshot. You can specify only one attribute at a time.

For more information about EBS snapshots, see Amazon EBS Snapshots in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = client.describe_snapshot_attribute(
    DryRun=True|False,
    SnapshotId='string',
    Attribute='productCodes'|'createVolumePermission'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **SnapshotId** *(string)* – [REQUIRED]
  The ID of the EBS snapshot.
- **Attribute** *(string)* – [REQUIRED]
  The snapshot attribute you would like to view.

**Return type** `dict`

**Response Syntax**

```python
{
    'SnapshotId': 'string',
    'CreateVolumePermissions': [
    {
        'UserId': 'string',
        'Group': 'all'
    },
```
Response Structure

- (dict) –
  - **SnapshotId** (string) –
    The ID of the EBS snapshot.
  - **CreateVolumePermissions** (list) –
    A list of permissions for creating volumes from the snapshot.
    * (dict) –
      Describes the user or group to be added or removed from the permissions for a volume.
      - **UserId** (string) –
        The specific AWS account ID that is to be added or removed from a volume’s list of create volume permissions.
      - **Group** (string) –
        The specific group that is to be added or removed from a volume’s list of create volume permissions.
  - **ProductCodes** (list) –
    A list of product codes.
    * (dict) –
      Describes a product code.
      - **ProductCodeId** (string) –
        The product code.
      - **ProductCodeType** (string) –
        The type of product code.

**describe_snapshots(** **kwargs** **)**

Describes one or more of the EBS snapshots available to you. Available snapshots include public snapshots available for any AWS account to launch, private snapshots that you own, and private snapshots owned by another AWS account but for which you’ve been given explicit create volume permissions.

The create volume permissions fall into the following categories:

* **public** : The owner of the snapshot granted create volume permissions for the snapshot to the all group. All AWS accounts have create volume permissions for these snapshots.
* **explicit** : The owner of the snapshot granted create volume permissions to a specific AWS account.
* **implicit** : An AWS account has implicit create volume permissions for all snapshots it owns.

The list of snapshots returned can be modified by specifying snapshot IDs, snapshot owners, or AWS accounts with create volume permissions. If no options are specified, Amazon EC2 returns all snapshots for which you have create volume permissions.

If you specify one or more snapshot IDs, only snapshots that have the specified IDs are returned. If you specify an invalid snapshot ID, an error is returned. If you specify a snapshot ID for which you do not have access, it is not included in the returned results.
If you specify one or more snapshot owners, only snapshots from the specified owners and for which you have access are returned. The results can include the AWS account IDs of the specified owners, `amazon` for snapshots owned by Amazon, or `self` for snapshots that you own.

If you specify a list of restorable users, only snapshots with create snapshot permissions for those users are returned. You can specify AWS account IDs (if you own the snapshots), `self` for snapshots for which you own or have explicit permissions, or `all` for public snapshots.

If you are describing a long list of snapshots, you can paginate the output to make the list more manageable. The `MaxResults` parameter sets the maximum number of results returned in a single page. If the list of results exceeds your `MaxResults` value, then that number of results is returned along with a `NextToken` value that can be passed to a subsequent `DescribeSnapshots` request to retrieve the remaining results.

For more information about EBS snapshots, see Amazon EBS Snapshots in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = client.describe_snapshots(
    DryRun=True|False,
    SnapshotIds=['string'],
    OwnerIds=['string'],
    RestorableByUserIds=['string'],
    Filters=[
        {'Name': 'string',
         'Values': ['string']},
    ],
    NextToken='string',
    MaxResults=123
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **SnapshotIds** *(list)* – One or more snapshot IDs.
  
  Default: Describes snapshots for which you have launch permissions.

  - *(string)* –
- **OwnerIds** *(list)* – Returns the snapshots owned by the specified owner. Multiple owners can be specified.

  - *(string)* –
- **RestorableByUserIds** *(list)* – One or more AWS accounts IDs that can create volumes from the snapshot.

  - *(string)* –
- **Filters** *(list)* – One or more filters.
- **description** - A description of the snapshot.
- **owner-alias** - The AWS account alias (for example, amazon) that owns the snapshot.
- **owner-id** - The ID of the AWS account that owns the snapshot.
- **progress** - The progress of the snapshot, as a percentage (for example, 80%).
- **snapshot-id** - The snapshot ID.
- **start-time** - The time stamp when the snapshot was initiated.
- **status** - The status of the snapshot (pending|completed|error).
- **tag :key =*value* - The key/value combination of a tag assigned to the resource.
- **tag-key** - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the **tag :key =*value* filter.
- **tag-value** - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- **volume-id** - The ID of the volume the snapshot is for.
- **volume-size** - The size of the volume, in GiB.

- **(dict)** –

  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  
  - **Name (string)** –
    
    The name of the filter. Filter names are case-sensitive.
  
  - **Values (list)** –
    
    One or more filter values. Filter values are case-sensitive.

  - **NextToken (string)** – The NextToken value returned from a previous paginated DescribeSnapshots request where MaxResults was used and the results exceeded the value of that parameter. Pagination continues from the end of the previous results that returned the NextToken value. This value is null when there are no more results to return.

  - **MaxResults (integer)** – The maximum number of snapshot results returned by DescribeSnapshots in paginated output. When this parameter is used, DescribeSnapshots only returns MaxResults results in a single page along with a NextToken response element. The remaining results of the initial request can be seen by sending another DescribeSnapshots request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. If this parameter is not used, then DescribeSnapshots returns all results. You cannot specify this parameter and the snapshot IDs parameter in the same request.

**Return type** dict

**Returns**

**Response Syntax**
```json
{
'Snapshots': [
{
'SnapshotId': 'string',
'VolumeId': 'string',
'State': 'pending'|'completed'|'error',
'StateMessage': 'string',
'StartTime': datetime(2015, 1, 1),
'Progress': 'string',
'OwnerId': 'string',
'Description': 'string',
'VolumeSize': 123,
'OwnerAlias': 'string',
'Tags': [
{
'Key': 'string',
'Value': 'string'
}
],
'Encrypted': True|False,
'KmsKeyId': 'string',
'DataEncryptionKeyId': 'string'
},
'NextToken': 'string'
}

Response Structure

• (dict) –
  • Snapshots (list) –
    Information about the snapshots.
    • (dict) –
      Describes a snapshot.
      • SnapshotId (string) –
        The ID of the snapshot. Each snapshot receives a unique identifier when it is created.
      • VolumeId (string) –
        The ID of the volume that was used to create the snapshot.
      • State (string) –
        The snapshot state.
      • StateMessage (string) –
        Encrypted Amazon EBS snapshots are copied asynchronously. If a snapshot copy operation fails (for example, if the proper AWS Key Management Service (AWS KMS) permissions are not obtained) this field displays error state details to help you diagnose why the error occurred. This parameter is only returned by the DescribeSnapshots API operation.
      • StartTime (datetime) –
        The time stamp when the snapshot was initiated.
      • Progress (string) –
        The progress of the snapshot, as a percentage.
```
· **OwnerId** *(string)* –
  The AWS account ID of the EBS snapshot owner.
· **Description** *(string)* –
  The description for the snapshot.
· **VolumeSize** *(integer)* –
  The size of the volume, in GiB.
· **OwnerAlias** *(string)* –
  The AWS account alias (for example, `amazon`, `self`) or AWS account ID that owns the snapshot.
· **Tags** *(list)* –
  Any tags assigned to the snapshot.
· *(dict)* –
  Describes a tag.
  · **Key** *(string)* –
    The key of the tag.
  Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws`:
· **Value** *(string)* –
  The value of the tag.
  Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.
· **Encrypted** *(boolean)* –
  Indicates whether the snapshot is encrypted.
· **KmsKeyId** *(string)* –
  The full ARN of the AWS Key Management Service (AWS KMS) customer master key (CMK) that was used to protect the volume encryption key for the parent volume.
· **DataEncryptionKeyId** *(string)* –
  The data encryption key identifier for the snapshot. This value is a unique identifier that corresponds to the data encryption key that was used to encrypt the original volume or snapshot copy. Because data encryption keys are inherited by volumes created from snapshots, and vice versa, if snapshots share the same data encryption key identifier, then they belong to the same volume/snapshot lineage. This parameter is only returned by the DescribeSnapshots API operation.
· **NextToken** *(string)* –
  The `NextToken` value to include in a future DescribeSnapshots request. When the results of a DescribeSnapshots request exceed `MaxResults`, this value can be used to retrieve the next page of results. This value is null when there are no more results to return.

**describe_spot_datafeed_subscription** (**kwargs)**

Describes the data feed for Spot instances. For more information, see Spot Instance Data Feed in the Amazon Elastic Compute Cloud User Guide.

Request Syntax
```
response = client.describe_spot_datafeed_subscription(
    DryRun=True|False
)
```

**Parameters**  
**DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Return type**  
dict

**Returns**

**Response Syntax**

```
{
    'SpotDatafeedSubscription': {
        'OwnerId': 'string',
        'Bucket': 'string',
        'Prefix': 'string',
        'State': 'Active'|'Inactive',
        'Fault': {
            'Code': 'string',
            'Message': 'string'
        }
    }
}
```

**Response Structure**

- *(dict)* – Contains the output of DescribeSpotDatafeedSubscription.

  - **SpotDatafeedSubscription (dict)** – The Spot instance data feed subscription.
    - **OwnerId (string)** – The AWS account ID of the account.
    - **Bucket (string)** – The Amazon S3 bucket where the Spot instance data feed is located.
    - **Prefix (string)** – The prefix that is prepended to data feed files.
    - **State (string)** – The state of the Spot instance data feed subscription.
    - **Fault (dict)** – The fault codes for the Spot instance request, if any.
      - **Code (string)** – The reason code for the Spot instance state change.
      - **Message (string)** – The message for the Spot instance state change.

```
define_spot_fleet_instances(**kwargs)
```

**Describes the running instances for the specified Spot fleet.**

**Request Syntax**
response = client.describe_spot_fleet_instances(
    DryRun=True|False,
    SpotFleetRequestId='string',
    NextToken='string',
    MaxResults=123
)

Parameters
- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **SpotFleetRequestId** *(string)* – [REQUIRED]
The ID of the Spot fleet request.
- **NextToken** *(string)* – The token for the next set of results.
- **MaxResults** *(integer)* – The maximum number of results to return in a single call. Specify a value between 1 and 1000. The default value is 1000. To retrieve the remaining results, make another call with the returned `NextToken` value.

Return type: **dict**

Returns

Response Syntax

```python
{
    'SpotFleetRequestId': 'string',
    'ActiveInstances': [
        {
            'InstanceType': 'string',
            'InstanceId': 'string',
            'SpotInstanceRequestId': 'string'
        },
        
        'NextToken': 'string'
    }
}
```

Response Structure
- **(dict)** –

  Contains the output of `DescribeSpotFleetInstances`.
  - **SpotFleetRequestId** *(string)* –
    The ID of the Spot fleet request.
  - **ActiveInstances** *(list)* –
    The running instances. Note that this list is refreshed periodically and might be out of date.
    * **(dict)** –
      Describes a running instance in a Spot fleet.
      - **InstanceType** *(string)* –
        The instance type.
      - **InstanceId** *(string)* –
        The ID of the instance.
      - **SpotInstanceRequestId** *(string)* –
        The ID of the Spot instance request.
– **NextToken** *(string)* –

The token required to retrieve the next set of results. This value is **null** when there are no more results to return.

describe_spot_fleet_request_history(**kwargs)**

Describes the events for the specified Spot fleet request during the specified time.

Spot fleet events are delayed by up to 30 seconds before they can be described. This ensures that you can query by the last evaluated time and not miss a recorded event.

**Request Syntax**

```python
response = client.describe_spot_fleet_request_history(
    DryRun=True|False,
    SpotFleetRequestId='string',
    EventType='instanceChange'|'fleetRequestChange'|'error',
    StartTime=datetime(2015, 1, 1),
    NextToken='string',
    MaxResults=123
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **SpotFleetRequestId** *(string)* – [REQUIRED]

  The ID of the Spot fleet request.

- **EventType** *(string)* – The type of events to describe. By default, all events are described.

- **StartTime** *(datetime)* – [REQUIRED]

  The starting date and time for the events, in UTC format (for example, *YYYY-MM-DD T*HH*:MM*:SSZ*).

- **NextToken** *(string)* – The token for the next set of results.

- **MaxResults** *(integer)* – The maximum number of results to return in a single call. Specify a value between 1 and 1000. The default value is 1000. To retrieve the remaining results, make another call with the returned `NextToken` value.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'SpotFleetRequestId': 'string',
    'StartTime': datetime(2015, 1, 1),
    'LastEvaluatedTime': datetime(2015, 1, 1),
    'HistoryRecords': [
        {
            'Timestamp': datetime(2015, 1, 1),
            'EventType': 'instanceChange'|'fleetRequestChange'|'error',
            'EventInformation': {
                'InstanceId': 'string',
                'EventSubType': 'string',
                'EventDescription': 'string'
            }
        }
    ],
}
```
Response Structure

- \( \text{(dict)} \) – Contains the output of DescribeSpotFleetRequestHistory.
  - \text{SpotFleetRequestId} (string) – The ID of the Spot fleet request.
  - \text{StartTime} (datetime) – The starting date and time for the events, in UTC format (for example, \( YYYY-MM-DD T*HH* :MM:SS Z \)).
  - \text{LastEvaluatedTime} (datetime) – The last date and time for the events, in UTC format (for example, \( YYYY-MM-DD T*HH* :MM:SS Z \)). All records up to this time were retrieved.
    - If \text{nextToken} indicates that there are more results, this value is not present.
  - \text{HistoryRecords} (list) – Information about the events in the history of the Spot fleet request.
    - \( \text{(dict)} \) – Describes an event in the history of the Spot fleet request.
      - \text{Timestamp} (datetime) – The date and time of the event, in UTC format (for example, \( YYYY-MM-DD T*HH* :MM:SS Z \)).
      - \text{EventType} (string) – The event type.
        - \text{error} - Indicates an error with the Spot fleet request.
        - \text{fleetRequestChange} - Indicates a change in the status or configuration of the Spot fleet request.
        - \text{instanceChange} - Indicates that an instance was launched or terminated.
      - \text{EventInformation} (dict) – Information about the event.
        - \text{InstanceId} (string) – The ID of the instance. This information is available only for \text{instanceChange} events.
        - \text{EventSubType} (string) – The event.
          - \text{iamFleetRoleInvalid} - Spot fleet did not have the required permissions either to launch or terminate an instance.
          - \text{spotFleetRequestConfigurationInvalid} - The configuration is not valid. For more information, see the description.
          - \text{spotInstanceCountLimitExceeded} - You’ve reached the limit on the number of Spot instances that you can launch.
The following are the **fleetRequestChange** events:

- **active** - The Spot fleet has been validated and Amazon EC2 is attempting to maintain the target number of running Spot instances.
- **cancelled** - The Spot fleet is canceled and has no running Spot instances. The Spot fleet will be deleted two days after its instances were terminated.
- **cancelled_running** - The Spot fleet is canceled and will not launch additional Spot instances, but its existing Spot instances continue to run until they are interrupted or terminated.
- **cancelled_terminating** - The Spot fleet is canceled and its Spot instances are terminating.
- **expired** - The Spot fleet request has expired. A subsequent event indicates that the instances were terminated, if the request was created with TerminateInstancesWithExpiration set.
- **price_update** - The bid price for a launch configuration was adjusted because it was too high. This change is permanent.
- **submitted** - The Spot fleet request is being evaluated and Amazon EC2 is preparing to launch the target number of Spot instances.

The following are the **instanceChange** events:

- **launched** - A bid was fulfilled and a new instance was launched.
- **terminated** - An instance was terminated by the user.

**EventDescription (string)** – The description of the event.

- **NextToken (string)** – The token required to retrieve the next set of results. This value is null when there are no more results to return.

```python
describe_spot_fleet_requests(**kwargs)
```

Describes your Spot fleet requests.

**Request Syntax**

```python
response = client.describe_spot_fleet_requests(
    DryRun=True|False,
    SpotFleetRequestIds=[
        'string',
    ],
    NextToken='string',
    MaxResults=123
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **SpotFleetRequestIds (list)** – The IDs of the Spot fleet requests.
  - (string)
- **NextToken (string)** – The token for the next set of results.
• **MaxResults** *(integer)* – The maximum number of results to return in a single call. Specify a value between 1 and 1000. The default value is 1000. To retrieve the remaining results, make another call with the returned `NextToken` value.

**Return type** dict

**Returns**

**Response Syntax**

Response Structure
• (dict) –
  Contains the output of DescribeSpotFleetRequests.
  – SpotFleetRequestConfigs (list) –
    Information about the configuration of your Spot fleet.
      * (dict) –
        Describes a Spot fleet request.
          • SpotFleetRequestId (string) –
            The ID of the Spot fleet request.
          • SpotFleetRequestState (string) –
            The state of the Spot fleet request.
          • SpotFleetRequestConfig (dict) –
            Information about the configuration of the Spot fleet request.
          • ClientToken (string) –
            A unique, case-sensitive identifier you provide to ensure
idempotency of your listings. This helps avoid duplicate list-
ing. For more information, see Ensuring Idempotency.

- **SpotPrice** *(string)*

  The bid price per unit hour.

- **TargetCapacity** *(integer)*

  The number of units to request. You can choose to set the
target capacity in terms of instances or a performance charac-
teristic that is important to your application workload, such as
vCPUs, memory, or I/O.

- **ValidFrom** *(datetime)*

  The start date and time of the request, in UTC format (for
example, *YYYY*-*MM*-*DD* *T*HH*:MM*:SS*Z*). The default is
to start fulfilling the request immediately.

- **ValidUntil** *(datetime)*

  The end date and time of the request, in UTC format (for ex-
ample, *YYYY*-*MM*-*DD* *T*HH*:MM*:SS*Z*). At this point, no
new Spot instance requests are placed or enabled to fulfill the
request.

- **TerminateInstancesWithExpiration** *(boolean)*

  Indicates whether running Spot instances should be termi-
nated when the Spot fleet request expires.

- **IamFleetRole** *(string)*

  Grants the Spot fleet permission to terminate Spot
instances on your behalf when you cancel its
Spot fleet request using CancelSpotFleetRequests
or when the Spot fleet request expires, if you set
terminateInstancesWithExpiration.

- **LaunchSpecifications** *(list)*

  Information about the launch specifications for the Spot fleet
request.

  *(dict)*

  Describes the launch specification for one or more Spot in-
stances.

  - **ImageId** *(string)*

    The ID of the AMI.

  - **KeyName** *(string)*

    The name of the key pair.

  - **SecurityGroups** *(list)*

    One or more security groups. To request an instance in a non-
default VPC, you must specify the ID of the security group.
To request an instance in EC2-Classic or a default VPC, you
can specify the name or the ID of the security group.

  *(dict)*

  Describes a security group.

  - **GroupName** *(string)*

    The name of the security group.

  - **GroupId** *(string)*
The ID of the security group.

- **UserData (string)** –
  The Base64-encoded MIME user data to make available to the instances.

- **AddressingType (string)** –
  Deprecated.

- **InstanceType (string)** –
  The instance type.

- **Placement (dict)** –
  The placement information.

- **AvailabilityZone (string)** –
  The Availability Zone.

- **GroupName (string)** –
  The name of the placement group (for cluster instances).

- **KernelId (string)** –
  The ID of the kernel.

- **RamdiskId (string)** –
  The ID of the RAM disk.

- **BlockDeviceMappings (list)** –
  One or more block device mapping entries.

  - (dict) –
    Describes a block device mapping.

  - **VirtualName (string)** –
    The virtual device name (ephemeral N). Instance store volumes are numbered starting from 0. An instance type with 2 available instance store volumes can specify mappings for ephemeral0 and ephemeral1. The number of available instance store volumes depends on the instance type. After you connect to the instance, you must mount the volume.

    Constraints: For M3 instances, you must specify instance store volumes in the block device mapping for the instance. When you launch an M3 instance, we ignore any instance store volumes specified in the block device mapping for the AMI.

  - **DeviceName (string)** –
    The device name exposed to the instance (for example, /dev/sdh or xvdh).

  - **Ebs (dict)** –
    Parameters used to automatically set up EBS volumes when the instance is launched.

  - **SnapshotId (string)** –
    The ID of the snapshot.

  - **VolumeSize (integer)** –
    The size of the volume, in GiB.
Constraints: 1-1024 for standard volumes, 1-16384 for gp2 volumes, and 4-16384 for io1 volumes. If you specify a snapshot, the volume size must be equal to or larger than the snapshot size.

Default: If you’re creating the volume from a snapshot and don’t specify a volume size, the default is the snapshot size.

- **DeleteOnTermination (boolean)** –
  Indicates whether the EBS volume is deleted on instance termination.

- **VolumeType (string)** –
  The volume type. gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, and standard for Magnetic volumes.
  Default: standard

- **Iops (integer)** –
  The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.
  Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.
  Condition: This parameter is required for requests to create io1 volumes; it is not used in requests to create standard or gp2 volumes.

- **Encrypted (boolean)** –
  Indicates whether the EBS volume is encrypted. Encrypted Amazon EBS volumes may only be attached to instances that support Amazon EBS encryption.

- **NoDevice (string)** –
  Suppresses the specified device included in the block device mapping of the AMI.

- **Monitoring (dict)** –
  Enable or disable monitoring for the instances.
  - **Enabled (boolean)** –
    Enables monitoring for the instance.
    Default: false

- **SubnetId (string)** –
  The ID of the subnet in which to launch the instances.

- **NetworkInterfaces (list)** –
  One or more network interfaces.
(dict) –
Describes a network interface.

- NetworkInterfaceId (string) –
The ID of the network interface.

- DeviceIndex (integer) –
The index of the device on the instance for the network interface attachment. If you are specifying a network interface in a RunInstances request, you must provide the device index.

- SubnetId (string) –
The ID of the subnet associated with the network string. Applies only if creating a network interface when launching an instance.

- Description (string) –
The description of the network interface. Applies only if creating a network interface when launching an instance.

- PrivateIpAddress (string) –
The private IP address of the network interface. Applies only if creating a network interface when launching an instance.

- Groups (list) –
The IDs of the security groups for the network interface. Applies only if creating a network interface when launching an instance.

- (string) –
- DeleteOnTermination (boolean) –
  If set to true, the interface is deleted when the instance is terminated. You can specify true only if creating a new network interface when launching an instance.

- PrivateIpAddresses (list) –
  One or more private IP addresses to assign to the network interface. Only one private IP address can be designated as primary.

  - (dict) –
    Describes a secondary private IP address for a network interface.

    - PrivateIpAddress (string) –
      The private IP addresses.

    - Primary (boolean) –
      Indicates whether the private IP address is the primary private IP address. Only one IP address can be designated as primary.

    - SecondaryPrivateIpAddressCount (integer) –
      The number of secondary private IP addresses. You can’t specify this option and specify more than one private IP address using the private IP addresses option.

    - AssociatePublicIpAddress (boolean) –
      Indicates whether to assign a public IP address to an instance you launch in a VPC. The public IP address can only be assigned to a network interface for eth0, and can only be as-
signed to a new network interface, not an existing one. You cannot specify more than one network interface in the request. If launching into a default subnet, the default value is `true`.

- **IamInstanceProfile** *(dict)*
  
  The IAM instance profile.

- **Arn** *(string)*
  
  The Amazon Resource Name (ARN) of the instance profile.

- **Name** *(string)*
  
  The name of the instance profile.

- **EbsOptimized** *(boolean)*
  
  Indicates whether the instances are optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal EBS I/O performance. This optimization isn’t available with all instance types. Additional usage charges apply when using an EBS Optimized instance.

  Default: `false`

- **WeightedCapacity** *(float)*
  
  The number of units provided by the specified instance type. These are the same units that you chose to set the target capacity in terms (instances or a performance characteristic such as vCPUs, memory, or I/O).

  If the target capacity divided by this value is not a whole number, we round the number of instances to the next whole number. If this value is not specified, the default is 1.

- **SpotPrice** *(string)*
  
  The bid price per unit hour for the specified instance type. If this value is not specified, the default is the Spot bid price specified for the fleet. To determine the bid price per unit hour, divide the Spot bid price by the value of `WeightedCapacity`.

- **AllocationStrategy** *(string)*
  
  Determines how to allocate the target capacity across the Spot pools specified by the Spot fleet request. The default is `lowestPrice`.

- **NextToken** *(string)*
  
  The token required to retrieve the next set of results. This value is `null` when there are no more results to return.

describe_spot_instance_requests(**kwargs)**

Describes the Spot instance requests that belong to your account. Spot instances are instances that Amazon EC2 launches when the bid price that you specify exceeds the current Spot price. Amazon EC2 periodically sets the Spot price based on available Spot instance capacity and current Spot instance requests. For more information, see Spot Instance Requests in the Amazon Elastic Compute Cloud User Guide.

You can use DescribeSpotInstanceRequests to find a running Spot instance by examining the response. If the status of the Spot instance is `fulfilled`, the instance ID appears in the response and contains the identifier of the instance. Alternatively, you can use DescribeInstances with a filter to look for instances where the instance lifecycle is `spot`.

3.1. Services 1313
Request Syntax

```python
response = client.describe_spot_instance_requests(
    DryRun=True|False,
    SpotInstanceRequestIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ],
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **SpotInstanceRequestIds** *(list)* – One or more Spot instance request IDs.
  - *(string)* –
- **Filters** *(list)* – One or more filters.
  - `availability-zone-group` - The Availability Zone group.
  - `create-time` - The time stamp when the Spot instance request was created.
  - `fault-code` - The fault code related to the request.
  - `fault-message` - The fault message related to the request.
  - `instance-id` - The ID of the instance that fulfilled the request.
  - `launch-group` - The Spot instance launch group.
  - `launch.block-device-mapping.delete-on-termination` - Indicates whether the Amazon EBS volume is deleted on instance termination.
  - `launch.block-device-mapping.device-name` - The device name for the Amazon EBS volume (for example, /dev/sdh).
  - `launch.block-device-mapping.snapshot-id` - The ID of the snapshot used for the Amazon EBS volume.
  - `launch.block-device-mapping.volume-size` - The size of the Amazon EBS volume, in GiB.
  - `launch.block-device-mapping.volume-type` - The type of the Amazon EBS volume (gp2|standard|io1).
  - `launch.group-id` - The security group for the instance.
  - `launch.image-id` - The ID of the AMI.
  - `launch.instance-type` - The type of instance (for example, m1.small).
  - `launch.kernel-id` - The kernel ID.
  - `launch.key-name` - The name of the key pair the instance launched with.
  - `launch.monitoring-enabled` - Whether monitoring is enabled for the Spot instance.
  - `launch.ramdisk-id` - The RAM disk ID.
  - `network-interface.network-interface-id` - The ID of the network interface.
- **network-interface.device-index** - The index of the device for the network interface attachment on the instance.
- **network-interface.subnet-id** - The ID of the subnet for the instance.
- **network-interface.private-ip-address** - The primary private IP address of the network interface.
- **network-interface.delete-on-termination** - Indicates whether the network interface is deleted when the instance is terminated.
- **network-interface.group-id** - The ID of the security group associated with the network interface.
- **network-interface.group-name** - The name of the security group associated with the network interface.
- **network-interface.addresses.primary** - Indicates whether the IP address is the primary private IP address.
- **product-description** - The product description associated with the instance (Linux/UNIX | Windows).
- **spot-instance-request-id** - The Spot instance request ID.
- **spot-price** - The maximum hourly price for any Spot instance launched to fulfill the request.
- **state** - The state of the Spot instance request (open | active | closed | cancelled | failed). Spot bid status information can help you track your Amazon EC2 Spot instance requests. For more information, see Spot Bid Status in the Amazon Elastic Compute Cloud User Guide.
- **status-code** - The short code describing the most recent evaluation of your Spot instance request.
- **status-message** - The message explaining the status of the Spot instance request.
- **tag :key =*value* - The key/value combination of a tag assigned to the resource.
- **tag-key** - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter "tag-key=Purpose" and the filter "tag-value=X", you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key =*value* filter.
- **tag-value** - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- **type** - The type of Spot instance request (one-time | persistent).
- **launched-availability-zone** - The Availability Zone in which the bid is launched.
- **valid-from** - The start date of the request.
- **valid-until** - The end date of the request.

**(dict)**

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* **Name (string)** –

  The name of the filter. Filter names are case-sensitive.

* **Values (list)** –
One or more filter values. Filter values are case-sensitive.

- **return_type** dict

**returns**

**Response Syntax**

```
{

        }
    ]
}
```
Response Structure

* *(dict)* –

Contains the output of DescribeSpotInstanceRequests.

  * **SpotInstanceRequests** *(list)* –

    One or more Spot instance requests.

    * *(dict)* –

      Describe a Spot instance request.

      * **SpotInstanceRequestId** *(string)* –
The ID of the Spot instance request.

- **SpotPrice (string)** –
  The maximum hourly price (bid) for any Spot instance launched to fulfill the request.

- **Type (string)** –
  The Spot instance request type.

- **State (string)** –
  The state of the Spot instance request. Spot bid status information can help you track your Spot instance requests. For more information, see Spot Bid Status in the Amazon Elastic Compute Cloud User Guide.

- **Fault (dict)** –
  The fault codes for the Spot instance request, if any.

  - **Code (string)** –
    The reason code for the Spot instance state change.

  - **Message (string)** –
    The message for the Spot instance state change.

- **Status (dict)** –
  The status code and status message describing the Spot instance request.

  - **Code (string)** –
    The status code.

  - **UpdateTime (datetime)** –
    The date and time of the most recent status update, in UTC format (for example, *YYYY-MM-DD T*HH* :MM* :SS Z*).

  - **Message (string)** –
    The description for the status code.

- **ValidFrom (datetime)** –
  The start date of the request, in UTC format (for example, *YYYY-MM-DD T*HH* :MM* :SS Z*). If this is a one-time request, the request becomes active at this date and time and remains active until all instances launch, the request expires, or the request is canceled. If the request is persistent, the request becomes active at this date and time and remains active until it expires or is canceled.

- **ValidUntil (datetime)** –
  The end date of the request, in UTC format (for example, *YYYY-MM-DD T*HH* :MM* :SS Z*). If this is a one-time request, the request remains active until all instances launch, the request is canceled, or this date is reached. If the request is persistent, it remains active until it is canceled or this date is reached.

- **LaunchGroup (string)** –
  The instance launch group. Launch groups are Spot instances that launch together and terminate together.

- **AvailabilityZoneGroup (string)** –
The Availability Zone group. If you specify the same Availability Zone group for all Spot instance requests, all Spot instances are launched in the same Availability Zone.

- **LaunchSpecification (dict)** –
  Additional information for launching instances.

  - **ImageId (string)** –
    The ID of the AMI.

  - **KeyName (string)** –
    The name of the key pair.

  - **SecurityGroups (list)** –
    One or more security groups. To request an instance in a non-default VPC, you must specify the ID of the security group. To request an instance in EC2-Classic or a default VPC, you can specify the name or the ID of the security group.

    - **(dict)** –
      Describes a security group.

      - **GroupName (string)** –
        The name of the security group.

      - **GroupId (string)** –
        The ID of the security group.

  - **UserData (string)** –
    The Base64-encoded MIME user data to make available to the instances.

  - **AddressingType (string)** –
    Deprecated.

  - **InstanceType (string)** –
    The instance type.

  - **Placement (dict)** –
    The placement information for the instance.

    - **AvailabilityZone (string)** –
      The Availability Zone.

    - **GroupName (string)** –
      The name of the placement group (for cluster instances).

  - **KernelId (string)** –
    The ID of the kernel.

  - **RamdiskId (string)** –
    The ID of the RAM disk.

  - **BlockDeviceMappings (list)** –
    One or more block device mapping entries.

    - **(dict)** –
      Describes a block device mapping.

    - **VirtualName (string)** –
      The virtual device name (ephemeral N). Instance store volumes are numbered starting from 0. An instance type with 2 available instance store volumes can specify mappings for
ephemeral0 and ephemeral1. The number of available instance store volumes depends on the instance type. After you connect to the instance, you must mount the volume.

Constraints: For M3 instances, you must specify instance store volumes in the block device mapping for the instance. When you launch an M3 instance, we ignore any instance store volumes specified in the block device mapping for the AMI.

- **DeviceName** *(string)*
  
  The device name exposed to the instance (for example, /dev/sdh or xvdh).

- **Ebs** *(dict)*
  
  Parameters used to automatically set up EBS volumes when the instance is launched.

- **SnapshotId** *(string)*
  
  The ID of the snapshot.

- **VolumeSize** *(integer)*
  
  The size of the volume, in GiB.

  Constraints: 1-1024 for standard volumes, 1-16384 for gp2 volumes, and 4-16384 for io1 volumes. If you specify a snapshot, the volume size must be equal to or larger than the snapshot size.

  Default: If you’re creating the volume from a snapshot and don’t specify a volume size, the default is the snapshot size.

- **DeleteOnTermination** *(boolean)*
  
  Indicates whether the EBS volume is deleted on instance termination.

- **VolumeType** *(string)*
  
  The volume type. gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, and standard for Magnetic volumes.

  Default: standard

- **Iops** *(integer)*
  
  The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.

  Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.

  Condition: This parameter is required for requests to create io1 volumes; it is not used in requests to create standard
or gp2 volumes.

- **Encrypted** *(boolean)* –
  Indicates whether the EBS volume is encrypted. Encrypted Amazon EBS volumes may only be attached to instances that support Amazon EBS encryption.

- **NoDevice** *(string)* –
  Suppresses the specified device included in the block device mapping of the AMI.

- **SubnetId** *(string)* –
  The ID of the subnet in which to launch the instance.

- **NetworkInterfaces** *(list)* –
  One or more network interfaces.

  - *(dict)* –
    Describes a network interface.

  - **NetworkInterfaceId** *(string)* –
    The ID of the network interface.

  - **DeviceIndex** *(integer)* –
    The index of the device on the instance for the network interface attachment. If you are specifying a network interface in a RunInstances request, you must provide the device index.

  - **SubnetId** *(string)* –
    The ID of the subnet associated with the network string. Applies only if creating a network interface when launching an instance.

  - **Description** *(string)* –
    The description of the network interface. Applies only if creating a network interface when launching an instance.

  - **PrivateIpAddress** *(string)* –
    The private IP address of the network interface. Applies only if creating a network interface when launching an instance.

  - **Groups** *(list)* –
    The IDs of the security groups for the network interface. Applies only if creating a network interface when launching an instance.

  - *(string)* –
  - **DeleteOnTermination** *(boolean)* –
    If set to `true`, the interface is deleted when the instance is terminated. You can specify `true` only if creating a new network interface when launching an instance.

  - **PrivateIpAddresses** *(list)* –
    One or more private IP addresses to assign to the network interface. Only one private IP address can be designated as primary.

  - *(dict)* –
    Describes a secondary private IP address for a network interface.
- **PrivateIpAddress** *(string)* –
  The private IP addresses.
- **Primary** *(boolean)* –
  Indicates whether the private IP address is the primary private IP address. Only one IP address can be designated as primary.
- **SecondaryPrivateIpAddressCount** *(integer)* –
  The number of secondary private IP addresses. You can’t specify this option and specify more than one private IP address using the private IP addresses option.
- **AssociatePublicIpAddress** *(boolean)* –
  Indicates whether to assign a public IP address to an instance you launch in a VPC. The public IP address can only be assigned to a network interface for eth0, and can only be assigned to a new network interface, not an existing one. You cannot specify more than one network interface in the request. If launching into a default subnet, the default value is `true`.
- **IamInstanceProfile** *(dict)* –
  The IAM instance profile.
  - **Arn** *(string)* –
    The Amazon Resource Name (ARN) of the instance profile.
  - **Name** *(string)* –
    The name of the instance profile.
- **EbsOptimized** *(boolean)* –
  Indicates whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal EBS I/O performance. This optimization isn’t available with all instance types. Additional usage charges apply when using an EBS Optimized instance.
  Default: `false`
- **Monitoring** *(dict)* –
  Describes the monitoring for the instance.
  - **Enabled** *(boolean)* –
    Indicates whether monitoring is enabled for the instance.
  - **InstanceId** *(string)* –
    The instance ID, if an instance has been launched to fulfill the Spot instance request.
  - **CreateTime** *(datetime)* –
    The date and time when the Spot instance request was created, in UTC format (for example, `YYYY-MM-DD T*HH:MM:SSZ`).
  - **ProductDescription** *(string)* –
    The product description associated with the Spot instance.
  - **Tags** *(list)* –
    Any tags assigned to the resource.
· (dict) –
  Describes a tag.
  · **Key**(string) –
    The key of the tag.
    Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`.
  · **Value**(string) –
    The value of the tag.
    Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.
  · **LaunchedAvailabilityZone**(string) –
    The Availability Zone in which the bid is launched.

**describe_spot_price_history(**kwargs)**

Describes the Spot price history. The prices returned are listed in chronological order, from the oldest to the most recent, for up to the past 90 days. For more information, see Spot Instance Pricing History in the Amazon Elastic Compute Cloud User Guide.

When you specify a start and end time, this operation returns the prices of the instance types within the time range that you specified and the time when the price changed. The price is valid within the time period that you specified; the response merely indicates the last time that the price changed.

**Request Syntax**

```python
response = client.describe_spot_price_history(
    DryRun=True|False,
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    InstanceTypes=[
        't1.micro'|'m1.small'|'m1.medium'|'m1.large'|'m1.xlarge'|'m3.medium'|'m3.large'|'m3.xlarge'|'m3.2xlarge'|'m4.large'|'m4.xl ... 4xlarge'|'r3.large'|'r3.xlarge'|'r3.2xlarge'|'r3.4xlarge'|'r3.8xlarge'|'d2.xlarge'|'d2.2xlarge'|'d2.4xlarge'|'d2.8xlarge',
    ProductDescriptions=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ]
        },
    ],
    AvailabilityZone='string',
    MaxResults=123,
    NextToken='string'
)
```

**Parameters**

- **DryRun**(boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.  

---

3.1. Services 1323
• **StartTime (datetime)** – The date and time, up to the past 90 days, from which to start retrieving the price history data, in UTC format (for example, *YYYY-MM-DD T*HH* :*MM :*SS Z*).

• **EndTime (datetime)** – The date and time, up to the current date, from which to stop retrieving the price history data, in UTC format (for example, *YYYY-MM-DD T*HH* :*MM :*SS Z*).

• **InstanceTypes (list)** – Filters the results by the specified instance types.
  
  – (string) –

• **ProductDescriptions (list)** – Filters the results by the specified basic product descriptions.
  
  – (string) –

• **Filters (list)** – One or more filters.
  
  – **availability-zone** - The Availability Zone for which prices should be returned.
  – **instance-type** - The type of instance (for example, *m1.small*).
  – **product-description** - The product description for the Spot price (Linux/UNIX|SUSE Linux|Windows|Linux/UNIX (Amazon VPC)|SUSE Linux (Amazon VPC)|Windows (Amazon VPC)).
  – **spot-price** - The Spot price. The value must match exactly (or use wildcards; greater than or less than comparison is not supported).
  – **timestamp** - The timestamp of the Spot price history, in UTC format (for example, *YYYY-MM-DD T*HH* :*MM :*SS Z*). You can use wildcards (* and ?). Greater than or less than comparison is not supported.
  
  – (dict) –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  * **Name (string)** – The name of the filter. Filter names are case-sensitive.
  
  * **Values (list)** – One or more filter values. Filter values are case-sensitive.

  – (string) –

• **AvailabilityZone (string)** – Filters the results by the specified Availability Zone.

• **MaxResults (integer)** – The maximum number of results to return in a single call. Specify a value between 1 and 1000. The default value is 1000. To retrieve the remaining results, make another call with the returned NextToken value.

• **NextToken (string)** – The token for the next set of results.

Return type: dict

Returns

Response Syntax

```python
{
    'SpotPriceHistory': [
        {
            'InstanceType': 't1.micro'|'m1.small'|'m1.medium'|'m1.large'|'m1.xlarge',
            'ProductDescription': 'Linux/UNIX'|'Linux/UNIX (Amazon VPC)'|'Windows',
            'SpotPrice': 'string',
            'Timestamp': datetime(2015, 1, 1),
            'AvailabilityZone': 'string'
        },
    ]
}
```
Response Structure

• **(dict)** –
  Contains the output of DescribeSpotPriceHistory.

  – **SpotPriceHistory (list)** –
    The historical Spot prices.
    *
    **(dict)** –
    Describes the maximum hourly price (bid) for any Spot instance launched to fulfill the request.
    · **InstanceType (string)** –
      The instance type.
    · **ProductDescription (string)** –
      A general description of the AMI.
    · **SpotPrice (string)** –
      The maximum price (bid) that you are willing to pay for a Spot instance.
    · **Timestamp (datetime)** –
      The date and time the request was created, in UTC format (for example, `YYYY-MM-DDThh:mm:ssZ`).
    · **AvailabilityZone (string)** –
      The Availability Zone.

  – **NextToken (string)** –
    The token required to retrieve the next set of results. This value is null when there are no more results to return.

**describe_subnets (** **kwargs)**
Describes one or more of your subnets.

For more information about subnets, see Your VPC and Subnets in the Amazon Virtual Private Cloud User Guide.

Request Syntax

```python
response = client.describe_subnets(
    DryRun=True|False,
    SubnetIds=[
        'string',
    ],
    Filters=[
        
        {  
            'Name': 'string',
            'Values': [  
                'string',
            ]
        },
        
    ]
)
```

Parameters
• **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

• **SubnetIds** *(list)* – One or more subnet IDs.
  
  Default: Describes all your subnets.
  
  – *(string)*

• **Filters** *(list)* – One or more filters.
  
  – `availabilityZone` - The Availability Zone for the subnet. You can also use `availability-zone` as the filter name.
  
  – `available-ip-address-count` - The number of IP addresses in the subnet that are available.
  
  – `cidrBlock` - The CIDR block of the subnet. The CIDR block you specify must exactly match the subnet’s CIDR block for information to be returned for the subnet. You can also use `cidr` or `cidr-block` as the filter names.
  
  – `defaultForAz` - Indicates whether this is the default subnet for the Availability Zone. You can also use `default-for-az` as the filter name.
  
  – `state` - The state of the subnet (`pending`|`available`).
  
  – `subnet-id` - The ID of the subnet.
  
  – `tag :key =*value*` - The key/value combination of a tag assigned to the resource.
  
  – `tag-key` - The key of a tag assigned to the resource. This filter is independent of the `tag-value` filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag :key =*value*` filter.
  
  – `tag-value` - The value of a tag assigned to the resource. This filter is independent of the `tag-key` filter.
  
  – `vpc-id` - The ID of the VPC for the subnet.

  – *(dict)*

  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  * **Name** *(string)*
    
    The name of the filter. Filter names are case-sensitive.

  * **Values** *(list)*
    
    One or more filter values. Filter values are case-sensitive.
    
    – *(string)*

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'Subnets': [
    {
        'SubnetId': 'string',
        'State': 'pending'|'available',
        'VpcId': 'string',
    }
    ]
}
```
Response Structure

- (dict) –
  - Subnets (list) –
    Information about one or more subnets.
    - (dict) –
      Describes a subnet.
      - SubnetId (string) –
        The ID of the subnet.
      - State (string) –
        The current state of the subnet.
      - VpcId (string) –
        The ID of the VPC the subnet is in.
      - CidrBlock (string) –
        The CIDR block assigned to the subnet.
      - AvailableIpAddressCount (integer) –
        The number of unused IP addresses in the subnet. Note that the IP addresses for any stopped instances are considered unavailable.
      - AvailabilityZone (string) –
        The Availability Zone of the subnet.
      - DefaultForAz (boolean) –
        Indicates whether this is the default subnet for the Availability Zone.
      - MapPublicIpOnLaunch (boolean) –
        Indicates whether instances launched in this subnet receive a public IP address.
      - Tags (list) –
        Any tags assigned to the subnet.
        - (dict) –
          Describes a tag.
          - Key (string) –
            The key of the tag.
Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`.

- **Value (string)** –
  
  The value of the tag.

Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

---

**describe_tags(****kwargs**)

Describes one or more of the tags for your EC2 resources.

For more information about tags, see Tagging Your Resources in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = client.describe_tags(
    DryRun=True|False,
    Filters=[
        {'Name': 'string',
         'Values': ['string',
                    ]}
    ],
    MaxResults=123,
    NextToken='string'
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **Filters (list)** – One or more filters.
  - key - The tag key.
  - resource-id - The resource ID.
  - value - The tag value.
  - (dict) –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

- **Name (string)** –

  The name of the filter. Filter names are case-sensitive.

- **Values (list)** –

  One or more filter values. Filter values are case-sensitive.

  - (string) –
• **MaxResults** (*integer*) – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned `NextToken` value. This value can be between 5 and 1000; if `MaxResults` is given a value larger than 1000, only 1000 results are returned.
• **NextToken** (*string*) – The token to retrieve the next page of results.

**Return type**  `dict`

**Returns**

**Response Syntax**

```python
{
    'Tags': [
        {
            'ResourceId': 'string',
            'ResourceType': 'customer-gateway'|'dhcp-options'|'image'|'instance'|'volume',
            'Key': 'string',
            'Value': 'string'
        },
    ],
    'NextToken': 'string'
}
```

**Response Structure**

• (*dict*) –
  – **Tags** (*list*) –
    A list of tags.
      • (*dict*) –
        Describes a tag.
          • **ResourceId** (*string*) –
            The ID of the resource. For example, ami-1a2b3c4d.
          • **ResourceType** (*string*) –
            The resource type.
          • **Key** (*string*) –
            The tag key.
          • **Value** (*string*) –
            The tag value.
  – **NextToken** (*string*) –
    The token to use to retrieve the next page of results. This value is `null` when there are no more results to return.

`describe_volume_attribute(**kwargs)`

Describes the specified attribute of the specified volume. You can specify only one attribute at a time.

For more information about EBS volumes, see Amazon EBS Volumes in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = client.describe_volume_attribute(
    DryRun=True|False,
    VolumeId='string',
)
```
Attributes='autoEnableIO'|'productCodes'

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **VolumeId** (string) – [REQUIRED]
  The ID of the volume.
- **Attribute** (string) – The instance attribute.

Return type: dict

Returns

Response Syntax

```json
{
  'VolumeId': 'string',
  'AutoEnableIO': {
    'Value': True|False
  },
  'ProductCodes': [
    {
      'ProductCodeId': 'string',
      'ProductCodeType': 'devpay'|'marketplace'
    }
  ]
}
```

Response Structure

- (dict) –
  - **VolumeId** (string) –
    The ID of the volume.
  - **AutoEnableIO** (dict) –
    The state of `autoEnableIO` attribute.
      - **Value** (boolean) –
        Valid values are true or false.
  - **ProductCodes** (list) –
    A list of product codes.
      - (dict) –
        Describes a product code.
          - **ProductCodeId** (string) –
            The product code.
          - **ProductCodeType** (string) –
            The type of product code.

**describe_volume_status(**kwargs)

Describes the status of the specified volumes. Volume status provides the result of the checks performed on your volumes to determine events that can impair the performance of your volumes. The performance of a volume can be affected if an issue occurs on the volume’s underlying host. If the volume’s underlying host experiences a power outage or system issue, after the system is restored, there could be data corruption. The purpose of describing volume status is to allow you to determine whether the performance of your volumes has been affected and to take appropriate actions.
inconsistencies on the volume. Volume events notify you if this occurs. Volume actions notify you if any action needs to be taken in response to the event.

The `DescribeVolumeStatus` operation provides the following information about the specified volumes:

**Status**: Reflects the current status of the volume. The possible values are `ok`, `impaired`, `warning`, or `insufficient-data`. If all checks pass, the overall status of the volume is `ok`. If the check fails, the overall status is `impaired`. If the status is `insufficient-data`, then the checks may still be taking place on your volume at the time. We recommend that you retry the request. For more information on volume status, see Monitoring the Status of Your Volumes.

**Events**: Reflect the cause of a volume status and may require you to take action. For example, if your volume returns an `impaired` status, then the volume event might be `potential-data-inconsistency`. This means that your volume has been affected by an issue with the underlying host, has all I/O operations disabled, and may have inconsistent data.

**Actions**: Reflect the actions you may have to take in response to an event. For example, if the status of the volume is `impaired` and the volume event shows `potential-data-inconsistency`, then the action shows `enable-volume-io`. This means that you may want to enable the I/O operations for the volume by calling the `EnableVolumeIO` action and then check the volume for data consistency.

**Note**: Volume status is based on the volume status checks, and does not reflect the volume state. Therefore, volume status does not indicate volumes in the `error` state (for example, when a volume is incapable of accepting I/O.)

**Request Syntax**

```python
def describe_volume_status(
    DryRun=True|False,
    VolumeIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ],
    NextToken='string',
    MaxResults=123
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **VolumeIds** *(list)* – One or more volume IDs.
  
  Default: Describes all your volumes.
  
  *(string)*
- **Filters** *(list)* – One or more filters.
  
  - **action.code** - The action code for the event (for example, `enable-volume-io`).
  - **action.description** - A description of the action.
– action.event-id - The event ID associated with the action.
– availability-zone - The Availability Zone of the instance.
– event.description - A description of the event.
– event.event-id - The event ID.
– event.not-after - The latest end time for the event.
– event.not-before - The earliest start time for the event.
– volume-status.status - The status of the volume (ok | impaired | warning | insufficient-data).

– (dict) –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* Name (string) –

The name of the filter. Filter names are case-sensitive.

* Values (list) –

One or more filter values. Filter values are case-sensitive.

* (string) –

• NextToken (string) – The NextToken value to include in a future DescribeVolumeStatus request. When the results of the request exceed MaxResults, this value can be used to retrieve the next page of results. This value is null when there are no more results to return.

• MaxResults (integer) – The maximum number of volume results returned by DescribeVolumeStatus in paginated output. When this parameter is used, the request only returns MaxResults results in a single page along with a NextToken response element. The remaining results of the initial request can be seen by sending another request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. If this parameter is not used, then DescribeVolumeStatus returns all results. You cannot specify this parameter and the volume IDs parameter in the same request.

Return type dict

Returns

Response Syntax

```json
{
  'VolumeStatuses': [
    {
      'VolumeId': 'string',
      'AvailabilityZone': 'string',
      'VolumeStatus': {
        'Status': 'ok' | 'impaired' | 'insufficient-data',
      }
    }
  ]
}
```
'Details': [
    {
        'Name': 'io-enabled'|'io-performance',
        'Status': 'string'
    },
],
',
'Events': [
    {
        'EventType': 'string',
        'Description': 'string',
        'NotBefore': datetime(2015, 1, 1),
        'NotAfter': datetime(2015, 1, 1),
        'EventId': 'string'
    },
],
',
'Actions': [
    {
        'Code': 'string',
        'Description': 'string',
        'EventType': 'string',
        'EventId': 'string'
    },
],
',
'NextToken': 'string'
}

Response Structure
• (dict) –
  – VolumeStatuses (list) –
  A list of volumes.
    * (dict) –
      Describes the volume status.
        • VolumeId (string) –
          The volume ID.
        • AvailabilityZone (string) –
          The Availability Zone of the volume.
        • VolumeStatus (dict) –
          The volume status.
          • Status (string) –
            The status of the volume.
          • Details (list) –
            The details of the volume status.
            * (dict) –
              Describes a volume status.
              • Name (string) –
                The name of the volume status.
              • Status (string) –
                The intended status of the volume status.
- **Events** *(list)* –
  A list of events associated with the volume.
  - *(dict)* –
    Describes a volume status event.
  - **EventType** *(string)* –
    The type of this event.
  - **Description** *(string)* –
    A description of the event.
  - **NotBefore** *(datetime)* –
    The earliest start time of the event.
  - **NotAfter** *(datetime)* –
    The latest end time of the event.
  - **EventId** *(string)* –
    The ID of this event.
  - **Actions** *(list)* –
    The details of the operation.
  - *(dict)* –
    Describes a volume status operation code.
  - **Code** *(string)* –
    The code identifying the operation, for example, enable-volume-io.
  - **Description** *(string)* –
    A description of the operation.
  - **EventType** *(string)* –
    The event type associated with this operation.
  - **EventId** *(string)* –
    The ID of the event associated with this operation.

- **NextToken** *(string)* –
  The token to use to retrieve the next page of results. This value is `null` when there are no more results to return.

### describe_volumes(**kwargs)**

Describes the specified EBS volumes.

If you are describing a long list of volumes, you can paginate the output to make the list more manageable. The **MaxResults** parameter sets the maximum number of results returned in a single page. If the list of results exceeds your **MaxResults** value, then that number of results is returned along with a **NextToken** value that can be passed to a subsequent **DescribeVolumes** request to retrieve the remaining results.

For more information about EBS volumes, see [Amazon EBS Volumes](https://docs.aws.amazon.com/AmazonEBS/latest/userguide/) in the *Amazon Elastic Compute Cloud User Guide*.

**Request Syntax**

```python
response = client.describe_volumes(
    DryRun=True|False,
    VolumeIds=['string'],
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **VolumeIds** *(list)* – One or more volume IDs.
  - *(string)*

- **Filters** *(list)* – One or more filters.
  - `attachment.attach-time` - The time stamp when the attachment initiated.
  - `attachment.delete-on-termination` - Whether the volume is deleted on instance termination.
  - `attachment.device` - The device name that is exposed to the instance (for example, /dev/sda1).
  - `attachment.instance-id` - The ID of the instance the volume is attached to.
  - `attachment.status` - The attachment state (`attaching | attached | detaching | detached`).
  - `availability-zone` - The Availability Zone in which the volume was created.
  - `create-time` - The time stamp when the volume was created.
  - `encrypted` - The encryption status of the volume.
  - `size` - The size of the volume, in GiB.
  - `snapshot-id` - The snapshot from which the volume was created.
  - `status` - The status of the volume (`creating | available | in-use | deleting | deleted | error`).
  - `tag :key =*value*` - The key/value combination of a tag assigned to the resource.
  - `tag :key` - The key of a tag assigned to the resource. This filter is independent of the `tag :value` filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag :key =*value*` filter.
  - `tag :value` - The value of a tag assigned to the resource. This filter is independent of the `tag :key` filter.
  - `volume-id` - The volume ID.
  - `volume-type` - The Amazon EBS volume type. This can be `gp2` for General Purpose (SSD) volumes, `io1` for Provisioned IOPS (SSD) volumes, or `standard` for Magnetic volumes.
  - *(dict)*
A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* Name (string) –
  The name of the filter. Filter names are case-sensitive.

* Values (list) –
  One or more filter values. Filter values are case-sensitive.

  - NextToken (string) – The NextToken value returned from a previous paginated DescribeVolumes request where MaxResults was used and the results exceeded the value of that parameter. Pagination continues from the end of the previous results that returned the NextToken value. This value is null when there are no more results to return.

  - MaxResults (integer) – The maximum number of volume results returned by DescribeVolumes in paginated output. When this parameter is used, DescribeVolumes only returns MaxResults results in a single page along with a NextToken response element. The remaining results of the initial request can be seen by sending another DescribeVolumes request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. If this parameter is not used, then DescribeVolumes returns all results. You cannot specify this parameter and the volume IDs parameter in the same request.

Return type dict

Returns

Response Syntax

```json
{
  'Volumes': [
    {
      'VolumeId': 'string',
      'Size': 123,
      'SnapshotId': 'string',
      'AvailabilityZone': 'string',
      'State': 'creating'|'available'|'in-use'|'deleting'|'deleted'|'error',
      'CreateTime': datetime(2015, 1, 1),
      'Attachments': [
        {
          'VolumeId': 'string',
          'InstanceId': 'string',
          'Device': 'string',
          'State': 'attaching'|'attached'|'detaching'|'detached',
          'AttachTime': datetime(2015, 1, 1),
          'DeleteOnTermination': True|False
        },
      ],
      'Tags': [
        {
          'Key': 'string',
          'Value': 'string'
        },
      ],
      'VolumeType': 'standard'|'io1'|'gp2',
      'Iops': 123,
      'Encrypted': True|False,
    },
  ]
}
```
Response Structure

* (dict) –

  - Volumes (list) –

    Information about the volumes.

      * (dict) –

        Describes a volume.

        · VolumeId (string) –

          The ID of the volume.

        · Size (integer) –

          The size of the volume, in GiBs.

        · SnapshotId (string) –

          The snapshot from which the volume was created, if applicable.

        · AvailabilityZone (string) –

          The Availability Zone for the volume.

        · State (string) –

          The volume state.

        · CreateTime (datetime) –

          The time stamp when volume creation was initiated.

      · Attachments (list) –

        Information about the volume attachments.

        · (dict) –

          Describes volume attachment details.

          · VolumeId (string) –

            The ID of the volume.

          · InstanceId (string) –

            The ID of the instance.

          · Device (string) –

            The device name.

          · State (string) –

            The attachment state of the volume.

          · AttachTime (datetime) –

            The time stamp when the attachment initiated.

          · DeleteOnTermination (boolean) –

            Indicates whether the EBS volume is deleted on instance termination.

          · Tags (list) –

            Any tags assigned to the volume.
· (dict) –
  · **Key** (string) –
    The key of the tag.
    Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws`:
  · **Value** (string) –
    The value of the tag.
    Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.
  · **VolumeType** (string) –
    The volume type. This can be `gp2` for General Purpose (SSD) volumes, `io1` for Provisioned IOPS (SSD) volumes, or `standard` for Magnetic volumes.
  · **Iops** (integer) –
    The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.
    Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.
    Condition: This parameter is required for requests to create `io1` volumes; it is not used in requests to create `standard` or `gp2` volumes.
  · **Encrypted** (boolean) –
    Indicates whether the volume will be encrypted.
  · **KmsKeyId** (string) –
    The full ARN of the AWS Key Management Service (AWS KMS) customer master key (CMK) that was used to protect the volume encryption key for the volume.

· **NextToken** (string) –
  The `NextToken` value to include in a future `DescribeVolumes` request. When the results of a `DescribeVolumes` request exceed `MaxResults`, this value can be used to retrieve the next page of results. This value is `null` when there are no more results to return.

**describe_vpc_attribute(**kwargs)**

Describes the specified attribute of the specified VPC. You can specify only one attribute at a time.

**Request Syntax**

```python
response = client.describe_vpc_attribute(
    DryRun=True|False,
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **VpcId** *(string)* – [REQUIRED]
  The ID of the VPC.
- **Attribute** *(string)* – The VPC attribute.

Return type  
dict

Returns

Response Syntax

```python
{
    'VpcId': 'string',
    'EnableDnsSupport': {
        'Value': True|False
    },
    'EnableDnsHostnames': {
        'Value': True|False
    }
}
```

Response Structure

- *(dict)* –
  - **VpcId** *(string)* –
    The ID of the VPC.
  - **EnableDnsSupport** *(dict)* –
    Indicates whether DNS resolution is enabled for the VPC. If this attribute is `true`, the Amazon DNS server resolves DNS hostnames for your instances to their corresponding IP addresses; otherwise, it does not.
      - **Value** *(boolean)* –
        Valid values are `true` or `false`.
  - **EnableDnsHostnames** *(dict)* –
    Indicates whether the instances launched in the VPC get DNS hostnames. If this attribute is `true`, instances in the VPC get DNS hostnames; otherwise, they do not.
      - **Value** *(boolean)* –
        Valid values are `true` or `false`.

`describe_vpc_classic_link(**kwargs)`

Describes the ClassicLink status of one or more VPCs.

Request Syntax

```python
response = client.describe_vpc_classic_link(
    DryRun=True|False,
    VpcIds=['string',
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **VpcIds** *(list)* – One or more VPCs for which you want to describe the ClassicLink status.
  - *(string)* –
- **Filters** *(list)* – One or more filters.
  - `is-classic-link-enabled` - Whether the VPC is enabled for ClassicLink *(true|false)*.
  - `tag :key =*value*` - The key/value combination of a tag assigned to the resource.
  - `tag-key` - The key of a tag assigned to the resource. This filter is independent of the `tag-value` filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag :key =*value*` filter.
  - `tag-value` - The value of a tag assigned to the resource. This filter is independent of the `tag-key` filter.
  - *(dict)* –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  * **Name** *(string)* –
    - The name of the filter. Filter names are case-sensitive.
  * **Values** *(list)* –
    - One or more filter values. Filter values are case-sensitive.
      - *(string)* –

Return type: dict

Returns

Response Syntax

```python
{
    'Vpcs': [
        {
            'VpcId': 'string',
            'ClassicLinkEnabled': True|False,  # Input
            'Tags': [
                {
                    ...  # Additional tags...
                }
            ]
        }
    ]
}
```
Response Structure

- (dict) –
  - Vpcs (list) –

  The ClassicLink status of one or more VPCs.

  * (dict) –
    - VpcId (string) –
      The ID of the VPC.
    - ClassicLinkEnabled (boolean) –
      Indicates whether the VPC is enabled for ClassicLink.
    - Tags (list) –
      Any tags assigned to the VPC.
      * (dict) –
        - Key (string) –
          The key of the tag.
          Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`
        - Value (string) –
          The value of the tag.
          Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

`describe_vpc_endpoint_services (**kwargs)`

Describes all supported AWS services that can be specified when creating a VPC endpoint.

Request Syntax

```python
response = client.describe_vpc_endpoint_services(
    DryRun=True|False,
    MaxResults=123,
    NextToken='string'
)
```

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **MaxResults** (integer) – The maximum number of items to return for this request. The request returns a token that you can specify in a subsequent call to get the next set of results.
Constraint: If the value is greater than 1000, we return only 1000 items.

- **NextToken (string)** – The token for the next set of items to return. (You received this token from a prior call.)

**Return type**  
**dict**

**Returns**

**Response Syntax**

```
{
    'ServiceNames': [  
        'string',  
    ],  
    'NextToken': 'string'
}
```

**Response Structure**

- *(dict)* –
  - **ServiceNames (list)** –
    A list of supported AWS services.
  - *(string)* –
  - **NextToken (string)** –
    The token to use when requesting the next set of items. If there are no additional items to return, the string is empty.

**describe_vpc_endpoints (**)kwargs**

Describes one or more of your VPC endpoints.

**Request Syntax**

```
response = client.describe_vpc_endpoints(
    DryRun=True|False,
    VpcEndpointIds=['string',
                    ],
    Filters=[
        {'Name': 'string',
         'Values': ['string',
                    ]},
        ],
    MaxResults=123,
    NextToken='string'
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **VpcEndpointIds (list)** – One or more endpoint IDs.
  - *(string)* –
- **Filters (list)** – One or more filters.
  - **service-name**: The name of the AWS service.
  - **vpc-id**: The ID of the VPC in which the endpoint resides.
- `vpc-endpoint-id`: The ID of the endpoint.
- `vpc-endpoint-state`: The state of the endpoint. (pending | available | deleting | deleted)

- `(dict)` –

  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  * **Name** *(string)* –
    The name of the filter. Filter names are case-sensitive.
  * **Values** *(list)* –
    One or more filter values. Filter values are case-sensitive.
    · *(string)* –

- **MaxResults** *(integer)* – The maximum number of items to return for this request. The request returns a token that you can specify in a subsequent call to get the next set of results.
  
  Constraint: If the value is greater than 1000, we return only 1000 items.

- **NextToken** *(string)* – The token for the next set of items to return. (You received this token from a prior call.)

**Return type** `dict`

**Returns**

**Response Syntax**

```
{   'VpcEndpoints': [   {       'VpcEndpointId': 'string',       'VpcId': 'string',       'ServiceName': 'string',       'State': 'Pending'|'Available'|'Deleting'|'Deleted',       'PolicyDocument': 'string',       'RouteTableIds': [       'string',       ],       'CreationTimestamp': datetime(2015, 1, 1)   },   ],   'NextToken': 'string'
}
```

**Response Structure**

- `(dict)` –
  - **VpcEndpoints** *(list)* –
    Information about the endpoints.
    · `(dict)` –
      Describes a VPC endpoint.
      * **VpcEndpointId** *(string)* –
        The ID of the VPC endpoint.
      * **VpcId** *(string)* –
        The ID of the VPC to which the endpoint is associated.
- **ServiceName** *(string)* –
  The name of the AWS service to which the endpoint is associated.
- **State** *(string)* –
  The state of the VPC endpoint.
- **PolicyDocument** *(string)* –
  The policy document associated with the endpoint.
- **RouteTableIds** *(list)* –
  One or more route tables associated with the endpoint.
- **CreationTimestamp** *(datetime)* –
  The date and time the VPC endpoint was created.

- **NextToken** *(string)* –
  The token to use when requesting the next set of items. If there are no additional items to return, the string is empty.

**describe_vpc_peering_connections**(**kwargs**)
Describes one or more of your VPC peering connections.

**Request Syntax**

```python
response = client.describe_vpc_peering_connections(
    DryRun=True|False,
    VpcPeeringConnectionIds=['string'],
    Filters=[
        {'Name': 'string',
         'Values': ['string'],
        }],
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **VpcPeeringConnectionIds** *(list)* – One or more VPC peering connection IDs.

  Default: Describes all your VPC peering connections.

  - *(string)* –
  - **Filters** *(list)* – One or more filters.

    - **accepter-vpc-info.cidr-block** - The CIDR block of the peer VPC.
    - **accepter-vpc-info.owner-id** - The AWS account ID of the owner of the peer VPC.
    - **accepter-vpc-info.vpc-id** - The ID of the peer VPC.
    - **expiration-time** - The expiration date and time for the VPC peering connection.
- requester-vpc-info.cidr-block - The CIDR block of the requester’s VPC.
- requester-vpc-info.owner-id - The AWS account ID of the owner of the requester VPC.
- requester-vpc-info.vpc-id - The ID of the requester VPC.
- status-code - The status of the VPC peering connection (pending-acceptance | failed | expired | provisioning | active | deleted | rejected).
- status-message - A message that provides more information about the status of the VPC peering connection, if applicable.
- tag: *key*=*value* - The key/value combination of a tag assigned to the resource.
- tag-key - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag: *key*=*value* filter.
- tag-value - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- vpc-peering-connection-id - The ID of the VPC peering connection.

(dict) –
A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* Name (string) –
The name of the filter. Filter names are case-sensitive.

* Values (list) –
One or more filter values. Filter values are case-sensitive.

· (string) –

Response Syntax

```json
{
  'VpcPeeringConnections': [ 
    { 
      'AccepterVpcInfo': { 
        'CidrBlock': 'string',
        'OwnerId': 'string',
        'VpcId': 'string'
      },
      'ExpirationTime': datetime(2015, 1, 1),
      'RequesterVpcInfo': { 
        'CidrBlock': 'string',
        'OwnerId': 'string',
        'VpcId': 'string'
      },
      'Status': { 
        'Code': 'initiating-request'|'pending-acceptance'|'active'|'deleted',
        'Message': 'string'
      }
    }
  ]
}
```
Response Structure

- (dict) –
  - VpcPeeringConnections (list) –
    Information about the VPC peering connections.
      * (dict) –
        Describes a VPC peering connection.
          - AccepterVpcInfo (dict) –
            The information of the peer VPC.
          - CidrBlock (string) –
            The CIDR block for the VPC.
          - OwnerId (string) –
            The AWS account ID of the VPC owner.
          - VpcId (string) –
            The ID of the VPC.
          - ExpirationTime (datetime) –
            The time that an unaccepted VPC peering connection will expire.
          - RequesterVpcInfo (dict) –
            The information of the requester VPC.
          - CidrBlock (string) –
            The CIDR block for the VPC.
          - OwnerId (string) –
            The AWS account ID of the VPC owner.
          - VpcId (string) –
            The ID of the VPC.
          - Status (dict) –
            The status of the VPC peering connection.
          - Code (string) –
            The status of the VPC peering connection.
          - Message (string) –
            A message that provides more information about the status, if applicable.
          - Tags (list) –
            Any tags assigned to the resource.
          - (dict) –
Describes a tag.

- **Key (string)** –
  The key of the tag.

  Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`.

- **Value (string)** –
  The value of the tag.

  Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

- **VpcPeeringConnectionId (string)** –
  The ID of the VPC peering connection.

### `describe_vpcs(**kwargs)`

Describes one or more of your VPCs.

### Request Syntax

```python
response = client.describe_vpcs(
    DryRun=True|False,
    VpcIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ],
)
```

### Parameters

- **DryRun (bool)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **VpcIds (list)** – One or more VPC IDs.
  Default: Describes all your VPCs.

- **Filters (list)** – One or more filters.
  - **cidr** - The CIDR block of the VPC. The CIDR block you specify must exactly match the VPC’s CIDR block for information to be returned for the VPC. Must contain the slash followed by one or two digits (for example, `/28`).
  - **dhcp-options-id** - The ID of a set of DHCP options.
  - **isDefault** - Indicates whether the VPC is the default VPC.
  - **state** - The state of the VPC (pending|available).
  - **tag :key =*value* - The key/value combination of a tag assigned to the resource.
  - **tag-key** - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter
"tag-key=Purpose" and the filter "tag-value=X", you get any resources assigned both the tag key Purpose (regardless of what the tag's value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key=*

- tag-value - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- vpc-id - The ID of the VPC.
- (dict) –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* Name (string) –

The name of the filter. Filter names are case-sensitive.
* Values (list) –

One or more filter values. Filter values are case-sensitive.

· (string) –

Return type  dict

Returns

Response Syntax

```python
{
    'Vpcs': [
        {
            'VpcId': 'string',
            'State': 'pending'|'available',
            'CidrBlock': 'string',
            'DhcpOptionsId': 'string',
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                },
            ],
            'InstanceTenancy': 'default'|'dedicated',
            'IsDefault': True|False
        },
    ]
}
```

Response Structure

· (dict) –

- Vpcs (list) –

Information about one or more VPCs.

· (dict) –

Describes a VPC.

- VpcId (string) –

The ID of the VPC.

- State (string) –

The current state of the VPC.

- CidrBlock (string) –

1348 Chapter 3. API Reference
The CIDR block for the VPC.

- **DhcpOptionsId** *(string)* –
  The ID of the set of DHCP options you’ve associated with the VPC (or default if the default options are associated with the VPC).

- **Tags** *(list)* –
  Any tags assigned to the VPC.

- **InstanceTenancy** *(string)* –
  The allowed tenancy of instances launched into the VPC.

- **IsDefault** *(boolean)* –
  Indicates whether the VPC is the default VPC.

**describe_vpn_connections**(**kwargs)**

Describes one or more of your VPN connections.

For more information about VPN connections, see Adding a Hardware Virtual Private Gateway to Your VPC in the Amazon Virtual Private Cloud User Guide.

**Request Syntax**

```python
response = client.describe_vpn_connections(
    DryRun=True|False,
    VpnConnectionIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ]
        }
    ]
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **VpnConnectionIds** *(list)* – One or more VPN connection IDs.
  Default: Describes your VPN connections.
- `string` –
  - **Filters (list)** – One or more filters.
    - `customer-gateway-configuration` - The configuration information for the customer gateway.
    - `customer-gateway-id` - The ID of a customer gateway associated with the VPN connection.
    - `state` - The state of the VPN connection (pending | available | deleting | deleted).
    - `option.static-routes-only` - Indicates whether the connection has static routes only. Used for devices that do not support Border Gateway Protocol (BGP).
    - `route.destination-cidr-block` - The destination CIDR block. This corresponds to the subnet used in a customer data center.
    - `bgp-asn` - The BGP Autonomous System Number (ASN) associated with a BGP device.
    - `tag :key =*value*` - The key/value combination of a tag assigned to the resource.
    - `tag-key` - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag :key =*value*` filter.
    - `tag-value` - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
    - `type` - The type of VPN connection. Currently the only supported type is `ipsec.1`.
    - `vpn-connection-id` - The ID of the VPN connection.
    - `vpn-gateway-id` - The ID of a virtual private gateway associated with the VPN connection.

- `dict` –
  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  - **Name (string)** –
    The name of the filter. Filter names are case-sensitive.
  - **Values (list)** –
    One or more filter values. Filter values are case-sensitive.

Return type: `dict`

Returns

Response Syntax

```python
{
    'VpnConnections': [
        {
            'VpnConnectionId': 'string',
            'State': 'pending' | 'available' | 'deleting' | 'deleted',
            'CustomerGatewayConfiguration': 'string',
            'Type': 'ipsec.1',
            'CustomerGatewayId': 'string',
            'VpnGatewayId': 'string',
        }
    ]
}
```
'Tags': [
    {'Key': 'string',
     'Value': 'string'},
],
'VgwTelemetry': [
    {'OutsideIpAddress': 'string',
     'Status': 'UP'|'DOWN',
     'LastStatusChange': datetime(2015, 1, 1),
     'StatusMessage': 'string',
     'AcceptedRouteCount': 123
    },
],
'Options': {
    'StaticRoutesOnly': True|False
},
'Routes': [
    {'DestinationCidrBlock': 'string',
     'Source': 'Static',
     'State': 'pending'|'available'|'deleting'|'deleted'
    },
],
}

Response Structure

• (dict) –
  – VpnConnections (list) –

Information about one or more VPN connections.

• (dict) –

  Describes a VPN connection.

  • VpnConnectionId (string) –

    The ID of the VPN connection.

  • State (string) –

    The current state of the VPN connection.

  • CustomerGatewayConfiguration (string) –

    The configuration information for the VPN connection’s customer gateway (in the native XML format). This element is always present in the CreateVpnConnection response; however, it’s present in the DescribeVpnConnections response only if the VPN connection is in the pending or available state.

  • Type (string) –

    The type of VPN connection.

  • CustomerGatewayId (string) –

    The ID of the customer gateway at your end of the VPN connection.

  • VpnGatewayId (string) –
The ID of the virtual private gateway at the AWS side of the VPN connection.

- **Tags** (list) –
  Any tags assigned to the VPN connection.
    - (dict) –
      Describes a tag.
      - **Key** (string) –
        The key of the tag.
        Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`.
      - **Value** (string) –
        The value of the tag.
        Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

- **VgwTelemetry** (list) –
  Information about the VPN tunnel.
    - (dict) –
      Describes telemetry for a VPN tunnel.
      - **OutsideIpAddress** (string) –
        The Internet-routable IP address of the virtual private gateway’s outside interface.
      - **Status** (string) –
        The status of the VPN tunnel.
      - **LastStatusChange** (datetime) –
        The date and time of the last change in status.
      - **StatusMessage** (string) –
        If an error occurs, a description of the error.
      - **AcceptedRouteCount** (integer) –
        The number of accepted routes.
      - **Options** (dict) –
        The VPN connection options.
      - **StaticRoutesOnly** (boolean) –
        Indicates whether the VPN connection uses static routes only. Static routes must be used for devices that don’t support BGP.
      - **Routes** (list) –
        The static routes associated with the VPN connection.
          - (dict) –
            Describes a static route for a VPN connection.
            - **DestinationCidrBlock** (string) –
              The CIDR block associated with the local subnet of the customer data center.
            - **Source** (string) –
              Indicates how the routes were provided.
· **State** *(string)* –
  The current state of the static route.

**describe_vpn_gateways**(**kwargs**)
Describes one or more of your virtual private gateways.

For more information about virtual private gateways, see Adding an IPsec Hardware VPN to Your VPC in the Amazon Virtual Private Cloud User Guide.

**Request Syntax**

```python
def client.describe_vpn_gateways(DryRun=True|False,
                                VpnGatewayIds=[
                                    'string',
                                ],
                                Filters=[
                                    {'Name': 'string',
                                    'Values': [n
                                        'string',
                                    ]}
                                ]):
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **VpnGatewayIds** *(list)* – One or more virtual private gateway IDs.
  Default: Describes all your virtual private gateways.
  - *(string)* –
- **Filters** *(list)* – One or more filters.
  - attachment.state - The current state of the attachment between the gateway and the VPC *(attaching | attached | detaching | detached)*.
  - attachment.vpc-id - The ID of an attached VPC.
  - availability-zone - The Availability Zone for the virtual private gateway.
  - state - The state of the virtual private gateway *(pending | available | deleting | deleted)*.
  - tag: *key* =*value* - The key/value combination of a tag assigned to the resource.
  - tag-key - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag: *key* =*value*` filter.
  - tag-value - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
  - type - The type of virtual private gateway. Currently the only supported type is `ipsec.1`.
  - vpn-gateway-id - The ID of the virtual private gateway.
A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* **Name (string)** –
  The name of the filter. Filter names are case-sensitive.

* **Values (list)** –
  One or more filter values. Filter values are case-sensitive.

**Return type** `dict`

**Response Syntax**

```python
{
    'VpnGateways': [
        {
            'VpnGatewayId': 'string',
            'State': 'pending'|'available'|'deleting'|'deleted',
            'Type': 'ipsec.1',
            'AvailabilityZone': 'string',
            'VpcAttachments': [
                {
                    'VpcId': 'string',
                    'State': 'attaching'|'attached'|'detaching'|'detached'
                }
            ],
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                }
            ]
        }
    ]
}
```

**Response Structure**

* **(dict)** –
  * **VpnGateways (list)** –
    Information about one or more virtual private gateways.

  * **(dict)** –
    Describes a virtual private gateway.

    * **VpnGatewayId (string)** –
      The ID of the virtual private gateway.

    * **State (string)** –
      The current state of the virtual private gateway.

    * **Type (string)** –
      The type of VPN connection the virtual private gateway supports.

    * **AvailabilityZone (string)** –
The Availability Zone where the virtual private gateway was created.

- **VpcAttachments (list)** –
  Any VPCs attached to the virtual private gateway.

- **(dict)** –
  Describes an attachment between a virtual private gateway and a VPC.

- **VpcId (string)** –
  The ID of the VPC.

- **State (string)** –
  The current state of the attachment.

- **Tags (list)** –
  Any tags assigned to the virtual private gateway.

- **(dict)** –
  Describes a tag.

- **Key (string)** –
  The key of the tag.

  Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws`.

- **Value (string)** –
  The value of the tag.

  Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

detach_classic_link_vpc(**kwargs)

Unlinks (detaches) a linked EC2-Classic instance from a VPC. After the instance has been unlinked, the VPC security groups are no longer associated with it. An instance is automatically unlinked from a VPC when it’s stopped.

**Request Syntax**

```python
response = client.detach_classic_link_vpc(
    DryRun=True|False,
   InstanceId='string',
    VpcId='string'
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **InstanceId (string)** – [REQUIRED]
  The ID of the instance to unlink from the VPC.

- **VpcId (string)** – [REQUIRED]
  The ID of the VPC to which the instance is linked.

**Return type**  dict

**Returns**

**Response Syntax**
detach_internet_gateway(**kwargs)
Detaches an Internet gateway from a VPC, disabling connectivity between the Internet and the VPC. The VPC must not contain any running instances with Elastic IP addresses.

Request Syntax

```
response = client.detach_internet_gateway(
    DryRun=True|False,
    InternetGatewayId='string',
    VpcId='string'
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **InternetGatewayId** *(string)* – [REQUIRED]
The ID of the Internet gateway.
- **VpcId** *(string)* – [REQUIRED]
The ID of the VPC.

Returns None

detach_network_interface(**kwargs)
Detaches a network interface from an instance.

Request Syntax

```
response = client.detach_network_interface(
    DryRun=True|False,
    AttachmentId='string',
    Force=True|False
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **AttachmentId** *(string)* – [REQUIRED]
The ID of the attachment.
- **Force** *(boolean)* – Specifies whether to force a detachment.

Returns None

detach_volume(**kwargs)
Detaches an EBS volume from an instance. Make sure to unmount any file systems on the device within
your operating system before detaching the volume. Failure to do so results in the volume being stuck in a busy state while detaching.

If an Amazon EBS volume is the root device of an instance, it can’t be detached while the instance is running. To detach the root volume, stop the instance first.

When a volume with an AWS Marketplace product code is detached from an instance, the product code is no longer associated with the instance.

For more information, see Detaching an Amazon EBS Volume in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = client.detach_volume(
    DryRun=True|False,
    VolumeId='string',
    InstanceId='string',
    Device='string',
    Force=True|False
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **VolumeId** *(string)* – [REQUIRED] The ID of the volume.
- **InstanceId** *(string)* – The ID of the instance.
- **Device** *(string)* – The device name.
- **Force** *(boolean)* – Forces detachment if the previous detachment attempt did not occur cleanly (for example, logging into an instance, unmounting the volume, and detaching normally). This option can lead to data loss or a corrupted file system. Use this option only as a last resort to detach a volume from a failed instance. The instance won’t have an opportunity to flush file system caches or file system metadata. If you use this option, you must perform file system check and repair procedures.

Return type: dict

Returns

Response Syntax

```python
{
    'VolumeId': 'string',
    'InstanceId': 'string',
    'Device': 'string',
    'State': 'attaching'|'attached'|'detaching'|'detached',
    'AttachTime': datetime(2015, 1, 1),
    'DeleteOnTermination': True|False
}
```

Response Structure

- *(dict)* – Information about the volume attachment.
– **VolumeId** *(string)* –
  The ID of the volume.
– **InstanceId** *(string)* –
  The ID of the instance.
– **Device** *(string)* –
  The device name.
– **State** *(string)* –
  The attachment state of the volume.
– **AttachTime** *(datetime)* –
  The time stamp when the attachment initiated.
– **DeleteOnTermination** *(boolean)* –
  Indicates whether the EBS volume is deleted on instance termination.

**detach_vpn_gateway** (**kwargs**)
Detaches a virtual private gateway from a VPC. You do this if you’re planning to turn off the VPC and not use it anymore. You can confirm a virtual private gateway has been completely detached from a VPC by describing the virtual private gateway (any attachments to the virtual private gateway are also described).

You must wait for the attachment’s state to switch to detached before you can delete the VPC or attach a different VPC to the virtual private gateway.

**Request Syntax**

```python
response = client.detach_vpn_gateway(
    DryRun=True|False,
    VpnGatewayId='string',
    VpcId='string'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **VpnGatewayId** *(string)* – [REQUIRED]
  The ID of the virtual private gateway.
- **VpcId** *(string)* – [REQUIRED]
  The ID of the VPC.

**Returns** None

**disable_vgw_route_propagation** (**kwargs**)
Disables a virtual private gateway (VGW) from propagating routes to a specified route table of a VPC.

**Request Syntax**

```python
response = client.disable_vgw_route_propagation(
    RouteTableId='string',
    GatewayId='string'
)
```

**Parameters**

- **RouteTableId** *(string)* – [REQUIRED]
  The ID of the route table.
• **GatewayId** *(string)* – [REQUIRED]

The ID of the virtual private gateway.

Returns None

disable_vpc_classic_link(**kwargs)

Disables ClassicLink for a VPC. You cannot disable ClassicLink for a VPC that has EC2-Classic instances linked to it.

Request Syntax

```python
response = client.disable_vpc_classic_link(
    DryRun=True|False,
    VpcId='string'
)
```

Parameters

• **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

• **VpcId** *(string)* – [REQUIRED]

The ID of the VPC.

Return type dict

Returns

Response Syntax

```python
{
    'Return': True|False
}
```

Response Structure

• *(dict)* –

  – **Return** *(boolean)* –

    Returns true if the request succeeds; otherwise, it returns an error.

disassociate_address(**kwargs)

Disassociates an Elastic IP address from the instance or network interface it’s associated with.

An Elastic IP address is for use in either the EC2-Classic platform or in a VPC. For more information, see Elastic IP Addresses in the Amazon Elastic Compute Cloud User Guide.

This is an idempotent operation. If you perform the operation more than once, Amazon EC2 doesn’t return an error.

Request Syntax

```python
response = client.disassociate_address(
    DryRun=True|False,
    PublicIp='string',
    AssociationId='string'
)
```

Parameters

• **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If
you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **AssociationId (string)** – [EC2-VPC] The association ID. Required for EC2-VPC.

**Returns** None

disassociate_route_table(**kwargs)**

Disassociates a subnet from a route table.

After you perform this action, the subnet no longer uses the routes in the route table. Instead, it uses the routes in the VPC's main route table. For more information about route tables, see Route Tables in the Amazon Virtual Private Cloud User Guide.

**Request Syntax**

```python
response = client.disassociate_route_table(
    DryRun=True|False,
    AssociationId='string'
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **AssociationId (string)** – [REQUIRED] The association ID representing the current association between the route table and subnet.

**Returns** None

enable_vgw_route_propagation(**kwargs)**

Enables a virtual private gateway (VGW) to propagate routes to the specified route table of a VPC.

**Request Syntax**

```python
response = client.enable_vgw_route_propagation(
    RouteTableId='string',
    GatewayId='string'
)
```

**Parameters**

- **RouteTableId (string)** – [REQUIRED] The ID of the route table.
- **GatewayId (string)** – [REQUIRED] The ID of the virtual private gateway.

**Returns** None

enable_volume_io(**kwargs)**

Enables I/O operations for a volume that had I/O operations disabled because the data on the volume was potentially inconsistent.

**Request Syntax**
response = client.enable_volume_io(
    DryRun=True|False,
    VolumeId='string'
)

Parameters
- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **VolumeId** (string) – [REQUIRED]
The ID of the volume.

Returns None

def enable_vpc_classic_link(**kwargs)
    Enables a VPC for ClassicLink. You can then link EC2-Classic instances to your ClassicLink-enabled VPC to allow communication over private IP addresses. You cannot enable your VPC for ClassicLink if any of your VPC’s route tables have existing routes for address ranges within the 10.0.0.0/8 IP address range, excluding local routes for VPCs in the 10.0.0.0/16 and 10.1.0.0/16 IP address ranges. For more information, see ClassicLink in the Amazon Elastic Compute Cloud User Guide.

Request Syntax
response = client.enable_vpc_classic_link(
    DryRun=True|False,
    VpcId='string'
)

Parameters
- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **VpcId** (string) – [REQUIRED]
The ID of the VPC.

Return type dict

Returns

Response Syntax

```python
{
    'Return': True|False
}
```

Response Structure
- *(dict)* –
  - **Return** (boolean) – Returns true if the request succeeds; otherwise, it returns an error.

def generate_presigned_url(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)
    Generate a presigned url given a client, its method, and arguments

Parameters
- **ClientMethod** (string) – The client method to presign for
- **Params** (dict) – The parameters normally passed to ClientMethod.
• **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
• **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

**Returns**
The presigned url

**get_console_output(**kwargs)**

Gets the console output for the specified instance.

Instances do not have a physical monitor through which you can view their console output. They also lack physical controls that allow you to power up, reboot, or shut them down. To allow these actions, we provide them through the Amazon EC2 API and command line interface.

Instance console output is buffered and posted shortly after instance boot, reboot, and termination. Amazon EC2 preserves the most recent 64 KB output which is available for at least one hour after the most recent post.

For Linux instances, the instance console output displays the exact console output that would normally be displayed on a physical monitor attached to a computer. This output is buffered because the instance produces it and then posts it to a store where the instance’s owner can retrieve it.

For Windows instances, the instance console output includes output from the EC2Config service.

**Request Syntax**

```python
response = client.get_console_output(
    DryRun=True|False,
    InstanceId='string'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **InstanceId** *(string)* – [REQUIRED]
The ID of the instance.

**Return type**
dict

**Returns**

**Response Syntax**

```python
{
    'InstanceId': 'string',
    'Timestamp': datetime(2015, 1, 1),
    'Output': 'string'
}
```

**Response Structure**

- *(dict)* –
  - **InstanceId** *(string)* –
    The ID of the instance.
  - **Timestamp** *(datetime)* –
    The time the output was last updated.
  - **Output** *(string)* –
    The console output, Base64 encoded.
**get Paginator (operation_name)**

Create a paginator for an operation.

Parameters operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you'd normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.getPaginator("create_foo").

Raises OperationNotPageableError Raised if the operation is not pageable. You can use the client.can_paginate method to check if an operation is pageable.

Return type L{botocore.paginate.Paginator}

Returns A paginator object.

**get_password_data (***kwargs)**

Retrieves the encrypted administrator password for an instance running Windows.

The Windows password is generated at boot if the EC2Config service plugin, Ec2SetPassword, is enabled. This usually only happens the first time an AMI is launched, and then Ec2SetPassword is automatically disabled. The password is not generated for rebundled AMIs unless Ec2SetPassword is enabled before bundling.

The password is encrypted using the key pair that you specified when you launched the instance. You must provide the corresponding key pair file.

Password generation and encryption takes a few moments. We recommend that you wait up to 15 minutes after launching an instance before trying to retrieve the generated password.

Request Syntax

```
response = client.get_password_data(
    DryRun=True|False,
    InstanceId='string'
)
```

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **InstanceId (string) – [REQUIRED]**

The ID of the Windows instance.

Return type dict

Returns

Response Syntax

```
{
    'InstanceId': 'string',
    'Timestamp': datetime(2015, 1, 1),
    'PasswordData': 'string'
}
```

Response Structure

- (dict) –
  - **InstanceId (string) –**

    The ID of the Windows instance.
– **Timestamp** *(datetime)* –
The time the data was last updated.
– **PasswordData** *(string)* –
The password of the instance.

`get_waiter(waiter_name)`

`import_image(**kwargs)`
Import single or multi-volume disk images or EBS snapshots into an Amazon Machine Image (AMI).

**Request Syntax**

```python
response = client.import_image(
    DryRun=True|False,
    Description='string',
    DiskContainers=[
        {
            'Description': 'string',
            'Format': 'string',
            'Url': 'string',
            'UserBucket': {
                'S3Bucket': 'string',
                'S3Key': 'string'
            },
            'DeviceName': 'string',
            'SnapshotId': 'string'
        },
    ],
    LicenseType='string',
    Hypervisor='string',
    Architecture='string',
    Platform='string',
    ClientData={
        'UploadStart': datetime(2015, 1, 1),
        'UploadEnd': datetime(2015, 1, 1),
        'UploadSize': 123.0,
        'Comment': 'string'
    },
    ClientToken='string',
    RoleName='string'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **Description** *(string)* – A description string for the import image task.
- **DiskContainers** *(list)* – Information about the disk containers.
  - *(dict)* –
    Describes the disk container object for an import image task.
    - **Description** *(string)* –
      The description of the disk image.
    - **Format** *(string)* –
      The format of the disk image being imported.
Valid values: RAW | VHD | VMDK | OVA
* `Url (string)` –
  The URL to the Amazon S3-based disk image being imported. The URL can either be a https URL (https://..) or an Amazon S3 URL (s3://..)
* `UserBucket (dict)` –
  The S3 bucket for the disk image.
   · `S3Bucket (string)` –
     The name of the S3 bucket where the disk image is located.
   · `S3Key (string)` –
     The key for the disk image.
* `DeviceName (string)` –
  The block device mapping for the disk.
* `SnapshotId (string)` –
  The ID of the EBS snapshot to be used for importing the snapshot.

  • `LicenseType (string)` – The license type to be used for the Amazon Machine Image (AMI) after importing.
    
    **Note:** You may only use BYOL if you have existing licenses with rights to use these licenses in a third party cloud like AWS. For more information, see VM Import/Export Prerequisites in the Amazon Elastic Compute Cloud User Guide.
    
    Valid values: AWS | BYOL
  • `Hypervisor (string)` – The target hypervisor platform.
    
    Valid values: xen
  • `Architecture (string)` – The architecture of the virtual machine.
    
    Valid values: i386 | x86_64
  • `Platform (string)` – The operating system of the virtual machine.
    
    Valid values: Windows | Linux
  • `ClientData (dict)` – The client-specific data.
    
    – `UploadStart (datetime)` –
      The time that the disk upload starts.
    – `UploadEnd (datetime)` –
      The time that the disk upload ends.
    – `UploadSize (float)` –
      The size of the uploaded disk image, in GiB.
    – `Comment (string)` –
      A user-defined comment about the disk upload.
  • `ClientToken (string)` – The token to enable idempotency for VM import requests.
  • `RoleName (string)` – The name of the role to use when not using the default role, ‘vmimport’.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'ImportTaskId': 'string',
    'Architecture': 'string',
    'LicenseType': 'string',
    'Platform': 'string',
    'Hypervisor': 'string',
    'Description': 'string',
    'SnapshotDetails': [
        {
            'DiskImageSize': 123.0,
            'Description': 'string',
            'Format': 'string',
            'Url': 'string',
            'UserBucket': {
                'S3Bucket': 'string',
                'S3Key': 'string'
            },
            'DeviceName': 'string',
            'SnapshotId': 'string',
            'Progress': 'string',
            'StatusMessage': 'string',
            'Status': 'string'
        },
        {
            'DiskImageSize': 123.0,
            'Description': 'string',
            'Format': 'string',
            'Url': 'string',
            'UserBucket': {
                'S3Bucket': 'string',
                'S3Key': 'string'
            },
            'DeviceName': 'string',
            'SnapshotId': 'string',
            'Progress': 'string',
            'StatusMessage': 'string',
            'Status': 'string'
        }
    ],
    'ImageId': 'string',
    'Progress': 'string',
    'StatusMessage': 'string',
    'Status': 'string'
}
```

Response Structure

- **(dict)** –
  - **ImportTaskId (string)** –
    The task ID of the import image task.
  - **Architecture (string)** –
    The architecture of the virtual machine.
  - **LicenseType (string)** –
    The license type of the virtual machine.
  - **Platform (string)** –
    The operating system of the virtual machine.
  - **Hypervisor (string)** –
    The target hypervisor of the import task.
  - **Description (string)** –
    A description of the import task.
  - **SnapshotDetails (list)** –
    Information about the snapshots.
      - **(dict)** –
        Describes the snapshot created from the imported disk.
          - **DiskImageSize (float)** –
            The size of the disk in the snapshot, in GiB.
          - **Description (string)** –
            ...
import_instance(**kwargs)

Creates an import instance task using metadata from the specified disk image. ImportInstance only supports single-volume VMs. To import multi-volume VMs, use ImportImage. After importing the image, you then upload it using the ec2-import-volume command in the EC2 command line tools. For more information, see Using the Command Line Tools to Import Your Virtual Machine to Amazon EC2 in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

response = client.import_instance(
    DryRun=True|False,
    Description='string',
    LaunchSpecification={
        'Architecture': 'i386'|'x86_64',
        'GroupNames': [ 'string'],
    },
)
'GroupIds': [
    'string',
],
'AdditionalInfo': 'string',
'UserData': {
    'Data': 'string'
},
'InstanceType': 't1.micro'|'m1.small'|'m1.medium'|'m1.large'|'m1.xlarge'|'m3.medium',
'Placement': {
    'AvailabilityZone': 'string',
    'GroupName': 'string',
    'Tenancy': 'default'|'dedicated'
},
'Monitoring': True|False,
'SubnetId': 'string',
'InstanceInitiatedShutdownBehavior': 'stop'|'terminate',
'PrivateIpAddress': 'string'
},
DiskImages=[
    {
        'Image': {
            'Format': 'VMDK'|'RAW'|'VHD',
            'Bytes': 123,
            'ImportManifestUrl': 'string'
        },
        'Description': 'string',
        'Volume': {
            'Size': 123
        }
    },
],
Platform='Windows'

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **Description** *(string)* – A description for the instance being imported.
- **LaunchSpecification** *(dict)* – The launch specification.
  - **Architecture** *(string)* –
    The architecture of the instance.
  - **GroupNames** *(list)* –
    One or more security group names.
    * *(string)* –
  - **GroupIds** *(list)* –
    One or more security group IDs.
    * *(string)* –
  - **AdditionalInfo** *(string)* –
    Reserved.
  - **UserData** *(dict)* –
    The Base64-encoded MIME user data to be made available to the instance.
    * **Data** *(string)* –
The Base64-encoded MIME user data for the instance.

- **InstanceType** *(string)* –
  The instance type. For more information about the instance types that you can import, see Before You Get Started in the Amazon Elastic Compute Cloud User Guide.

- **Placement** *(dict)* –
  The placement information for the instance.
  * **AvailabilityZone** *(string)* –
    The Availability Zone of the instance.
  * **GroupName** *(string)* –
    The name of the placement group the instance is in (for cluster compute instances).
  * **Tenancy** *(string)* –
    The tenancy of the instance (if the instance is running in a VPC). An instance with a tenancy of dedicated runs on single-tenant hardware.

- **Monitoring** *(boolean)* –
  Indicates whether monitoring is enabled.

- **SubnetId** *(string)* –
  [EC2-VPC] The ID of the subnet in which to launch the instance.

- **InstanceInitiatedShutdownBehavior** *(string)* –
  Indicates whether an instance stops or terminates when you initiate shutdown from the instance (using the operating system command for system shutdown).

- **PrivateIpAddress** *(string)* –
  [EC2-VPC] An available IP address from the IP address range of the subnet.

- **DiskImages** *(list)* – The disk image.
  - *(dict)* –
    Describes a disk image.
    * **Image** *(dict)* –
      Information about the disk image.
      * **Format** *(string)* – [REQUIRED]
        The disk image format.
      * **Bytes** *(integer)* – [REQUIRED]
        The size of the disk image, in GiB.
      * **ImportManifestUrl** *(string)* – [REQUIRED]
        A presigned URL for the import manifest stored in Amazon S3 and presented here as an Amazon S3 presigned URL. For information about creating a presigned URL for an Amazon S3 object, read the “Query String Request Authentication Alternative” section of the Authenticating REST Requests topic in the Amazon Simple Storage Service Developer Guide.
    * **Description** *(string)* –
      A description of the disk image.
Volume (dict) –

Information about the volume.

* Size (integer) – [REQUIRED]

The size of the volume, in GiB.

* Platform (string) – [REQUIRED]

The instance operating system.

Returns
dict

Response Syntax

```json
{
    'ConversionTask': {
        'ConversionTaskId': 'string',
        'ExpirationTime': 'string',

    'StatusMessage': 'string'
}
```
Response Structure

- **(dict)** –
  - **ConversionTask (dict)** –

  Information about the conversion task.
  - **ConversionTaskId (string)** –
    The ID of the conversion task.
  - **ExpirationTime (string)** –
    The time when the task expires. If the upload isn’t complete before the expiration time, we automatically cancel the task.
  - **ImportInstance (dict)** –
    If the task is for importing an instance, this contains information about the import instance task.
    - **Volumes (list)** –
      One or more volumes.
    - **(dict)** –
      Describes an import volume task.
        - **BytesConverted (integer)** –
          The number of bytes converted so far.
        - **AvailabilityZone (string)** –
          The Availability Zone where the resulting instance will reside.
        - **Image (dict)** –
          The image.
        - **Format (string)** –
          The disk image format.
        - **Size (integer)** –
          The size of the disk image, in GiB.
        - **ImportManifestUrl (string)** –
          A presigned URL for the import manifest stored in Amazon S3. For information about creating a presigned URL for an Amazon S3 object, read the “Query String Request Authentication Alternative” section of the Authenticating REST Requests topic in the Amazon Simple Storage Service Developer Guide.
        - **Checksum (string)** –
          The checksum computed for the disk image.
    - **Volume (dict)** –
      The volume.
**ImportVolume (dict)**

If the task is for importing a volume, this contains information about the import volume task.

- **BytesConverted (integer)** –
  The number of bytes converted so far.
- **AvailabilityZone (string)** –
  The Availability Zone where the resulting volume will reside.
- **Description (string)** –
  The description you provided when starting the import volume task.
- **Image (dict)** –
  The image.
- **Format (string)** –
  The disk image format.
- **Size (integer)** –
  The size of the disk image, in GiB.
- **ImportManifestUrl (string)** –
  A presigned URL for the import manifest stored in Amazon S3. For information about creating a presigned URL for an Amazon S3 object, read the “Query String Request Authentication Alternative” section of the Authenticating REST Requests topic in the Amazon Simple Storage Service Developer Guide.
- **Checksum (string)** –
  The checksum computed for the disk image.
- **Volume (dict)** –
  The volume.

- **Size (integer)** –
  The size of the volume, in GiB.
- **Id (string)** –
  The volume identifier.
- **Status (string)** –
  The status of the import of this particular disk image.
- **StatusMessage (string)** –
  The status information or errors related to the disk image.
- **Description (string)** –
  A description of the task.
- **InstanceId (string)** –
  The ID of the instance.
- **Platform (string)** –
  The instance operating system.
- **Description (string)** –
  A description of the task.
· **Size** *(integer)* –
  The size of the volume, in GiB.

· **Id** *(string)* –
  The volume identifier.

* **State** *(string)* –
  The state of the conversion task.

* **StatusMessage** *(string)* –
  The status message related to the conversion task.

* **Tags** *(list)* –
  Any tags assigned to the task.

  · *(dict)* –
    Describes a tag.

    · **Key** *(string)* –
      The key of the tag.

      Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`.

    · **Value** *(string)* –
      The value of the tag.

      Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

**import_key_pair(**kwargs**)**

Imports the public key from an RSA key pair that you created with a third-party tool. Compare this with `CreateKeyPair`, in which AWS creates the key pair and gives the keys to you (AWS keeps a copy of the public key). With `ImportKeyPair`, you create the key pair and give AWS just the public key. The private key is never transferred between you and AWS.

For more information about key pairs, see Key Pairs in the [Amazon Elastic Compute Cloud User Guide](https://docs.aws.amazon.com/AmazonECS/latest/userguide/).  

**Request Syntax**

```python
response = client.import_key_pair(
    DryRun=True|False,
    KeyName='string',
    PublicKeyMaterial=b'bytes'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **KeyName** *(string)* – [REQUIRED]
  A unique name for the key pair.

- **PublicKeyMaterial** *(bytes)* – [REQUIRED]
  The public key. You must base64 encode the public key material before sending it to AWS.

**Return type** `dict`
Returns

Response Syntax

```
{
    'KeyName': 'string',
    'KeyFingerprint': 'string'
}
```

Response Structure

- (dict) –
  - **KeyName** (string) –
    The key pair name you provided.
  - **KeyFingerprint** (string) –
    The MD5 public key fingerprint as specified in section 4 of RFC 4716.

**import_snapshot(**kwargs)**

Imports a disk into an EBS snapshot.

Request Syntax

```python
response = client.import_snapshot(
    DryRun=True|False,
    Description='string',
    DiskContainer={
        'Description': 'string',
        'Format': 'string',
        'Url': 'string',
        'UserBucket': {
            'S3Bucket': 'string',
            'S3Key': 'string'
        }
    },
    ClientData={
        'UploadStart': datetime(2015, 1, 1),
        'UploadEnd': datetime(2015, 1, 1),
        'UploadSize': 123.0,
        'Comment': 'string'
    },
    ClientToken='string',
    RoleName='string'
)
```

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **Description** (string) – The description string for the import snapshot task.
- **DiskContainer** (dict) – Information about the disk container.
  - **Description** (string) –
    The description of the disk image being imported.
  - **Format** (string) –
    The format of the disk image being imported.

Valid values: RAW | VHD | VMDK | OVA
– **Url (string)** –
  The URL to the Amazon S3-based disk image being imported. It can either be a https URL (https://..) or an Amazon S3 URL (s3://..).

– **UserBucket (dict)** –
  Describes the S3 bucket for the disk image.
  * **S3Bucket (string)** –
    The name of the S3 bucket where the disk image is located.
  * **S3Key (string)** –
    The key for the disk image.

• **ClientData (dict)** – The client-specific data.
  – **UploadStart (datetime)** –
    The time that the disk upload starts.
  – **UploadEnd (datetime)** –
    The time that the disk upload ends.
  – **UploadSize (float)** –
    The size of the uploaded disk image, in GiB.
  – **Comment (string)** –
    A user-defined comment about the disk upload.

• **ClientToken (string)** – Token to enable idempotency for VM import requests.

• **RoleName (string)** – The name of the role to use when not using the default role, 'vmimport'.

**Return type**  
dict

**Returns**

**Response Syntax**

```
{
    'ImportTaskId': 'string',
    'SnapshotTaskDetail': {
        'DiskImageSize': 123.0,
        'Description': 'string',
        'Format': 'string',
        'Url': 'string',
        'UserBucket': {
            'S3Bucket': 'string',
            'S3Key': 'string'
        },
        'SnapshotId': 'string',
        'Progress': 'string',
        'StatusMessage': 'string',
        'Status': 'string'
    },
    'Description': 'string'
}
```

**Response Structure**

• (dict) –
  – **ImportTaskId (string)** –
    The ID of the import snapshot task.
  – **SnapshotTaskDetail (dict)** –
    Information about the import snapshot task.
* DiskImageSize (float) –
  The size of the disk in the snapshot, in GiB.
* Description (string) –
  The description of the snapshot.
* Format (string) –
  The format of the disk image from which the snapshot is created.
* Url (string) –
  The URL of the disk image from which the snapshot is created.
* UserBucket (dict) –
  The S3 bucket for the disk image.
  - S3Bucket (string) –
    The S3 bucket from which the disk image was created.
  - S3Key (string) –
    The key from which the disk image was created.
* SnapshotId (string) –
  The snapshot ID of the disk being imported.
* Progress (string) –
  The percentage of completion for the import snapshot task.
* StatusMessage (string) –
  A detailed status message for the import snapshot task.
* Status (string) –
  A brief status for the import snapshot task.
  - Description (string) –
    A description of the import snapshot task.

import_volume(**kwargs)

Creates an import volume task using metadata from the specified disk image. After importing the image, you then upload it using the ec2-import-volume command in the Amazon EC2 command-line interface (CLI) tools. For more information, see Using the Command Line Tools to Import Your Virtual Machine to Amazon EC2 in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = client.import_volume(
    DryRun=True|False,
    AvailabilityZone='string',
    Image={
        'Format': 'VMDK'|'RAW'|'VHD',
        'Bytes': 123,
        'ImportManifestUrl': 'string'
    },
    Description='string',
    Volume={
        'Size': 123
    }
)
```

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If
you have the required permissions, the error response is \texttt{DryRunOperation}.
Otherwise, it is \texttt{UnauthorizedOperation}.

- **AvailabilityZone** \texttt{(string)} – [REQUIRED]

  The Availability Zone for the resulting EBS volume.

- **Image** \texttt{(dict)} – [REQUIRED]

  The disk image.
  - **Format** \texttt{(string)} – [REQUIRED]
    
    The disk image format.
  - **Bytes** \texttt{(integer)} – [REQUIRED]
    
    The size of the disk image, in GiB.
  - **ImportManifestUrl** \texttt{(string)} – [REQUIRED]
    
    A presigned URL for the import manifest stored in Amazon S3 and presented here as an Amazon S3 presigned URL. For information about creating a presigned URL for an Amazon S3 object, read the “Query String Request Authentication Alternative” section of the Authenticating REST Requests topic in the Amazon Simple Storage Service Developer Guide.

- **Description** \texttt{(string)} – A description of the volume.

- **Volume** \texttt{(dict)} – [REQUIRED]

  The volume size.
  - **Size** \texttt{(integer)} – [REQUIRED]
    
    The size of the volume, in GiB.

Return type \texttt{dict}

Returns

Response Syntax

```python
{
    'ConversionTask': {
        'ConversionTaskId': 'string',
        'ExpirationTime': 'string',
        'ImportInstance': {
            'Volumes': [
                {
                    'BytesConverted': 123,
                    'AvailabilityZone': 'string',
                    'Image': {
                        'Format': 'VMDK'|'RAW'|'VHD',
                        'Size': 123,
                        'ImportManifestUrl': 'string',
                        'Checksum': 'string'
                    },
                    'Volume': {
                        'Size': 123,

Response Structure

- (dict) –
  - ConversionTask (dict) –
    Information about the conversion task.
      - ConversionTaskId (string) –
        The ID of the conversion task.
      - ExpirationTime (string) –
        The time when the task expires. If the upload isn’t complete before the expiration time, we automatically cancel the task.
      - ImportInstance (dict) –
        If the task is for importing an instance, this contains information about the import instance task.
          - Volumes (list) –
            One or more volumes.
          - (dict) –
            Describes an import volume task.
              - BytesConverted (integer) –
                The number of bytes converted so far.
              - AvailabilityZone (string) –
                The Availability Zone where the resulting instance will reside.
              - Image (dict) –
                The image.
              - Format (string) –
                The disk image format.
· Size (integer) –
  The size of the disk image, in GiB.
· ImportManifestUrl (string) –
  A presigned URL for the import manifest stored in Amazon S3. For information about creating a presigned URL for an Amazon S3 object, read the “Query String Request Authentication Alternative” section of the Authenticating REST Requests topic in the Amazon Simple Storage Service Developer Guide.
· Checksum (string) –
  The checksum computed for the disk image.
· Volume (dict) –
  The volume.
  · Size (integer) –
    The size of the volume, in GiB.
  · Id (string) –
    The volume identifier.
  · Status (string) –
    The status of the import of this particular disk image.
  · StatusMessage (string) –
    The status information or errors related to the disk image.
  · Description (string) –
    A description of the task.
  · InstanceId (string) –
    The ID of the instance.
  · Platform (string) –
    The instance operating system.
  · Description (string) –
    A description of the task.
· ImportVolume (dict) –
  If the task is for importing a volume, this contains information about the import volume task.
  · BytesConverted (integer) –
    The number of bytes converted so far.
  · AvailabilityZone (string) –
    The Availability Zone where the resulting volume will reside.
  · Description (string) –
    The description you provided when starting the import volume task.
· Image (dict) –
  The image.
  · Format (string) –
    The disk image format.
· **Size (integer)** –
  The size of the disk image, in GiB.

· **ImportManifestUrl (string)** –
  A presigned URL for the import manifest stored in Amazon S3. For information about creating a presigned URL for an Amazon S3 object, read the “Query String Request Authentication Alternative” section of the Authenticating REST Requests topic in the Amazon Simple Storage Service Developer Guide.

· **Checksum (string)** –
  The checksum computed for the disk image.

· **Volume (dict)** –
  The volume.
  · **Size (integer)** –
    The size of the volume, in GiB.
  · **Id (string)** –
    The volume identifier.

  · **State (string)** –
    The state of the conversion task.

· **StatusMessage (string)** –
  The status message related to the conversion task.

· **Tags (list)** –
  Any tags assigned to the task.
  · (dict) –
    Describes a tag.
  · **Key (string)** –
    The key of the tag.
    Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with aws:
  · **Value (string)** –
    The value of the tag.
    Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

modify_image_attribute(**kwargs)
  Modifies the specified attribute of the specified AMI. You can specify only one attribute at a time.

**Note:** AWS Marketplace product codes cannot be modified. Images with an AWS Marketplace product code cannot be made public.

**Request Syntax**

```python
response = client.modify_image_attribute(
    DryRun=True|False,
    ImageId='string',
    Attribute='string',
    OperationType='add'|'remove',
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **ImageId** *(string)* – [REQUIRED]
  The ID of the AMI.
- **Attribute** *(string)* – The name of the attribute to modify.
- **OperationType** *(string)* – The operation type.
- **UserIds** *(list)* – One or more AWS account IDs. This is only valid when modifying the launchPermission attribute.
  - *(string)* –
- **UserGroups** *(list)* – One or more user groups. This is only valid when modifying the launchPermission attribute.
  - *(string)* –
- **ProductCodes** *(list)* – One or more product codes. After you add a product code to an AMI, it can’t be removed. This is only valid when modifying the productCodes attribute.
  - *(string)* –
- **Value** *(string)* – The value of the attribute being modified. This is only valid when modifying the description attribute.
- **LaunchPermission** *(dict)* – A launch permission modification.
  - **Add** *(list)* –
    The AWS account ID to add to the list of launch permissions for the AMI.
  - *(dict)* –
Describes a launch permission.
- **UserId** *(string)* –
  The AWS account ID.
- **Group** *(string)* –
  The name of the group.
- **Remove** *(list)* –
  The AWS account ID to remove from the list of launch permissions for the AMI.

* *(dict)* –
Describes a launch permission.
- **UserId** *(string)* –
  The AWS account ID.
- **Group** *(string)* –
  The name of the group.
- **Description** *(dict)* – A description for the AMI.
  - **Value** *(string)* –
    Valid values are case-sensitive and vary by action.

Returns None

modify_instance_attribute(**kwargs)
Modifies the specified attribute of the specified instance. You can specify only one attribute at a time.

To modify some attributes, the instance must be stopped. For more information, see Modifying Attributes of a Stopped Instance in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = client.modify_instance_attribute(
    DryRun=True|False,
    InstanceId='string',
    Attribute='instanceType'|'kernel'|'ramdisk'|'userData'|'disableApiTermination'|'instanceInitiatedShutdownBehavior'|'rootDeviceName'|'blockDeviceMapping'|'productCodes'|'sourceDestCheck'|'groupSet'|'ebsOptimized'|'sriovNetSupport',
    Value='string',
    BlockDeviceMappings=[
        {
            'DeviceName': 'string',
            'Ebs': {
                'VolumeId': 'string',
                'DeleteOnTermination': True|False
            },
            'VirtualName': 'string',
            'NoDevice': 'string'
        },
    ],
    SourceDestCheck={
        'Value': True|False
    },
    DisableApiTermination={
        'Value': True|False
    },
    InstanceType={
        'Value': 'string'
    },
    Kernel={
        'Value': 'string'
    }
)```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **InstanceId** *(string)* – [REQUIRED]

  The ID of the instance.

- **Attribute** *(string)* – The name of the attribute.

- **Value** *(string)* – A new value for the attribute. Use only with the kernel, ramdisk, userData, disableApiTermination, or instanceInitiatedShutdownBehavior attribute.

- **BlockDeviceMappings** *(list)* – Modifies the DeleteOnTermination attribute for volumes that are currently attached. The volume must be owned by the caller. If no value is specified for DeleteOnTermination, the default is true and the volume is deleted when the instance is terminated.

To add instance store volumes to an Amazon EBS-backed instance, you must add them when you launch the instance. For more information, see Updating the Block Device Mapping when Launching an Instance in the Amazon Elastic Compute Cloud User Guide.

- *(dict)* –

  Describes a block device mapping entry.

  - **DeviceName** *(string)* –

    The device name exposed to the instance (for example, /dev/sdh or xvdh).

  - **Ebs** *(dict)* –

    Parameters used to automatically set up EBS volumes when the instance is launched.

    - **VolumeId** *(string)* –

      The ID of the EBS volume.

    - **DeleteOnTermination** *(boolean)* –
Indicates whether the volume is deleted on instance termination.

* **VirtualName (string)** –

  The virtual device name.

* **NoDevice (string)** –

  suppress the specified device included in the block device mapping.

- **SourceDestCheck (dict)** – Specifies whether source/destination checking is enabled. A value of `true` means that checking is enabled, and `false` means checking is disabled. This value must be `false` for a NAT instance to perform NAT.
  
  - **Value (boolean)** –

    Valid values are `true` or `false`.

- **DisableApiTermination (dict)** – If the value is `true`, you can’t terminate the instance using the Amazon EC2 console, CLI, or API; otherwise, you can. You cannot use this parameter for Spot Instances.
  
  - **Value (boolean)** –

    Valid values are `true` or `false`.

- **InstanceType (dict)** – Changes the instance type to the specified value. For more information, see Instance Types. If the instance type is not valid, the error returned is `InvalidInstanceAttributeValue`.
  
  - **Value (string)** –

    Valid values are case-sensitive and vary by action.

- **Kernel (dict)** – Changes the instance’s kernel to the specified value. We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see PV-GRUB.
  
  - **Value (string)** –

    Valid values are case-sensitive and vary by action.

- **Ramdisk (dict)** – Changes the instance’s RAM disk to the specified value. We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see PV-GRUB.
  
  - **Value (string)** –

    Valid values are case-sensitive and vary by action.

- **UserData (dict)** – Changes the instance’s user data to the specified value.
  
  - **Value (bytes)** –

- **InstanceInitiatedShutdownBehavior (dict)** – Specifies whether an instance stops or terminates when you initiate shutdown from the instance (using the operating system command for system shutdown).
  
  - **Value (string)** –

    Valid values are case-sensitive and vary by action.

- **Groups (list)** – [EC2-VPC] Changes the security groups of the instance. You must specify at least one security group, even if it’s just the default security group for the VPC. You must specify the security group ID, not the security group name.
  
  - **(string)** –

- **EbsOptimized (dict)** – Specifies whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal EBS I/O performance. This optimization isn’t available with all instance types. Additional usage charges apply when using an EBS Optimized instance.
  
  - **Value (boolean)** –
Valid values are `true` or `false`.

- **SriovNetSupport** *(dict)* – Set to `simple` to enable enhanced networking for the instance.

  There is no way to disable enhanced networking at this time.

  This option is supported only for HVM instances. Specifying this option with a PV instance can make it unreachable.
  - **Value** *(string)* –

    Valid values are case-sensitive and vary by action.

**modify_network_interface_attribute** (**kwargs)**

Modifies the specified network interface attribute. You can specify only one attribute at a time.

**Request Syntax**

```python
response = client.modify_network_interface_attribute(
    DryRun=True|False,
    NetworkInterfaceId='string',
    Description={
        'Value': 'string'
    },
    SourceDestCheck={
        'Value': True|False
    },
    Groups=[
        'string',
    ],
    Attachment={
        'AttachmentId': 'string',
        'DeleteOnTermination': True|False
    }
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **NetworkInterfaceId** *(string)* – [REQUIRED]

  The ID of the network interface.

- **Description** *(dict)* – A description for the network interface.
  - **Value** *(string)* –

    Valid values are case-sensitive and vary by action.

- **SourceDestCheck** *(dict)* – Indicates whether source/destination checking is enabled. A value of `true` means checking is enabled, and `false` means checking is disabled. This value must be `false` for a NAT instance to perform NAT. For more information, see **NAT Instances** in the Amazon Virtual Private Cloud User Guide.
  - **Value** *(boolean)* –

    Valid values are `true` or `false`.

- **Groups** *(list)* – Changes the security groups for the network interface. The new set of groups you specify replaces the current set. You must specify at least one.
group, even if it’s just the default security group in the VPC. You must specify the ID of the security group, not the name.

• **Attachment** *(dict)* – Information about the interface attachment. If modifying the ‘delete on termination’ attribute, you must specify the ID of the interface attachment.

  – **AttachmentId** *(string)* –

  The ID of the network interface attachment.

  – **DeleteOnTermination** *(boolean)* –

  Indicates whether the network interface is deleted when the instance is terminated.

**Returns** None

modify_reserved_instances(**kwargs)**

Modifies the Availability Zone, instance count, instance type, or network platform (EC2-Classical or EC2-VPC) of your Reserved Instances. The Reserved Instances to be modified must be identical, except for Availability Zone, network platform, and instance type.

For more information, see Modifying Reserved Instances in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = client.modify_reserved_instances(
    ClientToken='string',
    ReservedInstancesIds=['string'],
    TargetConfigurations=[
        {
            'AvailabilityZone': 'string',
            'Platform': 'string',
            'InstanceCount': 123,
            'InstanceType': 't1.micro'|'ml.small'|'ml.medium'|'ml.large'|'ml.xlarge'|'m3.medium'|'m3.large'|'m3.xlarge'|'m3.2xlarge'|'m3.4xlarge'|'m3.8xlarge'|'r3.xlarge'|'r3.2xlarge'|'r3.4xlarge'|'r3.8xlarge'|'d2.xlarge'|'d2.2xlarge'|'d2.4xlarge'|'d2.8xlarge',
        }
    ]
)
```

**Parameters**

• **ClientToken** *(string)* – A unique, case-sensitive token you provide to ensure idempotency of your modification request. For more information, see Ensuring Idempotency.

• **ReservedInstancesIds** *(list)* – [REQUIRED]

  The IDs of the Reserved Instances to modify.

  – *(string)* –

• **TargetConfigurations** *(list)* – [REQUIRED]

  The configuration settings for the Reserved Instances to modify.

  – *(dict)* –

  Describes the configuration settings for the modified Reserved Instances.

    * **AvailabilityZone** *(string)* –

      The Availability Zone for the modified Reserved Instances.

    * **Platform** *(string)* –
The network platform of the modified Reserved Instances, which is either EC2-Classic or EC2-VPC.

* InstanceCount (integer) –

 The number of modified Reserved Instances.

* InstanceType (string) –

 The instance type for the modified Reserved Instances.

Return type  dict

Returns

Response Syntax

```py
{
    'ReservedInstancesModificationId': 'string'
}
```

Response Structure

- (dict) –
  - ReservedInstancesModificationId (string) –

    The ID for the modification.

modify_snapshot_attribute(**kwargs)

Adds or removes permission settings for the specified snapshot. You may add or remove specified AWS account IDs from a snapshot’s list of create volume permissions, but you cannot do both in a single API call. If you need to both add and remove account IDs for a snapshot, you must use multiple API calls.

For more information on modifying snapshot permissions, see Sharing Snapshots in the Amazon Elastic Compute Cloud User Guide.

Note: Snapshots with AWS Marketplace product codes cannot be made public.

Request Syntax

```py
response = client.modify_snapshot_attribute(
    DryRun=True|False,
    SnapshotId='string',
    Attribute='productCodes'|'createVolumePermission',
    OperationType='add'|'remove',
    UserIds=[
        'string',
    ],
    GroupNames=[
        'string',
    ],
    CreateVolumePermission={
        'Add': [
            {'UserId': 'string',
             'Group': 'all'}
        ],
        'Remove': [
            {'UserId': 'string',
             'Group': 'all'}
        ]
    }
)
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **SnapshotId** *(string)* – [REQUIRED]
  The ID of the snapshot.

- **Attribute** *(string)* – The snapshot attribute to modify.

- **OperationType** *(string)* – The type of operation to perform to the attribute.

- **UserIds** *(list)* – The account ID to modify for the snapshot.
  - *(string)* –

- **GroupNames** *(list)* – The group to modify for the snapshot.
  - *(string)* –

- **CreateVolumePermission** *(dict)* – A JSON representation of the snapshot attribute modification.
  - **Add** *(list)* –
    Adds a specific AWS account ID or group to a volume’s list of create volume permissions.
    * *(dict)* –
      Describes the user or group to be added or removed from the permissions for a volume.
      - **UserId** *(string)* –
        The specific AWS account ID that is to be added or removed from a volume’s list of create volume permissions.
      - **Group** *(string)* –
        The specific group that is to be added or removed from a volume’s list of create volume permissions.

  - **Remove** *(list)* –
    Removes a specific AWS account ID or group from a volume’s list of create volume permissions.
    * *(dict)* –
      Describes the user or group to be added or removed from the permissions for a volume.
      - **UserId** *(string)* –
        The specific AWS account ID that is to be added or removed from a volume’s list of create volume permissions.
      - **Group** *(string)* –
        The specific group that is to be added or removed from a volume’s list of create volume permissions.

**Returns** None

```
modify_subnet_attribute(**kwargs)
```
Modifies a subnet attribute.

**Request Syntax**
response = client.modify_subnet_attribute(
    SubnetId='string',
    MapPublicIpOnLaunch={
        'Value': True|False
    }
)

Parameters
- **SubnetId (string)** – [REQUIRED]
  The ID of the subnet.
- **MapPublicIpOnLaunch (dict)** – Specify `true` to indicate that instances launched into the specified subnet should be assigned public IP address.
  - **Value (boolean)** –
    Valid values are `true` or `false`.

Returns None

modify_volume_attribute(**kwargs)
Modifies a volume attribute.

By default, all I/O operations for the volume are suspended when the data on the volume is determined to be potentially inconsistent, to prevent undetectable, latent data corruption. The I/O access to the volume can be resumed by first enabling I/O access and then checking the data consistency on your volume.

You can change the default behavior to resume I/O operations. We recommend that you change this only for boot volumes or for volumes that are stateless or disposable.

Request Syntax

response = client.modify_volume_attribute(
    DryRun=True|False,
    VolumeId='string',
    AutoEnableIO={
        'Value': True|False
    }
)

Parameters
- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **VolumeId (string)** – [REQUIRED]
  The ID of the volume.
- **AutoEnableIO (dict)** – Indicates whether the volume should be auto-enabled for I/O operations.
  - **Value (boolean)** –
    Valid values are `true` or `false`.

Returns None

modify_vpc_attribute(**kwargs)
Modifies the specified attribute of the specified VPC.

Request Syntax

3.1. Services
response = client.modify_vpc_attribute(
    VpcId='string',
    EnableDnsSupport={
        'Value': True|False
    },
    EnableDnsHostnames={
        'Value': True|False
    }
)

Parameters

- **VpcId** *(string)* – [REQUIRED]
  
  The ID of the VPC.

- **EnableDnsSupport** *(dict)* – Indicates whether the DNS resolution is supported for the VPC. If enabled, queries to the Amazon provided DNS server at the 169.254.169.253 IP address, or the reserved IP address at the base of the VPC network range “plus two” will succeed. If disabled, the Amazon provided DNS service in the VPC that resolves public DNS hostnames to IP addresses is not enabled.
  - **Value** *(boolean)* –
    
    Valid values are true or false.

- **EnableDnsHostnames** *(dict)* – Indicates whether the instances launched in the VPC get DNS hostnames. If enabled, instances in the VPC get DNS hostnames; otherwise, they do not.
  
  You can only enable DNS hostnames if you also enable DNS support.
  - **Value** *(boolean)* –
    
    Valid values are true or false.

Returns

None

modify_vpc_endpoint (**kwargs)

Modifies attributes of a specified VPC endpoint. You can modify the policy associated with the endpoint, and you can add and remove route tables associated with the endpoint.

Request Syntax

response = client.modify_vpc_endpoint(
    DryRun=True|False,
    VpcEndpointId='string',
    ResetPolicy=True|False,
    PolicyDocument='string',
    AddRouteTableIds=[
        'string',
    ],
    RemoveRouteTableIds=[
        'string',
    ]
)

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
• **VpcEndpointId (string)** – **[REQUIRED]**
  The ID of the endpoint.
• **ResetPolicy (boolean)** – Specify `true` to reset the policy document to the default policy. The default policy allows access to the service.
• **PolicyDocument (string)** – A policy document to attach to the endpoint. The policy must be in valid JSON format.
• **AddRouteTableIds (list)** – One or more route tables IDs to associate with the endpoint.
  - (string)
• **RemoveRouteTableIds (list)** – One or more route table IDs to disassociate from the endpoint.
  - (string)

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'Return': True|False
}
```

**Response Structure**

- (dict)
  - **Return (boolean)** – Returns `true` if the request succeeds; otherwise, it returns an error.

### monitor_instances(**kwargs)**

Enables monitoring for a running instance. For more information about monitoring instances, see Monitoring Your Instances and Volumes in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = client.monitor_instances(
    DryRun=True|False,
    InstanceIds=[
        'string',
    ]
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **InstanceIds (list)** – **[REQUIRED]**
  One or more instance IDs.
  - (string)

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'InstanceMonitorings': [
    
```
Response Structure

- (dict) –
  - InstanceMonitorings (list) –
    Monitoring information for one or more instances.
    * (dict) –
      Describes the monitoring information of the instance.
      - InstanceId (string) –
        The ID of the instance.
      - Monitoring (dict) –
        The monitoring information.
      - State (string) –
        Indicates whether monitoring is enabled for the instance.

move_address_to_vpc(**kwargs)

Moves an Elastic IP address from the EC2-Classic platform to the EC2-VPC platform. The Elastic IP address must be allocated to your account, and it must not be associated with an instance. After the Elastic IP address is moved, it is no longer available for use in the EC2-Classic platform, unless you move it back using the RestoreAddressToClassic request. You cannot move an Elastic IP address that’s allocated for use in the EC2-VPC platform to the EC2-Classic platform.

Request Syntax

```python
response = client.move_address_to_vpc(
    DryRun=True|False,
    PublicIp='string'
)
```

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **PublicIp** (string) – [REQUIRED]

  The Elastic IP address.

Return type  dict

Returns

Response Syntax

```python
{
    'AllocationId': 'string',
    'Status': 'MoveInProgress'|'InVpc'|'InClassic'
}
```

Response Structure

- (dict) –
– **AllocationId** *(string)* –
  The allocation ID for the Elastic IP address.

– **Status** *(string)* –
  The status of the move of the IP address.

**purchase_reserved_instances_offering(**kwargs)**

Purchases a Reserved Instance for use with your account. With Amazon EC2 Reserved Instances, you obtain a capacity reservation for a certain instance configuration over a specified period of time and pay a lower hourly rate compared to on-Demand Instance pricing.

Use DescribeReservedInstancesOfferings to get a list of Reserved Instance offerings that match your specifications. After you’ve purchased a Reserved Instance, you can check for your new Reserved Instance with DescribeReservedInstances.

For more information, see **Reserved Instances** and **Reserved Instance Marketplace** in the *Amazon Elastic Compute Cloud User Guide*.

**Request Syntax**

```python
response = client.purchase_reserved_instances_offering(
    DryRun=True|False,
    ReservedInstancesOfferingId='string',
    InstanceCount=123,
    LimitPrice=
    'Amount': 123.0,
    'CurrencyCode': 'USD'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **ReservedInstancesOfferingId** *(string)* – [REQUIRED]
  The ID of the Reserved Instance offering to purchase.

- **InstanceCount** *(integer)* – [REQUIRED]
  The number of Reserved Instances to purchase.

- **LimitPrice** *(dict)* – Specified for Reserved Instance Marketplace offerings to limit the total order and ensure that the Reserved Instances are not purchased at unexpected prices.
  - **Amount** *(float)* –
    Used for Reserved Instance Marketplace offerings. Specifies the limit price on the total order (instanceCount * price).
  - **CurrencyCode** *(string)* –
    The currency in which the limitPrice amount is specified. At this time, the only supported currency is USD.

**Return type** *dict*

**Returns**

**Response Syntax**

3.1. Services 1393
{  
  'ReservedInstancesId': 'string' 
}

Response Structure
- (dict) –
  - **ReservedInstancesId** *(string)* –
    The IDs of the purchased Reserved Instances.

**reboot Instances(****kwargs***)**
Requests a reboot of one or more instances. This operation is asynchronous; it only queues a request to reboot the specified instances. The operation succeeds if the instances are valid and belong to you. Requests to reboot terminated instances are ignored.

If a Linux/Unix instance does not cleanly shut down within four minutes, Amazon EC2 performs a hard reboot.

For more information about troubleshooting, see Getting Console Output and Rebooting Instances in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = client.reboot_instances(
    DryRun=True|False,
    InstanceIds=[
        'string',
    ]
)
```

**Parameters**
- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **InstanceIds** *(list)* – [REQUIRED]
  One or more instance IDs.

**Returns**  None

**register_image(****kwargs***)**
Registers an AMI. When you’re creating an AMI, this is the final step you must complete before you can launch an instance from the AMI. For more information about creating AMIs, see Creating Your Own AMIs in the Amazon Elastic Compute Cloud User Guide.

**Note:** For Amazon EBS-backed instances, CreateImage creates and registers the AMI in a single request, so you don’t have to register the AMI yourself.

You can also use RegisterImage to create an Amazon EBS-backed Linux AMI from a snapshot of a root device volume. For more information, see Launching an Instance from a Snapshot in the Amazon Elastic Compute Cloud User Guide.
Warning: Some Linux distributions, such as Red Hat Enterprise Linux (RHEL) and SUSE Linux Enterprise Server (SLES), use the EC2 billingProduct code associated with an AMI to verify subscription status for package updates. Creating an AMI from an EBS snapshot does not maintain this billing code, and subsequent instances launched from such an AMI will not be able to connect to package update infrastructure.

Similarly, although you can create a Windows AMI from a snapshot, you can’t successfully launch an instance from the AMI.

To create Windows AMIs or to create AMIs for Linux operating systems that must retain AMI billing codes to work properly, see CreateImage.

If needed, you can deregister an AMI at any time. Any modifications you make to an AMI backed by an instance store volume invalidates its registration. If you make changes to an image, deregister the previous image and register the new image.

Note: You can’t register an image where a secondary (non-root) snapshot has AWS Marketplace product codes.

Request Syntax

response = client.register_image(
    DryRun=True|False,
    ImageLocation='string',
    Name='string',
    Description='string',
    Architecture='i386'|'x86_64',
    KernelId='string',
    RamdiskId='string',
    RootDeviceName='string',
    BlockDeviceMappings=[
        {'VirtualName': 'string',
         'DeviceName': 'string',
         'Ebs': {
             'SnapshotId': 'string',
             'VolumeSize': 123,
             'DeleteOnTermination': True|False,
             'VolumeType': 'standard'|'io1'|'gp2',
             'Iops': 123,
             'Encrypted': True|False
         },
         'NoDevice': 'string'},
    ],
    VirtualizationType='string',
    SriovNetSupport='string'
)
A name for your AMI.

Constraints: 3-128 alphanumeric characters, parentheses (()), square brackets ([]), spaces ( ), periods (.), slashes (/), dashes (-), single quotes ('), at-signs (@), or underscores(_)

- **Description (string)** – A description for your AMI.
- **Architecture (string)** – The architecture of the AMI.

Default: For Amazon EBS-backed AMIs, `i386`. For instance store-backed AMIs, the architecture specified in the manifest file.

- **KernelId (string)** – The ID of the kernel.
- **RamdiskId (string)** – The ID of the RAM disk.
- **RootDeviceName (string)** – The name of the root device (for example, `/dev/sda1` or `/dev/xvda`).
- **BlockDeviceMappings (list)** – One or more block device mapping entries.
  - (dict) – Describes a block device mapping.
    - **VirtualName (string)** – The virtual device name (ephemeral N). Instance store volumes are numbered starting from 0. An instance type with 2 available instance store volumes can specify mappings for ephemeral0 and ephemeral1. The number of available instance store volumes depends on the instance type. After you connect to the instance, you must mount the volume.
    - **DeviceName (string)** – The device name exposed to the instance (for example, `/dev/sdh` or `/dev/xvdh`).
    - **Ebs (dict)** – Parameters used to automatically set up EBS volumes when the instance is launched.
      - **SnapshotId (string)** – The ID of the snapshot.
      - **VolumeSize (integer)** – The size of the volume, in GiB.
        Constraints: 1-1024 for standard volumes, 1-16384 for gp2 volumes, and 4-16384 for io1 volumes. If you specify a snapshot, the volume size must be equal to or larger than the snapshot size.
        Default: If you’re creating the volume from a snapshot and don’t specify a volume size, the default is the snapshot size.
      - **DeleteOnTermination (boolean)** – Indicates whether the EBS volume is deleted on instance termination.
      - **VolumeType (string)** – The volume type. gp2 for General Purpose (SSD) volumes,
io1 for Provisioned IOPS (SSD) volumes, and standard for Magnetic volumes.

Default: standard

- **Iops (integer)** –

  The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.

  Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.

  Condition: This parameter is required for requests to create io1 volumes; it is not used in requests to create standard or gp2 volumes.

- **Encrypted (boolean)** –

  Indicates whether the EBS volume is encrypted. Encrypted Amazon EBS volumes may only be attached to instances that support Amazon EBS encryption.

- **NoDevice (string)** –

  Suppresses the specified device included in the block device mapping of the AMI.

- **VirtualizationType (string)** – The type of virtualization.

  Default: paravirtual

- **SriovNetSupport (string)** – Set to simple to enable enhanced networking for the AMI and any instances that you launch from the AMI.

  There is no way to disable enhanced networking at this time.

  This option is supported only for HVM AMIs. Specifying this option with a PV AMI can make instances launched from the AMI unreachable.

Return type  dict

Returns

Response Syntax

```
{
  'ImageId': 'string'
}
```

Response Structure

- (**dict**) –
  - **ImageId (string)** –

    The ID of the newly registered AMI.

**reject_vpc_peering_connection(**kwargs)**

Rejects a VPC peering connection request. The VPC peering connection must be in the
pending-acceptance state. Use the DescribeVpcPeeringConnections request to view your outstanding VPC peering connection requests. To delete an active VPC peering connection, or to delete a VPC peering connection request that you initiated, use DeleteVpcPeeringConnection.

Request Syntax

```python
response = client.reject_vpc_peering_connection(
    DryRun=True|False,
    VpcPeeringConnectionId='string'
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **VpcPeeringConnectionId** *(string)* – [REQUIRED]
The ID of the VPC peering connection.

Return type: dict

Returns

Response Syntax

```python
{
    'Return': True|False
}
```

Response Structure

- *(dict)* –
  - **Return** *(boolean)* –
    Returns true if the request succeeds; otherwise, it returns an error.

`release_address(**kwargs)`

Releases the specified Elastic IP address.

After releasing an Elastic IP address, it is released to the IP address pool and might be unavailable to you. Be sure to update your DNS records and any servers or devices that communicate with the address. If you attempt to release an Elastic IP address that you already released, you’ll get an `AuthFailure` error if the address is already allocated to another AWS account.

[EC2-Classic, default VPC] Releasing an Elastic IP address automatically disassociates it from any instance that it’s associated with. To disassociate an Elastic IP address without releasing it, use DisassociateAddress.

[Nondefault VPC] You must use DisassociateAddress to disassociate the Elastic IP address before you try to release it. Otherwise, Amazon EC2 returns an error (`InvalidIPAddress.InUse`).

Request Syntax

```python
response = client.release_address(
    DryRun=True|False,
    PublicIp='string',
    AllocationId='string'
)
```

Parameters
**DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**AllocationId** *(string)* – [EC2-VPC] The allocation ID. Required for EC2-VPC.

**Returns**  None

`replace_network_acl_association(**kwargs)`

Changes which network ACL a subnet is associated with. By default when you create a subnet, it's automatically associated with the default network ACL. For more information about network ACLs, see Network ACLs in the *Amazon Virtual Private Cloud User Guide*.

**Request Syntax**

```python
response = client.replace_network_acl_association(
    DryRun=True|False,
    AssociationId='string',
    NetworkAclId='string'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **AssociationId** *(string)* – [REQUIRED]
  
  The ID of the current association between the original network ACL and the subnet.

- **NetworkAclId** *(string)* – [REQUIRED]
  
  The ID of the new network ACL to associate with the subnet.

**Return type**  dict

**Returns**

**Response Syntax**

```python
{
    'NewAssociationId': 'string'
}
```

**Response Structure**

- *(dict)* –
  - **NewAssociationId** *(string)* –
    
    The ID of the new association.

`replace_network_acl_entry(**kwargs)`

Replaces an entry (rule) in a network ACL. For more information about network ACLs, see Network ACLs in the *Amazon Virtual Private Cloud User Guide*.

**Request Syntax**

```python
response = client.replace_network_acl_entry(
    DryRun=True|False,
    NetworkAclId='string',
    RuleNumber=123,
    RuleAction='allow'|'deny',
    RulePosition=0,
    CidrBlock='192.168.0.0/16',
    IcmpTypeCode=('echo'|'echo-reply'),
    Protocol=('tcp'|'udp'|'icmp'),
    PortRanges=('all'|'0-65535'|'0-1023'),
    EntityOwnerId='string',
    RuleOwnerAccount='string',
    RuleOwnerGroup='string',
    RuleOwnerIdentity='string'
)
```
Protocol='string',
RuleAction='allow'|'deny',
Egress=True|False,
CidrBlock='string',
IcmpTypeCode={
    'Type': 123,
    'Code': 123
},
PortRange={
    'From': 123,
    'To': 123
}
}

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **NetworkAclId** (string) – [REQUIRED]
  The ID of the ACL.

- **RuleNumber** (integer) – [REQUIRED]
  The rule number of the entry to replace.

- **Protocol** (string) – [REQUIRED]
  The IP protocol. You can specify **all** or **-1** to mean all protocols.

- **RuleAction** (string) – [REQUIRED]
  Indicates whether to allow or deny the traffic that matches the rule.

- **Egress** (boolean) – [REQUIRED]
  Indicates whether to replace the egress rule.
  Default: If no value is specified, we replace the ingress rule.

- **CidrBlock** (string) – [REQUIRED]
  The network range to allow or deny, in CIDR notation.

- **IcmpTypeCode** (dict) – ICMP protocol: The ICMP type and code. Required if specifying 1 (ICMP) for the protocol.
  - **Type** (integer) –
    The ICMP code. A value of -1 means all codes for the specified ICMP type.
  - **Code** (integer) –
    The ICMP type. A value of -1 means all types.

- **PortRange** (dict) – TCP or UDP protocols: The range of ports the rule applies to. Required if specifying 6 (TCP) or 17 (UDP) for the protocol.
  - **From** (integer) –
    The first port in the range.
  - **To** (integer) –
    The last port in the range.

Returns None

**replace_route(**kwargs**)

Replaces an existing route within a route table in a VPC. You must provide only one of the following:
Internet gateway or virtual private gateway, NAT instance, VPC peering connection, or network interface.
For more information about route tables, see Route Tables in the Amazon Virtual Private Cloud User Guide.

Request Syntax

```python
response = client.replace_route(
    DryRun=True|False,
    RouteTableId='string',
    DestinationCidrBlock='string',
    GatewayId='string',
    InstanceId='string',
    NetworkInterfaceId='string',
    VpcPeeringConnectionId='string'
)
```

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **RouteTableId** (string) – [REQUIRED]
  The ID of the route table.
- **DestinationCidrBlock** (string) – [REQUIRED]
  The CIDR address block used for the destination match. The value you provide must match the CIDR of an existing route in the table.
- **GatewayId** (string) – The ID of an Internet gateway or virtual private gateway.
- **InstanceId** (string) – The ID of a NAT instance in your VPC.
- **NetworkInterfaceId** (string) – The ID of a network interface.
- **VpcPeeringConnectionId** (string) – The ID of a VPC peering connection.

Returns None

`replace_route_table_association(**kwargs)`

Changes the route table associated with a given subnet in a VPC. After the operation completes, the subnet uses the routes in the new route table it’s associated with. For more information about route tables, see Route Tables in the Amazon Virtual Private Cloud User Guide.

You can also use ReplaceRouteTableAssociation to change which table is the main route table in the VPC. You just specify the main route table’s association ID and the route table to be the new main route table.

Request Syntax

```python
response = client.replace_route_table_association(
    DryRun=True|False,
    AssociationId='string',
    RouteTableId='string'
)
```

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **AssociationId** (string) – [REQUIRED]
  The association ID.
• **RouteTableId (string)** – [REQUIRED]

  The ID of the new route table to associate with the subnet.

  **Return type**  dict

  **Returns**

  **Response Syntax**

  ```
  {
    'NewAssociationId': 'string'
  }
  ```

  **Response Structure**

  • (dict) –
  
  – **NewAssociationId (string)** –

  The ID of the new association.

  **report_instance_status(**kwargs**)**

  Submits feedback about the status of an instance. The instance must be in the running state. If your experience with the instance differs from the instance status returned by DescribeInstanceStatus, use ReportInstanceStatus to report your experience with the instance. Amazon EC2 collects this information to improve the accuracy of status checks.

  Use of this action does not change the value returned by DescribeInstanceStatus.

  **Request Syntax**

  ```python
  response = client.report_instance_status(
    DryRun=True|False,
    Instances=['string'],
    Status='ok'|'impaired',
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    ReasonCodes=['instance-stuck-in-state'|'unresponsive'|'not-accepting-credentials'|'password-not-available'|'performance-network'|'performance-instance-store'|'performance-ebs-volume'|'performance-other'|'other'],
    Description='string'
  )
  ```

  **Parameters**

  • **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

  • **Instances (list)** – [REQUIRED]

    One or more instances.
    
    – (string) –

  • **Status (string)** – [REQUIRED]

    The status of all instances listed.

  • **StartTime (datetime)** – The time at which the reported instance health state began.

  • **EndTime (datetime)** – The time at which the reported instance health state ended.
• **ReasonCodes (list)** – [REQUIRED]
  
  One or more reason codes that describes the health state of your instance.
  
  - **instance-stuck-in-state**: My instance is stuck in a state.
  - **unresponsive**: My instance is unresponsive.
  - **not-accepting-credentials**: My instance is not accepting my credentials.
  - **password-not-available**: A password is not available for my instance.
  - **performance-network**: My instance is experiencing performance problems which I believe are network related.
  - **performance-instance-store**: My instance is experiencing performance problems which I believe are related to the instance stores.
  - **performance-ebs-volume**: My instance is experiencing performance problems which I believe are related to an EBS volume.
  - **performance-other**: My instance is experiencing performance problems.
  - **other**: [explain using the description parameter]

• **Description (string)** – Descriptive text about the health state of your instance.

**Returns** None

`request_spot_fleet(**kwargs)`

Creates a Spot fleet request.

You can submit a single request that includes multiple launch specifications that vary by instance type, AMI, Availability Zone, or subnet.

By default, the Spot fleet requests Spot instances in the Spot pool where the price per unit is the lowest. Each launch specification can include its own instance weighting that reflects the value of the instance type to your application workload.

Alternatively, you can specify that the Spot fleet distribute the target capacity across the Spot pools included in its launch specifications. By ensuring that the Spot instances in your Spot fleet are in different Spot pools, you can improve the availability of your fleet.

For more information, see Spot Fleet Requests in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = client.request_spot_fleet(
    DryRun=True|False,
    SpotFleetRequestConfig={
        'ClientToken': 'string',
        'SpotPrice': 'string',
        'TargetCapacity': 123,
        'ValidFrom': datetime(2015, 1, 1),
        'ValidUntil': datetime(2015, 1, 1),
        'TerminateInstancesWithExpiration': True|False,
        'IamFleetRole': 'string',
        'LaunchSpecifications': [
            {
                'ImageId': 'string',
                'KeyName': 'string',
                'SecurityGroups': [
                    {
                        'GroupName': 'string',
                        'GroupId': 'string'
                    }
                ]
            }
        ]
    }
)
```

},

'UserData': 'string',
'AddressingType': 'string',
'InstanceType': 't1.micro'|'ml.small'|'ml.medium'|'ml.large'|'ml.xlarge'|'m1.micro'|'m1.small'|'m1.medium'|'m1.large'|'m1.xlarge'|'c1.large'|'c1.xlarge'|'c3.large'|'c3.xlarge'|'c4.large'|'c4.xlarge'|'c5.large'|'c5.xlarge'|'r3.large'|'r3.xlarge'|'r3.2xlarge'|'r3.4xlarge'|'r3.8xlarge'|'d2.xlarge'|'d2.2xlarge'|'d2.4xlarge'|'d2.8xlarge',

    'Groups': [  
      'string',
    ],
    'DeleteOnTermination': True|False,
    'PrivateIpAddresses': [ 
      {  
        'PrivateIpAddress': 'string',
        'Primary': True|False
      },
      'SecondaryPrivateIpAddressCount': 123,
      'AssociatePublicIpAddress': True|False
    ]
  },
  'IamInstanceProfile': {  
    'Arn': 'string',
    'Name': 'string'
  },
  'EbsOptimized': True|False,
  'WeightedCapacity': 123.0,
  'SpotPrice': 'string'
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **SpotFleetRequestConfig** *(dict)* – [REQUIRED]

  The configuration for the Spot fleet request.
  
  - **ClientToken** *(string)* –
    
    A unique, case-sensitive identifier you provide to ensure idempotency of your listings. This helps avoid duplicate listings. For more information, see [Ensuring Idempotency](#).
  
  - **SpotPrice** *(string)* – [REQUIRED]

    The bid price per unit hour.
  
  - **TargetCapacity** *(integer)* – [REQUIRED]

    The number of units to request. You can choose to set the target capacity in terms of instances or a performance characteristic that is important to your application workload, such as vCPUs, memory, or I/O.
  
  - **ValidFrom** *(datetime)* –

    The start date and time of the request, in UTC format (for example, `YYYY-MM-DD T*HH* :MM* :SS Z`). The default is to start fulfilling the request immediately.
  
  - **ValidUntil** *(datetime)* –

    The end date and time of the request, in UTC format (for example, `YYYY-MM-DD T*HH* :MM* :SS Z`). At this point, no new Spot instance requests are placed or enabled to fulfill the request.
  
  - **TerminateInstancesWithExpiration** *(boolean)* –

    Indicates whether running Spot instances should be terminated when the Spot fleet request expires.
  
  - **IamFleetRole** *(string)* – [REQUIRED]

    Grants the Spot fleet permission to terminate Spot instances on your behalf when you cancel its Spot fleet request using `CancelSpotFleetRequests` or when the Spot fleet request expires, if you set `terminateInstancesWithExpiration`.
  
  - **LaunchSpecifications** *(list)* – [REQUIRED]

    Information about the launch specifications for the Spot fleet request.
    
    * *(dict)* –

      Describes the launch specification for one or more Spot instances.
      
      - **ImageId** *(string)* –

        The ID of the AMI.
      
      - **KeyName** *(string)* –

        The name of the key pair.
· **SecurityGroups** (*list*) –

One or more security groups. To request an instance in a non-default VPC, you must specify the ID of the security group. To request an instance in EC2-Classic or a default VPC, you can specify the name or the ID of the security group.

· **(dict)** –

Describes a security group.

· **GroupName** (*string*) –

The name of the security group.

· **GroupId** (*string*) –

The ID of the security group.

· **UserData** (*string*) –

The Base64-encoded MIME user data to make available to the instances.

· **AddressingType** (*string*) –

Deprecated.

· **InstanceType** (*string*) –

The instance type.

· **Placement** (*dict*) –

The placement information.

· **AvailabilityZone** (*string*) –

The Availability Zone.

· **GroupName** (*string*) –

The name of the placement group (for cluster instances).

· **KernelId** (*string*) –

The ID of the kernel.

· **RamdiskId** (*string*) –

The ID of the RAM disk.

· **BlockDeviceMappings** (*list*) –

One or more block device mapping entries.

· **(dict)** –

Describes a block device mapping.

· **VirtualName** (*string*) –

The virtual device name (*ephemeral N*). Instance store volumes are numbered starting from 0. An instance type with 2 available instance store volumes can specify mappings for *ephemeral0* and *ephemeral1*. The number of available instance store volumes depends on the instance type. After you connect to the instance, you must mount the volume.

Constraints: For M3 instances, you must specify instance store volumes in the block device mapping for the instance. When you launch an M3 instance, we ignore any instance store volumes specified in the block device mapping for the AMI.

· **DeviceName** (*string*) –
The device name exposed to the instance (for example, /dev/sdh or xvdh).

- **Ebs (dict)** –
  
  Parameters used to automatically set up EBS volumes when the instance is launched.

- **SnapshotId (string)** –
  
  The ID of the snapshot.

- **VolumeSize (integer)** –
  
  The size of the volume, in GiB.
  
  Constraints: 1-1024 for standard volumes, 1-16384 for gp2 volumes, and 4-16384 for io1 volumes. If you specify a snapshot, the volume size must be equal to or larger than the snapshot size.
  
  Default: If you’re creating the volume from a snapshot and don’t specify a volume size, the default is the snapshot size.

- **DeleteOnTermination (boolean)** –
  
  Indicates whether the EBS volume is deleted on instance termination.

- **VolumeType (string)** –
  
  The volume type. gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, and standard for Magnetic volumes.
  
  Default: standard

- **Iops (integer)** –
  
  The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.
  
  Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.
  
  Condition: This parameter is required for requests to create io1 volumes; it is not used in requests to create standard or gp2 volumes.

- **Encrypted (boolean)** –
  
  Indicates whether the EBS volume is encrypted. Encrypted Amazon EBS volumes may only be attached to instances that support Amazon EBS encryption.

- **NoDevice (string)** –
  
  Suppresses the specified device included in the block device mapping of the AMI.
- **Monitoring** (*dict*) –
  Enable or disable monitoring for the instances.
- **Enabled** (*boolean*) –
  Enables monitoring for the instance.
  Default: `false`
- **SubnetId** (*string*) –
  The ID of the subnet in which to launch the instances.
- **NetworkInterfaces** (*list*) –
  One or more network interfaces.
  - (*dict*) –
    Describes a network interface.
  - **NetworkInterfaceId** (*string*) –
    The ID of the network interface.
  - **DeviceIndex** (*integer*) –
    The index of the device on the instance for the network interface attachment. If you are specifying a network interface in a RunInstances request, you must provide the device index.
  - **SubnetId** (*string*) –
    The ID of the subnet associated with the network string. Applies only if creating a network interface when launching an instance.
  - **Description** (*string*) –
    The description of the network interface. Applies only if creating a network interface when launching an instance.
  - **PrivateIpAddress** (*string*) –
    The private IP address of the network interface. Applies only if creating a network interface when launching an instance.
  - **Groups** (*list*) –
    The IDs of the security groups for the network interface. Applies only if creating a network interface when launching an instance.
  - (*string*) –
    - **DeleteOnTermination** (*boolean*) –
      If set to `true`, the interface is deleted when the instance is terminated. You can specify `true` only if creating a new network interface when launching an instance.
  - **PrivateIpAddresses** (*list*) –
    One or more private IP addresses to assign to the network interface. Only one private IP address can be designated as primary.
    - (*dict*) –
      Describes a secondary private IP address for a network interface.
    - **PrivateIpAddress** (*string*) – [REQUIRED]
      The private IP addresses.
- **Primary** *(boolean)* –
  Indicates whether the private IP address is the primary private IP address. Only one IP address can be designated as primary.

- **SecondaryPrivateIpAddressCount** *(integer)* –
  The number of secondary private IP addresses. You can't specify this option and specify more than one private IP address using the private IP addresses option.

- **AssociatePublicIpAddress** *(boolean)* –
  Indicates whether to assign a public IP address to an instance you launch in a VPC. The public IP address can only be assigned to a network interface for eth0, and can only be assigned to a new network interface, not an existing one. You cannot specify more than one network interface in the request. If launching into a default subnet, the default value is `true`.

- **IamInstanceProfile** *(dict)* –
  The IAM instance profile.
  - **Arn** *(string)* –
    The Amazon Resource Name (ARN) of the instance profile.
  - **Name** *(string)* –
    The name of the instance profile.

- **EbsOptimized** *(boolean)* –
  Indicates whether the instances are optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal EBS I/O performance. This optimization isn’t available with all instance types. Additional usage charges apply when using an EBS Optimized instance.
  
  Default: `false`

- **WeightedCapacity** *(float)* –
  The number of units provided by the specified instance type. These are the same units that you chose to set the target capacity in terms (instances or a performance characteristic such as vCPUs, memory, or I/O).
  
  If the target capacity divided by this value is not a whole number, we round the number of instances to the next whole number. If this value is not specified, the default is 1.

- **SpotPrice** *(string)* –
  The bid price per unit hour for the specified instance type. If this value is not specified, the default is the Spot bid price specified for the fleet. To determine the bid price per unit hour, divide the Spot bid price by the value of `WeightedCapacity`.

- **AllocationStrategy** *(string)* –
  Determines how to allocate the target capacity across the Spot pools specified by the Spot fleet request. The default is `lowestPrice`.

**Return type** `dict`

**Returns**
Response Syntax

```
{
    'SpotFleetRequestId': 'string'
}
```

Response Structure

- (dict) –

Contains the output of RequestSpotFleet.

- **SpotFleetRequestId** *(string)* –

The ID of the Spot fleet request.

```
request_spot_instances(**kwargs)
```

Creates a Spot instance request. Spot instances are instances that Amazon EC2 launches when the bid price that you specify exceeds the current Spot price. Amazon EC2 periodically sets the Spot price based on available Spot Instance capacity and current Spot instance requests. For more information, see Spot Instance Requests in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```
response = client.request_spot_instances(
    DryRun=True|False,
    SpotPrice='string',
    ClientToken='string',
    InstanceCount=123,
    Type='one-time'|'persistent',
    ValidFrom=datetime(2015, 1, 1),
    ValidUntil=datetime(2015, 1, 1),
    LaunchGroup='string',
    AvailabilityZoneGroup='string',
    LaunchSpecification={
        'ImageId': 'string',
        'KeyName': 'string',
        'SecurityGroups': [
        'string',
        ],
        'UserData': 'string',

  'Enabled': True|False
},
'SecurityGroupIds': [
  'string',
]
}

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **SpotPrice (string) – [REQUIRED]**

  The maximum hourly price (bid) for any Spot instance launched to fulfill the request.

- **ClientToken (string)** – Unique, case-sensitive identifier that you provide to ensure the idempotency of the request. For more information, see [How to Ensure Idempotency in the Amazon Elastic Compute Cloud User Guide](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/spot-instance-requests.html) .

- **InstanceCount (integer)** – The maximum number of Spot instances to launch.

  Default: 1

- **Type (string)** – The Spot instance request type.

  Default: one-time

- **ValidFrom (datetime)** – The start date of the request. If this is a one-time re-
quest, the request becomes active at this date and time and remains active until all instances launch, the request expires, or the request is canceled. If the request is persistent, the request becomes active at this date and time and remains active until it expires or is canceled.

Default: The request is effective indefinitely.

- **ValidUntil (datetime)** – The end date of the request. If this is a one-time request, the request remains active until all instances launch, the request is canceled, or this date is reached. If the request is persistent, it remains active until it is canceled or this date and time is reached.

Default: The request is effective indefinitely.

- **LaunchGroup (string)** – The instance launch group. Launch groups are Spot instances that launch together and terminate together.

Default: Instances are launched and terminated individually.

- **AvailabilityZoneGroup (string)** – The user-specified name for a logical grouping of bids.

When you specify an Availability Zone group in a Spot Instance request, all Spot instances in the request are launched in the same Availability Zone. Instance proximity is maintained with this parameter, but the choice of Availability Zone is not. The group applies only to bids for Spot Instances of the same instance type. Any additional Spot instance requests that are specified with the same Availability Zone group name are launched in that same Availability Zone, as long as at least one instance from the group is still active.

If there is no active instance running in the Availability Zone group that you specify for a new Spot instance request (all instances are terminated, the bid is expired, or the bid falls below current market), then Amazon EC2 launches the instance in any Availability Zone where the constraint can be met. Consequently, the subsequent set of Spot instances could be placed in a different zone from the original request, even if you specified the same Availability Zone group.

Default: Instances are launched in any available Availability Zone.

- **LaunchSpecification (dict)** – Describes the launch specification for an instance.
  - **ImageId (string)** – The ID of the AMI.
  - **KeyName (string)** – The name of the key pair.
  - **SecurityGroups (list)** –
    - **(string)** –
  - **UserData (string)** – The Base64-encoded MIME user data to make available to the instances.
  - **AddressingType (string)** – Deprecated.
  - **InstanceType (string)** – The instance type.
  - **Placement (dict)** – The placement information for the instance.
    - **AvailabilityZone (string)** – The Availability Zone.
    - **GroupName (string)** –
The name of the placement group (for cluster instances).

- **KernelId (string)** –
  The ID of the kernel.
- **RamdiskId (string)** –
  The ID of the RAM disk.
- **BlockDeviceMappings (list)** –
  One or more block device mapping entries.
  *
  
  Describes a block device mapping.
  
  - **VirtualName (string)** –
    The virtual device name (ephemeral N). Instance store volumes are numbered starting from 0. An instance type with 2 available instance store volumes can specify mappings for ephemeral0 and ephemeral1. The number of available instance store volumes depends on the instance type. After you connect to the instance, you must mount the volume.
    Constraints: For M3 instances, you must specify instance store volumes in the block device mapping for the instance. When you launch an M3 instance, we ignore any instance store volumes specified in the block device mapping for the AMI.
  
  - **DeviceName (string)** –
    The device name exposed to the instance (for example, /dev/sdh or xvdh).
  
  - **Ebs (dict)** –
    Parameters used to automatically set up EBS volumes when the instance is launched.
    
  - **SnapshotId (string)** –
    The ID of the snapshot.
  
  - **VolumeSize (integer)** –
    The size of the volume, in GiB.
    Constraints: 1-1024 for standard volumes, 1-16384 for gp2 volumes, and 4-16384 for io1 volumes. If you specify a snapshot, the volume size must be equal to or larger than the snapshot size.
    Default: If you’re creating the volume from a snapshot and don’t specify a volume size, the default is the snapshot size.
  
  - **DeleteOnTermination (boolean)** –
    Indicates whether the EBS volume is deleted on instance termination.
  
  - **VolumeType (string)** –
    The volume type. gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, and standard for Magnetic volumes.
    Default: standard
· **Iops (integer)** –

The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.

Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.

Condition: This parameter is required for requests to create io1 volumes; it is not used in requests to create standard or gp2 volumes.

· **Encrypted (boolean)** –

Indicates whether the EBS volume is encrypted. Encrypted Amazon EBS volumes may only be attached to instances that support Amazon EBS encryption.

· **NoDevice (string)** –

Suppresses the specified device included in the block device mapping of the AMI.

- **SubnetId (string)** –

The ID of the subnet in which to launch the instance.

- **NetworkInterfaces (list)** –

One or more network interfaces.

  * (dict) –

  Describes a network interface.

  · **NetworkInterfaceId (string)** –

    The ID of the network interface.

  · **DeviceIndex (integer)** –

    The index of the device on the instance for the network interface attachment. If you are specifying a network interface in a RunInstances request, you must provide the device index.

  · **SubnetId (string)** –

    The ID of the subnet associated with the network string. Applies only if creating a network interface when launching an instance.

  · **Description (string)** –

    The description of the network interface. Applies only if creating a network interface when launching an instance.

  · **PrivateIpAddress (string)** –

    The private IP address of the network interface. Applies only if creating a network interface when launching an instance.

  · **Groups (list)** –
The IDs of the security groups for the network interface. Applies only if creating a network interface when launching an instance.

- (string)

- **DeleteOnTermination** (boolean)

  If set to `true`, the interface is deleted when the instance is terminated. You can specify `true` only if creating a new network interface when launching an instance.

- **PrivateIpAddresses** (list)

  One or more private IP addresses to assign to the network interface. Only one private IP address can be designated as primary.

  - (dict)

    Describes a secondary private IP address for a network interface.

    - **PrivateIpAddress** (string) – [REQUIRED]

      The private IP addresses.

    - **Primary** (boolean)

      Indicates whether the private IP address is the primary private IP address. Only one IP address can be designated as primary.

    - **SecondaryPrivateIpAddressCount** (integer)

      The number of secondary private IP addresses. You can’t specify this option and specify more than one private IP address using the private IP addresses option.

    - **AssociatePublicIpAddress** (boolean)

      Indicates whether to assign a public IP address to an instance you launch in a VPC. The public IP address can only be assigned to a network interface for eth0, and can only be assigned to a new network interface, not an existing one. You cannot specify more than one network interface in the request. If launching into a default subnet, the default value is `true`.

- **IamInstanceProfile** (dict)

  The IAM instance profile.

  - **Arn** (string)

    The Amazon Resource Name (ARN) of the instance profile.

  - **Name** (string)

    The name of the instance profile.

- **EbsOptimized** (boolean)

  Indicates whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal EBS I/O performance. This optimization isn’t available with all instance types. Additional usage charges apply when using an EBS Optimized instance.

  Default: `false`

- **Monitoring** (dict)

  Describes the monitoring for the instance.

  - **Enabled** (boolean) – [REQUIRED]
Indicates whether monitoring is enabled for the instance.

- **SecurityGroupIds** *(list)*
  
  * *(string)* –

Return type **dict**

Returns

Response Structure

- *(dict)* –

  Contains the output of RequestSpotInstances.

  - **SpotInstanceRequests** *(list)* –

    One or more Spot instance requests.

    - *(dict)* –

      Describe a Spot instance request.

      - **SpotInstanceRequestId** *(string)* –
The ID of the Spot instance request.

- **SpotPrice** *(string)* –
  The maximum hourly price (bid) for any Spot instance launched to fulfill the request.

- **Type** *(string)* –
  The Spot instance request type.

- **State** *(string)* –
  The state of the Spot instance request. Spot bid status information can help you track your Spot instance requests. For more information, see Spot Bid Status in the Amazon Elastic Compute Cloud User Guide.

- **Fault** *(dict)* –
  The fault codes for the Spot instance request, if any.

  - **Code** *(string)* –
    The reason code for the Spot instance state change.

  - **Message** *(string)* –
    The message for the Spot instance state change.

- **Status** *(dict)* –
  The status code and status message describing the Spot instance request.

  - **Code** *(string)* –
    The status code.

  - **UpdateTime** *(datetime)* –
    The date and time of the most recent status update, in UTC format (for example, `YYYY-MM-DDTHH:MM:SSZ`).

  - **Message** *(string)* –
    The description for the status code.

- **ValidFrom** *(datetime)* –
  The start date of the request, in UTC format (for example, `YYYY-MM-DDTHH:MM:SSZ`). If this is a one-time request, the request becomes active at this date and time and remains active until all instances launch, the request expires, or the request is canceled. If the request is persistent, the request becomes active at this date and time and remains active until it expires or is canceled.

- **ValidUntil** *(datetime)* –
  The end date of the request, in UTC format (for example, `YYYY-MM-DDTHH:MM:SSZ`). If this is a one-time request, the request remains active until all instances launch, the request is canceled, or this date is reached. If the request is persistent, it remains active until it is canceled or this date is reached.

- **LaunchGroup** *(string)* –
  The instance launch group. Launch groups are Spot instances that launch together and terminate together.

- **AvailabilityZoneGroup** *(string)* –
The Availability Zone group. If you specify the same Availability Zone group for all Spot instance requests, all Spot instances are launched in the same Availability Zone.

- **LaunchSpecification (dict)** –
  Additional information for launching instances.
  - **ImageId (string)** –
    The ID of the AMI.
  - **KeyName (string)** –
    The name of the key pair.
  - **SecurityGroups (list)** –
    One or more security groups. To request an instance in a non-default VPC, you must specify the ID of the security group. To request an instance in EC2-Classic or a default VPC, you can specify the name or the ID of the security group.
    - **(dict)** –
      Describes a security group.
      - **GroupName (string)** –
        The name of the security group.
      - **GroupId (string)** –
        The ID of the security group.
  - **UserData (string)** –
    The Base64-encoded MIME user data to make available to the instances.
  - **AddressingType (string)** –
    Deprecated.
  - **InstanceType (string)** –
    The instance type.
  - **Placement (dict)** –
    The placement information for the instance.
    - **AvailabilityZone (string)** –
      The Availability Zone.
    - **GroupName (string)** –
      The name of the placement group (for cluster instances).
  - **KernelId (string)** –
    The ID of the kernel.
  - **RamdiskId (string)** –
    The ID of the RAM disk.
  - **BlockDeviceMappings (list)** –
    One or more block device mapping entries.
    - **(dict)** –
      Describes a block device mapping.
    - **VirtualName (string)** –
      The virtual device name (ephemeral N). Instance store volumes are numbered starting from 0. An instance type with 2 available instance store volumes can specify mappings for
ephemeral0 and ephemeral1. The number of available instance store volumes depends on the instance type. After you connect to the instance, you must mount the volume.

Constraints: For M3 instances, you must specify instance store volumes in the block device mapping for the instance. When you launch an M3 instance, we ignore any instance store volumes specified in the block device mapping for the AMI.

- **DeviceName (string)** –
  The device name exposed to the instance (for example, /dev/sdh or xvdx).

- **Ebs (dict)** –
  Parameters used to automatically set up EBS volumes when the instance is launched.

- **SnapshotId (string)** –
  The ID of the snapshot.

- **VolumeSize (integer)** –
  The size of the volume, in GiB.
  Constraints: 1-1024 for **standard** volumes, 1-16384 for **gp2** volumes, and 4-16384 for **io1** volumes. If you specify a snapshot, the volume size must be equal to or larger than the snapshot size.
  Default: If you’re creating the volume from a snapshot and don’t specify a volume size, the default is the snapshot size.

- **DeleteOnTermination (boolean)** –
  Indicates whether the EBS volume is deleted on instance termination.

- **VolumeType (string)** –
  The volume type. **gp2** for General Purpose (SSD) volumes, **io1** for Provisioned IOPS (SSD) volumes, and **standard** for Magnetic volumes.
  Default: **standard**

- **Iops (integer)** –
  The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.
  Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.
  Condition: This parameter is required for requests to create **io1** volumes; it is not used in requests to create **standard** volumes.
or gp2 volumes.

- **Encrypted** (boolean) –

  Indicates whether the EBS volume is encrypted. Encrypted Amazon EBS volumes may only be attached to instances that support Amazon EBS encryption.

- **NoDevice** (string) –

  Suppresses the specified device included in the block device mapping of the AMI.

- **SubnetId** (string) –

  The ID of the subnet in which to launch the instance.

- **NetworkInterfaces** (list) –

  One or more network interfaces.

    - **(dict)** –

      Describes a network interface.

    - **NetworkInterfaceId** (string) –

      The ID of the network interface.

    - **DeviceIndex** (integer) –

      The index of the device on the instance for the network interface attachment. If you are specifying a network interface in a RunInstances request, you must provide the device index.

    - **SubnetId** (string) –

      The ID of the subnet associated with the network string. Applies only if creating a network interface when launching an instance.

    - **Description** (string) –

      The description of the network interface. Applies only if creating a network interface when launching an instance.

- **PrivateIpAddress** (string) –

  The private IP address of the network interface. Applies only if creating a network interface when launching an instance.

- **Groups** (list) –

  The IDs of the security groups for the network interface. Applies only if creating a network interface when launching an instance.

    - **(string)** –

      - **DeleteOnTermination** (boolean) –

        If set to `true`, the interface is deleted when the instance is terminated. You can specify `true` only if creating a new network interface when launching an instance.

- **PrivateIpAddresses** (list) –

  One or more private IP addresses to assign to the network interface. Only one private IP address can be designated as primary.

    - **(dict)** –

      Describes a secondary private IP address for a network interface.
- **PrivateIpAddress** *(string)* –
  The private IP addresses.
- **Primary** *(boolean)* –
  Indicates whether the private IP address is the primary private IP address. Only one IP address can be designated as primary.
- **SecondaryPrivateIpAddressCount** *(integer)* –
  The number of secondary private IP addresses. You can’t specify this option and specify more than one private IP address using the private IP addresses option.
- **AssociatePublicIpAddress** *(boolean)* –
  Indicates whether to assign a public IP address to an instance you launch in a VPC. The public IP address can only be assigned to a network interface for eth0, and can only be assigned to a new network interface, not an existing one. You cannot specify more than one network interface in the request. If launching into a default subnet, the default value is `true`.
- **IamInstanceProfile** *(dict)* –
  The IAM instance profile.
  - **Arn** *(string)* –
    The Amazon Resource Name (ARN) of the instance profile.
  - **Name** *(string)* –
    The name of the instance profile.
- **EbsOptimized** *(boolean)* –
  Indicates whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal EBS I/O performance. This optimization isn’t available with all instance types. Additional usage charges apply when using an EBS Optimized instance.
  Default: `false`
- **Monitoring** *(dict)* –
  Describes the monitoring for the instance.
  - **Enabled** *(boolean)* –
    Indicates whether monitoring is enabled for the instance.
  - **InstanceId** *(string)* –
    The instance ID, if an instance has been launched to fulfill the Spot instance request.
  - **CreateTime** *(datetime)* –
    The date and time when the Spot instance request was created, in UTC format (for example, `YYYY-MM-DDThh:mm:ssZ`).
  - **ProductDescription** *(string)* –
    The product description associated with the Spot instance.
  - **Tags** *(list)* –
    Any tags assigned to the resource.
· *(dict)* –
  Describes a tag.
  · **Key** *(string)* –
    The key of the tag.
  Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with *aws:*
  · **Value** *(string)* –
    The value of the tag.
  Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.
  · **LaunchedAvailabilityZone** *(string)* –
    The Availability Zone in which the bid is launched.

**reset_image_attribute(** **kwargs)**
Resets an attribute of an AMI to its default value.

**Note:** The *productCodes* attribute can’t be reset.

**Request Syntax**

```python
def response = client.reset_image_attribute(
  DryRun=True|False,
  ImageId='string',
  Attribute='launchPermission'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **ImageId** *(string)* – [REQUIRED]
  The ID of the AMI.
- **Attribute** *(string)* – [REQUIRED]
  The attribute to reset (currently you can only reset the launch permission attribute).

**Returns** None

**reset_instance_attribute(** **kwargs)**
Resets an attribute of an instance to its default value. To reset the *kernel* or *ramdisk*, the instance must be in a stopped state. To reset the *SourceDestCheck*, the instance can be either running or stopped.

The *SourceDestCheck* attribute controls whether source/destination checking is enabled. The default value is `true`, which means checking is enabled. This value must be `false` for a NAT instance to perform NAT. For more information, see *NAT Instances* in the *Amazon Virtual Private Cloud User Guide*.

**Request Syntax**

```python
def response = client.reset_instance_attribute(
  DryRun=True|False,
```
InstanceId='string',
Attribute='instanceType'|'kernel'|'ramdisk'|'userData'|'disableApiTermination'|'instanceInitiatedShutdownBehavior'|'rootDeviceName'|'blockDeviceMapping'|'productCodes'|'sourceDestCheck'|'groupSet'|'ebsOptimized'|'sriovNetSupport'

Parameters

• **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

• **InstanceId** (string) – [REQUIRED]
The ID of the instance.

• **Attribute** (string) – [REQUIRED]
The attribute to reset.

Returns None

reset_network_interface_attribute(**kwargs)
Resets a network interface attribute. You can specify only one attribute at a time.

Request Syntax

response = client.reset_network_interface_attribute(
    DryRun=True|False,
    NetworkInterfaceId='string',
    SourceDestCheck='string'
)

Parameters

• **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

• **NetworkInterfaceId** (string) – [REQUIRED]
The ID of the network interface.

• **SourceDestCheck** (string) – The source/destination checking attribute. Resets the value to true.

Returns None

reset_snapshot_attribute(**kwargs)
Resets permission settings for the specified snapshot.

For more information on modifying snapshot permissions, see Sharing Snapshots in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

response = client.reset_snapshot_attribute(
    DryRun=True|False,
    SnapshotId='string',
    Attribute='productCodes'|'createVolumePermission'
)

Parameters

• **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
• **SnapshotId (string)** – [REQUIRED]
  The ID of the snapshot.
• **Attribute (string)** – [REQUIRED]
  The attribute to reset. Currently, only the attribute for permission to create volumes can be reset.

Returns None

**restore_address_to_classic(**kwargs**)**
Restores an Elastic IP address that was previously moved to the EC2-VPC platform back to the EC2-Classic platform. You cannot move an Elastic IP address that was originally allocated for use in EC2-VPC. The Elastic IP address must not be associated with an instance or network interface.

Request Syntax

```python
response = client.restore_address_to_classic(
    DryRun=True|False,
    PublicIp='string'
)
```

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **PublicIp** (string) – [REQUIRED]
  The Elastic IP address.

Return type dict

Returns

Response Syntax

```python
{
    'Status': 'MoveInProgress'|'InVpc'|'InClassic',
    'PublicIp': 'string'
}
```

Response Structure

- **(dict)** –
  - **Status (string)** –
    The move status for the IP address.
  - **PublicIp (string)** –
    The Elastic IP address.

**revoke_security_group_egress(**kwargs**)**
Removes one or more egress rules from a security group for EC2-VPC. The values that you specify in the revoke request (for example, ports) must match the existing rule’s values for the rule to be revoked.

Each rule consists of the protocol and the CIDR range or source security group. For the TCP and UDP protocols, you must also specify the destination port or range of ports. For the ICMP protocol, you must also specify the ICMP type and code.

Rule changes are propagated to instances within the security group as quickly as possible. However, a small delay might occur.

Request Syntax
Boto3 Documentation, Release 1.1.4

```python
response = client.revoke_security_group_egress(
    DryRun=True|False,
    GroupId='string',
    SourceSecurityGroupName='string',
    SourceSecurityGroupOwnerId='string',
    IpProtocol='string',
    FromPort=123,
    ToPort=123,
    CidrIp='string',
    IpPermissions=[
        {'IpProtocol': 'string',
         'FromPort': 123,
         'ToPort': 123,
         'UserIdGroupPairs': [
             {'UserId': 'string',
              'GroupName': 'string',
              'GroupId': 'string'},
         ],
         'IpRanges': [
             {'CidrIp': 'string'},
         ],
         'PrefixListIds': [
             {'PrefixListId': 'string'},
         ],
        ],
    )
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **GroupId** *(string)* – [REQUIRED] The ID of the security group.

- **SourceSecurityGroupName** *(string)* – The name of a destination security group. To revoke outbound access to a destination security group, we recommend that you use a set of IP permissions instead.

- **SourceSecurityGroupOwnerId** *(string)* – The AWS account number for a destination security group. To revoke outbound access to a destination security group, we recommend that you use a set of IP permissions instead.

- **IpProtocol** *(string)* – The IP protocol name (tcp, udp, icmp) or number (see Protocol Numbers). Use -1 to specify all.

- **FromPort** *(integer)* – The start of port range for the TCP and UDP protocols, or an ICMP type number. For the ICMP type number, use -1 to specify all ICMP types.

- **ToPort** *(integer)* – The end of port range for the TCP and UDP protocols, or an ICMP code number. For the ICMP code number, use -1 to specify all ICMP types.
codes for the ICMP type.

- **CidrIp** *(string)* – The CIDR IP address range. You can’t specify this parameter when specifying a source security group.

- **IpPermissions** *(list)* – A set of IP permissions. You can’t specify a destination security group and a CIDR IP address range.
  
  - *(dict)* – Describes a security group rule.
    
      
      When you call DescribeSecurityGroups, the protocol value returned is the number. Exception: For TCP, UDP, and ICMP, the value returned is the name (for example, *tcp*, *udp*, or *icmp*). For a list of protocol numbers, see Protocol Numbers. (VPC only) When you call AuthorizeSecurityGroupIngress, you can use \-1 to specify all.
    
    * **FromPort** *(integer)* – The start of port range for the TCP and UDP protocols, or an ICMP type number. A value of \-1 indicates all ICMP types.
    
    * **ToPort** *(integer)* – The end of port range for the TCP and UDP protocols, or an ICMP code. A value of \-1 indicates all ICMP codes for the specified ICMP type.
    
    * **UserIdGroupPairs** *(list)* – One or more security group and AWS account ID pairs.
      
      - *(dict)* – Describes a security group and AWS account ID pair.
        
        * **UserId** *(string)* – The ID of an AWS account. EC2-Classic only.
        
        * **GroupName** *(string)* – The name of the security group. In a request, use this parameter for a security group in EC2-Classic or a default VPC only. For a security group in a nondefault VPC, use **GroupId**.
        
        * **GroupId** *(string)* – The ID of the security group.
      
    * **IpRanges** *(list)* – One or more IP ranges.
      
      - *(dict)* – Describes an IP range.
        
        * **CidrIp** *(string)* – The CIDR range. You can either specify a CIDR range or a source security group, not both.
      
    * **PrefixListIds** *(list)* – (Valid for AuthorizeSecurityGroupEgress, RevokeSecurityGroupEgress and DescribeSecurityGroups only) One or more prefix list IDs for an AWS service. In an AuthorizeSecurityGroupEgress request, this is the AWS service that you want to access through a VPC endpoint from instances associated with the security group.
(dict) –
     The ID of the prefix.
- PrefixListId (string) –
     The ID of the prefix.

Returns None

revoke_security_group_ingress(**kwargs)

Removes one or more ingress rules from a security group. The values that you specify in the revoke request (for example, ports) must match the existing rule’s values for the rule to be removed.

Each rule consists of the protocol and the CIDR range or source security group. For the TCP and UDP protocols, you must also specify the destination port or range of ports. For the ICMP protocol, you must also specify the ICMP type and code.

Rule changes are propagated to instances within the security group as quickly as possible. However, a small delay might occur.

Request Syntax

response = client.revoke_security_group_ingress(
    DryRun=True|False,
    GroupName='string',
    GroupId='string',
    SourceSecurityGroupName='string',
    SourceSecurityGroupOwnerId='string',
    IpProtocol='string',
    FromPort=123,
    ToPort=123,
    CidrIp='string',
    IpPermissions=[
        {  
            'IpProtocol': 'string',
            'FromPort': 123,
            'ToPort': 123,
            'UserIdGroupPairs': [  
                {  
                    'UserId': 'string',
                    'GroupName': 'string',
                    'GroupId': 'string'
                },
            ],
            'IpRanges': [  
                {  
                    'CidrIp': 'string'
                },
            ],
            'PrefixListIds': [  
                {  
                    'PrefixListId': 'string'
                },
            ],
        ],
    ]
)

Parameters
- DryRun (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If
you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **GroupName** *(string)* – [EC2-Classic, default VPC] The name of the security group.
- **GroupId** *(string)* – The ID of the security group. Required for a security group in a nondefault VPC.
- **SourceSecurityGroupName** *(string)* – [EC2-Classic, default VPC] The name of the source security group. You can’t specify this parameter in combination with the following parameters: the CIDR IP address range, the start of the port range, the IP protocol, and the end of the port range. For EC2-VPC, the source security group must be in the same VPC.
- **SourceSecurityGroupOwnerId** *(string)* – [EC2-Classic, default VPC] The AWS account ID of the source security group. For EC2-VPC, the source security group must be in the same VPC. You can’t specify this parameter in combination with the following parameters: the CIDR IP address range, the IP protocol, the start of the port range, and the end of the port range. To revoke a specific rule for an IP protocol and port range, use a set of IP permissions instead.
- **IpProtocol** *(string)* – The IP protocol name *(tcp, udp, icmp)* or number (see Protocol Numbers). Use `-1` to specify all.
- **FromPort** *(integer)* – The start of port range for the TCP and UDP protocols, or an ICMP type number. For the ICMP type number, use `-1` to specify all ICMP types.
- **ToPort** *(integer)* – The end of port range for the TCP and UDP protocols, or an ICMP code number. A value of `-1` indicates all ICMP codes for the specified ICMP type.
- **CidrIp** *(string)* – The CIDR IP address range. You can’t specify this parameter when specifying a source security group.
- **IpPermissions** *(list)* – A set of IP permissions. You can’t specify a source security group and a CIDR IP address range.

  - *(dict)* – Describes a security group rule.
    - **IpProtocol** *(string)* –
      The protocol.
      When you call `DescribeSecurityGroups`, the protocol value returned is the number. Exception: For TCP, UDP, and ICMP, the value returned is the name (for example, `tcp`, `udp`, or `icmp`). For a list of protocol numbers, see Protocol Numbers. (VPC only) When you call `AuthorizeSecurityGroupIngress`, you can use `-1` to specify all.
    - **FromPort** *(integer)* –
      The start of port range for the TCP and UDP protocols, or an ICMP type number. A value of `-1` indicates all ICMP types.
    - **ToPort** *(integer)* –
      The end of port range for the TCP and UDP protocols, or an ICMP code. A value of `-1` indicates all ICMP codes for the specified ICMP type.
    - **UserIdGroupPairs** *(list)* –
      One or more security group and AWS account ID pairs.
      - *(dict)* –
        Describes a security group and AWS account ID pair.
The ID of an AWS account. EC2-Classic only.

- **GroupName** *(string)* –
  The name of the security group. In a request, use this parameter for a security group in EC2-Classic or a default VPC only. For a security group in a nondefault VPC, use **GroupId**.

- **GroupId** *(string)* –
  The ID of the security group.

  * **IpRanges** *(list)* –
    One or more IP ranges.
    - *(dict)* –
      Describes an IP range.
    - **CidrIp** *(string)* –
      The CIDR range. You can either specify a CIDR range or a source security group, not both.

  * **PrefixListIds** *(list)* –
    (Valid for AuthorizeSecurityGroupEgress, RevokeSecurityGroupEgress and DescribeSecurityGroups only) One or more prefix list IDs for an AWS service. In an AuthorizeSecurityGroupEgress request, this is the AWS service that you want to access through a VPC endpoint from instances associated with the security group.
    - *(dict)* –
      The ID of the prefix.
    - **PrefixListId** *(string)* –
      The ID of the prefix.

**Returns** None

**run_instances** (**kwargs**)
Launches the specified number of instances using an AMI for which you have permissions.

When you launch an instance, it enters the pending state. After the instance is ready for you, it enters the running state. To check the state of your instance, call DescribeInstances.

If you don’t specify a security group when launching an instance, Amazon EC2 uses the default security group. For more information, see Security Groups in the Amazon Elastic Compute Cloud User Guide.

[EC2-VPC only accounts] If you don’t specify a subnet in the request, we choose a default subnet from your default VPC for you.

[EC2-Classic accounts] If you’re launching into EC2-Classic and you don’t specify an Availability Zone, we choose one for you.

Linux instances have access to the public key of the key pair at boot. You can use this key to provide secure access to the instance. Amazon EC2 public images use this feature to provide secure access without passwords. For more information, see Key Pairs in the Amazon Elastic Compute Cloud User Guide.

You can provide optional user data when launching an instance. For more information, see Instance Metadata in the Amazon Elastic Compute Cloud User Guide.

If any of the AMIs have a product code attached for which the user has not subscribed, **RunInstances** fails.
T2 instance types can only be launched into a VPC. If you do not have a default VPC, or if you do not specify a subnet ID in the request, `RunInstances` fails.

For more information about troubleshooting, see What To Do If An Instance Immediately Terminates , and Troubleshooting Connecting to Your Instance in the Amazon Elastic Compute Cloud User Guide .

### Request Syntax

```python
response = client.run_instances(
    DryRun=True|False,
    ImageId='string',
    MinCount=123,
    MaxCount=123,
    KeyName='string',
    SecurityGroups=[
        'string',
    ],
    SecurityGroupIds=[
        'string',
    ],
    UserData='string',
    InstanceType='t1.micro'|'m1.small'|'m1.medium'|'m1.large'|'m1.xlarge'|'m3.medium'|'m3.large'|'m3.xlarge'|'m3.2xlarge'|'m4.10xlarge'|'m4.16xlarge'|'m4.2xlarge'|'m4.4xlarge'|'m4.8xlarge'|'r3.large'|'r3.xlarge'|'r3.2xlarge'|'r3.4xlarge'|'r3.8xlarge'|'d2.xlarge'|'d2.2xlarge'|'d2.4xlarge'|'d2.8xlarge',
    Placement=
        {'AvailabilityZone': 'string',
         'GroupName': 'string',
         'Tenancy': 'default'|'dedicated'},
    KernelId='string',
    RamdiskId='string',
    BlockDeviceMappings=[
        {'VirtualName': 'string',
         'DeviceName': 'string',
         'Ebs': {
             'SnapshotId': 'string',
             'VolumeSize': 123,
             'DeleteOnTermination': True|False,
             'VolumeType': 'standard'|'io1'|'gp2',
             'Iops': 123,
             'Encrypted': True|False
         },
         'NoDevice': 'string'},
    ],
    Monitoring={
        'Enabled': True|False
    },
    SubnetId='string',
    DisableApiTermination=True|False,
    InstanceInitiatedShutdownBehavior='stop'|'terminate',
    PrivateIpAddress='string',
    ClientToken='string',
    AdditionalInfo='string',
    NetworkInterfaces=[
        {'NetworkInterfaceId': 'string',
         'DeviceIndex': 123,
         'SubnetId': 'string',
         'Description': 'string'},
    ],
)
{'PrivateIpAddress': 'string',
'Groups': [
  'string',
],
'DeleteOnTermination': True|False,
'PrivateIpAddresses': [
  {
    'PrivateIpAddress': 'string',
    'Primary': True|False
  },
],
'SecondaryPrivateIpAddressCount': 123,
'AssociatePublicIpAddress': True|False
},
IamInstanceProfile={
  'Arn': 'string',
  'Name': 'string'
},
EbsOptimized=True|False
)

Parameters

• **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

• **ImageId** *(string)* – [REQUIRED]

  The ID of the AMI, which you can get by calling DescribeImages.

• **MinCount** *(integer)* – [REQUIRED]

  The minimum number of instances to launch. If you specify a minimum that is more instances than Amazon EC2 can launch in the target Availability Zone, Amazon EC2 launches no instances.

  Constraints: Between 1 and the maximum number you’re allowed for the specified instance type. For more information about the default limits, and how to request an increase, see How many instances can I run in Amazon EC2 in the Amazon EC2 General FAQ.

• **MaxCount** *(integer)* – [REQUIRED]

  The maximum number of instances to launch. If you specify more instances than Amazon EC2 can launch in the target Availability Zone, Amazon EC2 launches the largest possible number of instances above MinCount.

  Constraints: Between 1 and the maximum number you’re allowed for the specified instance type. For more information about the default limits, and how to request an increase, see How many instances can I run in Amazon EC2 in the Amazon EC2 General FAQ.

• **KeyName** *(string)* – The name of the key pair. You can create a key pair using CreateKeyPair or ImportKeyPair.

**Warning:** If you do not specify a key pair, you can’t connect to the instance unless you choose an AMI that is configured to allow users another way to log in.
• **SecurityGroups** *(list)* – [EC2-Classic, default VPC] One or more security group names. For a nondefault VPC, you must use security group IDs instead.

Default: Amazon EC2 uses the default security group.
  
  – *(string)* –

• **SecurityGroupIds** *(list)* – One or more security group IDs. You can create a security group using `CreateSecurityGroup`.

Default: Amazon EC2 uses the default security group.
  
  – *(string)* –

• **UserData** *(string)* – The Base64-encoded MIME user data for the instances. This value will be base64 encoded automatically. Do not base64 encode this value prior to performing the operation.

• **InstanceType** *(string)* – The instance type. For more information, see Instance Types in the Amazon Elastic Compute Cloud User Guide.

Default: `m1.small`

• **Placement** *(dict)* – The placement for the instance.
  
  – **AvailabilityZone** *(string)* –

  The Availability Zone of the instance.

  – **GroupName** *(string)* –

  The name of the placement group the instance is in (for cluster compute instances).

  – **Tenancy** *(string)* –

  The tenancy of the instance (if the instance is running in a VPC). An instance with a tenancy of dedicated runs on single-tenant hardware.

• **KernelId** *(string)* – The ID of the kernel.

  **Warning:** We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see PV-GRUB in the Amazon Elastic Compute Cloud User Guide.

• **RamdiskId** *(string)* – The ID of the RAM disk.

  **Warning:** We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see PV-GRUB in the Amazon Elastic Compute Cloud User Guide.

• **BlockDeviceMappings** *(list)* – The block device mapping.
  
  – *(dict)* –

  Describes a block device mapping.

  * **VirtualName** *(string)* –

  The virtual device name (ephemeral N). Instance store volumes are numbered starting from 0. An instance type with 2 available instance store volumes can specify mappings for ephemeral0 and ephemeral1. The number of available instance store volumes depends on the instance type. After you connect to the instance, you must mount the volume.

  Constraints: For M3 instances, you must specify instance store volumes in the block device mapping for the instance. When you launch an M3 instance, we ignore any instance store volumes specified in the block device mapping for the AMI.
∗ **DeviceName** (*string*) —

  The device name exposed to the instance (for example, /dev/sdh or xvdh).

∗ **Ebs** (*dict*) —

  Parameters used to automatically set up EBS volumes when the instance is launched.

  * **SnapshotId** (*string*) —

    The ID of the snapshot.

  * **VolumeSize** (*integer*) —

    The size of the volume, in GiB.

    Constraints: 1-1024 for standard volumes, 1-16384 for gp2 volumes, and 4-16384 for io1 volumes. If you specify a snapshot, the volume size must be equal to or larger than the snapshot size.

    Default: If you’re creating the volume from a snapshot and don’t specify a volume size, the default is the snapshot size.

  * **DeleteOnTermination** (*boolean*) —

    Indicates whether the EBS volume is deleted on instance termination.

  * **VolumeType** (*string*) —

    The volume type. gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, and standard for Magnetic volumes.

    Default: standard

  * **Iops** (*integer*) —

    The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.

    Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.

    Condition: This parameter is required for requests to create io1 volumes; it is not used in requests to create standard or gp2 volumes.

  * **Encrypted** (*boolean*) —

    Indicates whether the EBS volume is encrypted. Encrypted Amazon EBS volumes may only be attached to instances that support Amazon EBS encryption.

∗ **NoDevice** (*string*) —

  Suppresses the specified device included in the block device mapping of the AMI.
• **Monitoring** *(dict)* – The monitoring for the instance.
  – **Enabled** *(boolean)* – [REQUIRED]
    Indicates whether monitoring is enabled for the instance.

• **SubnetId** *(string)* – [EC2-VPC] The ID of the subnet to launch the instance into.

• **DisableApiTermination** *(boolean)* – If you set this parameter to `true`, you can’t terminate the instance using the Amazon EC2 console, CLI, or API; otherwise, you can. If you set this parameter to `true` and then later want to be able to terminate the instance, you must first change the value of the `disableApiTermination` attribute to `false` using `ModifyInstanceAttribute`. Alternatively, if you set `InstanceInitiatedShutdownBehavior` to `terminate`, you can terminate the instance by running the shutdown command from the instance.

  Default: `false`

• **InstanceInitiatedShutdownBehavior** *(string)* – Indicates whether an instance stops or terminates when you initiate shutdown from the instance (using the operating system command for system shutdown).

  Default: `stop`

• **PrivateIpAddress** *(string)* – [EC2-VPC] The primary IP address. You must specify a value from the IP address range of the subnet.

  Only one private IP address can be designated as primary. Therefore, you can’t specify this parameter if `PrivateIpAddresses.n.Primary` is set to `true` and `PrivateIpAddresses.n.PrivateIpAddress` is set to an IP address.

  Default: We select an IP address from the IP address range of the subnet.

• **ClientToken** *(string)* – Unique, case-sensitive identifier you provide to ensure the idempotency of the request. For more information, see [Ensuring Idempotency](#).

  Constraints: Maximum 64 ASCII characters

• **AdditionalInfo** *(string)* – Reserved.

• **NetworkInterfaces** *(list)* – One or more network interfaces.
  – *(dict)*

  Describes a network interface.
  
  • **NetworkInterfaceId** *(string)* –
    The ID of the network interface.
  
  • **DeviceIndex** *(integer)* –
    The index of the device on the instance for the network interface attachment. If you are specifying a network interface in a `RunInstances` request, you must provide the device index.

  • **SubnetId** *(string)* –
    The ID of the subnet associated with the network string. Applies only if creating a network interface when launching an instance.

  • **Description** *(string)* –
    The description of the network interface. Applies only if creating a network interface when launching an instance.

  • **PrivateIpAddress** *(string)* –
    The private IP address of the network interface. Applies only if creating a network interface when launching an instance.
* **Groups** *(list)* –
  The IDs of the security groups for the network interface. Applies only if creating a network interface when launching an instance.
  · *(string)* –

* **DeleteOnTermination** *(boolean)* –
  If set to `true`, the interface is deleted when the instance is terminated. You can specify `true` only if creating a new network interface when launching an instance.

* **PrivateIpAddresses** *(list)* –
  One or more private IP addresses to assign to the network interface. Only one private IP address can be designated as primary.
  · *(dict)* –
    · **PrivateIpAddress** *(string)* – [REQUIRED]
      The private IP addresses.
    · **Primary** *(boolean)* –
      Indicates whether the private IP address is the primary private IP address. Only one IP address can be designated as primary.

* **SecondaryPrivateIpAddressCount** *(integer)* –
  The number of secondary private IP addresses. You can’t specify this option and specify more than one private IP address using the private IP addresses option.

* **AssociatePublicIpAddress** *(boolean)* –
  Indicates whether to assign a public IP address to an instance you launch in a VPC. The public IP address can only be assigned to a network interface for eth0, and can only be assigned to a new network interface, not an existing one. You cannot specify more than one network interface in the request. If launching into a default subnet, the default value is `true`.

* **IamInstanceProfile** *(dict)* – The IAM instance profile.
  · **Arn** *(string)* –
    The Amazon Resource Name (ARN) of the instance profile.
  · **Name** *(string)* –
    The name of the instance profile.

* **EbsOptimized** *(boolean)* – Indicates whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal EBS I/O performance. This optimization isn’t available with all instance types. Additional usage charges apply when using an EBS-optimized instance.

  Default: `false`

Return type: `dict`
Returns

Response Structure

• (dict) –

One or more reservations.

– **ReservationId** (string) –
  The ID of the reservation.

– **OwnerId** (string) –
  The ID of the AWS account that owns the reservation.

– **RequesterId** (string) –
  The ID of the requester that launched the instances on your behalf (for example, AWS Management Console or Auto Scaling).

– **Groups** (list) –
  One or more security groups.
  * (dict) –
    Describes a security group.
    • **GroupName** (string) –
      The name of the security group.
    • **GroupId** (string) –
      The ID of the security group.

– **Instances** (list) –
  One or more instances.
  * (dict) –
    Describes an instance.
    • **InstanceId** (string) –
      The ID of the instance.
    • **ImageId** (string) –
      The ID of the AMI used to launch the instance.
    • **State** (dict) –
      The current state of the instance.
    • **Code** (integer) –
      The low byte represents the state. The high byte is an opaque internal value and should be ignored.
- 0: pending
- 16: running
- 32: shutting-down
- 48: terminated
- 64: stopping
- 80: stopped
- **Name (string)** –
  
  The current state of the instance.

- **PrivateDnsName (string)** –
  
  The private DNS name assigned to the instance. This DNS name can only be used inside the Amazon EC2 network. This name is not available until the instance enters the **running** state.

- **PublicDnsName (string)** –
  
  The public DNS name assigned to the instance. This name is not available until the instance enters the **running** state.

- **StateTransitionReason (string)** –
  
  The reason for the most recent state transition. This might be an empty string.

- **KeyName (string)** –
  
  The name of the key pair, if this instance was launched with an associated key pair.

- **AmiLaunchIndex (integer)** –
  
  The AMI launch index, which can be used to find this instance in the launch group.

- **ProductCodes (list)** –
  
  The product codes attached to this instance.

  - **(dict)** –
    
    Describes a product code.

    - **ProductCodeId (string)** –
      
      The product code.

    - **ProductCodeType (string)** –
      
      The type of product code.

    - **InstanceType (string)** –
      
      The instance type.

    - **LaunchTime (datetime)** –
      
      The time the instance was launched.

- **Placement (dict)** –
  
  The location where the instance launched.

- **AvailabilityZone (string)** –
  
  The Availability Zone of the instance.

- **GroupName (string)** –
  
  The name of the placement group the instance is in (for cluster compute instances).

- **Tenancy (string)** –
The tenancy of the instance (if the instance is running in a VPC). An instance with a tenancy of dedicated runs on single-tenant hardware.

- **KernelId (string)** –
  The kernel associated with this instance.

- **RamdiskId (string)** –
  The RAM disk associated with this instance.

- **Platform (string)** –
  The value is Windows for Windows instances; otherwise blank.

- **Monitoring (dict)** –
  The monitoring information for the instance.

- **State (string)** –
  Indicates whether monitoring is enabled for the instance.

- **SubnetId (string)** –
  The ID of the subnet in which the instance is running.

- **VpcId (string)** –
  The ID of the VPC in which the instance is running.

- **PrivateIpAddress (string)** –
  The private IP address assigned to the instance.

- **PublicIpAddress (string)** –
  The public IP address assigned to the instance.

- **StateReason (dict)** –
  The reason for the most recent state transition.

  - **Code (string)** –
    The reason code for the state change.

  - **Message (string)** –
    The message for the state change.

- **Server.SpotInstanceTermination**: A Spot Instance was terminated due to an increase in the market price.
- **Server.InternalError**: An internal error occurred during instance launch, resulting in termination.
- **Server.InsufficientInstanceCapacity**: There was insufficient instance capacity to satisfy the launch request.
- **Client.InternalError**: A client error caused the instance to terminate on launch.
- **Client.InstanceInitiatedShutdown**: The instance was shut down using the `shutdown -h` command from the instance.
- **Client.UserInitiatedShutdown**: The instance was shut down using the Amazon EC2 API.
- **Client.VolumeLimitExceeded**: The volume limit was exceeded.
- **Client.InvalidSnapshot.NotFound**: The specified snapshot was not found.

- **Architecture (string)** –
The architecture of the image.

- **RootDeviceType** *(string)* –
  The root device type used by the AMI. The AMI can use an EBS volume or an instance store volume.

- **RootDeviceName** *(string)* –
  The root device name (for example, `/dev/sda1` or `/dev/xvda`).

- **BlockDeviceMappings** *(list)* –
  Any block device mapping entries for the instance.
  - *(dict)* –
    Describes a block device mapping.

- **DeviceName** *(string)* –
  The device name exposed to the instance (for example, `/dev/sdh` or `/xvdh`).

- **Ebs** *(dict)* –
  Parameters used to automatically set up EBS volumes when the instance is launched.
  - **VolumeId** *(string)* –
    The ID of the EBS volume.
  - **Status** *(string)* –
    The attachment state.
  - **AttachTime** *(datetime)* –
    The time stamp when the attachment initiated.

- **DeleteOnTermination** *(boolean)* –
  Indicates whether the volume is deleted on instance termination.

- **VirtualizationType** *(string)* –
  The virtualization type of the instance.

- **InstanceLifecycle** *(string)* –
  Indicates whether this is a Spot Instance.

- **SpotInstanceRequestId** *(string)* –
  The ID of the Spot Instance request.

- **ClientToken** *(string)* –
  The idempotency token you provided when you launched the instance.

- **Tags** *(list)* –
  Any tags assigned to the instance.
  - *(dict)* –
    Describes a tag.

- **Key** *(string)* –
  The key of the tag.

Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`
· Value (string) –
  The value of the tag.

  Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

· SecurityGroups (list) –
  One or more security groups for the instance.

  (dict) –

  Describes a security group.

  · GroupName (string) –
    The name of the security group.

  · GroupId (string) –
    The ID of the security group.

· SourceDestCheck (boolean) –
  Specifies whether to enable an instance launched in a VPC to perform NAT. This controls whether source/destination checking is enabled on the instance. A value of true means checking is enabled, and false means checking is disabled. The value must be false for the instance to perform NAT. For more information, see NAT Instances in the Amazon Virtual Private Cloud User Guide.

· Hypervisor (string) –
  The hypervisor type of the instance.

· NetworkInterfaces (list) –
  [EC2-VPC] One or more network interfaces for the instance.

  (dict) –

  Describes a network interface.

  · NetworkInterfaceId (string) –
    The ID of the network interface.

  · SubnetId (string) –
    The ID of the subnet.

  · VpcId (string) –
    The ID of the VPC.

· Description (string) –
  The description.

· OwnerId (string) –
  The ID of the AWS account that created the network interface.

· Status (string) –
  The status of the network interface.

· MacAddress (string) –
  The MAC address.

· PrivateIpAddress (string) –
  The IP address of the network interface within the subnet.

· PrivateDnsName (string) –
  The private DNS name.
· **SourceDestCheck** *(boolean)* –

Indicates whether to validate network traffic to or from this network interface.

· **Groups** *(list)* –

One or more security groups.

· **GroupName** *(string)* –

The name of the security group.

· **GroupId** *(string)* –

The ID of the security group.

· **Attachment** *(dict)* –

The network interface attachment.

· **AttachmentId** *(string)* –

The ID of the network interface attachment.

· **DeviceIndex** *(integer)* –

The index of the device on the instance for the network interface attachment.

· **Status** *(string)* –

The attachment state.

· **AttachTime** *(datetime)* –

The time stamp when the attachment initiated.

· **DeleteOnTermination** *(boolean)* –

Indicates whether the network interface is deleted when the instance is terminated.

· **Association** *(dict)* –

The association information for an Elastic IP associated with the network interface.

· **PublicIp** *(string)* –

The public IP address or Elastic IP address bound to the network interface.

· **PublicDnsName** *(string)* –

The public DNS name.

· **IpOwnerId** *(string)* –

The ID of the owner of the Elastic IP address.

· **PrivateIpAddresses** *(list)* –

The private IP addresses associated with the network interface.

· **PrivateIpAddress** *(string)* –

Describes a private IP address.

· **PrivateIpAddress** *(string)* –

The private IP address of the network interface.

· **PrivateDnsName** *(string)* –

The private DNS name.
Primary (boolean) –
Indicates whether this IP address is the primary private IP address of the network interface.

Association (dict) –
The association information for an Elastic IP address for the network interface.

PublicIp (string) –
The public IP address or Elastic IP address bound to the network interface.

PublicDnsName (string) –
The public DNS name.

IpOwnerId (string) –
The ID of the owner of the Elastic IP address.

IamInstanceProfile (dict) –
The IAM instance profile associated with the instance.

Arn (string) –
The Amazon Resource Name (ARN) of the instance profile.

Id (string) –
The ID of the instance profile.

EbsOptimized (boolean) –
Indicates whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal I/O performance. This optimization isn’t available with all instance types. Additional usage charges apply when using an EBS Optimized instance.

SriovNetSupport (string) –
Specifies whether enhanced networking is enabled.

start_instances(**kwargs)
Starts an Amazon EBS-backed AMI that you’ve previously stopped.

Instances that use Amazon EBS volumes as their root devices can be quickly stopped and started. When an instance is stopped, the compute resources are released and you are not billed for hourly instance usage. However, your root partition Amazon EBS volume remains, continues to persist your data, and you are charged for Amazon EBS volume usage. You can restart your instance at any time. Each time you transition an instance from stopped to started, Amazon EC2 charges a full instance hour, even if transitions happen multiple times within a single hour.

Before stopping an instance, make sure it is in a state from which it can be restarted. Stopping an instance does not preserve data stored in RAM.

Performing this operation on an instance that uses an instance store as its root device returns an error.

For more information, see Stopping Instances in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

response = client.start_instances(
    InstanceIds=[
        'string',
    ],
)
Parameters

- **InstanceIds (list)** – [REQUIRED]
  One or more instance IDs.
  - (string)
- **AdditionalInfo (string)** – Reserved.
- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

Returns

**Response Syntax**

```python
{
    'StartingInstances': [
        {
            'InstanceId': 'string',
            'CurrentState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped'
            },
            'PreviousState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped'
            }
        },
    ]
}
```

**Response Structure**

- (dict) –
  - **StartingInstances (list)** –
    Information about one or more started instances.
    - (dict) –
      Describes an instance state change.
      - **InstanceId (string)** –
        The ID of the instance.
      - **CurrentState (dict)** –
        The current state of the instance.
        - **Code (integer)** –
          The low byte represents the state. The high byte is an opaque internal value and should be ignored.
          - 0: pending
          - 16: running
          - 32: shutting-down
          - 48: terminated
          - 64: stopping
          - 80: stopped
• **Name** *(string)* –
  The current state of the instance.

• **PreviousState** *(dict)* –
  The previous state of the instance.

• **Code** *(integer)* –
  The low byte represents the state. The high byte is an opaque internal value and should be ignored.
  - 0: pending
  - 16: running
  - 32: shutting-down
  - 48: terminated
  - 64: stopping
  - 80: stopped
  - **Name** *(string)* –
  The current state of the instance.

**stop_instances(****kwargs**)**

Stops an Amazon EBS-backed instance. Each time you transition an instance from stopped to started, Amazon EC2 charges a full instance hour, even if transitions happen multiple times within a single hour.

You can’t start or stop Spot Instances.

Instances that use Amazon EBS volumes as their root devices can be quickly stopped and started. When an instance is stopped, the compute resources are released and you are not billed for hourly instance usage. However, your root partition Amazon EBS volume remains, continues to persist your data, and you are charged for Amazon EBS volume usage. You can restart your instance at any time.

Before stopping an instance, make sure it is in a state from which it can be restarted. Stopping an instance does not preserve data stored in RAM.

Performing this operation on an instance that uses an instance store as its root device returns an error.

You can stop, start, and terminate EBS-backed instances. You can only terminate instance store-backed instances. What happens to an instance differs if you stop it or terminate it. For example, when you stop an instance, the root device and any other devices attached to the instance persist. When you terminate an instance, the root device and any other devices attached during the instance launch are automatically deleted. For more information about the differences between stopping and terminating instances, see Instance Lifecycle in the *Amazon Elastic Compute Cloud User Guide*.

For more information about troubleshooting, see Troubleshooting Stopping Your Instance in the *Amazon Elastic Compute Cloud User Guide*.

**Request Syntax**

```python
response = client.stop_instances(
    DryRun=True|False,
    InstanceIds=['string',
                 ],
    Force=True|False)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.
• **InstanceIds** *(list)* – [REQUIRED]

   One or more instance IDs.
   
   – *(string)* –

• **Force** *(boolean)* – Forces the instances to stop. The instances do not have an opportunity to flush file system caches or file system metadata. If you use this option, you must perform file system check and repair procedures. This option is not recommended for Windows instances.

   Default: *false*

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'StoppingInstances': [
        {
            'InstanceId': 'string',
            'CurrentState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|
                'PreviousState': {
                    'Code': 123,
                    'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'
                }
            }
        }
    ]
}
```

**Response Structure**

• *(dict)* –

  – **StoppingInstances** *(list)* –

    Information about one or more stopped instances.

    • *(dict)* –

      Describes an instance state change.

      • **InstanceId** *(string)* –

        The ID of the instance.

      • **CurrentState** *(dict)* –

        The current state of the instance.

      • **Code** *(integer)* –

        The low byte represents the state. The high byte is an opaque internal value and should be ignored.

        • 0: pending
        • 16: running
        • 32: shutting-down
        • 48: terminated
        • 64: stopping
        • 80: stopped

      • **Name** *(string)* –

        The current state of the instance.

      • **PreviousState** *(dict)* –
The previous state of the instance.

- **Code (integer)** –
  
The low byte represents the state. The high byte is an opaque internal value and should be ignored.
  - 0: pending
  - 16: running
  - 32: shutting-down
  - 48: terminated
  - 64: stopping
  - 80: stopped
- **Name (string)** –
  
The current state of the instance.

**terminate_instances** (**kwargs**)

Shuts down one or more instances. This operation is idempotent; if you terminate an instance more than once, each call succeeds.

Terminated instances remain visible after termination (for approximately one hour).

By default, Amazon EC2 deletes all EBS volumes that were attached when the instance launched. Volumes attached after instance launch continue running.

You can stop, start, and terminate EBS-backed instances. You can only terminate instance store-backed instances. What happens to an instance differs if you stop it or terminate it. For example, when you stop an instance, the root device and any other devices attached to the instance persist. When you terminate an instance, any attached EBS volumes with the **DeleteOnTermination** block device mapping parameter set to **true** are automatically deleted. For more information about the differences between stopping and terminating instances, see Instance Lifecycle in the Amazon Elastic Compute Cloud User Guide.

For more information about troubleshooting, see Troubleshooting Terminating Your Instance in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = client.terminate_instances(
    DryRun=True|False,
    InstanceIds=[
        'string',
    ]
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.
- **InstanceIds (list)** – [REQUIRED]
  
  One or more instance IDs.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'TerminatingInstances': [
```

3.1. Services 1449
Response Structure

- **(dict)** –
  - **TerminatingInstances** *(list)* –
    Information about one or more terminated instances.
    - **(dict)** –
      Describes an instance state change.
      - **InstanceId** *(string)* –
        The ID of the instance.
      - **CurrentState** *(dict)* –
        The current state of the instance.
        - **Code** *(integer)* –
          The low byte represents the state. The high byte is an opaque internal value and should be ignored.
          - 0: pending
          - 16: running
          - 32: shutting-down
          - 48: terminated
          - 64: stopping
          - 80: stopped
          - **Name** *(string)* –
            The current state of the instance.
        - **PreviousState** *(dict)* –
          The previous state of the instance.
          - **Code** *(integer)* –
            The low byte represents the state. The high byte is an opaque internal value and should be ignored.
            - 0: pending
            - 16: running
            - 32: shutting-down
            - 48: terminated
            - 64: stopping
            - 80: stopped
            - **Name** *(string)* –
              The current state of the instance.

**unassign_private_ip_addresses** (**kwargs**)

Unassigns one or more secondary private IP addresses from a network interface.
Request Syntax

```python
response = client.unassign_private_ip_addresses(
    NetworkInterfaceId='string',
    PrivateIpAddresses=[
        'string',
    ],
)
```

Parameters

- **NetworkInterfaceId** *(string)* – [REQUIRED]
  
  The ID of the network interface.

- **PrivateIpAddresses** *(list)* – [REQUIRED]
  
  The secondary private IP addresses to unassign from the network interface. You can specify this option multiple times to unassign more than one IP address.

Returns  None

`unmonitor_instances(**kwargs)`

Disables monitoring for a running instance. For more information about monitoring instances, see Monitoring Your Instances and Volumes in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = client.unmonitor_instances(
    DryRun=True|False,
    InstanceIds=[
        'string',
    ],
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **InstanceIds** *(list)* – [REQUIRED]
  
  One or more instance IDs.

Returns  dict

Response Syntax

```json
{
    'InstanceMonitorings': [
        {
            'InstanceId': 'string',
            'Monitoring': {
                'State': 'disabled'|'disabling'|'enabled'|'pending'
            }
        },
    ]
}
```

Response Structure
• (dict) –
  – InstanceMonitorings (list) –
      Monitoring information for one or more instances.
    * (dict) –
      Describes the monitoring information of the instance.
        • InstanceId (string) –
          The ID of the instance.
        • Monitoring (dict) –
          The monitoring information.
        • State (string) –
          Indicates whether monitoring is enabled for the instance.

Paginators

The available paginators are:
• EC2 Paginator DescribeInstanceStatus
• EC2 Paginator DescribeInstances
• EC2 Paginator DescribeReservedInstancesModifications
• EC2 Paginator DescribeReservedInstancesOfferings
• EC2 Paginator DescribeSnapshots
• EC2 Paginator DescribeSpotPriceHistory
• EC2 Paginator DescribeTags
• EC2 Paginator DescribeVolumeStatus

class EC2 Paginator DescribeInstanceStatus

    paginator = client.get_paginator('describe_instance_status')

    paginate (**kwargs)
      Creates an iterator that will paginate through responses from
      EC2.Client.describe_instance_status().

  Request Syntax

    response_iterator = paginator.paginate(
        DryRun=True|False,
        InstanceIds=[
            'string',
        ],
        Filters=[
            {
                'Name': 'string',
                'Values':[
                    'string',
                ],
            },
        ],
    )

IncludeAllInstances=True|False,
PaginationConfig={
    'MaxItems': 123,
    'PageSize': 123,
    'StartingToken': 'string'
}
}

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **InstanceIds** *(list)* – One or more instance IDs.

  Default: Describes all your instances.

  Constraints: Maximum 100 explicitly specified instance IDs.

  - *(string)* –

- **Filters** *(list)* – One or more filters.

  - **availability-zone** - The Availability Zone of the instance.
  - **event.code** - The code for the scheduled event (instance-reboot | system-reboot | system-maintenance | instance-retirement | instance-stop).
  - **event.description** - A description of the event.
  - **event.not-after** - The latest end time for the scheduled event (for example, 2014-09-15T17:15:20.000Z).
  - **event.not-before** - The earliest start time for the scheduled event (for example, 2014-09-15T17:15:20.000Z).
  - **instance-state-code** - The code for the instance state, as a 16-bit unsigned integer. The high byte is an opaque internal value and should be ignored. The low byte is set based on the state represented. The valid values are 0 (pending), 16 (running), 32 (shutting-down), 48 (terminated), 64 (stopping), and 80 (stopped).
  - **instance-state-name** - The state of the instance (pending | running | shutting-down | terminated | stopping | stopped).
  - **instance-status.reachability** - Filters on instance status where the name is reachability (passed | failed | initializing | insufficient-data).
  - **instance-status.status** - The status of the instance (ok | impaired | initializing | insufficient-data | not-applicable).
  - **system-status.reachability** - Filters on system status where the name is reachability (passed | failed | initializing | insufficient-data).
  - **system-status.status** - The system status of the instance (ok | impaired | initializing | insufficient-data | not-applicable).

  - *(dict)* –

    A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

    - **Name** *(string)* –
The name of the filter. Filter names are case-sensitive.

- **Values (list)**
  
  One or more filter values. Filter values are case-sensitive.

- **IncludeAllInstances (boolean)**
  
  When true, includes the health status for all instances. When false, includes the health status for running instances only.

  Default: false

- **PaginationConfig (dict)**
  
  A dictionary that provides parameters to control pagination.

  - **MaxItems (integer)**
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

  - **PageSize (integer)**
    
    The size of each page.

  - **StartingToken (string)**
    
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type dict

Returns

Response Syntax

```json
{}

,

Response Structure

• (dict) –
  – InstanceStatuses (list) –

  One or more instance status descriptions.
  * (dict) –

  Describes the status of an instance.
  · InstanceId (string) –
    The ID of the instance.
  · AvailabilityZone (string) –
    The Availability Zone of the instance.
  · Events (list) –
    Any scheduled events associated with the instance.
    * (dict) –

    Describes a scheduled event for an instance.
    · Code (string) –
      The event code.
    · Description (string) –
      A description of the event.
      After a scheduled event is completed, it can still be described
      for up to a week. If the event has been completed, this de-
      scription starts with the following text: [Completed].
    · NotBefore (datetime) –
      The earliest scheduled start time for the event.
    · NotAfter (datetime) –
      The latest scheduled end time for the event.
  · InstanceState (dict) –
    The intended state of the instance. DescribeInstanceStatus
    requires that an instance be in the running state.
    · Code (integer) –
      The low byte represents the state. The high byte is an opaque
      internal value and should be ignored.
      · 0: pending
      · 16: running
      · 32: shutting-down
      · 48: terminated
      · 64: stopping
      · 80: stopped
- **Name** *(string)* – The current state of the instance.
- **SystemStatus** *(dict)* – Reports impaired functionality that stems from issues related to the systems that support an instance, such as hardware failures and network connectivity problems.
- **Status** *(string)* – The status.
- **Details** *(list)* – The system instance health or application instance health.
  - *(dict)* –
    - **Name** *(string)* – The type of instance status.
    - **Status** *(string)* – The status.
    - **ImpairedSince** *(datetime)* – The time when a status check failed. For an instance that was launched and impaired, this is the time when the instance was launched.
- **InstanceStatus** *(dict)* – Reports impaired functionality that stems from issues internal to the instance, such as impaired reachability.
  - **Status** *(string)* – The status.
  - **Details** *(list)* – The system instance health or application instance health.
    - *(dict)* –
      - **Name** *(string)* – The type of instance status.
      - **Status** *(string)* – The status.
      - **ImpairedSince** *(datetime)* – The time when a status check failed. For an instance that was launched and impaired, this is the time when the instance was launched.

```python
class EC2.Paginator.DescribeInstances

paginator = client.get_paginator('describe_instances')

paginate(**kwars)
```

Creates an iterator that will paginate through responses from `EC2.Client.describe_instances()`. 
Request Syntax

```python
response_iterator = paginator.paginate(
    DryRun=True|False,
    InstanceIds=['string'],
    Filters=[
        {'Name': 'string',
         'Values': ['string'],
        },
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **InstanceIds** *(list)* – One or more instance IDs.
  Default: Describes all your instances.
  - *(string)*
- **Filters** *(list)* – One or more filters.
  - **architecture** - The instance architecture (`i386`|`x86_64`).
  - **availability-zone** - The Availability Zone of the instance.
  - **block-device-mapping.attach-time** - The attach time for an EBS volume mapped to the instance, for example, `2010-09-15T17:15:20.000Z`.
  - **block-device-mapping.delete-on-termination** - A Boolean that indicates whether the EBS volume is deleted on instance termination.
  - **block-device-mapping.device-name** - The device name for the EBS volume (for example, `/dev/sdh` or `xvdh`).
  - **block-device-mapping.status** - The status for the EBS volume (attaching|attached|detaching|detached).
  - **block-device-mapping.volume-id** - The volume ID of the EBS volume.
  - **client-token** - The idempotency token you provided when you launched the instance.
  - **dns-name** - The public DNS name of the instance.
  - **group-id** - The ID of the security group for the instance. EC2-Classic only.
  - **group-name** - The name of the security group for the instance. EC2-Classic only.
  - **hypervisor** - The hypervisor type of the instance (`ovm`|`xen`).
  - **iam-instance-profile.arn** - The instance profile associated with the instance. Specified as an ARN.
- **image-id** - The ID of the image used to launch the instance.
- **instance-id** - The ID of the instance.
- **instance-lifecycle** - Indicates whether this is a Spot Instance (spot).
- **instance-state-code** - The state of the instance, as a 16-bit unsigned integer. The high byte is an opaque internal value and should be ignored. The low byte is set based on the state represented. The valid values are: 0 (pending), 16 (running), 32 (shutting-down), 48 (terminated), 64 (stopping), and 80 (stopped).
- **instance-state-name** - The state of the instance (pending | running | shutting-down | terminated | stopping | stopped).
- **instance-type** - The type of instance (for example, t2.micro).
- **instance-group-id** - The ID of the security group for the instance.
- **instance-group-name** - The name of the security group for the instance.
- **ip-address** - The public IP address of the instance.
- **kernel-id** - The kernel ID.
- **key-name** - The name of the key pair used when the instance was launched.
- **launch-index** - When launching multiple instances, this is the index for the instance in the launch group (for example, 0, 1, 2, and so on).
- **launch-time** - The time when the instance was launched.
- **monitoring-state** - Indicates whether monitoring is enabled for the instance (disabled | enabled).
- **owner-id** - The AWS account ID of the instance owner.
- **placement-group-name** - The name of the placement group for the instance.
- **platform** - The platform. Use windows if you have Windows instances; otherwise, leave blank.
- **private-dns-name** - The private DNS name of the instance.
- **private-ip-address** - The private IP address of the instance.
- **product-code** - The product code associated with the AMI used to launch the instance.
- **product-code.type** - The type of product code (devpay | marketplace).
- **ramdisk-id** - The RAM disk ID.
- **reason** - The reason for the current state of the instance (for example, shows “User Initiated [date]” when you stop or terminate the instance). Similar to the state-reason-code filter.
- **requester-id** - The ID of the entity that launched the instance on your behalf (for example, AWS Management Console, Auto Scaling, and so on).
- **reservation-id** - The ID of the instance’s reservation. A reservation ID is created any time you launch an instance. A reservation ID has a one-to-one relationship with an instance launch request, but can be associated with more than one instance if you launch multiple instances using the same launch request. For example, if you launch one instance, you’ll get one reservation ID. If you launch ten instances using the same launch request, you’ll also get one reservation ID.
- **root-device-name** - The name of the root device for the instance (for example, /dev/sdal or /dev/xvda).
- **root-device-type** - The type of root device that the instance uses (ebs | instance-store).
- `source-dest-check` - Indicates whether the instance performs source/destination checking. A value of `true` means that checking is enabled, and `false` means checking is disabled. The value must be `false` for the instance to perform network address translation (NAT) in your VPC.
- `spot-instance-request-id` - The ID of the Spot Instance request.
- `state-reason-code` - The reason code for the state change.
- `state-reason-message` - A message that describes the state change.
- `subnet-id` - The ID of the subnet for the instance.
- `tag :key =*value*` - The key/value combination of a tag assigned to the resource, where `tag :key` is the tag’s key.
- `tag-key` - The key of a tag assigned to the resource. This filter is independent of the `tag-value` filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag :key =*value*` filter.
- `tag-value` - The value of a tag assigned to the resource. This filter is independent of the `tag-key` filter.
- `tenancy` - The tenancy of an instance (`dedicated` | `default`).
- `virtualization-type` - The virtualization type of the instance (`paravirtual` | `hvm`).
- `vpc-id` - The ID of the VPC that the instance is running in.
- `network-interface.description` - The description of the network interface.
- `network-interface.subnet-id` - The ID of the subnet for the network interface.
- `network-interface.vpc-id` - The ID of the VPC for the network interface.
- `network-interface.network-interface.id` - The ID of the network interface.
- `network-interface.owner-id` - The ID of the owner of the network interface.
- `network-interface.availability-zone` - The Availability Zone for the network interface.
- `network-interface.requester-id` - The requester ID for the network interface.
- `network-interface.requester-managed` - Indicates whether the network interface is being managed by AWS.
- `network-interface.status` - The status of the network interface (`available` | `in-use`).
- `network-interface.mac-address` - The MAC address of the network interface.
- `network-interface-private-dns-name` - The private DNS name of the network interface.
- `network-interface-source-dest-check` - Whether the network interface performs source/destination checking. A value of `true` means checking is enabled, and `false` means checking is disabled. The value must be `false` for the network interface to perform network address translation (NAT) in your VPC.
- `network-interface-group-id` - The ID of a security group associated with the network interface.
- `network-interface-group-name` - The name of a security group associated with the network interface.
- `network-interface.attachment.attachment-id` - The ID of the interface attachment.
- `network-interface.attachment.instance-id` - The ID of the instance to which the network interface is attached.
- `network-interface.attachment.instance-owner-id` - The owner ID of the instance to which the network interface is attached.
- `network-interface.addresses.private-ip-address` - The private IP address associated with the network interface.
- `network-interface.attachment.device-index` - The device index to which the network interface is attached.
- `network-interface.attachment.status` - The status of the attachment (attaching | attached | detaching | detached).
- `network-interface.attachment.attach-time` - The time that the network interface was attached to an instance.
- `network-interface.attachment.delete-on-termination` - Specifies whether the attachment is deleted when an instance is terminated.
- `network-interface.addresses.primary` - Specifies whether the IP address of the network interface is the primary private IP address.
- `network-interface.addresses.association.public-ip` - The ID of the association of an Elastic IP address with a network interface.
- `network-interface.addresses.association.ip-owner-id` - The owner ID of the private IP address associated with the network interface.
- `association.public-ip` - The address of the Elastic IP address bound to the network interface.
- `association.ip-owner-id` - The owner of the Elastic IP address associated with the network interface.
- `association.allocation-id` - The allocation ID returned when you allocated the Elastic IP address for your network interface.
- `association.association-id` - The association ID returned when the network interface was associated with an IP address.

 `(dict)` —

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  * **Name** *(string)* —
    
    The name of the filter. Filter names are case-sensitive.
  * **Values** *(list)* —
    
    One or more filter values. Filter values are case-sensitive.
    
    *(string)* —

- **PaginationConfig** *(dict)* — A dictionary that provides parameters to control pagination.

  * **MaxItems** *(integer)* —
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  * **PageSize** *(integer)* —
    
    The size of each page.
  * **StartingToken** *(string)* —
A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type:** dict

**Returns**

Response Structure
• (dict) –
  – Reservations (list) –
    One or more reservations.
      • (dict) –
        Describes a reservation.
          • ReservationId (string) –
            The ID of the reservation.
          • OwnerId (string) –
            The ID of the AWS account that owns the reservation.
          • RequesterId (string) –
            The ID of the requester that launched the instances on your behalf (for example, AWS Management Console or Auto Scaling).
          • Groups (list) –
            One or more security groups.
              • (dict) –
                Describes a security group.
                  • GroupName (string) –
                    The name of the security group.
- **GroupId** *(string)*
  The ID of the security group.

- **Instances** *(list)*
  One or more instances.

  - *(dict)*
    Describes an instance.

    - **InstanceId** *(string)*
      The ID of the instance.

    - **ImageId** *(string)*
      The ID of the AMI used to launch the instance.

    - **State** *(dict)*
      The current state of the instance.

      - **Code** *(integer)*
        The low byte represents the state. The high byte is an opaque internal value and should be ignored.

        - 0: pending
        - 16: running
        - 32: shutting-down
        - 48: terminated
        - 64: stopping
        - 80: stopped

    - **Name** *(string)*
      The current state of the instance.

- **KeyName** *(string)*
  The name of the key pair, if this instance was launched with an associated key pair.

- **AmiLaunchIndex** *(integer)*
  The AMI launch index, which can be used to find this instance in the launch group.

- **ProductCodes** *(list)*
  The product codes attached to this instance.

  - *(dict)*
    Describes a product code.

    - **ProductCodeId** *(string)*
      The product code.
- **ProductCodeType** *(string)* –
  The type of product code.
- **InstanceType** *(string)* –
  The instance type.
- **LaunchTime** *(datetime)* –
  The time the instance was launched.
- **Placement** *(dict)* –
  The location where the instance launched.
- **AvailabilityZone** *(string)* –
  The Availability Zone of the instance.
- **GroupName** *(string)* –
  The name of the placement group the instance is in (for cluster compute instances).
- **Tenancy** *(string)* –
  The tenancy of the instance (if the instance is running in a VPC). An instance with a tenancy of dedicated runs on single-tenant hardware.
- **KernelId** *(string)* –
  The kernel associated with this instance.
- **RamdiskId** *(string)* –
  The RAM disk associated with this instance.
- **Platform** *(string)* –
  The value is Windows for Windows instances; otherwise blank.
- **Monitoring** *(dict)* –
  The monitoring information for the instance.
- **State** *(string)* –
  Indicates whether monitoring is enabled for the instance.
- **SubnetId** *(string)* –
  The ID of the subnet in which the instance is running.
- **VpcId** *(string)* –
  The ID of the VPC in which the instance is running.
- **PrivateIpAddress** *(string)* –
  The private IP address assigned to the instance.
- **PublicIpAddress** *(string)* –
  The public IP address assigned to the instance.
- **StateReason** *(dict)* –
  The reason for the most recent state transition.
- **Code** *(string)* –
  The reason code for the state change.
- **Message** *(string)* –
  The message for the state change.

- `Server.SpotInstanceTermination`: A Spot Instance was terminated due to an increase in the market price.
· **Server.InternalError**: An internal error occurred during instance launch, resulting in termination.
· **Server.InsufficientInstanceCapacity**: There was insufficient instance capacity to satisfy the launch request.
· **Client.InternalError**: A client error caused the instance to terminate on launch.
· **Client.InstanceInitiatedShutdown**: The instance was shut down using the `shutdown -h` command from the instance.
· **Client.UserInitiatedShutdown**: The instance was shut down using the Amazon EC2 API.
· **Client.VolumeLimitExceeded**: The volume limit was exceeded.
· **Client.InvalidSnapshot.NotFound**: The specified snapshot was not found.
· **Architecture** *(string)* –
  The architecture of the image.
· **RootDeviceType** *(string)* –
  The root device type used by the AMI. The AMI can use an EBS volume or an instance store volume.
· **RootDeviceName** *(string)* –
  The root device name (for example, `/dev/sda1` or `/dev/xvda`).
· **BlockDeviceMappings** *(list)* –
  Any block device mapping entries for the instance.
· *(dict)* –
  Describes a block device mapping.
· **DeviceName** *(string)* –
  The device name exposed to the instance (for example, `/dev/sdh` or `/dev/xvdh`).
· **Ebs** *(dict)* –
  Parameters used to automatically set up EBS volumes when the instance is launched.
· **VolumeId** *(string)* –
  The ID of the EBS volume.
· **Status** *(string)* –
  The attachment state.
· **AttachTime** *(datetime)* –
  The time stamp when the attachment initiated.
· **DeleteOnTermination** *(boolean)* –
  Indicates whether the volume is deleted on instance termination.
· **VirtualizationType** *(string)* –
  The virtualization type of the instance.
· **InstanceLifecycle** *(string)* –
  Indicates whether this is a Spot Instance.
- **SpotInstanceRequestId** *(string)* –
  The ID of the Spot Instance request.
- **ClientToken** *(string)* –
  The idempotency token you provided when you launched the instance.
- **Tags** *(list)* –
  Any tags assigned to the instance.
  *(dict)* –
  Describes a tag.
  - **Key** *(string)* –
    The key of the tag.
    Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`
  - **Value** *(string)* –
    The value of the tag.
    Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.
- **SecurityGroups** *(list)* –
  One or more security groups for the instance.
  *(dict)* –
  Describes a security group.
  - **GroupName** *(string)* –
    The name of the security group.
  - **GroupId** *(string)* –
    The ID of the security group.
  - **SourceDestCheck** *(boolean)* –
    Specifies whether to enable an instance launched in a VPC to perform NAT. This controls whether source/destination checking is enabled on the instance. A value of `true` means checking is enabled, and `false` means checking is disabled. The value must be `false` for the instance to perform NAT. For more information, see [NAT Instances](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/using-nat.html) in the *Amazon Virtual Private Cloud User Guide*.
- **Hypervisor** *(string)* –
  The hypervisor type of the instance.
- **NetworkInterfaces** *(list)* –
  [EC2-VPC] One or more network interfaces for the instance.
  *(dict)* –
  Describes a network interface.
  - **NetworkInterfaceId** *(string)* –
    The ID of the network interface.
- **VpcId** *(string)* – The ID of the VPC.
- **Description** *(string)* – The description.
- **OwnerId** *(string)* – The ID of the AWS account that created the network interface.
- **Status** *(string)* – The status of the network interface.
- **MacAddress** *(string)* – The MAC address.
- **PrivateIpAddress** *(string)* – The IP address of the network interface within the subnet.
- **PrivateDnsName** *(string)* – The private DNS name.
- **SourceDestCheck** *(boolean)* – Indicates whether to validate network traffic to or from this network interface.
- **Groups** *(list)* – One or more security groups.
  - **GroupName** *(string)* – The name of the security group.
  - **GroupId** *(string)* – The ID of the security group.
- **Attachment** *(dict)* – The network interface attachment.
  - **AttachmentId** *(string)* – The ID of the network interface attachment.
  - **DeviceIndex** *(integer)* – The index of the device on the instance for the network interface attachment.
- **Associate** *(datetime)* – The attachment state.
- **AttachTime** *(datetime)* – The time stamp when the attachment initiated.
- **DeleteOnTermination** *(boolean)* – Indicates whether the network interface is deleted when the instance is terminated.
- **Association** *(dict)* – The association information for an Elastic IP associated with the network interface.
- **PublicIp** *(string)* –
The public IP address or Elastic IP address bound to the network interface.

- **PublicDnsName** *(string)* –
  The public DNS name.

- **IpOwnerId** *(string)* –
  The ID of the owner of the Elastic IP address.

- **PrivateIpAddresses** *(list)* –
  The private IP addresses associated with the network interface.
  
  *(dict)* –
  Describes a private IP address.

- **PrivateIpAddress** *(string)* –
  The private IP address of the network interface.

- **PrivateDnsName** *(string)* –
  The private DNS name.

- **Primary** *(boolean)* –
  Indicates whether this IP address is the primary private IP address of the network interface.

- **Association** *(dict)* –
  The association information for an Elastic IP address for the network interface.

- **PublicIp** *(string)* –
  The public IP address or Elastic IP address bound to the network interface.

- **PublicDnsName** *(string)* –
  The public DNS name.

- **IpOwnerId** *(string)* –
  The ID of the owner of the Elastic IP address.

- **IamInstanceProfile** *(dict)* –
  The IAM instance profile associated with the instance.

- **Arn** *(string)* –
  The Amazon Resource Name (ARN) of the instance profile.

- **Id** *(string)* –
  The ID of the instance profile.

- **EbsOptimized** *(boolean)* –
  Indicates whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal I/O performance. This optimization isn’t available with all instance types. Additional usage charges apply when using an EBS Optimized instance.

- **SriovNetSupport** *(string)* –
  Specifies whether enhanced networking is enabled.

```python
class EC2.Paginator.DescribeReservedInstancesModifications
```
paginator = client.get_paginator('describe_reserved_instances_modifications')

paginate(**kwargs)

Creates an iterator that will paginate through responses from `EC2.Client.describe_reserved_instances_modifications()`.

Request Syntax

```python
response_iterator = paginator.paginate(
    ReservedInstancesModificationIds=[
        'string',
    ],
    Filters=[
        {'Name': 'string',
         'Values': ['string'],
        },
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **ReservedInstancesModificationIds** *(list)* – IDs for the submitted modification request.
  - *(string)* –
- **Filters** *(list)* – One or more filters.
  - client-token - The idempotency token for the modification request.
  - create-date - The time when the modification request was created.
  - effective-date - The time when the modification becomes effective.
  - modification-result.reserved-instances-id - The ID for the Reserved Instances created as part of the modification request. This ID is only available when the status of the modification is fulfilled.
  - modification-result.target-configuration.availability-zone - The Availability Zone for the new Reserved Instances.
  - modification-result.target-configuration.instance-count - The number of new Reserved Instances.
  - modification-result.target-configuration.instance-type - The instance type of the new Reserved Instances.
  - modification-result.target-configuration.platform - The network platform of the new Reserved Instances (EC2-Classic | EC2-VPC).
  - reserved-instances-id - The ID of the Reserved Instances modified.
  - reserved-instances-modification-id - The ID of the modification request.
  - status - The status of the Reserved Instances modification request (processing | fulfilled | failed).
  - status-message - The reason for the status.
- `update-date` - The time when the modification request was last updated.
- `(dict)` –
  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  * **Name** *(string)*
    The name of the filter. Filter names are case-sensitive.
  * **Values** *(list)*
    One or more filter values. Filter values are case-sensitive.
  - *(string)*
    • **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
      - **MaxItems** *(integer)* –
        The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
      - **PageSize** *(integer)* –
        The size of each page.
      - **StartingToken** *(string)* –
        A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'ReservedInstancesModifications': [
        {
            'ReservedInstancesModificationId': 'string',
            'ReservedInstancesIds': [
                {
                    'ReservedInstancesId': 'string'
                },
            ],
            'ModificationResults': [
                {
                    'ReservedInstancesId': 'string',
                    'TargetConfiguration': {
                        'AvailabilityZone': 'string',
                        'Platform': 'string',
                        'InstanceCount': 123,
                        'InstanceType': 't1.micro'|'ml.small'|'ml.medium'|'ml.large'
                    }
                },
            ],
            'CreateDate': datetime(2015, 1, 1),
            'UpdateDate': datetime(2015, 1, 1),
            'EffectiveDate': datetime(2015, 1, 1),
            'Status': 'string',
            'StatusMessage': 'string',
            'ClientToken': 'string'
        }
    ]
}
```
Response Structure

- (dict) –
  - ReservedInstancesModifications (list) –
    The Reserved Instance modification information.
    - (dict) –
      - ReservedInstancesModificationId (string) –
        A unique ID for the Reserved Instance modification.
      - ReservedInstancesIds (list) –
        The IDs of one or more Reserved Instances.
      - (dict) –
        Describes the ID of a Reserved Instance.
        - ReservedInstancesId (string) –
          The ID of the Reserved Instance.
        - ModificationResults (list) –
          Contains target configurations along with their corresponding new Reserved Instance IDs.
        - (dict) –
          - ReservedInstancesId (string) –
            The ID for the Reserved Instances that were created as part of the modification request. This field is only available when the modification is fulfilled.
          - TargetConfiguration (dict) –
            The target Reserved Instances configurations supplied as part of the modification request.
          - AvailabilityZone (string) –
            The Availability Zone for the modified Reserved Instances.
          - Platform (string) –
            The network platform of the modified Reserved Instances, which is either EC2-Classic or EC2-VPC.
          - InstanceCount (integer) –
            The number of modified Reserved Instances.
          - InstanceType (string) –
            The instance type for the modified Reserved Instances.
          - CreateDate (datetime) –
            The time when the modification request was created.
          - UpdateDate (datetime) –
            The time when the modification request was last updated.
          - EffectiveDate (datetime) –
            The time for the modification to become effective.
### Status (string)
The status of the Reserved Instances modification request.

#### StatusMessage (string)
The reason for the status.

#### ClientToken (string)
A unique, case-sensitive key supplied by the client to ensure that the request is idempotent. For more information, see Ensuring Idempotency.

```python
class EC2.Paginator.DescribeReservedInstancesOfferings

paginator = client.get_paginator('describe_reserved_instances_offerings')

paginate(**kwargs)
Creates an iterator that will paginate through responses from EC2.Client.describe_reserved_instances_offerings().

Request Syntax

response_iterator = paginator.paginate(
    DryRun=True|False,
    ReservedInstancesOfferingIds=['string',
    ],
    InstanceType='t1.micro'|'m1.small'|'m1.medium'|'m1.large'|'m1.xlarge'|'m3.medium'|'m3.large'|'m3.xlarge'|'m3.2xlarge'|'m4. ... 4xlarge'|'r3.large'|'r3.xlarge'|'r3.2xlarge'|'r3.8xlarge'|'d2.xlarge'|'d2.2xlarge'|'d2.4xlarge'|'d2.8xlarge',
    AvailabilityZone='string',
    ProductDescription='Linux/UNIX'|'Linux/UNIX (Amazon VPC)'|'Windows'|'Windows (Amazon VPC)',
    Filters=[
        {'Name': 'string',
         'Values': [ 'string',
         ]},
    ],
    InstanceTenancy='default'|'dedicated',
    OfferingType='Heavy Utilization'|'Medium Utilization'|'Light Utilization'|'No Upfront'|'Partial Upfront'|'All Upfront',
    IncludeMarketplace=True|False,
    MinDuration=123,
    MaxDuration=123,
    MaxInstanceCount=123,
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **ReservedInstancesOfferingIds (list)** – One or more Reserved Instances offering IDs.
(string) –

- **InstanceType** *(string)* – The instance type on which the Reserved Instance can be used. For more information, see Instance Types in the Amazon Elastic Compute Cloud User Guide.
- **AvailabilityZone** *(string)* – The Availability Zone in which the Reserved Instance can be used.
- **ProductDescription** *(string)* – The Reserved Instance product platform description. Instances that include (Amazon VPC) in the description are for use with Amazon VPC.
- **Filters** *(list)* – One or more filters.
  - *availability-zone* - The Availability Zone where the Reserved Instance can be used.
  - *duration* - The duration of the Reserved Instance (for example, one year or three years), in seconds (31536000 | 94608000).
  - *fixed-price* - The purchase price of the Reserved Instance (for example, 9800.0).
  - *instance-type* - The instance type on which the Reserved Instance can be used.
  - *marketplace* - Set to true to show only Reserved Instance Marketplace offerings. When this filter is not used, which is the default behavior, all offerings from AWS and Reserved Instance Marketplace are listed.
  - *product-description* - The Reserved Instance product platform description. Instances that include (Amazon VPC) in the product platform description will only be displayed to EC2-Classic account holders and are for use with Amazon VPC. (Linux/UNIX | Linux/UNIX (Amazon VPC) | SUSE Linux | SUSE Linux (Amazon VPC) | Red Hat Enterprise Linux | Red Hat Enterprise Linux (Amazon VPC) | Windows | Windows (Amazon VPC) | Windows with SQL Server Standard | Windows with SQL Server Standard (Amazon VPC) | Windows with SQL Server Web | Windows with SQL Server Web (Amazon VPC) | Windows with SQL Server Enterprise | Windows with SQL Server Enterprise (Amazon VPC))
  - *reserved-instances-offering-id* - The Reserved Instances offering ID.
  - *usage-price* - The usage price of the Reserved Instance, per hour (for example, 0.84).
  - *(dict)* –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

- **Name** *(string)* –
  The name of the filter. Filter names are case-sensitive.
- **Values** *(list)* –

One or more filter values. Filter values are case-sensitive.

- *(string)* –

- **InstanceTenancy** *(string)* – The tenancy of the Reserved Instance offering. A Reserved Instance with dedicated tenancy runs on single-tenant hardware and can only be launched within a VPC.

  Default: default
- **OfferingType** *(string)* – The Reserved Instance offering type. If you are us-
Tools that predate the 2011-11-01 API version, you only have access to the Medium Utilization Reserved Instance offering type.

- **IncludeMarketplace** *(boolean)* – Include Marketplace offerings in the response.
- **MinDuration** *(integer)* – The minimum duration (in seconds) to filter when searching for offerings.
  
  Default: 2592000 (1 month)
- **MaxDuration** *(integer)* – The maximum duration (in seconds) to filter when searching for offerings.
  
  Default: 94608000 (3 years)
- **MaxInstanceCount** *(integer)* – The maximum number of instances to filter when searching for offerings.
  
  Default: 20
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  - **MaxItems** *(integer)* – The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* – The size of each page.
  - **StartingToken** *(string)* – A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{

    }
  ]
}
```
Response Structure

* (dict) –
  
  – **ReservedInstancesOfferings** (list) –
    A list of Reserved Instances offerings.

  * (dict) –
    Describes a Reserved Instance offering.
    
    • **ReservedInstancesOfferingId** (string) –
      The ID of the Reserved Instance offering.
    
    • **InstanceType** (string) –
      The instance type on which the Reserved Instance can be used.
    
    • **AvailabilityZone** (string) –
      The Availability Zone in which the Reserved Instance can be used.
    
    • **Duration** (integer) –
      The duration of the Reserved Instance, in seconds.
    
    • **UsagePrice** (float) –
      The usage price of the Reserved Instance, per hour.
    
    • **FixedPrice** (float) –
      The purchase price of the Reserved Instance.
    
    • **ProductDescription** (string) –
      The Reserved Instance product platform description.
    
    • **InstanceTenancy** (string) –
      The tenancy of the reserved instance.
    
    • **CurrencyCode** (string) –
      The currency of the Reserved Instance offering you are purchasing. It’s specified using ISO 4217 standard currency codes. At this time, the only supported currency is **USD**.
    
    • **OfferingType** (string) –
      The Reserved Instance offering type.
    
    • **RecurringCharges** (list) –
      The recurring charge tag assigned to the resource.
  
  * (dict) –
    Describes a recurring charge.
    
    • **Frequency** (string) –
      The frequency of the recurring charge.
    
    • **Amount** (float) –
      The amount of the recurring charge.
· **Marketplace** *(boolean)* –
  Indicates whether the offering is available through the Reserved Instance Marketplace (resale) or AWS. If it’s a Reserved Instance Marketplace offering, this is `true`.

· **PricingDetails** *(list)* –
  The pricing details of the Reserved Instance offering.
  *(dict)* –
  Describes a Reserved Instance offering.

· **Price** *(float)* –
  The price per instance.

· **Count** *(integer)* –
  The number of instances available for the price.

```python
class EC2.Paginator.DescribeSnapshots

paginator = client.get_paginator('describe_snapshots')

paginate(**kwargs)

Creates an iterator that will paginate through responses from EC2.Client.describe_snapshots().

Request Syntax

```python
response_iterator = paginator.paginate(
   DryRun=True|False,
   SnapshotIds=[
      'string',
   ],
   OwnerIds=[
      'string',
   ],
   RestorableByUserIds=[
      'string',
   ],
   Filters=[
      {
         'Name': 'string',
         'Values': [?
            'string',
         ]
      },
   ],
   PaginationConfig={
      'MaxItems': 123,
      'PageSize': 123,
      'StartingToken': 'string'
   }
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
• **SnapshotIds** *(list)* – One or more snapshot IDs.

  Default: Describes snapshots for which you have launch permissions.

  – *(string)* –

• **OwnerIds** *(list)* – Returns the snapshots owned by the specified owner. Multiple owners can be specified.

  – *(string)* –

• **RestorableByUserIds** *(list)* – One or more AWS accounts IDs that can create volumes from the snapshot.

  – *(string)* –

• **Filters** *(list)* – One or more filters.

  – **description** - A description of the snapshot.
  – **owner-alias** - The AWS account alias (for example, amazon) that owns the snapshot.
  – **owner-id** - The ID of the AWS account that owns the snapshot.
  – **progress** - The progress of the snapshot, as a percentage (for example, 80%).
  – **snapshot-id** - The snapshot ID.
  – **start-time** - The time stamp when the snapshot was initiated.
  – **status** - The status of the snapshot *(pending|completed|error)*.
  – **tag :key =*value*** - The key/value combination of a tag assigned to the resource.
  – **tag-key** - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the **tag :key =*value*” filter.
  – **tag-value** - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
  – **volume-id** - The ID of the volume the snapshot is for.
  – **volume-size** - The size of the volume, in GiB.

  – *(dict)* –

  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  * **Name** *(string)* –

    The name of the filter. Filter names are case-sensitive.

  * **Values** *(list)* –

    One or more filter values. Filter values are case-sensitive.

  – *(string)* –

• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

  – **MaxItems** *(integer)* –

    The total number of items to return. If the total number of items available is more than the value specified in max-items then a **NextToken** will be provided in the output that you can use to resume pagination.

  – **PageSize** *(integer)* –

    The size of each page.

  – **StartingToken** *(string)* –
A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict
Returns

Response Syntax

```
{
    'Snapshots': [

        {
            'SnapshotId': 'string',
            'VolumeId': 'string',
            'State': 'pending'|'completed'|'error',
            'StateMessage': 'string',
            'StartTime': datetime(2015, 1, 1),
            'Progress': 'string',
            'OwnerId': 'string',
            'Description': 'string',
            'VolumeSize': 123,
            'OwnerAlias': 'string',
            'Tags': [
                {
                    'Key': 'string',
                    'Value': 'string'
                }
            ],
            'Encrypted': True|False,
            'KmsKeyId': 'string',
            'DataEncryptionKeyId': 'string'
        }
    ],
}
```

Response Structure

- (dict) –
  - Snapshots (list) –

  Information about the snapshots.
  - (dict) –

  Describes a snapshot.
  - SnapshotId (string) –

    The ID of the snapshot. Each snapshot receives a unique identifier when it is created.
  - VolumeId (string) –

    The ID of the volume that was used to create the snapshot.
  - State (string) –

    The snapshot state.
  - StateMessage (string) –

    Encrypted Amazon EBS snapshots are copied asynchronously. If a snapshot copy operation fails (for example, if the proper AWS Key Management Service (AWS KMS) permissions are not obtained) this field displays error state details to help you diagnose why the error occurred. This parameter is only returned by the DescribeSnapshots API operation.
· **StartTime (datetime)** –
  The time stamp when the snapshot was initiated.

· **Progress (string)** –
  The progress of the snapshot, as a percentage.

· **OwnerId (string)** –
  The AWS account ID of the EBS snapshot owner.

· **Description (string)** –
  The description for the snapshot.

· **VolumeSize (integer)** –
  The size of the volume, in GiB.

· **OwnerAlias (string)** –
  The AWS account alias (for example, `amazon`, `self`) or AWS account ID that owns the snapshot.

· **Tags (list)** –
  Any tags assigned to the snapshot.

  · (dict) –
    Describes a tag.

  · **Key (string)** –
    The key of the tag.

    Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws`:

  · **Value (string)** –
    The value of the tag.

    Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

· **Encrypted (boolean)** –
  Indicates whether the snapshot is encrypted.

· **KmsKeyId (string)** –
  The full ARN of the AWS Key Management Service (AWS KMS) customer master key (CMK) that was used to protect the volume encryption key for the parent volume.

· **DataEncryptionKeyId (string)** –
  The data encryption key identifier for the snapshot. This value is a unique identifier that corresponds to the data encryption key that was used to encrypt the original volume or snapshot copy. Because data encryption keys are inherited by volumes created from snapshots, and vice versa, if snapshots share the same data encryption key identifier, then they belong to the same volume/snapshot lineage. This parameter is only returned by the DescribeSnapshots API operation.

class EC2.Paginator.DescribeSpotPriceHistory

    paginator = client.get_paginator('describe_spot_price_history')
paginate(**kwargs)

Creates an iterator that will paginate through responses from EC2.Client.describe_spot_price_history().

Request Syntax

response_iterator = paginator.paginate(
    DryRun=True|False,
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    InstanceTypes=[
        't1.micro'|'m1.small'|'m1.medium'|'m1.large'|'m1.xlarge'|'m3.medium'|'m3.large'|'m3.xlarge'|'m3.2xlarge'|'m4.large'|'m4.xlarge'|'m4.2xlarge'|'m4.4xlarge'|'m4.8xlarge'|'r3.large'|'r3.xlarge'|'r3.2xlarge'|'r3.4xlarge'|'r3.8xlarge'|'d2.xlarge'|'d2.2xlarge'|'d2.4xlarge'|'d2.8xlarge',
    ],
    ProductDescriptions=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ],
    AvailabilityZone='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **StartTime** (datetime) – The date and time, up to the past 90 days, from which to start retrieving the price history data, in UTC format (for example, YYYY-MM-DD T*HH* :MM :SS Z).
- **EndTime** (datetime) – The date and time, up to the current date, from which to stop retrieving the price history data, in UTC format (for example, YYYY-MM-DD T*HH* :MM :SS Z).
- **InstanceTypes** (list) – Filters the results by the specified instance types.
  - (string)
- **ProductDescriptions** (list) – Filters the results by the specified basic product descriptions.
  - (string)
- **Filters** (list) – One or more filters.
  - availability-zone - The Availability Zone for which prices should be returned.
  - instance-type - The type of instance (for example, m1.small ).
– **spot-price** - The Spot price. The value must match exactly (or use wildcards; greater than or less than comparison is not supported).

– **timestamp** - The timestamp of the Spot price history, in UTC format (for example, *YYYY-MM-DD HH:*MM:*SS.*Z*). You can use wildcards (* and ?). Greater than or less than comparison is not supported.

– *(dict)*

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* **Name (string)** –

The name of the filter. Filter names are case-sensitive.

* **Values (list)** –

One or more filter values. Filter values are case-sensitive.

  * (string) –

• **AvailabilityZone (string)** – Filters the results by the specified Availability Zone.

• **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.

  * **MaxItems (integer)** –

The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

  * **PageSize (integer)** –

The size of each page.

  * **StartingToken (string)** –

A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** dict

**Returns**

**Response Syntax**

```
{
    'SpotPriceHistory': [
        
        'InstanceType': 't1.micro'|'m1.small'|'m1.medium'|'m1.large'|'m1.xlarge',
        'ProductDescription': 'Linux/UNIX'|'Linux/UNIX (Amazon VPC)'|'Windows',
        'SpotPrice': 'string',
        'Timestamp': datetime(2015, 1, 1),
        'AvailabilityZone': 'string'
    ],
}
```

**Response Structure**

* *(dict)* –

Contains the output of DescribeSpotPriceHistory.

– **SpotPriceHistory (list)** –

The historical Spot prices.

  * *(dict)* –
Describes the maximum hourly price (bid) for any Spot instance launched to fulfill the request.

- **InstanceType (string)** – The instance type.
- **ProductDescription (string)** – A general description of the AMI.
- **SpotPrice (string)** – The maximum price (bid) that you are willing to pay for a Spot instance.
- **Timestamp (datetime)** – The date and time the request was created, in UTC format (for example, `YYYY-MM-DDT*HH:*MM:*SS Z`).
- **AvailabilityZone (string)** – The Availability Zone.

```python
class EC2.Paginator.DescribeTags

paginator = client.get_paginator('describe_tags')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `EC2.Client.describe_tags()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    DryRun=True|False,
    Filters=[
        {'Name': 'string',
        'Values': ['string'],
    },
],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **Filters (list)** – One or more filters.
  - `key` - The tag key.
  - `resource-id` - The resource ID.
  - `resource-type` - The resource type (`customer-gateway | dhcp-options | image | instance | internet-gateway | network-acl | network-interface | reserved-instances | route-table | security-group | snapshot | ...`
spot-instances-request | subnet | volume | vpc | vpn-connection | vpn-gateway).

- value - The tag value.

- (dict) –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  * Name (string) –
    The name of the filter. Filter names are case-sensitive.
  * Values (list) –
    One or more filter values. Filter values are case-sensitive.

- (string) –

  * PaginationConfig (dict) – A dictionary that provides parameters to control pagination.

    - MaxItems (integer) –
      The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

    - PageSize (integer) –
      The size of each page.

    - StartingToken (string) –
      A token to specify where to start paginating. This is the NextToken from a previous response.

Return type dict

Returns

**Response Syntax**

```
{
    'Tags': [
        {
            'ResourceId': 'string',
            'ResourceType': 'customer-gateway'|'dhcp-options'|'image'|'instance'|'key'|'volume'|'vpc'|'vpn-connection'|'vpn-gateway',
            'Key': 'string',
            'Value': 'string'
        },
    ],
}
```

**Response Structure**

- (dict) –

  - Tags (list) –

    A list of tags.

    - (dict) –

      Describes a tag.

        - ResourceId (string) –
          The ID of the resource. For example, ami-1a2b3c4d.

        - ResourceType (string) –
          The resource type.
• **Key** *(string)* – The tag key.

• **Value** *(string)* – The tag value.

```python
class EC2.Paginator.DescribeVolumeStatus

paginator = client.get_paginator('describe_volume_status')
paginate(**kwargs)

Creates an iterator that will paginate through responses from
EC2.Client.describe_volume_status().

**Request Syntax**

```python
response_iterator = paginator.paginate(
    DryRun=True|False,
    VolumeIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ],
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

• **DryRun** *(boolean)* – Checks whether you have the required permissions for the
  action, without actually making the request, and provides an error response. If
  you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

• **VolumeIds** *(list)* – One or more volume IDs.
  Default: Describes all your volumes.

  – *(string)*

• **Filters** *(list)* – One or more filters.
  - action.code - The action code for the event (for example,
    enable-volume-io).
  - action.description - A description of the action.
  - action.event-id - The event ID associated with the action.
  - availability-zone - The Availability Zone of the instance.
  - event.description - A description of the event.
  - event.event-id - The event ID.
  - event.event-type - The event type (for io-enabled: passed | failed; for io-performance: io-performance: degraded...
|---|

- **event.not-after** - The latest end time for the event.
- **event.not-before** - The earliest start time for the event.
- **volume-status.details-name** - The cause for the status of the volume.
- **volume-status.details-status** - The status of the details-name.
- **volume-status.status** - The status of the volume.
- **(dict)** - A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  - **Name** (string) –
    The name of the filter. Filter names are case-sensitive.
  - **Values** (list) –
    One or more filter values. Filter values are case-sensitive.
  - **PaginationConfig** (dict) – A dictionary that provides parameters to control pagination.
    - **MaxItems** (integer) –
      The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
    - **PageSize** (integer) –
      The size of each page.
    - **StartingToken** (string) –
      A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type**: dict

**Returns**:

**Response Syntax**

```
{
    'VolumeStatuses': [
        {
            'VolumeId': 'string',
            'AvailabilityZone': 'string',
            'VolumeStatus': {
                'Status': 'ok'|'impaired'|'insufficient-data',
                'Details': [
                    {
                        'Name': 'io-enabled'|'io-performance',
                        'Status': 'string'
                    }
                ],
            'Status': 'ok'|'impaired'|'insufficient-data'
        }
    ]
```
'Events': [
    {
        'EventType': 'string',
        'Description': 'string',
        'NotBefore': datetime(2015, 1, 1),
        'NotAfter': datetime(2015, 1, 1),
        'EventId': 'string'
    },
],
'Actions': [
    {
        'Code': 'string',
        'Description': 'string',
        'EventType': 'string',
        'EventId': 'string'
    },
],
]

Response Structure

- (dict) –
  - VolumeStatuses (list) –
    A list of volumes.
      * (dict) –
        Describes the volume status.
          - VolumeId (string) –
            The volume ID.
          - AvailabilityZone (string) –
            The Availability Zone of the volume.
          - VolumeStatus (dict) –
            The volume status.
          - Status (string) –
            The status of the volume.
          - Details (list) –
            The details of the volume status.
              * (dict) –
                Describes a volume status.
              - Name (string) –
                The name of the volume status.
              - Status (string) –
                The intended status of the volume status.
              - Events (list) –
                A list of events associated with the volume.
                  * (dict) –
                    Describes a volume status event.
                    - EventType (string) –
The type of this event.

- **Description** *(string)* –
  
  A description of the event.

- **NotBefore** *(datetime)* –
  
  The earliest start time of the event.

- **NotAfter** *(datetime)* –
  
  The latest end time of the event.

- **EventId** *(string)* –
  
  The ID of this event.

- **Actions** *(list)* –
  
  The details of the operation.

  - *(dict)* –
    
    Describes a volume status operation code.

  - **Code** *(string)* –
    
    The code identifying the operation, for example, enable-volume-io.

  - **Description** *(string)* –
    
    A description of the operation.

  - **EventType** *(string)* –
    
    The event type associated with this operation.

  - **EventId** *(string)* –
    
    The ID of the event associated with this operation.

**Waiters**

The available waiters are:

- EC2.Waiter.BundleTaskComplete
- EC2.Waiter.ConversionTaskCancelled
- EC2.Waiter.ConversionTaskCompleted
- EC2.Waiter.ConversionTaskDeleted
- EC2.Waiter.CustomerGatewayAvailable
- EC2.Waiter.ExportTaskCancelled
- EC2.Waiter.ExportTaskCompleted
- EC2.Waiter.ImageAvailable
- EC2.Waiter.InstanceExists
- EC2.Waiter.InstanceRunning
- EC2.Waiter.InstanceStatusOk
- EC2.Waiter.InstanceStopped
- EC2.Waiter.InstanceTerminated
- EC2.Waiter.PasswordDataAvailable
• EC2.Waiter.SnapshotCompleted
• EC2.Waiter.SpotInstanceRequestFulfilled
• EC2.Waiter.SubnetAvailable
• EC2.Waiter.SystemStatusOk
• EC2.Waiter.VolumeAvailable
• EC2.Waiter.VolumeDeleted
• EC2.Waiter.VolumeInUse
• EC2.Waiter.VpcAvailable
• EC2.Waiter.VpnConnectionAvailable
• EC2.Waiter.VpnConnectionDeleted

class EC2.Waiter.BundleTaskComplete

waiter = client.get_waiter('bundle_task_complete')

wait(**kwargs)

Polls EC2.Client.describe_bundle_tasks() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

waiter.wait(
    DryRun=True|False,
    BundleIds=[
        'string',
    ],
    Filters=[
        {'Name': 'string',
         'Values': [
            'string',
            'string',
         ]},
    ],
)

Parameters

• **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
• **BundleIds** (*list*) – One or more bundle task IDs.
  Default: Describes all your bundle tasks.
  – (string) –
• **Filters** (*list*) – One or more filters.
  – bundle-id - The ID of the bundle task.
  – error-code - If the task failed, the error code returned.
  – error-message - If the task failed, the error message returned.
  – instance-id - The ID of the instance.
– **progress** - The level of task completion, as a percentage (for example, 20%).
– **s3-bucket** - The Amazon S3 bucket to store the AMI.
– **s3-prefix** - The beginning of the AMI name.
– **start-time** - The time the task started (for example, 2013-09-15T17:15:20.000Z).
– **state** - The state of the task (pending|waiting-for-shutdown|bundling|storing|cancelling|complete|failed).
– **update-time** - The time of the most recent update for the task.
– **(dict)**

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* **Name (string)** –
  The name of the filter. Filter names are case-sensitive.
* **Values (list)** –
  One or more filter values. Filter values are case-sensitive.

- **(string)**

**Returns** None

class EC2.Waiter.ConversionTaskCancelled

```
waiter = client.get_waiter('conversion_task_cancelled')

wait(**kwargs)
```

Polls `EC2.Client.describe_conversion_tasks()` every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

**Request Syntax**

```
waiter.wait(
    DryRun=True|False,
    Filters=[
        {'Name': 'string',
         'Values': [ 'string',
                     ]},
    ],
    ConversionTaskIds=[ 'string',
    ]
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **Filters (list)** – One or more filters.
  - **(dict)** –
A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* **Name** *(string)*
  The name of the filter. Filter names are case-sensitive.

* **Values** *(list)*
  One or more filter values. Filter values are case-sensitive.
  
    • **ConversionTaskIds** *(list)* – One or more conversion task IDs.

**Returns** None

class EC2.Waiter.ConversionTaskCompleted

waiter = client.get_waiter('conversion_task_completed')

wait(**kwargs)
Polls EC2.Client.describe_conversion_tasks() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

**Request Syntax**

waiter.wait(
    DryRun=True|False,
    Filters=[
        {
            'Name': 'string',
            'Values': ['string',]
        },
    ],
    ConversionTaskIds=['string',]
)

**Parameters**

* **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

* **Filters** *(list)* – One or more filters.
  
    • **ConversionTaskIds** *(list)* – One or more conversion task IDs.
Returns None

class EC2.Waiter.ConversionTaskDeleted

waiter = client.get_waiter('conversion_task_deleted')

wait(**kwargs)

Polls EC2.Client.describe_conversion_tasks() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

waiter.wait(
    DryRun=True|False,
    Filters=[
    {'Name': 'string',
     'Values': ['string',
     ]},
    ],
    ConversionTaskIds=['string',
    ]
)

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **Filters** (list) – One or more filters.
  - (dict) –
    A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
    - **Name** (string) –
      The name of the filter. Filter names are case-sensitive.
    - **Values** (list) –
      One or more filter values. Filter values are case-sensitive.
- **ConversionTaskIds** (list) – One or more conversion task IDs.

Returns None

class EC2.Waiter.CustomerGatewayAvailable

waiter = client.get_waiter('customer_gateway_available')
wait(**kwargs)

Polls `EC2.Client.describe_customer_gateways()` every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

**Request Syntax**

```python
waiter.wait(
    DryRun=True|False,
    CustomerGatewayIds=[
        'string',
    ],
    Filters=[
        {'Name': 'string',
         'Values': [ 'string',
        ]},
    ],
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **CustomerGatewayIds** *(list)* – One or more customer gateway IDs.

Default: Describes all your customer gateways.

- *(string)* –
- **Filters** *(list)* – One or more filters.
  - `customer-gateway-id` - The ID of the customer gateway.
  - `ip-address` - The IP address of the customer gateway’s Internet-routable external interface.
  - `state` - The state of the customer gateway (pending | available | deleting | deleted).
  - `type` - The type of customer gateway. Currently, the only supported type is `ipsec.1`.
  - `tag :key =*value*` - The key/value combination of a tag assigned to the resource.
  - `tag-key` - The key of a tag assigned to the resource. This filter is independent of the `tag-value` filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag :key =*value*` filter.
  - `tag-value` - The value of a tag assigned to the resource. This filter is independent of the `tag-key` filter.

- *(dict)* –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

- **Name** *(string)* –
The name of the filter. Filter names are case-sensitive.

* **Values (list)** –
  One or more filter values. Filter values are case-sensitive.
  • **(string)** –

**Returns** None

class EC2.Waiter.ExportTaskCancelled

```python
waiter = client.get_waiter('export_task_cancelled')

wait(**kwargs)
Polls EC2.Client.describe_export_tasks() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

**Request Syntax**

```python
waiter.wait(
    ExportTaskIds=[
        'string',
    ]
)
```

**Parameters** ExportTaskIds (list) – One or more export task IDs.
  • **(string)** –

**Returns** None

class EC2.Waiter.ExportTaskCompleted

```python
waiter = client.get_waiter('export_task_completed')

wait(**kwargs)
Polls EC2.Client.describe_export_tasks() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

**Request Syntax**

```python
waiter.wait(
    ExportTaskIds=[
        'string',
    ]
)
```

**Parameters** ExportTaskIds (list) – One or more export task IDs.
  • **(string)** –

**Returns** None

class EC2.Waiter.ImageAvailable

```python
waiter = client.get_waiter('image_available')

wait(**kwargs)
Polls EC2.Client.describe_images() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

**Request Syntax**
waiter.wait(
    DryRun=True|False,
    ImageIds=[
        'string',
    ],
    Owners=[
        'string',
    ],
    ExecutableUsers=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ]
        },
    ],
)

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **ImageIds** *(list)* – One or more image IDs.
  
  Default: Describes all images available to you.
  
  – *(string)* –
- **Owners** *(list)* – Filters the images by the owner. Specify an AWS account ID, `amazon` (owner is Amazon), `aws-marketplace` (owner is AWS Marketplace), `self` (owner is the sender of the request). Omitting this option returns all images for which you have launch permissions, regardless of ownership.
  
  – *(string)* –
- **ExecutableUsers** *(list)* – Scopes the images by users with explicit launch permissions. Specify an AWS account ID, `self` (the sender of the request), or `all` (public AMIs).
  
  – *(string)* –
- **Filters** *(list)* – One or more filters.
  
  – **architecture** - The image architecture (i386|x86_64).
  
  – **block-device-mapping.delete-on-termination** - A Boolean value that indicates whether the Amazon EBS volume is deleted on instance termination.
  
  – **block-device-mapping.device-name** - The device name for the EBS volume (for example, /dev/sdh).
  
  – **block-device-mapping.snapshot-id** - The ID of the snapshot used for the EBS volume.
  
  – **block-device-mapping.volume-size** - The volume size of the EBS volume, in GiB.
  
  – **block-device-mapping.volume-type** - The volume type of the EBS volume (gp2|standard|io1).
  
  – **description** - The description of the image (provided during image creation).
  
  – **hypervisor** - The hypervisor type (ovm|xen).
- image-id - The ID of the image.
- image-type - The image type (machine | kernel | ramdisk).
- is-public - A Boolean that indicates whether the image is public.
- kernel-id - The kernel ID.
- manifest-location - The location of the image manifest.
- name - The name of the AMI (provided during image creation).
- owner-alias - The AWS account alias (for example, amazon).
- owner-id - The AWS account ID of the image owner.
- platform - The platform. To only list Windows-based AMIs, use windows.
- product-code - The product code.
- product-code.type - The type of the product code (devpay | marketplace).
- ramdisk-id - The RAM disk ID.
- root-device-name - The name of the root device volume (for example, /dev/sda1).
- root-device-type - The type of the root device volume (ebs | instance-store).
- state - The state of the image (available | pending | failed).
- state-reason-code - The reason code for the state change.
- state-reason-message - The message for the state change.
- tag :key =*value* - The key/value combination of a tag assigned to the resource.
- tag-key - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter "tag-key=Purpose" and the filter "tag-value=X", you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key =*value* filter.
- tag-value - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- virtualization-type - The virtualization type (paravirtual | hvm).

(dict) –
A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* Name (string) –
The name of the filter. Filter names are case-sensitive.

* Values (list) –
One or more filter values. Filter values are case-sensitive.

Returns None

```python
class EC2.Waiter.InstanceExists

waiter = client.get_waiter('instance_exists')

wait (**kwargs)
Polls EC2.Client.describe_instances() every 5 seconds until a successful state is reached. An error is returned after 40 failed checks.
```
Request Syntax

```python
waiter.wait(
    DryRun=True|False,
    InstanceIds=['string'],
    Filters=[
        {'Name': 'string',
         'Values': ['string'],
        },
    ],
    NextToken='string',
    MaxResults=123
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is *DryRunOperation*. Otherwise, it is *UnauthorizedOperation*.

- **InstanceIds** *(list)* – One or more instance IDs.
  
  Default: Describes all your instances.

  - *(string)* –

- **Filters** *(list)* – One or more filters.
  
  - **architecture** - The instance architecture (i386|x86_64).
  
  - **availability-zone** - The Availability Zone of the instance.
  
  - **block-device-mapping.attach-time** - The attach time for an EBS volume mapped to the instance, for example, 2010-09-15T17:15:20.000Z.
  
  - **block-device-mapping.delete-on-termination** - A Boolean that indicates whether the EBS volume is deleted on instance termination.
  
  - **block-device-mapping.device-name** - The device name for the EBS volume (for example, /dev/sdh or xvdh).
  
  - **block-device-mapping.status** - The status for the EBS volume (attaching|attached|detaching|detached).
  
  - **block-device-mapping.volume-id** - The volume ID of the EBS volume.
  
  - **client-token** - The idempotency token you provided when you launched the instance.
  
  - **dns-name** - The public DNS name of the instance.
  
  - **group-id** - The ID of the security group for the instance. EC2-Classic only.
  
  - **group-name** - The name of the security group for the instance. EC2-Classic only.
  
  - **hypervisor** - The hypervisor type of the instance (ovm|xen).
  
  - **iam-instance-profile.arn** - The instance profile associated with the instance. Specified as an ARN.
  
  - **image-id** - The ID of the image used to launch the instance.
  
  - **instance-id** - The ID of the instance.
- `instance-lifecycle` - Indicates whether this is a Spot Instance (spot).
- `instance-state-code` - The state of the instance, as a 16-bit unsigned integer. The high byte is an opaque internal value and should be ignored. The low byte is set based on the state represented. The valid values are: 0 (pending), 16 (running), 32 (shutting-down), 48 (terminated), 64 (stopping), and 80 (stopped).
- `instance-state-name` - The state of the instance (pending | running | shutting-down | terminated | stopping | stopped).
- `instance-type` - The type of instance (for example, t2.micro).
- `instance.group-id` - The ID of the security group for the instance.
- `instance.group-name` - The name of the security group for the instance.
- `ip-address` - The public IP address of the instance.
- `kernel-id` - The kernel ID.
- `key-name` - The name of the key pair used when the instance was launched.
- `launch-index` - When launching multiple instances, this is the index for the instance in the launch group (for example, 0, 1, 2, and so on).
- `launch-time` - The time when the instance was launched.
- `monitoring-state` - Indicates whether monitoring is enabled for the instance (disabled | enabled).
- `owner-id` - The AWS account ID of the instance owner.
- `placement-group-name` - The name of the placement group for the instance.
- `platform` - The platform. Use windows if you have Windows instances; otherwise, leave blank.
- `private-dns-name` - The private DNS name of the instance.
- `private-ip-address` - The private IP address of the instance.
- `product-code` - The product code associated with the AMI used to launch the instance.
- `product-code.type` - The type of product code (devpay | marketplace).
- `ramdisk-id` - The RAM disk ID.
- `reason` - The reason for the current state of the instance (for example, shows “User Initiated [date]” when you stop or terminate the instance). Similar to the state-reason-code filter.
- `requester-id` - The ID of the entity that launched the instance on your behalf (for example, AWS Management Console, Auto Scaling, and so on).
- `reservation-id` - The ID of the instance’s reservation. A reservation ID is created any time you launch an instance. A reservation ID has a one-to-one relationship with an instance launch request, but can be associated with more than one instance if you launch multiple instances using the same launch request. For example, if you launch one instance, you’ll get one reservation ID. If you launch ten instances using the same launch request, you’ll also get one reservation ID.
- `root-device-name` - The name of the root device for the instance (for example, /dev/sda1 or /dev/xvda).
- `root-device-type` - The type of root device that the instance uses (ebs | instance-store).
- `source-dest-check` - Indicates whether the instance performs source/destination checking. A value of true means that checking is
enabled, and false means checking is disabled. The value must be false for the instance to perform network address translation (NAT) in your VPC.

- **spot-instance-request-id** - The ID of the Spot Instance request.
- **state-reason-code** - The reason code for the state change.
- **state-reason-message** - A message that describes the state change.
- **subnet-id** - The ID of the subnet for the instance.
- **tag :key =*value* - The key/value combination of a tag assigned to the resource, where tag :key is the tag’s key.
- **tag-key** - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key =*value* filter.
- **tag-value** - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- **tenancy** - The tenancy of an instance (dedicated | default).
- **virtualization-type** - The virtualization type of the instance (paravirtual | hvm).
- **vpc-id** - The ID of the VPC that the instance is running in.
- **network-interface.description** - The description of the network interface.
- **network-interface.subnet-id** - The ID of the subnet for the network interface.
- **network-interface.vpc-id** - The ID of the VPC for the network interface.
- **network-interface.network-interface.id** - The ID of the network interface.
- **network-interface.owner-id** - The ID of the owner of the network interface.
- **network-interface.availability-zone** - The Availability Zone for the network interface.
- **network-interface.requester-id** - The requester ID for the network interface.
- **network-interface.requester-managed** - Indicates whether the network interface is being managed by AWS.
- **network-interface.status** - The status of the network interface (available | in-use).
- **network-interface.mac-address** - The MAC address of the network interface.
- **network-interface-private-dns-name** - The private DNS name of the network interface.
- **network-interface.source-dest-check** - Whether the network interface performs source/destination checking. A value of true means checking is enabled, and false means checking is disabled. The value must be false for the network interface to perform network address translation (NAT) in your VPC.
- **network-interface.group-id** - The ID of a security group associated with the network interface.
- **network-interface.group-name** - The name of a security group associated with the network interface.
- **network-interface.attachment.attachment-id** - The ID of the interface attachment.
- network-interface.attachment.instance-id - The ID of the instance to which the network interface is attached.
- network-interface.attachment.instance-owner-id - The owner ID of the instance to which the network interface is attached.
- network-interface.addresses.private-ip-address - The private IP address associated with the network interface.
- network-interface.attachment.device-index - The device index to which the network interface is attached.
- network-interface.attachment.status - The status of the attachment (attaching | attached | detaching | detached).
- network-interface.attachment.attach-time - The time that the network interface was attached to an instance.
- network-interface.attachment.delete-on-termination - Specifies whether the attachment is deleted when an instance is terminated.
- network-interface.addresses.primary - Specifies whether the IP address of the network interface is the primary private IP address.
- network-interface.addresses.association.public-ip - The ID of the association of an Elastic IP address with a network interface.
- network-interface.addresses.association.ip-owner-id - The owner ID of the private IP address associated with the network interface.
- association.public-ip - The address of the Elastic IP address bound to the network interface.
- association.ip-owner-id - The owner of the Elastic IP address associated with the network interface.
- association.allocation-id - The allocation ID returned when you allocated the Elastic IP address for your network interface.
- association.association-id - The association ID returned when the network interface was associated with an IP address.

- (dict) –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  * Name (string) –

    The name of the filter. Filter names are case-sensitive.

  * Values (list) –

    One or more filter values. Filter values are case-sensitive.

- (string) –

  * NextToken (string) – The token to request the next page of results.
  * MaxResults (integer) – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. You cannot specify this parameter and the instance IDs parameter in the same request.

**Returns** None

```python
class EC2.Waiter.InstanceRunning
```
waiter = client.get_waiter('instance_running')

wait(**kwargs)

Polls EC2.Client.describe_instances() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

waiter.wait(
    DryRun=True|False,
    InstanceIds=[
        'string',
    ],
    Filters=[
        {'Name': 'string',
         'Values': [
            'string',
         ]},
    ],
    NextToken='string',
    MaxResults=123
)

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **InstanceIds** *(list)* – One or more instance IDs. Default: Describes all your instances.

- **Filters** *(list)* – One or more filters.
  - **architecture** - The instance architecture (i386|x86_64).
  - **availability-zone** - The Availability Zone of the instance.
  - **block-device-mapping.attach-time** - The attach time for an EBS volume mapped to the instance, for example, 2010-09-15T17:15:20.000Z.
  - **block-device-mapping.delete-on-termination** - A Boolean that indicates whether the EBS volume is deleted on instance termination.
  - **block-device-mapping.device-name** - The device name for the EBS volume (for example, /dev/sdh or xvdh).
  - **block-device-mapping.status** - The status for the EBS volume (attaching|attached|detaching|detached).
  - **block-device-mapping.volume-id** - The volume ID of the EBS volume.
  - **client-token** - The idempotency token you provided when you launched the instance.
  - **dns-name** - The public DNS name of the instance.
  - **group-id** - The ID of the security group for the instance. EC2-Classic only.
  - **group-name** - The name of the security group for the instance. EC2-Classic only.
- **hypervisor** - The hypervisor type of the instance (ovm\|xen).
- **iam-instance-profile.arn** - The instance profile associated with the instance. Specified as an ARN.
- **image-id** - The ID of the image used to launch the instance.
- **instance-id** - The ID of the instance.
- **instance-lifecycle** - Indicates whether this is a Spot Instance (spot).
- **instance-state-code** - The state of the instance, as a 16-bit unsigned integer. The high byte is an opaque internal value and should be ignored. The low byte is set based on the state represented. The valid values are: 0 (pending), 16 (running), 32 (shutting-down), 48 (terminated), 64 (stopping), and 80 (stopped).
- **instance-state-name** - The state of the instance (pending | running|shutting-down|terminated|stopping|stopped).
- **instance-type** - The type of instance (for example, t2.micro).
- **instance.group-id** - The ID of the security group for the instance.
- **instance.group-name** - The name of the security group for the instance.
- **ip-address** - The public IP address of the instance.
- **kernel-id** - The kernel ID.
- **key-name** - The name of the key pair used when the instance was launched.
- **launch-index** - When launching multiple instances, this is the index for the instance in the launch group (for example, 0, 1, 2, and so on).
- **launch-time** - The time when the instance was launched.
- **monitoring-state** - Indicates whether monitoring is enabled for the instance (disabled|enabled).
- **owner-id** - The AWS account ID of the instance owner.
- **placement-group-name** - The name of the placement group for the instance.
- **platform** - The platform. Use windows if you have Windows instances; otherwise, leave blank.
- **private-dns-name** - The private DNS name of the instance.
- **private-ip-address** - The private IP address of the instance.
- **product-code** - The product code associated with the AMI used to launch the instance.
- **product-code.type** - The type of product code (devpay | marketplace).
- **ramdisk-id** - The RAM disk ID.
- **reason** - The reason for the current state of the instance (for example, shows “User Initiated [date]” when you stop or terminate the instance). Similar to the state-reason-code filter.
- **requester-id** - The ID of the entity that launched the instance on your behalf (for example, AWS Management Console, Auto Scaling, and so on).
- **reservation-id** - The ID of the instance’s reservation. A reservation ID is created any time you launch an instance. A reservation ID has a one-to-one relationship with an instance launch request, but can be associated with more than one instance if you launch multiple instances using the same launch request. For example, if you launch one instance, you’ll get one reservation ID. If you launch ten instances using the same launch request, you’ll also get one reservation ID.
- **root-device-name** - The name of the root device for the instance (for
example, /dev/sda1 or /dev/xvda.

- **root-device-type** - The type of root device that the instance uses (ebs | instance-store).

- **source-dest-check** - Indicates whether the instance performs source/destination checking. A value of true means that checking is enabled, and false means checking is disabled. The value must be false for the instance to perform network address translation (NAT) in your VPC.

- **spot-instance-request-id** - The ID of the Spot Instance request.

- **state-reason-code** - The reason code for the state change.

- **state-reason-message** - A message that describes the state change.

- **subnet-id** - The ID of the subnet for the instance.

- **tag :key = *value*** - The key/value combination of a tag assigned to the resource, where tag :key is the tag’s key.

- **tag-key** - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key = *value* filter.

- **tag-value** - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.

- **tenancy** - The tenancy of an instance (dedicated | default).

- **virtualization-type** - The virtualization type of the instance (paravirtual | hvm).

- **vpc-id** - The ID of the VPC that the instance is running in.

- **network-interface.description** - The description of the network interface.

- **network-interface.subnet-id** - The ID of the subnet for the network interface.

- **network-interface.vpc-id** - The ID of the VPC for the network interface.

- **network-interface.network-interface.id** - The ID of the network interface.

- **network-interface.owner-id** - The ID of the owner of the network interface.

- **network-interface.availability-zone** - The Availability Zone for the network interface.

- **network-interface.requester-id** - The requester ID for the network interface.

- **network-interface.requester-managed** - Indicates whether the network interface is being managed by AWS.

- **network-interface.status** - The status of the network interface (available | in-use).

- **network-interface.mac-address** - The MAC address of the network interface.

- **network-interface-private-dns-name** - The private DNS name of the network interface.

- **network-interface-source-dest-check** - Whether the network interface performs source/destination checking. A value of true means checking is enabled, and false means checking is disabled. The value must be false for the network interface to perform network address translation (NAT) in your VPC.

- **network-interface-group-id** - The ID of a security group asso-
associated with the network interface.

- **network-interface.group-name** - The name of a security group associated with the network interface.
- **network-interface.attachment.attachment-id** - The ID of the interface attachment.
- **network-interface.attachment.instance-id** - The ID of the instance to which the network interface is attached.
- **network-interface.attachment.instance-owner-id** - The owner ID of the instance to which the network interface is attached.
- **network-interface.addresses.private-ip-address** - The private IP address associated with the network interface.
- **network-interface.attachment.device-index** - The device index to which the network interface is attached.
- **network-interface.attachment.status** - The status of the attachment (attaching | attached | detaching | detached).
- **network-interface.attachment.attach-time** - The time that the network interface was attached to an instance.
- **network-interface.attachment.delete-on-termination** - Specifies whether the attachment is deleted when an instance is terminated.
- **network-interface.addresses.primary** - Specifies whether the IP address of the network interface is the primary private IP address.
- **network-interface.addresses.association.public-ip** - The ID of the association of an Elastic IP address with a network interface.
- **network-interface.addresses.association.ip-owner-id** - The owner ID of the private IP address associated with the network interface.
- **association.public-ip** - The address of the Elastic IP address bound to the network interface.
- **association.ip-owner-id** - The owner of the Elastic IP address associated with the network interface.
- **association.allocation-id** - The allocation ID returned when you allocated the Elastic IP address for your network interface.
- **association.association-id** - The association ID returned when the network interface was associated with an IP address.

- **(dict)**

  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  * **Name** *(string)*

    The name of the filter. Filter names are case-sensitive.

  * **Values** *(list)*

    One or more filter values. Filter values are case-sensitive.

    * **(string)**

  * **NextToken** *(string)* - The token to request the next page of results.
  * **MaxResults** *(integer)* - The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. You cannot specify this parameter and the instance IDs parameter in the same request.
Returns  None

class EC2.Waiter.InstanceStatusOk

waiter = client.get_waiter('instance_status_ok')

wait(**kwargs)
Polls EC2.Client.describe_instance_status() every 15 seconds until a successful state is
reached. An error is returned after 40 failed checks.

Request Syntax

waiter.wait(
    DryRun=True|False,
    InstanceIds=[
        'string',
    ],
    Filters=[
        {'Name': 'string',
         'Values': [
             'string',
         ]},
    ],
    NextToken='string',
    MaxResults=123,
    IncludeAllInstances=True|False
)

Parameters

• **DryRun** (boolean) – Checks whether you have the required permissions for the
  action, without actually making the request, and provides an error response. If
  you have the required permissions, the error response is DryRunOperation. 
  Otherwise, it is UnauthorizedOperation.

• **InstanceIds** (list) – One or more instance IDs.

  Default: Describes all your instances.

Constraints: Maximum 100 explicitly specified instance IDs.

  – (string) –

• **Filters** (list) – One or more filters.

  – availability-zone - The Availability Zone of the instance.

  – event.code - The code for the scheduled event
    (instance-reboot | system-reboot | system-maintenance
    | instance-retirement | instance-stop).

  – event.description - A description of the event.

  – event.not-after - The latest end time for the scheduled event (for

  – event.not-before - The earliest start time for the scheduled event
    (for example, 2014-09-15T17:15:20.000Z).

  – instance-state-code - The code for the instance state, as a 16-bit
    unsigned integer. The high byte is an opaque internal value and should
    be ignored. The low byte is set based on the state represented. The valid
    values are 0 (pending), 16 (running), 32 (shutting-down), 48 (terminated),
    64 (stopping), and 80 (stopped).
- instance-state-name - The state of the instance (pending | running | shutting-down | terminated | stopping | stopped).
- instance-status.reachability - Filters on instance status where the name is reachability (passed | failed | initializing | insufficient-data).
- instance-status.status - The status of the instance (ok | impaired | initializing | insufficient-data | not-applicable).
- system-status.reachability - Filters on system status where the name is reachability (passed | failed | initializing | insufficient-data).
- system-status.status - The system status of the instance (ok | impaired | initializing | insufficient-data | not-applicable).

- (dict) –
  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  * Name (string) –
    The name of the filter. Filter names are case-sensitive.
  * Values (list) –
    One or more filter values. Filter values are case-sensitive.
    - (string) –
      • NextToken (string) – The token to retrieve the next page of results.
      • MaxResults (integer) – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. You cannot specify this parameter and the instance IDs parameter in the same request.
      • IncludeAllInstances (boolean) – When true, includes the health status for all instances. When false, includes the health status for running instances only.

Default: false

Returns None

class EC2.Waiter.InstanceStopped

waiter = client.get_waiter('instance_stopped')

wait(**kwargs)
Polls EC2.Client.describe_instances() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

waiter.wait(
    DryRun=True|False,
    InstanceIds=[
        'string',
    ],
    Filters=[

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **InstanceIds** *(list)* – One or more instance IDs.

  Default: Describes all your instances.

  - *(string)* –

- **Filters** *(list)* – One or more filters.

  - **architecture** - The instance architecture (i386 | x86_64).
  - **availability-zone** - The Availability Zone of the instance.
  - **block-device-mapping.attach-time** - The attach time for an EBS volume mapped to the instance, for example, 2010-09-15T17:15:20.000Z.
  - **block-device-mapping.delete-on-termination** - A Boolean that indicates whether the EBS volume is deleted on instance termination.
  - **block-device-mapping.device-name** - The device name for the EBS volume (for example, /dev/sdh or xvdh).
  - **block-device-mapping.status** - The status for the EBS volume (attaching | attached | detaching | detached).
  - **block-device-mapping.volume-id** - The volume ID of the EBS volume.
  - **client-token** - The idempotency token you provided when you launched the instance.
  - **dns-name** - The public DNS name of the instance.
  - **group-id** - The ID of the security group for the instance. EC2-Classic only.
  - **group-name** - The name of the security group for the instance. EC2-Classic only.
  - **hypervisor** - The hypervisor type of the instance (ovm | xen).
  - **iam-instance-profile.arn** - The instance profile associated with the instance. Specified as an ARN.
  - **image-id** - The ID of the image used to launch the instance.
  - **instance-id** - The ID of the instance.
  - **instance-lifecycle** - Indicates whether this is a Spot Instance (spot).
  - **instance-state-code** - The state of the instance, as a 16-bit unsigned integer. The high byte is an opaque internal value and should be ignored. The low byte is set based on the state represented. The valid values are: 0 (pending), 16 (running), 32 (shutting-down), 48 (terminated), 64 (stopping), and 80 (stopped).
  - **instance-state-name** - The state of the instance (pending |
- instance-type - The type of instance (for example, t2.micro).
- instance.group-id - The ID of the security group for the instance.
- instance.group-name - The name of the security group for the instance.
- ip-address - The public IP address of the instance.
- kernel-id - The kernel ID.
- key-name - The name of the key pair used when the instance was launched.
- launch-index - When launching multiple instances, this is the index for the instance in the launch group (for example, 0, 1, 2, and so on).
- launch-time - The time when the instance was launched.
- monitoring-state - Indicates whether monitoring is enabled for the instance (disabled | enabled).
- owner-id - The AWS account ID of the instance owner.
- placement-group-name - The name of the placement group for the instance.
- platform - The platform. Use windows if you have Windows instances; otherwise, leave blank.
- private-dns-name - The private DNS name of the instance.
- private-ip-address - The private IP address of the instance.
- product-code - The product code associated with the AMI used to launch the instance.
- product-code.type - The type of product code (devpay | marketplace).
- ramdisk-id - The RAM disk ID.
- reason - The reason for the current state of the instance (for example, shows “User Initiated [date]” when you stop or terminate the instance). Similar to the state-reason-code filter.
- requester-id - The ID of the entity that launched the instance on your behalf (for example, AWS Management Console, Auto Scaling, and so on).
- reservation-id - The ID of the instance’s reservation. A reservation ID is created any time you launch an instance. A reservation ID has a one-to-one relationship with an instance launch request, but can be associated with more than one instance if you launch multiple instances using the same launch request. For example, if you launch one instance, you’ll get one reservation ID. If you launch ten instances using the same launch request, you’ll also get one reservation ID.
- root-device-name - The name of the root device for the instance (for example, /dev/sdal or /dev/xvda).
- root-device-type - The type of root device that the instance uses (ebs | instance-store).
- source-dest-check - Indicates whether the instance performs source/destination checking. A value of true means that checking is enabled, and false means checking is disabled. The value must be false for the instance to perform network address translation (NAT) in your VPC.
- spot-instance-request-id - The ID of the Spot Instance request.
- state-reason-code - The reason code for the state change.
- state-reason-message - A message that describes the state change.
- subnet-id - The ID of the subnet for the instance.
- tag :key =*value* - The key/value combination of a tag assigned to the
resource, where tag :key is the tag’s key.

- tag-key - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key=*value* filter.

- tag-value - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.

- tenancy - The tenancy of an instance (dedicated|default).

- virtualization-type - The virtualization type of the instance (paravirtual|hvm).

- vpc-id - The ID of the VPC that the instance is running in.

- network-interface.description - The description of the network interface.

- network-interface.subnet-id - The ID of the subnet for the network interface.

- network-interface.vpc-id - The ID of the VPC for the network interface.

- network-interface.network-interface.id - The ID of the network interface.

- network-interface.owner-id - The ID of the owner of the network interface.

- network-interface.availability-zone - The Availability Zone for the network interface.

- network-interface.requester-id - The requester ID for the network interface.

- network-interface.requester-managed - Indicates whether the network interface is being managed by AWS.

- network-interface.status - The status of the network interface (available|in-use).

- network-interface.mac-address - The MAC address of the network interface.

- network-interface-private-dns-name - The private DNS name of the network interface.

- network-interface.source-dest-check - Whether the network interface performs source/destination checking. A value of true means checking is enabled, and false means checking is disabled. The value must be false for the network interface to perform network address translation (NAT) in your VPC.

- network-interface.group-id - The ID of a security group associated with the network interface.

- network-interface.group-name - The name of a security group associated with the network interface.

- network-interface.attachment.attachment-id - The ID of the interface attachment.

- network-interface.attachment.instance-id - The ID of the instance to which the network interface is attached.

- network-interface.attachment.instance-owner-id - The owner ID of the instance to which the network interface is attached.

- network-interface.addresses.private-ip-address - The private IP address associated with the network interface.

- network-interface.attachment.device-index - The device index to which the network interface is attached.
- network-interface.attachment.status - The status of the attachment (attaching|attached|detaching|detached).
- network-interface.attachment.attach-time - The time that the network interface was attached to an instance.
- network-interface.attachment.delete-on-termination - Specifies whether the attachment is deleted when an instance is terminated.
- network-interface.addresses.primary - Specifies whether the IP address of the network interface is the primary private IP address.
- network-interface.addresses.association.public-ip - The ID of the association of an Elastic IP address with a network interface.
- network-interface.addresses.association.ip-owner-id - The owner ID of the private IP address associated with the network interface.
- association.public-ip - The address of the Elastic IP address bound to the network interface.
- association.ip-owner-id - The owner of the Elastic IP address associated with the network interface.
- association.allocation-id - The allocation ID returned when you allocated the Elastic IP address for your network interface.
- association.association-id - The association ID returned when the network interface was associated with an IP address.

(dict) –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* Name (string) –

The name of the filter. Filter names are case-sensitive.

* Values (list) –

One or more filter values. Filter values are case-sensitive.

  - (string) –

  • NextToken (string) – The token to request the next page of results.

  • MaxResults (integer) – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. You cannot specify this parameter and the instance IDs parameter in the same request.

Returns None

class EC2.Waiter.InstanceTerminated

waiter = client.get_waiter('instance_terminated')

wait(**kwargs)

Polls EC2.Client.describe_instances() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax
waiter.wait(
    DryRun=True|False,
    InstanceIds=[
        'string',
    ],
    Filters=[
        
    ],
    NextToken='string',
    MaxResults=123
)

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **InstanceIds (list)** – One or more instance IDs.

  Default: Describes all your instances.

  - (string)

- **Filters (list)** – One or more filters.

  - **architecture** - The instance architecture (**i386|x86_64**).
  - **availability-zone** - The Availability Zone of the instance.
  - **block-device-mapping.attach-time** - The attach time for an EBS volume mapped to the instance, for example, **2010-09-15T17:15:20.000Z**.
  - **block-device-mapping.delete-on-termination** - A Boolean that indicates whether the EBS volume is deleted on instance termination.
  - **block-device-mapping.device-name** - The device name for the EBS volume (for example, /dev/sdh or xvdh).
  - **block-device-mapping.status** - The status for the EBS volume (attaching|attached|detaching|detached).
  - **block-device-mapping.volume-id** - The volume ID of the EBS volume.
  - **client-token** - The idempotency token you provided when you launched the instance.
  - **dns-name** - The public DNS name of the instance.
  - **group-id** - The ID of the security group for the instance. EC2-Classic only.
  - **group-name** - The name of the security group for the instance. EC2-Classic only.
  - **hypervisor** - The hypervisor type of the instance (**ovm|xen**).
  - **iam-instance-profile.arn** - The instance profile associated with the instance. Specified as an ARN.
  - **image-id** - The ID of the image used to launch the instance.
  - **instance-id** - The ID of the instance.
  - **instance-lifecycle** - Indicates whether this is a Spot Instance (spot).
- **instance-state-code** - The state of the instance, as a 16-bit unsigned integer. The high byte is an opaque internal value and should be ignored. The low byte is set based on the state represented. The valid values are: 0 (pending), 16 (running), 32 (shutting-down), 48 (terminated), 64 (stopping), and 80 (stopped).

- **instance-state-name** - The state of the instance (pending | running | shutting-down | terminated | stopping | stopped).

- **instance-type** - The type of instance (for example, t2.micro).

- **instance.group-id** - The ID of the security group for the instance.

- **instance.group-name** - The name of the security group for the instance.

- **ip-address** - The public IP address of the instance.

- **kernel-id** - The kernel ID.

- **key-name** - The name of the key pair used when the instance was launched.

- **launch-index** - When launching multiple instances, this is the index for the instance in the launch group (for example, 0, 1, 2, and so on).

- **launch-time** - The time when the instance was launched.

- **monitoring-state** - Indicates whether monitoring is enabled for the instance (disabled | enabled).

- **owner-id** - The AWS account ID of the instance owner.

- **placement-group-name** - The name of the placement group for the instance.

- **platform** - The platform. Use windows if you have Windows instances; otherwise, leave blank.

- **private-dns-name** - The private DNS name of the instance.

- **private-ip-address** - The private IP address of the instance.

- **product-code** - The product code associated with the AMI used to launch the instance.

- **product-code.type** - The type of product code (devpay | marketplace).

- **ramdisk-id** - The RAM disk ID.

- **reason** - The reason for the current state of the instance (for example, shows “User Initiated [date]” when you stop or terminate the instance). Similar to the state-reason-code filter.

- **requester-id** - The ID of the entity that launched the instance on your behalf (for example, AWS Management Console, Auto Scaling, and so on).

- **reservation-id** - The ID of the instance’s reservation. A reservation ID is created any time you launch an instance. A reservation ID has a one-to-one relationship with an instance launch request, but can be associated with more than one instance if you launch multiple instances using the same launch request. For example, if you launch one instance, you’ll get one reservation ID. If you launch ten instances using the same launch request, you’ll also get one reservation ID.

- **root-device-name** - The name of the root device for the instance (for example, /dev/sda1 or /dev/xvda).

- **root-device-type** - The type of root device that the instance uses (ebs | instance-store).

- **source-dest-check** - Indicates whether the instance performs source/destination checking. A value of true means that checking is enabled, and false means checking is disabled. The value must be false for the instance to perform network address translation (NAT) in
your VPC.

- **spot-instance-request-id** - The ID of the Spot Instance request.
- **state-reason-code** - The reason code for the state change.
- **state-reason-message** - A message that describes the state change.
- **subnet-id** - The ID of the subnet for the instance.
- **tag :key =*value* - The key/value combination of a tag assigned to the resource, where tag :key is the tag's key.
- **tag-key** - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key =*value* filter.
- **tag-value** - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- **tenancy** - The tenancy of an instance (dedicated | default).
- **virtualization-type** - The virtualization type of the instance (paravirtual | hvm).
- **vpc-id** - The ID of the VPC that the instance is running in.
- **network-interface.description** - The description of the network interface.
- **network-interfacesubnet-id** - The ID of the subnet for the network interface.
- **network-interface.vpc-id** - The ID of the VPC for the network interface.
- **network-interface.network-interface.id** - The ID of the network interface.
- **network-interface.owner-id** - The ID of the owner of the network interface.
- **network-interface.availability-zone** - The Availability Zone for the network interface.
- **network-interface.requester-id** - The requester ID for the network interface.
- **network-interface.requester-managed** - Indicates whether the network interface is being managed by AWS.
- **network-interface.status** - The status of the network interface (available | in-use).
- **network-interface.mac-address** - The MAC address of the network interface.
- **network-interface-private-dns-name** - The private DNS name of the network interface.
- **network-interface.source-dest-check** - Whether the network interface performs source/destination checking. A value of true means checking is enabled, and false means checking is disabled. The value must be false for the network interface to perform network address translation (NAT) in your VPC.
- **network-interface.group-id** - The ID of a security group associated with the network interface.
- **network-interface.group-name** - The name of a security group associated with the network interface.
- **network-interface.attachment.attachment-id** - The ID of the interface attachment.
- **network-interface.attachment.instance-id** - The ID of the instance to which the network interface is attached.
- `network-interface.attachment.instance-owner-id` - The owner ID of the instance to which the network interface is attached.
- `network-interface.addresses.private-ip-address` - The private IP address associated with the network interface.
- `network-interface.attachment.device-index` - The device index to which the network interface is attached.
- `network-interface.attachment.status` - The status of the attachment (attaching | attached | detaching | detached).
- `network-interface.attachment.attach-time` - The time that the network interface was attached to an instance.
- `network-interface.attachment.delete-on-termination` - Specifies whether the attachment is deleted when an instance is terminated.
- `network-interface.addresses.primary` - Specifies whether the IP address of the network interface is the primary private IP address.
- `network-interface.addresses.association.public-ip` - The ID of the association of an Elastic IP address with a network interface.
- `network-interface.addresses.association.ip-owner-id` - The owner ID of the private IP address associated with the network interface.
- `association.public-ip` - The address of the Elastic IP address bound to the network interface.
- `association.ip-owner-id` - The owner of the Elastic IP address associated with the network interface.
- `association.allocation-id` - The allocation ID returned when you allocated the Elastic IP address for your network interface.
- `association.association-id` - The association ID returned when the network interface was associated with an IP address.
- `(dict)` – A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  - * Name *(string)* – The name of the filter. Filter names are case-sensitive.
  - * Values *(list)* – One or more filter values. Filter values are case-sensitive.
    - * NextToken *(string)* – The token to request the next page of results.
    - * MaxResults *(integer)* – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. You cannot specify this parameter and the instance IDs parameter in the same request.

**Returns** None

class EC2.Watcher.PasswordDataAvailable

    waiter = client.get_waiter('password_data_available')
wait(**kwargs)
Polls EC2.Client.get_password_data() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

```python
waiter.wait(
    DryRun=True|False,
    InstanceId='string'
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **InstanceId** *(string)* – [REQUIRED]
The ID of the Windows instance.

Returns None

class EC2.Waiter.SnapshotCompleted

```python
waiter = client.get_waiter('snapshot_completed')
wait(**kwargs)
Polls EC2.Client.describe_snapshots() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

```python
waiter.wait(
    DryRun=True|False,
    SnapshotIds=[
        'string',
    ],
    OwnerIds=[
        'string',
    ],
    RestorableByUserIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ],
    NextToken='string',
    MaxResults=123
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If
you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **SnapshotIds (list)** – One or more snapshot IDs.
  
  Default: Describes snapshots for which you have launch permissions.
  
  - *(string)* –

- **OwnerIds (list)** – Returns the snapshots owned by the specified owner. Multiple owners can be specified.
  
  - *(string)* –

- **RestorableByUserIds (list)** – One or more AWS accounts IDs that can create volumes from the snapshot.
  
  - *(string)* –

- **Filters (list)** – One or more filters.
  
  - **description** - A description of the snapshot.
  
  - **owner-alias** - The AWS account alias (for example, amazon) that owns the snapshot.
  
  - **owner-id** - The ID of the AWS account that owns the snapshot.
  
  - **progress** - The progress of the snapshot, as a percentage (for example, 80%).
  
  - **snapshot-id** - The snapshot ID.
  
  - **start-time** - The time stamp when the snapshot was initiated.
  
  - **status** - The status of the snapshot (pending|completed|error).
  
  - **tag :key =*value*** - The key/value combination of a tag assigned to the resource.
  
  - **tag-key** - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the **tag :key =*value*** filter.
  
  - **tag-value** - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
  
  - **volume-id** - The ID of the volume the snapshot is for.
  
  - **volume-size** - The size of the volume, in GiB.
  
  - *(dict)* –

  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  - **Name (string)** –
    
    The name of the filter. Filter names are case-sensitive.

  - **Values (list)** –
    
    One or more filter values. Filter values are case-sensitive.

  - *(string)* –

- **NextToken (string)** – The NextToken value returned from a previous paginated DescribeSnapshots request where MaxResults was used and the results exceeded the value of that parameter. Pagination continues from the end of the previous results that returned the NextToken value. This value is null when there are no more results to return.

- **MaxResults (integer)** – The maximum number of snapshot results returned by DescribeSnapshots in paginated output. When this parameter is used, DescribeSnapshots only returns MaxResults results in a single page.
along with a `NextToken` response element. The remaining results of the initial request can be seen by sending another `DescribeSnapshots` request with the returned `NextToken` value. This value can be between 5 and 1000; if `MaxResults` is given a value larger than 1000, only 1000 results are returned. If this parameter is not used, then `DescribeSnapshots` returns all results. You cannot specify this parameter and the snapshot IDs parameter in the same request.

**Returns** None

class EC2.Waiter.SpotInstanceRequestFulfilled

```python
waiter = client.get_waiter('spot_instance_request_fulfilled')
```

```python
wait(**kwargs)
```

Polls `EC2.Client.describe_spot_instance_requests()` every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

**Request Syntax**

```python
waiter.wait(
    DryRun=True|False,
    SpotInstanceRequestIds=[
        'string',
    ],
    Filters=[
        {'Name': 'string',
         'Values': [
            'string',
        ]},
    ],
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **SpotInstanceRequestIds** *(list)* – One or more Spot instance request IDs.
  - *(string)*

- **Filters** *(list)* – One or more filters.
  - `availability-zone-group` - The Availability Zone group.
  - `create-time` - The time stamp when the Spot instance request was created.
  - `fault-code` - The fault code related to the request.
  - `fault-message` - The fault message related to the request.
  - `instance-id` - The ID of the instance that fulfilled the request.
  - `launch-group` - The Spot instance launch group.
  - `launch.block-device-mapping.delete-on-termination` - Indicates whether the Amazon EBS volume is deleted on instance termination.
  - `launch.block-device-mapping.device-name` - The device name for the Amazon EBS volume (for example, `/dev/sdh`).

---

3.1. Services 1517
- `launch.block-device-mapping.snapshot-id` - The ID of the snapshot used for the Amazon EBS volume.
- `launch.block-device-mapping.volume-size` - The size of the Amazon EBS volume, in GiB.
- `launch.block-device-mapping.volume-type` - The type of the Amazon EBS volume (gp2|standard|io1).
- `launch.group-id` - The security group for the instance.
- `launch.image-id` - The ID of the AMI.
- `launch.instance-type` - The type of instance (for example, m1.small).
- `launch.kernel-id` - The kernel ID.
- `launch.key-name` - The name of the key pair the instance launched with.
- `launch.monitoring-enabled` - Whether monitoring is enabled for the Spot instance.
- `launch.ramdisk-id` - The RAM disk ID.
- `network-interface.network-interface-id` - The ID of the network interface.
- `network-interface.device-index` - The index of the device for the network interface attachment on the instance.
- `network-interface.subnet-id` - The ID of the subnet for the instance.
- `network-interface.private-ip-address` - The primary private IP address of the network interface.
- `network-interface.delete-on-termination` - Indicates whether the network interface is deleted when the instance is terminated.
- `network-interface.group-id` - The ID of the security group associated with the network interface.
- `network-interface.group-name` - The name of the security group associated with the network interface.
- `network-interface.addresses.primary` - Indicates whether the IP address is the primary private IP address.
- `product-description` - The product description associated with the instance (Linux/UNIX|Windows).
- `spot-instance-request-id` - The Spot instance request ID.
- `spot-price` - The maximum hourly price for any Spot instance launched to fulfill the request.
- `state` - The state of the Spot instance request (open|active|closed|cancelled|failed). Spot bid status information can help you track your Amazon EC2 Spot instance requests. For more information, see Spot Bid Status in the Amazon Elastic Compute Cloud User Guide.
- `status-code` - The short code describing the most recent evaluation of your Spot instance request.
- `status-message` - The message explaining the status of the Spot instance request.
- `tag.key = *value*` - The key/value combination of a tag assigned to the resource.
- `tag-key` - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and
the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag key =*value* filter.

- **tag-value** - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- **type** - The type of Spot instance request (one-time | persistent).
- **launched-availability-zone** - The Availability Zone in which the bid is launched.
- **valid-from** - The start date of the request.
- **valid-until** - The end date of the request.

- **(dict)** – A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  - **Name**(string) – The name of the filter. Filter names are case-sensitive.
  - **Values**(list) – One or more filter values. Filter values are case-sensitive.

**Returns** None

```python
class EC2.Waiter.SubnetAvailable

waiter = client.get_waiter('subnet_available')

wait(**kwargs)
Waiter.polls EC2.Client.describe_subnets() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

**Request Syntax**

```python
waiter.wait(
    DryRun=True|False,
    SubnetIds=[
        'string',
    ],
    Filters=[
        {'Name': 'string',
         'Values': [string','
             string'],
    ]
)
```

**Parameters**

- **DryRun**(boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **SubnetIds**(list) – One or more subnet IDs.

Default: Describes all your subnets.

- **(string)** –
Filters (list) – One or more filters.
- availabilityZone - The Availability Zone for the subnet. You can also use availability-zone as the filter name.
- available-ip-address-count - The number of IP addresses in the subnet that are available.
- cidrBlock - The CIDR block of the subnet. The CIDR block you specify must exactly match the subnet’s CIDR block for information to be returned for the subnet. You can also use cidr or cidr-block as the filter names.
- defaultForAz - Indicates whether this is the default subnet for the Availability Zone. You can also use default-for-az as the filter name.
- state - The state of the subnet (pending|available).
- subnet-id - The ID of the subnet.
- tag:key=value - The key/value combination of a tag assigned to the resource.
- tag-key - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag:key=value filter.
- tag-value - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- vpc-id - The ID of the VPC for the subnet.

(dict) –
A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* Name (string) –
The name of the filter. Filter names are case-sensitive.
* Values (list) –
One or more filter values. Filter values are case-sensitive.

Returns None

class EC2.Waiter.SystemStatusOk

waiter = client.get_waiter('system_status_ok')

wait(**kwargs)
Polls EC2.Client.describe_instance_status() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

waiter.wait(
    DryRun=True|False,
    InstanceIds=['string'],
    Filters=[
        'string',
    ],
)
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **InstanceIds** *(list)* – One or more instance IDs.
  
  Default: Describes all your instances.

  Constraints: Maximum 100 explicitly specified instance IDs.

  - *(string)* –
  
- **Filters** *(list)* – One or more filters.

  - **availability-zone** - The Availability Zone of the instance.
  
  - **event.code** - The code for the scheduled event
    (instance-reboot | system-reboot | system-maintenance | instance-retirement | instance-stop).
  
  - **event.description** - A description of the event.
  
  - **event.not-after** - The latest end time for the scheduled event (for example, 2014-09-15T17:15:20.000Z).
  
  - **event.not-before** - The earliest start time for the scheduled event (for example, 2014-09-15T17:15:20.000Z).
  
  - **instance-state-code** - The code for the instance state, as a 16-bit unsigned integer. The high byte is an opaque internal value and should be ignored. The low byte is set based on the state represented. The valid values are 0 (pending), 16 (running), 32 (shutting-down), 48 (terminated), 64 (stopping), and 80 (stopped).
  
  - **instance-state-name** - The state of the instance (pending | running | shutting-down | terminated | stopping | stopped).
  
  - **instance-status.reachability** - Filters on instance status where the name is reachability (passed | failed | initializing | insufficient-data).
  
  - **instance-status.status** - The status of the instance (ok | impaired | initializing | insufficient-data | not-applicable).
  
  - **system-status.reachability** - Filters on system status where the name is reachability (passed | failed | initializing | insufficient-data).
  
  - **system-status.status** - The system status of the instance (ok | impaired | initializing | insufficient-data | not-applicable).

  - *(dict)* –

    A filter name and value pair that is used to return a more specific list of
results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* **Name** (string) –
  The name of the filter. Filter names are case-sensitive.

* **Values** (list) –
  One or more filter values. Filter values are case-sensitive.

  - (string) –

- **NextToken** (string) – The token to retrieve the next page of results.
- **MaxResults** (integer) – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. You cannot specify this parameter and the instance IDs parameter in the same request.

- **IncludeAllInstances** (boolean) – When true, includes the health status for all instances. When false, includes the health status for running instances only. Default: false

Returns None

```python
class EC2.Waiter.VolumeAvailable

waiter = client.get_waiter('volume_available')

wait(**kwargs)
Polls EC2.Client.describe_volumes() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

```python
waiter.wait(
    DryRun=True|False,
    VolumeIds=[
        'string',
    ],
    Filters=[
        {  
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ],
    NextToken='string',
    MaxResults=123
)
```

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **VolumeIds** (list) – One or more volume IDs.
  - (string) –

- **Filters** (list) – One or more filters.
- attachment.attach-time - The time stamp when the attachment initiated.
- attachment.delete-on-termination - Whether the volume is deleted on instance termination.
- attachment.device - The device name that is exposed to the instance (for example, /dev/sda1).
- attachment.instance-id - The ID of the instance the volume is attached to.
- attachment.status - The attachment state (attaching | attached | detaching | detached).
- availability-zone - The Availability Zone in which the volume was created.
- create-time - The time stamp when the volume was created.
- encrypted - The encryption status of the volume.
- size - The size of the volume, in GiB.
- snapshot-id - The snapshot from which the volume was created.
- status - The status of the volume (creating | available | in-use | deleting | deleted | error).
- tag :key =*value* - The key/value combination of a tag assigned to the resource.
- tag-key - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key =*value* filter.
- tag-value - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- volume-id - The volume ID.
- volume-type - The Amazon EBS volume type. This can be gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, or standard for Magnetic volumes.

(dict) –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* Name (string) –
  The name of the filter. Filter names are case-sensitive.

* Values (list) –
  One or more filter values. Filter values are case-sensitive.

  *(string)* –

* NextToken (string) – The NextToken value returned from a previous paginated DescribeVolumes request where MaxResults was used and the results exceeded the value of that parameter. Pagination continues from the end of the previous results that returned the NextToken value. This value is null when there are no more results to return.

* MaxResults (integer) – The maximum number of volume results returned by DescribeVolumes in paginated output. When this parameter is used, DescribeVolumes only returns MaxResults results in a single page along with a NextToken response element. The remaining results of the initial request can be seen by sending another DescribeVolumes request with the returned NextToken value. This value can be between 5 and 1000; if
MaxResults is given a value larger than 1000, only 1000 results are returned. If this parameter is not used, then DescribeVolumes returns all results. You cannot specify this parameter and the volume IDs parameter in the same request.

Returns None

class EC2.Waiter.VolumeDeleted

waiter = client.get_waiter('volume_deleted')

wait(**kwargs)
Polls EC2.Client.describe_volumes() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

waiter.wait(
    DryRun=True|False,
    VolumeIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ],
    NextToken='string',
    MaxResults=123
)

Parameters

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **VolumeIds** (*list*) – One or more volume IDs.
  - *(string)* –
- **Filters** (*list*) – One or more filters.
  - attachment.attach-time - The time stamp when the attachment initiated.
  - attachment.delete-on-termination - Whether the volume is deleted on instance termination.
  - attachment.device - The device name that is exposed to the instance (for example, /dev/sdal).
  - attachment.instance-id - The ID of the instance the volume is attached to.
  - attachment.status - The attachment state (attaching | attached | detaching | detached).
  - availability-zone - The Availability Zone in which the volume was created.
  - create-time - The time stamp when the volume was created.
  - encrypted - The encryption status of the volume.
  - size - The size of the volume, in GiB.
- **snapshot-id** - The snapshot from which the volume was created.
- **status** - The status of the volume (creating | available | in-use | deleting | deleted | error).
- **tag **key=*value* - The key/value combination of a tag assigned to the resource.
- **tag-key** - The key of a tag assigned to the resource. This filter is independent of the **tag-value** filter. For example, if you use both the filter "tag-key=Purpose" and the filter "tag-value=X", you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the **tag **key=*value* filter.
- **tag-value** - The value of a tag assigned to the resource. This filter is independent of the **tag-key** filter.
- **volume-id** - The volume ID.
- **volume-type** - The Amazon EBS volume type. This can be gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, or standard for Magnetic volumes.

- *(dict)* –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* **Name (string)** –

  The name of the filter. Filter names are case-sensitive.

* **Values (list)** –

  One or more filter values. Filter values are case-sensitive.

  - *(string)* –

  - **NextToken (string)** – The NextToken value returned from a previous paginated DescribeVolumes request where MaxResults was used and the results exceeded the value of that parameter. Pagination continues from the end of the previous results that returned the NextToken value. This value is null when there are no more results to return.

  - **MaxResults (integer)** – The maximum number of volume results returned by DescribeVolumes in paginated output. When this parameter is used, DescribeVolumes only returns MaxResults results in a single page along with a NextToken response element. The remaining results of the initial request can be seen by sending another DescribeVolumes request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. If this parameter is not used, then DescribeVolumes returns all results. You cannot specify this parameter and the volume IDs parameter in the same request.

**Returns** None

```python
class EC2.Waiter.VolumeInUse

waiter = client.get_waiter('volume_in_use')

wait(**kwargs)
```

Polls EC2.Client.describe_volumes() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

**Request Syntax**
```
waiter.wait(
    DryRun=True|False,
    VolumeIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ],
    NextToken='string',
    MaxResults=123
)
```

**Parameters**

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **VolumeIds** (*list*) – One or more volume IDs.
  - *(string)* –
- **Filters** (*list*) – One or more filters.
  - `attachment.attach-time` - The time stamp when the attachment initiated.
  - `attachment.delete-on-termination` - Whether the volume is deleted on instance termination.
  - `attachment.device` - The device name that is exposed to the instance (for example, /dev/sdal).
  - `attachment.instance-id` - The ID of the instance the volume is attached to.
  - `attachment.status` - The attachment state (attaching | attached | detaching | detached).
  - `availability-zone` - The Availability Zone in which the volume was created.
  - `create-time` - The time stamp when the volume was created.
  - `encrypted` - The encryption status of the volume.
  - `size` - The size of the volume, in GiB.
  - `snapshot-id` - The snapshot from which the volume was created.
  - `status` - The status of the volume (creating | available | in-use | deleting | deleted | error).
  - `tag :key =*value*` - The key/value combination of a tag assigned to the resource.
  - `tag-key` - The key of a tag assigned to the resource. This filter is independent of the `tag-value` filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag :key =*value*` filter.
  - `tag-value` - The value of a tag assigned to the resource. This filter is independent of the `tag-key` filter.
  - `volume-id` - The volume ID.
- **volume-type** - The Amazon EBS volume type. This can be gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, or standard for Magnetic volumes.

- **(dict)** –
  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  
  * **Name (string)** –
    The name of the filter. Filter names are case-sensitive.
  
  * **Values (list)** –
    One or more filter values. Filter values are case-sensitive.

  - **NextToken (string)** – The NextToken value returned from a previous paginated DescribeVolumes request where MaxResults was used and the results exceeded the value of that parameter. Pagination continues from the end of the previous results that returned the NextToken value. This value is null when there are no more results to return.

  - **MaxResults (integer)** – The maximum number of volume results returned by DescribeVolumes in paginated output. When this parameter is used, DescribeVolumes only returns MaxResults results in a single page along with a NextToken response element. The remaining results of the initial request can be seen by sending another DescribeVolumes request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. If this parameter is not used, then DescribeVolumes returns all results. You cannot specify this parameter and the volume IDs parameter in the same request.

Returns None

class EC2.Waiter.VpcAvailable

waiter = client.get_waiter('vpc_available')

wait(**kwargs)

Polls EC2.Client.describe_vpcs() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

waiter.wait(
    DryRun=True|False,
    VpcIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [ 'string',
        ]
    ],
)
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **VpcIds** *(list)* – One or more VPC IDs.
  
  Default: Describes all your VPCs.
  
  - *(string)* –

- **Filters** *(list)* – One or more filters.
  
  - **cidr** - The CIDR block of the VPC. The CIDR block you specify must exactly match the VPC’s CIDR block for information to be returned for the VPC. Must contain the slash followed by one or two digits (for example, `/28`).
  
  - **dhcp-options-id** - The ID of a set of DHCP options.
  
  - **isDefault** - Indicates whether the VPC is the default VPC.
  
  - **state** - The state of the VPC *(pending|available)*.
  
  - **tag :key =*value*** - The key/value combination of a tag assigned to the resource.
  
  - **tag-key** - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the **tag :key=*value*** filter.
  
  - **tag-value** - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
  
  - **vpc-id** - The ID of the VPC.
  
  - *(dict)* –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  - **Name** *(string)* –

    The name of the filter. Filter names are case-sensitive.

  - **Values** *(list)* –

    One or more filter values. Filter values are case-sensitive.

    - *(string)* –

Returns

None

class EC2.Waiter.VpnConnectionAvailable

```python
waiter = client.get_waiter('vpn_connection_available')

wait(**kwargs)

Polls EC2.Client.describe_vpn_connections() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

```python
waiter.wait(
    DryRun=True|False,
    VpnConnectionIds=[
```
{'string',
},
Filters=[
{
    'Name': 'string',
    'Values': [ 'string',
    ],
},
]
)

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **VpnConnectionIds** *(list)* – One or more VPN connection IDs.

    Default: Describes your VPN connections.

    - *(string)* –

- **Filters** *(list)* – One or more filters.

    - customer-gateway-configuration - The configuration information for the customer gateway.
    - customer-gateway-id - The ID of a customer gateway associated with the VPN connection.
    - state - The state of the VPN connection (pending | available | deleting | deleted).
    - option.static-routes-only - Indicates whether the connection has static routes only. Used for devices that do not support Border Gateway Protocol (BGP).
    - route.destination-cidr-block - The destination CIDR block. This corresponds to the subnet used in a customer data center.
    - bgp-asn - The BGP Autonomous System Number (ASN) associated with a BGP device.
    - tag :key =*value* - The key/value combination of a tag assigned to the resource.
    - tag-key - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key =*value* filter.
    - tag-value - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
    - type - The type of VPN connection. Currently the only supported type is ipsec.1.
    - vpn-connection-id - The ID of the VPN connection.
    - vpn-gateway-id - The ID of a virtual private gateway associated with the VPN connection.

    - *(dict)* –

    A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
* **Name** *(string)* –
  The name of the filter. Filter names are case-sensitive.

* **Values** *(list)* –
  One or more filter values. Filter values are case-sensitive.

**Returns** None

class EC2.Waiter.VpnConnectionDeleted

waiter = client.get_waiter('vpn_connection_deleted')

**wait(**kwargs**)

Polls EC2.Client.describe_vpn_connections() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

**Request Syntax**

```python
waiter.wait(
    DryRun=True|False,
    VpnConnectionIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ]
        },
    ]
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **VpnConnectionIds** *(list)* – One or more VPN connection IDs.

  Default: Describes your VPN connections.

  - *(string)* –

- **Filters** *(list)* – One or more filters.

  - **customer-gateway-configuration** - The configuration information for the customer gateway.
  - **customer-gateway-id** - The ID of a customer gateway associated with the VPN connection.
  - **state** - The state of the VPN connection (pending | available | deleting | deleted).
  - **option.static-routes-only** - Indicates whether the connection has static routes only. Used for devices that do not support Border Gateway Protocol (BGP).
  - **route.destination-cidr-block** - The destination CIDR block. This corresponds to the subnet used in a customer data center.
  - **bgp-asn** - The BGP Autonomous System Number (ASN) associated with a BGP device.
- **tag :key =*value*** - The key/value combination of a tag assigned to the resource.
- **tag-key** - The key of a tag assigned to the resource. This filter is independent of the **tag-value** filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the **tag :key =*value*** filter.
- **tag-value** - The value of a tag assigned to the resource. This filter is independent of the **tag-key** filter.
- **type** - The type of VPN connection. Currently the only supported type is ipsec.1.
- **vpn-connection-id** - The ID of the VPN connection.
- **vpn-gateway-id** - The ID of a virtual private gateway associated with the VPN connection.

- **(dict)**
  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  *
  **Name** *(string)* –
  The name of the filter. Filter names are case-sensitive.
  *
  **Values** *(list)* –
  One or more filter values. Filter values are case-sensitive.
  · *(string)* –

  **Returns** None

### Service Resource

class **EC2**.ServiceResource
A resource representing Amazon Elastic Compute Cloud (EC2):

```python
import boto3

ec2 = boto3.resource('ec2')
```

These are the resource’s available actions:
- `create_dhcp_options()`
- `create_instances()`
- `create_internet_gateway()`
- `create_key_pair()`
- `create_network_acl()`
- `create_network_interface()`
- `create_placement_group()`
- `create_route_table()`
- `create_security_group()`
- `create_snapshot()`
- `create_subnet()`
- `create_tags()`
- `create_volume()`
- `create_vpc()`
- `create_vpc_peering_connection()`
• disassociate_route_table()
• import_key_pair()
• register_image()

These are the resource’s available sub-resources:
• DhcpOptions()
• Image()
• Instance()
• InternetGateway()
• KeyPair()
• NetworkAcl()
• NetworkInterface()
• PlacementGroup()
• RouteTable()
• RouteTableAssociation()
• SecurityGroup()
• Snapshot()
• Subnet()
• Tag()
• Volume()
• Vpc()
• VpcPeeringConnection()

These are the resource’s available collections:
• dhcp_options_sets
• images
• instances
• internet_gateways
• key_pairs
• network_acls
• network_interfaces
• placement_groups
• route_tables
• security_groups
• snapshots
• subnets
• volumes
• vpc_peering_connections
• vpcs

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

create_dhcp_options (**kwargs)

Creates a set of DHCP options for your VPC. After creating the set, you must associate it with the VPC, causing all existing and new instances that you launch in the VPC to use this set of DHCP options. The following are the individual DHCP options you can specify. For more information about the options, see RFC 2132.

• domain-name-servers - The IP addresses of up to four domain name servers, or AmazonProvidedDNS. The default DHCP option set specifies AmazonProvidedDNS. If specifying more than one domain name server, specify the IP addresses in a single parameter, separated by commas.
• domain-name - If you’re using AmazonProvidedDNS in us-east-1, specify ec2.internal. If you’re using AmazonProvidedDNS in another region, specify region.compute.internal (for example, ap-northeast-1.compute.internal). Otherwise, specify a domain name (for example, MyCompany.com). Important: Some Linux
operating systems accept multiple domain names separated by spaces. However, Windows and other Linux operating systems treat the value as a single domain, which results in unexpected behavior. If your DHCP options set is associated with a VPC that has instances with multiple operating systems, specify only one domain name.

• **ntp-servers** - The IP addresses of up to four Network Time Protocol (NTP) servers.
• **netbios-name-servers** - The IP addresses of up to four NetBIOS name servers.
• **netbios-node-type** - The NetBIOS node type (1, 2, 4, or 8). We recommend that you specify 2 (broadcast and multicast are not currently supported). For more information about these node types, see RFC 2132.

Your VPC automatically starts out with a set of DHCP options that includes only a DNS server that we provide (AmazonProvidedDNS). If you create a set of options, and if your VPC has an Internet gateway, make sure to set the **domain-name-servers** option either to AmazonProvidedDNS or to a domain name server of your choice. For more information about DHCP options, see DHCP Options Sets in the Amazon Virtual Private Cloud User Guide.

**Request Syntax**

```python
dhcp_options = ec2.create_dhcp_options(
    DryRun=True|False,
    DhcpConfigurations=[
        {
            'Key': 'string',
            'Values': [ 'string',
                        ]
        },
    ]
)
```

**Parameters**

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **DhcpConfigurations** (*list*) – [REQUIRED]
  
  A DHCP configuration option.
  
  - (*dict*) –
    
    * **Key** (*string*) –
    
    * **Values** (*list*) –
      
      · (*string*) –

  **Return type** ec2.DhcpOptions

**Returns** DhcpOptions resource

**create_instances(****kwargs**)**

Launches the specified number of instances using an AMI for which you have permissions.

When you launch an instance, it enters the pending state. After the instance is ready for you, it enters the running state. To check the state of your instance, call DescribeInstances.

If you don’t specify a security group when launching an instance, Amazon EC2 uses the default security group. For more information, see Security Groups in the Amazon Elastic Compute Cloud User Guide.

[EC2-VPC only accounts] If you don’t specify a subnet in the request, we choose a default subnet from your default VPC for you.

[EC2-Classic accounts] If you’re launching into EC2-Classic and you don’t specify an Availability Zone, we choose one for you.
Linux instances have access to the public key of the key pair at boot. You can use this key to provide secure access to the instance. Amazon EC2 public images use this feature to provide secure access without passwords. For more information, see Key Pairs in the Amazon Elastic Compute Cloud User Guide.

You can provide optional user data when launching an instance. For more information, see Instance Metadata in the Amazon Elastic Compute Cloud User Guide.

If any of the AMIs have a product code attached for which the user has not subscribed, RunInstances fails.

T2 instance types can only be launched into a VPC. If you do not have a default VPC, or if you do not specify a subnet ID in the request, RunInstances fails.

For more information about troubleshooting, see What To Do If An Instance Immediately Terminates, and Troubleshooting Connecting to Your Instance in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
instance = ec2.create_instances(
    DryRun=True|False,
    ImageId='string',
    MinCount=123,
    MaxCount=123,
    KeyName='string',
    SecurityGroups=[
        'string',
    ],
    SecurityGroupIds=[
        'string',
    ],
    UserData='string',
    InstanceType='t1.micro'|'m1.small'|'m1.medium'|'m1.large'|'m1.xlarge'|'m3.medium'|'m3.large'|'m3.xlarge'|'m3.2xlarge'|'m4.large'|'m4.xlarge'|'m4.2xlarge'|'m4.10xlarge'|'m4.20xlarge'|'m5.large'|'m5.xlarge'|'m5.2xlarge'|'m5.4xlarge'|'m5.10xlarge'|'m5.20xlarge'|'m5.40xlarge'|'c4.large'|'c4.xlarge'|'c4.2xlarge'|'c4.4xlarge'|'c4.8xlarge'|'c5.large'|'c5.xlarge'|'c5.2xlarge'|'c5.4xlarge'|'c5.8xlarge'|'i2.large'|'i2.xlarge'|'i2.2xlarge'|'i2.4xlarge'|'i3.large'|'i3.xlarge'|'i3.2xlarge'|'i3.4xlarge'|'i3.8xlarge'|'r3.large'|'r3.xlarge'|'r3.2xlarge'|'r3.4xlarge'|'r3.8xlarge'|'d2.xlarge'|'d2.2xlarge'|'d2.4xlarge'|'d2.8xlarge',
    Placement={
        'AvailabilityZone': 'string',
        'GroupName': 'string',
        'Tenancy': 'default'|'dedicated'
    },
    KernelId='string',
    RamdiskId='string',
    BlockDeviceMappings=[
        {
            'VirtualName': 'string',
            'DeviceName': 'string',
            'Ebs': {
                'SnapshotId': 'string',
                'VolumeSize': 123,
                'DeleteOnTermination': True|False,
                'VolumeType': 'standard'|'io1'|'gp2',
                'Iops': 123,
                'Encrypted': True|False
            },
            'NoDevice': 'string'
        },
    ],
    Monitoring={
        'Enabled': True|False
    },
    SubnetId='string',
)```
DisableApiTermination=True|False,
InstanceInitiatedShutdownBehavior='stop'|'terminate',
PrivateIpAddress='string',
ClientToken='string',
AdditionalInfo='string',
NetworkInterfaces=[
  {
    'NetworkInterfaceId': 'string',
    'DeviceIndex': 123,
    'SubnetId': 'string',
    'Description': 'string',
    'PrivateIpAddress': 'string',
    'Groups': [',
      'string',
    ],
    'DeleteOnTermination': True|False,
    'PrivateIpAddresses': [
      {
        'PrivateIpAddress': 'string',
        'Primary': True|False
      }
    ],
    'SecondaryPrivateIpAddressCount': 123,
    'AssociatePublicIpAddress': True|False
  }
],
IamInstanceProfile={
  'Arn': 'string',
  'Name': 'string'
},
EbsOptimized=True|False

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **ImageId (string)** – [REQUIRED]
  The ID of the AMI, which you can get by calling DescribeImages.
- **MinCount (integer)** – [REQUIRED]
  The minimum number of instances to launch. If you specify a minimum that is more instances than Amazon EC2 can launch in the target Availability Zone, Amazon EC2 launches no instances.

  Constraints: Between 1 and the maximum number you’re allowed for the specified instance type. For more information about the default limits, and how to request an increase, see How many instances can I run in Amazon EC2 in the Amazon EC2 General FAQ.
- **MaxCount (integer)** – [REQUIRED]
  The maximum number of instances to launch. If you specify more instances than Amazon EC2 can launch in the target Availability Zone, Amazon EC2 launches the largest possible number of instances above MinCount.

  Constraints: Between 1 and the maximum number you’re allowed for the specified instance type. For more information about the default limits, and how to
request an increase, see How many instances can I run in Amazon EC2 in the
Amazon EC2 General FAQ.

- **KeyName** *(string)* – The name of the key pair. You can create a key pair using
CreateKeyPair or ImportKeyPair.

**Warning:** If you do not specify a key pair, you can’t connect to the instance
unless you choose an AMI that is configured to allow users another way to
log in.

- **SecurityGroups** *(list)* – [EC2-Classic, default VPC] One or more security group
names. For a nondefault VPC, you must use security group IDs instead.

Default: Amazon EC2 uses the default security group.

  - *(string)*

- **SecurityGroupIds** *(list)* – One or more security group IDs. You can create a
security group using CreateSecurityGroup.

Default: Amazon EC2 uses the default security group.

  - *(string)*

- **UserData** *(string)* – The Base64-encoded MIME user data for the instances.

  This value will be base64 encoded automatically. Do not base64
  encode this value prior to performing the operation.

- **InstanceType** *(string)* – The instance type. For more information, see Instance
Types in the Amazon Elastic Compute Cloud User Guide.

Default: m1.small

- **Placement** *(dict)* – The placement for the instance.

  - **AvailabilityZone** *(string)* –

    The Availability Zone of the instance.

  - **GroupName** *(string)* –

    The name of the placement group the instance is in (for cluster compute
    instances).

  - **Tenancy** *(string)* –

    The tenancy of the instance (if the instance is running in a VPC). An in-
    stance with a tenancy of dedicated runs on single-tenant hardware.

- **KernelId** *(string)* – The ID of the kernel.

**Warning:** We recommend that you use PV-GRUB instead of kernels and
RAM disks. For more information, see PV-GRUB in the Amazon Elastic
Compute Cloud User Guide.

- **RamdiskId** *(string)* – The ID of the RAM disk.

**Warning:** We recommend that you use PV-GRUB instead of kernels and
RAM disks. For more information, see PV-GRUB in the Amazon Elastic
Compute Cloud User Guide.

- **BlockDeviceMappings** *(list)* – The block device mapping.

  - *(dict)* –

    Describes a block device mapping.

    - **VirtualName** *(string)* –

      The virtual device name (ephemeral N). Instance store volumes
      are numbered starting from 0. An instance type with 2 available in-
      stance store volumes can specify mappings for ephemeral0 and
The number of available instance store volumes depends on the instance type. After you connect to the instance, you must mount the volume.

Constraints: For M3 instances, you must specify instance store volumes in the block device mapping for the instance. When you launch an M3 instance, we ignore any instance store volumes specified in the block device mapping for the AMI.

* **DeviceName** *(string)* –

The device name exposed to the instance (for example, `/dev/sdh` or `xvdh`).

* **Ebs** *(dict)* –

Parameters used to automatically set up EBS volumes when the instance is launched.

  - **SnapshotId** *(string)* –
    
    The ID of the snapshot.
  
  - **VolumeSize** *(integer)* –
    
    The size of the volume, in GiB.

    Constraints: 1-1024 for standard volumes, 1-16384 for gp2 volumes, and 4-16384 for io1 volumes. If you specify a snapshot, the volume size must be equal to or larger than the snapshot size.

    Default: If you're creating the volume from a snapshot and don't specify a volume size, the default is the snapshot size.
  
  - **DeleteOnTermination** *(boolean)* –
    
    Indicates whether the EBS volume is deleted on instance termination.
  
  - **VolumeType** *(string)* –
    
    The volume type. `gp2` for General Purpose (SSD) volumes, `io1` for Provisioned IOPS (SSD) volumes, and `standard` for Magnetic volumes.

    Default: `standard`
  
  - **Iops** *(integer)* –
    
    The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.

    Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.

    Condition: This parameter is required for requests to create `io1` volumes; it is not used in requests to create `standard` or `gp2` volumes.
- **Encrypted** *(boolean)* –

Indicates whether the EBS volume is encrypted. Encrypted Amazon EBS volumes may only be attached to instances that support Amazon EBS encryption.

* **NoDevice** *(string)* –

Suppresses the specified device included in the block device mapping of the AMI.

- **Monitoring** *(dict)* – The monitoring for the instance.
  - **Enabled** *(boolean)* – [REQUIRED]

Indicates whether monitoring is enabled for the instance.

- **SubnetId** *(string)* – [EC2-VPC] The ID of the subnet to launch the instance into.

- **DisableApiTermination** *(boolean)* – If you set this parameter to true, you can’t terminate the instance using the Amazon EC2 console, CLI, or API; otherwise, you can. If you set this parameter to true and then later want to be able to terminate the instance, you must first change the value of the disableApiTermination attribute to false using ModifyInstanceAttribute. Alternatively, if you set InstanceInitiatedShutdownBehavior to terminate, you can terminate the instance by running the shutdown command from the instance.

Default: false

- **InstanceInitiatedShutdownBehavior** *(string)* – Indicates whether an instance stops or terminates when you initiate shutdown from the instance (using the operating system command for system shutdown).

Default: stop

- **PrivateIpAddress** *(string)* – [EC2-VPC] The primary IP address. You must specify a value from the IP address range of the subnet.

Only one private IP address can be designated as primary. Therefore, you can’t specify this parameter if PrivateIpAddresses.n.Primary is set to true and PrivateIpAddresses.n.PrivateIpAddress is set to an IP address.

Default: We select an IP address from the IP address range of the subnet.

- **ClientToken** *(string)* – Unique, case-sensitive identifier you provide to ensure the idempotency of the request. For more information, see Ensuring Idempotency.

Constraints: Maximum 64 ASCII characters

- **AdditionalInfo** *(string)* – Reserved.

- **NetworkInterfaces** *(list)* – One or more network interfaces.
  - *(dict)* –

Describes a network interface.

- **NetworkInterfaceId** *(string)* –

The ID of the network interface.

- **DeviceIndex** *(integer)* –

The index of the device on the instance for the network interface attachment. If you are specifying a network interface in a RunInstances request, you must provide the device index.

- **SubnetId** *(string)* –

The ID of the subnet associated with the network string. Applies only if creating a network interface when launching an instance.
* **Description** *(string)* –
  The description of the network interface. Applies only if creating a network interface when launching an instance.

* **PrivateIpAddress** *(string)* –
  The private IP address of the network interface. Applies only if creating a network interface when launching an instance.

* **Groups** *(list)* –
  The IDs of the security groups for the network interface. Applies only if creating a network interface when launching an instance.

  · **(string)** –

* **DeleteOnTermination** *(boolean)* –
  If set to *true*, the interface is deleted when the instance is terminated. You can specify *true* only if creating a new network interface when launching an instance.

* **PrivateIpAddresses** *(list)* –
  One or more private IP addresses to assign to the network interface. Only one private IP address can be designated as primary.

  · **(dict)** –
    Describes a secondary private IP address for a network interface.

  · **PrivateIpAddress** *(string)* – [REQUIRED]
    The private IP addresses.

  · **Primary** *(boolean)* –
    Indicates whether the private IP address is the primary private IP address. Only one IP address can be designated as primary.

* **SecondaryPrivateIpAddressCount** *(integer)* –
  The number of secondary private IP addresses. You can’t specify this option and specify more than one private IP address using the private IP addresses option.

* **AssociatePublicIpAddress** *(boolean)* –
  Indicates whether to assign a public IP address to an instance you launch in a VPC. The public IP address can only be assigned to a network interface for eth0, and can only be assigned to a new network interface, not an existing one. You cannot specify more than one network interface in the request. If launching into a default subnet, the default value is *true*.

• **IamInstanceProfile** *(dict)* – The IAM instance profile.
  – **Arn** *(string)* –
    The Amazon Resource Name (ARN) of the instance profile.

  – **Name** *(string)* –
    The name of the instance profile.

• **EbsOptimized** *(boolean)* – Indicates whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal EBS I/O performance. This optimization isn’t available with all instance types. Additional usage charges apply when using an EBS-optimized instance.

  Default: *false*
create_internet_gateway(**kwargs)

Creates an Internet gateway for use with a VPC. After creating the Internet gateway, you attach it to a
VPC using AttachInternetGateway.

For more information about your VPC and Internet gateway, see the Amazon Virtual Private Cloud User
Guide.

Request Syntax

internet_gateway = ec2.create_internet_gateway(
    DryRun=True|False
)

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the
  action, without actually making the request, and provides an error response. If you have
  the required permissions, the error response is DryRunOperation. Otherwise, it is
  UnauthorizedOperation.

Return type:

- ec2.InternetGateway

Returns:

- InternetGateway resource

create_key_pair(**kwargs)

Creates a 2048-bit RSA key pair with the specified name. Amazon EC2 stores the public key and displays
the private key for you to save to a file. The private key is returned as an unencrypted PEM encoded
PKCS#8 private key. If a key with the specified name already exists, Amazon EC2 returns an error.

You can have up to five thousand key pairs per region.

The key pair returned to you is available only in the region in which you create it. To create a key pair
that is available in all regions, use ImportKeyPair.

For more information about key pairs, see Key Pairs in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

key_pair = ec2.create_key_pair(
    DryRun=True|False, 
    KeyName='string'
)

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the
  action, without actually making the request, and provides an error response. If you have
  the required permissions, the error response is DryRunOperation. Otherwise, it is
  UnauthorizedOperation.

- **KeyName** (string) – [REQUIRED]
  A unique name for the key pair.
  Constraints: Up to 255 ASCII characters

Return type:

- ec2.KeyPair

Returns:

- KeyPair resource

create_network_acl(**kwargs)

Creates a network ACL in a VPC. Network ACLs provide an optional layer of security (in addition to
security groups) for the instances in your VPC.

For more information about network ACLs, see Network ACLs in the Amazon Virtual Private Cloud User
Guide.
Request Syntax

```python
network_acl = ec2.create_network_acl(
    DryRun=True|False,
    VpcId='string'
)
```

Parameters

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **VpcId** (*string*) – [REQUIRED]
  
The ID of the VPC.

Return type `ec2.NetworkAcl`

Returns NetworkAcl resource

`create_network_interface(**kwargs)`

Creates a network interface in the specified subnet.

For more information about network interfaces, see Elastic Network Interfaces in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
network_interface = ec2.create_network_interface(
    SubnetId='string',
    Description='string',
    PrivateIpAddress='string',
    Groups=['string',
            'string'],
    PrivateIpAddresses=[
        {'PrivateIpAddress': 'string',
        'Primary': True|False }
    ],
    SecondaryPrivateIpAddressCount=123,
    DryRun=True|False
)
```

Parameters

- **SubnetId** (*string*) – [REQUIRED]
  
The ID of the subnet to associate with the network interface.
- **Description** (*string*) – A description for the network interface.
- **PrivateIpAddress** (*string*) – The primary private IP address of the network interface. If you don’t specify an IP address, Amazon EC2 selects one for you from the subnet range. If you specify an IP address, you cannot indicate any IP addresses specified in `privateIpAddresses` as primary (only one IP address can be designated as primary).
- **Groups** (*list*) – The IDs of one or more security groups.
  
  - ([string])
- **PrivateIpAddresses** (*list*) – One or more private IP addresses.
  
  - ([dict])

  Describes a secondary private IP address for a network interface.
**PrivateIpAddress** *(string) – [REQUIRED]*

The private IP addresses.

**Primary** *(boolean) –*

Indicates whether the private IP address is the primary private IP address. Only one IP address can be designated as primary.

- **SecondaryPrivateIpAddressCount** *(integer)* – The number of secondary private IP addresses to assign to a network interface. When you specify a number of secondary IP addresses, Amazon EC2 selects these IP addresses within the subnet range. You can’t specify this option and specify more than one private IP address using `privateIpAddresses`.

The number of IP addresses you can assign to a network interface varies by instance type. For more information, see Private IP Addresses Per ENI Per Instance Type in the Amazon Elastic Compute Cloud User Guide.

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Return type** `ec2.NetworkInterface`

**Returns** NetworkInterface resource

`create_placement_group(**kwargs)`

Creates a placement group that you launch cluster instances into. You must give the group a name that’s unique within the scope of your account.

For more information about placement groups and cluster instances, see Cluster Instances in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
placement_group = ec2.create_placement_group(
    DryRun=True|False,
    GroupName='string',
    Strategy='cluster' 
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **GroupName** *(string)* – [REQUIRED]

  A name for the placement group.

  Constraints: Up to 255 ASCII characters

- **Strategy** *(string)* – [REQUIRED]

  The placement strategy.

  **Return type** `ec2.PlacementGroup`

  **Returns** PlacementGroup resource

`create_route_table(**kwargs)`

Creates a route table for the specified VPC. After you create a route table, you can add routes and associate the table with a subnet.

For more information about route tables, see Route Tables in the Amazon Virtual Private Cloud User Guide.
### Request Syntax

```python
route_table = ec2.create_route_table(
    DryRun=True|False,
    VpcId='string'
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **VpcId (string)** – [REQUIRED]
  
  The ID of the VPC.

**Return type** `ec2.RouteTable`

**Returns** RouteTable resource

### create_security_group(**kwargs)**

Creates a security group.

A security group is for use with instances either in the EC2-Classic platform or in a specific VPC. For more information, see [Amazon EC2 Security Groups](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/what-is-security-group.html) in the Amazon Elastic Compute Cloud User Guide and [Security Groups for Your VPC](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/what-is-security-group-vpc.html) in the Amazon Virtual Private Cloud User Guide.

**Warning:** EC2-Classic: You can have up to 500 security groups. EC2-VPC: You can create up to 100 security groups per VPC.

When you create a security group, you specify a friendly name of your choice. You can have a security group for use in EC2-Classic with the same name as a security group for use in a VPC. However, you can’t have two security groups for use in EC2-Classic with the same name or two security groups for use in a VPC with the same name.

You have a default security group for use in EC2-Classic and a default security group for use in your VPC. If you don’t specify a security group when you launch an instance, the instance is launched into the appropriate default security group. A default security group includes a default rule that grants instances unrestricted network access to each other.

You can add or remove rules from your security groups using `AuthorizeSecurityGroupIngress`, `AuthorizeSecurityGroupEgress`, `RevokeSecurityGroupIngress`, and `RevokeSecurityGroupEgress`.

### Request Syntax

```python
security_group = ec2.create_security_group(
    DryRun=True|False,
    GroupName='string',
    Description='string',
    VpcId='string'
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **GroupName (string)** – [REQUIRED]
  
  The name of the security group.
Constraints: Up to 255 characters in length
Constraints for EC2-Classic: ASCII characters
Constraints for EC2-VPC: a-z, A-Z, 0-9, spaces, and _-/.@#[,]!$*

- **Description** *(string)* – [REQUIRED]
  A description for the security group. This is informational only.
  Constraints: Up to 255 characters in length
  Constraints for EC2-Classic: ASCII characters
  Constraints for EC2-VPC: a-z, A-Z, 0-9, spaces, and _-/.@#[,]!$*

- **VpcId** *(string)* – [EC2-VPC] The ID of the VPC. Required for EC2-VPC.

Return type ec2.SecurityGroup
Returns SecurityGroup resource

**create_snapshot** (**kwargs**)

Creates a snapshot of an EBS volume and stores it in Amazon S3. You can use snapshots for backups, to make copies of EBS volumes, and to save data before shutting down an instance.

When a snapshot is created, any AWS Marketplace product codes that are associated with the source volume are propagated to the snapshot.

You can take a snapshot of an attached volume that is in use. However, snapshots only capture data that has been written to your EBS volume at the time the snapshot command is issued; this may exclude any data that has been cached by any applications or the operating system. If you can pause any file systems on the volume long enough to take a snapshot, your snapshot should be complete. However, if you cannot pause all file writes to the volume, you should unmount the volume from within the instance, issue the snapshot command, and then remount the volume to ensure a consistent and complete snapshot. You may remount and use your volume while the snapshot status is **pending**.

To create a snapshot for EBS volumes that serve as root devices, you should stop the instance before taking the snapshot.

Snapshots that are taken from encrypted volumes are automatically encrypted. Volumes that are created from encrypted snapshots are also automatically encrypted. Your encrypted volumes and any associated snapshots always remain protected.

For more information, see Amazon Elastic Block Store and Amazon EBS Encryption in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
snapshot = ec2.create_snapshot(
    DryRun=True|False,
    VolumeId='string',
    Description='string'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **VolumeId** *(string)* – [REQUIRED]
  The ID of the EBS volume.

- **Description** *(string)* – A description for the snapshot.

Return type ec2.Snapshot
create_subnet(**kwargs)

Creates a subnet in an existing VPC.

When you create each subnet, you provide the VPC ID and the CIDR block you want for the subnet. After you create a subnet, you can’t change its CIDR block. The subnet’s CIDR block can be the same as the VPC’s CIDR block (assuming you want only a single subnet in the VPC), or a subset of the VPC’s CIDR block. If you create more than one subnet in a VPC, the subnets’ CIDR blocks must not overlap. The smallest subnet (and VPC) you can create uses a /28 netmask (16 IP addresses), and the largest uses a /16 netmask (65,536 IP addresses).

Warning: AWS reserves both the first four and the last IP address in each subnet’s CIDR block. They’re not available for use.

If you add more than one subnet to a VPC, they’re set up in a star topology with a logical router in the middle.

If you launch an instance in a VPC using an Amazon EBS-backed AMI, the IP address doesn’t change if you stop and restart the instance (unlike a similar instance launched outside a VPC, which gets a new IP address when restarted). It’s therefore possible to have a subnet with no running instances (they’re all stopped), but no remaining IP addresses available.

For more information about subnets, see Your VPC and Subnets in the Amazon Virtual Private Cloud User Guide.

Request Syntax

```python
subnet = ec2.create_subnet(
    DryRun=True|False,
    VpcId='string',
    CidrBlock='string',
    AvailabilityZone='string'
)
```

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **VpcId** (string) – [REQUIRED]
  The ID of the VPC.
- **CidrBlock** (string) – [REQUIRED]
  The network range for the subnet, in CIDR notation. For example, 10.0.0.0/24.
- **AvailabilityZone** (string) – The Availability Zone for the subnet.
  Default: Amazon EC2 selects one for you (recommended).

Return type **ec2.Subnet**

Returns Subnet resource

create_tags(**kwargs)

Adds or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each resource can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys must be unique per resource.
For more information about tags, see Tagging Your Resources in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

tag = ec2.create_tags(
    DryRun=True|False,
    Resources=['string'],
    Tags=[
        {'Key': 'string',
         'Value': 'string'}
    ]
)

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **Resources** (list) – [REQUIRED]
  The IDs of one or more resources to tag. For example, ami-1a2b3c4d.
  - (string) –

- **Tags** (list) – [REQUIRED]
  One or more tags. The value parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.
  - (dict) –
    Describes a tag.
    - **Key** (string) –
      The key of the tag.
      Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with aws:
    - **Value** (string) –
      The value of the tag.
      Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

Return type  list(ec2.Tag)
Returns  A list of Tag resources

create_volume(**kwargs)
Creates an EBS volume that can be attached to an instance in the same Availability Zone. The volume is created in the regional endpoint that you send the HTTP request to. For more information see Regions and Endpoints.

You can create a new empty volume or restore a volume from an EBS snapshot. Any AWS Marketplace product codes from the snapshot are propagated to the volume.

You can create encrypted volumes with the Encrypted parameter. Encrypted volumes may only be attached to instances that support Amazon EBS encryption. Volumes that are created from encrypted
snapshots are also automatically encrypted. For more information, see Amazon EBS Encryption in the Amazon Elastic Compute Cloud User Guide.

For more information, see Creating or Restoring an Amazon EBS Volume in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
volume = ec2.create_volume(
    DryRun=True|False,
    Size=123,
    SnapshotId='string',
    AvailabilityZone='string',
    VolumeType='standard'|'io1'|'gp2',
    Iops=123,
    Encrypted=True|False,
    KmsKeyId='string'
)
```

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **Size** (integer) – The size of the volume, in GiBs.
  
  Constraints: 1-1024 for standard volumes, 1-16384 for gp2 volumes, and 4-16384 for io1 volumes. If you specify a snapshot, the volume size must be equal to or larger than the snapshot size.
  
  Default: If you’re creating the volume from a snapshot and don’t specify a volume size, the default is the snapshot size.
- **SnapshotId** (string) – The snapshot from which to create the volume.
- **AvailabilityZone** (string) – [REQUIRED] The Availability Zone in which to create the volume. Use DescribeAvailabilityZones to list the Availability Zones that are currently available to you.
- **VolumeType** (string) – The volume type. This can be gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, or standard for Magnetic volumes.
  
  Default: standard
- **Iops** (integer) – Only valid for Provisioned IOPS (SSD) volumes. The number of I/O operations per second (IOPS) to provision for the volume, with a maximum ratio of 30 IOPS/GiB.
  
  Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes
- **Encrypted** (boolean) – Specifies whether the volume should be encrypted. Encrypted Amazon EBS volumes may only be attached to instances that support Amazon EBS encryption. Volumes that are created from encrypted snapshots are automatically encrypted. There is no way to create an encrypted volume from an unencrypted snapshot or vice versa. If your AMI uses encrypted volumes, you can only launch it on supported instance types. For more information, see Amazon EBS Encryption in the Amazon Elastic Compute Cloud User Guide.
  
  - **KmsKeyId** (string) – The full ARN of the AWS Key Management Service (AWS KMS) customer master key (CMK) to use when creating the encrypted volume. This parameter is only required if you want to use a non-default CMK; if this
parameter is not specified, the default CMK for EBS is used. The ARN contains the `arn:aws:kms` namespace, followed by the region of the CMK, the AWS account ID of the CMK owner, the `key` namespace, and then the CMK ID. For example, `arn:aws:kms:us-east-1:012345678910:key/abcd1234-a123-456a-a12b-a123b4cd56ef`. If a `KmsKeyId` is specified, the `Encrypted` flag must also be set.

**Return type**: `ec2.Volume`

**Returns**: `Volume resource`

### create_vpc(**kwargs)**

Creates a VPC with the specified CIDR block.

The smallest VPC you can create uses a /28 netmask (16 IP addresses), and the largest uses a /16 netmask (65,536 IP addresses). To help you decide how big to make your VPC, see Your VPC and Subnets in the Amazon Virtual Private Cloud User Guide.

By default, each instance you launch in the VPC has the default DHCP options, which includes only a default DNS server that we provide (AmazonProvidedDNS). For more information about DHCP options, see DHCP Options Sets in the Amazon Virtual Private Cloud User Guide.

**Request Syntax**

```python
vpc = ec2.create_vpc(
    DryRun=True|False,
    CidrBlock='string',
    InstanceTenancy='default'|'dedicated'
)
```

**Parameters**

- **DryRun**(boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **CidrBlock**(string) – [REQUIRED]
  The network range for the VPC, in CIDR notation. For example, `10.0.0.0/16`.

- **InstanceTenancy**(string) – The supported tenancy options for instances launched into the VPC. A value of `default` means that instances can be launched with any tenancy; a value of `dedicated` means all instances launched into the VPC are launched as dedicated tenancy instances regardless of the tenancy assigned to the instance at launch. Dedicated tenancy instances run on single-tenant hardware.

  Default: `default`

**Return type**: `ec2.Vpc`

**Returns**: `Vpc resource`

### create_vpc_peering_connection(**kwargs)**

Requests a VPC peering connection between two VPCs: a requester VPC that you own and a peer VPC with which to create the connection. The peer VPC can belong to another AWS account. The requester VPC and peer VPC cannot have overlapping CIDR blocks.

The owner of the peer VPC must accept the peering request to activate the peering connection. The VPC peering connection request expires after 7 days, after which it cannot be accepted or rejected.

A `CreateVpcPeeringConnection` request between VPCs with overlapping CIDR blocks results in the VPC peering connection having a status of `failed`. 
Request Syntax

```python
vpc_peering_connection = ec2.create_vpc_peering_connection(
    DryRun=True|False,
    VpcId='string',
    PeerVpcId='string',
    PeerOwnerId='string'
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **VpcId** *(string)* – The ID of the requester VPC.
- **PeerVpcId** *(string)* – The ID of the VPC with which you are creating the VPC peering connection.
- **PeerOwnerId** *(string)* – The AWS account ID of the owner of the peer VPC.

Default: Your AWS account ID

Return type: `ec2.VpcPeeringConnection`

Returns: VpcPeeringConnection resource

`disassociate_route_table(**kwargs)`

Disassociates a subnet from a route table.

After you perform this action, the subnet no longer uses the routes in the route table. Instead, it uses the routes in the VPC’s main route table. For more information about route tables, see Route Tables in the Amazon Virtual Private Cloud User Guide.

Request Syntax

```python
response = ec2.disassociate_route_table(
    DryRun=True|False,
    AssociationId='string'
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **AssociationId** *(string)* – [REQUIRED]

The association ID representing the current association between the route table and subnet.

Returns: None

`import_key_pair(**kwargs)`

Imports the public key from an RSA key pair that you created with a third-party tool. Compare this with CreateKeyPair, in which AWS creates the key pair and gives the keys to you (AWS keeps a copy of the public key). With ImportKeyPair, you create the key pair and give AWS just the public key. The private key is never transferred between you and AWS.

For more information about key pairs, see Key Pairs in the Amazon Elastic Compute Cloud User Guide.

Request Syntax
key_pair = ec2.import_key_pair(
    DryRun=True|False,
    KeyName='string',
    PublicKeyMaterial=b'bytes'
)

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.
- **KeyName** *(string)* – [REQUIRED] A unique name for the key pair.
- **PublicKeyMaterial** *(bytes)* – [REQUIRED] The public key. You must base64 encode the public key material before sending it to AWS.

Return type **ec2.KeyPair**

Returns **KeyPair resource**

**register_image(**kwargs**)

Registers an AMI. When you’re creating an AMI, this is the final step you must complete before you can launch an instance from the AMI. For more information about creating AMIs, see **Creating Your Own AMIs** in the **Amazon Elastic Compute Cloud User Guide**.

**Note:** For Amazon EBS-backed instances, CreateImage creates and registers the AMI in a single request, so you don’t have to register the AMI yourself.

You can also use RegisterImage to create an Amazon EBS-backed Linux AMI from a snapshot of a root device volume. For more information, see **Launching an Instance from a Snapshot** in the **Amazon Elastic Compute Cloud User Guide**.

**Warning:** Some Linux distributions, such as Red Hat Enterprise Linux (RHEL) and SUSE Linux Enterprise Server (SLES), use the EC2 **billingProduct** code associated with an AMI to verify subscription status for package updates. Creating an AMI from an EBS snapshot does not maintain this billing code, and subsequent instances launched from such an AMI will not be able to connect to package update infrastructure.

Similarly, although you can create a Windows AMI from a snapshot, you can’t successfully launch an instance from the AMI.

To create Windows AMIs or to create AMIs for Linux operating systems that must retain AMI billing codes to work properly, see CreateImage.

If needed, you can deregister an AMI at any time. Any modifications you make to an AMI backed by an instance store volume invalidates its registration. If you make changes to an image, deregister the previous image and register the new image.

**Note:** You can’t register an image where a secondary (non-root) snapshot has AWS Marketplace product codes.

**Request Syntax**

```python
image = ec2.register_image(
    DryRun=True|False,
```

---

**1550 Chapter 3. API Reference**
ImageLocation='string',
Name='string',
Description='string',
Architecture='i386'|'x86_64',
KernelId='string',
RamdiskId='string',
RootDeviceName='string',
BlockDeviceMappings=[
    {
        'VirtualName': 'string',
        'DeviceName': 'string',
        'Ebs': {
            'SnapshotId': 'string',
            'VolumeSize': 123,
            'DeleteOnTermination': True|False,
            'VolumeType': 'standard'|'io1'|'gp2',
            'Iops': 123,
            'Encrypted': True|False
        },
        'NoDevice': 'string'
    },
],
VirtualizationType='string',
SriovNetSupport='string'

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **ImageLocation** *(string)* – The full path to your AMI manifest in Amazon S3 storage.

- **Name** *(string)* – [REQUIRED]
  A name for your AMI.
  Constraints: 3-128 alphanumeric characters, parentheses (()), square brackets ([]), spaces ( ), periods (.), slashes (/), dashes (-), single quotes (’), at-signs (@), or underscores(_)

- **Description** *(string)* – A description for your AMI.

- **Architecture** *(string)* – The architecture of the AMI.
  Default: For Amazon EBS-backed AMIs, i386. For instance store-backed AMIs, the architecture specified in the manifest file.

- **KernelId** *(string)* – The ID of the kernel.

- **RamdiskId** *(string)* – The ID of the RAM disk.

- **RootDeviceName** *(string)* – The name of the root device (for example, /dev/sda1, or /dev/xvda).

- **BlockDeviceMappings** *(list)* – One or more block device mapping entries.
  - *(dict)* –
    Describes a block device mapping.
    * **VirtualName** *(string)* –
      The virtual device name (ephemeral N). Instance store volumes are numbered starting from 0. An instance type with 2 available instance store volumes can specify mappings for ephemeral0 and...
The number of available instance store volumes depends on the instance type. After you connect to the instance, you must mount the volume.

Constraints: For M3 instances, you must specify instance store volumes in the block device mapping for the instance. When you launch an M3 instance, we ignore any instance store volumes specified in the block device mapping for the AMI.

* **DeviceName (string)** –

  The device name exposed to the instance (for example, /dev/sdh or xvdh).

* **Ebs (dict)** –

  Parameters used to automatically set up EBS volumes when the instance is launched.
  
  - **SnapshotId (string)** –
    
    The ID of the snapshot.
  
  - **VolumeSize (integer)** –
    
    The size of the volume, in GiB.
    
    Constraints: 1-1024 for standard volumes, 1-16384 for gp2 volumes, and 4-16384 for io1 volumes. If you specify a snapshot, the volume size must be equal to or larger than the snapshot size.
    
    Default: If you’re creating the volume from a snapshot and don’t specify a volume size, the default is the snapshot size.
  
  - **DeleteOnTermination (boolean)** –
    
    Indicates whether the EBS volume is deleted on instance termination.
  
  - **VolumeType (string)** –
    
    The volume type. gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, and standard for Magnetic volumes.
    
    Default: standard
  
  - **Iops (integer)** –
    
    The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.
    
    Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.
    
    Condition: This parameter is required for requests to create io1 volumes; it is not used in requests to create standard or gp2 volumes.
- **Encrypted** *(boolean)* –
  Indicates whether the EBS volume is encrypted. Encrypted Amazon EBS volumes may only be attached to instances that support Amazon EBS encryption.

- **NoDevice** *(string)* –
  Suppresses the specified device included in the block device mapping of the AMI.

- **VirtualizationType** *(string)* – The type of virtualization.
  Default: paravirtual

- **SriovNetSupport** *(string)* – Set to simple to enable enhanced networking for the AMI and any instances that you launch from the AMI.

There is no way to disable enhanced networking at this time.

This option is supported only for HVM AMIs. Specifying this option with a PV AMI can make instances launched from the AMI unreachable.

**Return type** `ec2.Image`
**Returns** Image resource

### Sub-resources

Sub-resources are methods that create a new instance of a child resource. This resource’s identifiers get passed along to the child. For more information about sub-resources refer to the Resources Introduction Guide.

**DhcpOptions** *(id)*

Creates a DhcpOptions resource:

```python
dhcp_options = ec2.DhcpOptions('id')
```

**Parameters**
- **id** *(string)* – The DhcpOptions’s id identifier. This must be set.

**Return type** `EC2.DhcpOptions`
**Returns** A DhcpOptions resource

**Image** *(id)*

Creates a Image resource:

```python
image = ec2.Image('id')
```

**Parameters**
- **id** *(string)* – The Image’s id identifier. This must be set.

**Return type** `EC2.Image`
**Returns** A Image resource

**Instance** *(id)*

Creates a Instance resource:

```python
instance = ec2.Instance('id')
```

**Parameters**
- **id** *(string)* – The Instance’s id identifier. This must be set.

**Return type** `EC2.Instance`
**Returns** A Instance resource

**InternetGateway** *(id)*

Creates a InternetGateway resource:

```python
internet_gateway = ec2.InternetGateway('id')
```

**Parameters**
- **id** *(string)* – The InternetGateway’s id identifier. This must be set.
**Return type** `EC2.InternetGateway`  
**Returns** A InternetGateway resource

**KeyPair** *(name)*  
Creates a KeyPair resource.:  

```python
type KeyPair = ec2.KeyPair('name')
```

**Parameters** name *(string)* – The KeyPair’s name identifier. This **must** be set.  
**Return type** `EC2.KeyPair`  
**Returns** A KeyPair resource

**NetworkAcl** *(id)*  
Creates a NetworkAcl resource.:  

```python
type NetworkAcl = ec2.NetworkAcl('id')
```

**Parameters** id *(string)* – The NetworkAcl’s id identifier. This **must** be set.  
**Return type** `EC2.NetworkAcl`  
**Returns** A NetworkAcl resource

**NetworkInterface** *(id)*  
Creates a NetworkInterface resource.:  

```python
type NetworkInterface = ec2.NetworkInterface('id')
```

**Parameters** id *(string)* – The NetworkInterface’s id identifier. This **must** be set.  
**Return type** `EC2.NetworkInterface`  
**Returns** A NetworkInterface resource

**PlacementGroup** *(name)*  
Creates a PlacementGroup resource.:  

```python
type PlacementGroup = ec2.PlacementGroup('name')
```

**Parameters** name *(string)* – The PlacementGroup’s name identifier. This **must** be set.  
**Return type** `EC2.PlacementGroup`  
**Returns** A PlacementGroup resource

**RouteTable** *(id)*  
Creates a RouteTable resource.:  

```python
type RouteTable = ec2.RouteTable('id')
```

**Parameters** id *(string)* – The RouteTable’s id identifier. This **must** be set.  
**Return type** `EC2.RouteTable`  
**Returns** A RouteTable resource

**RouteTableAssociation** *(id)*  
Creates a RouteTableAssociation resource.:  

```python
type RouteTableAssociation = ec2.RouteTableAssociation('id')
```

**Parameters** id *(string)* – The RouteTableAssociation’s id identifier. This **must** be set.  
**Return type** `EC2.RouteTableAssociation`  
**Returns** A RouteTableAssociation resource
**SecurityGroup** *(id)*

Creates a SecurityGroup resource:

```python
category = ec2.SecurityGroup('id')
```

- **Parameters**
  - **id** *(string)* – The SecurityGroup’s id identifier. This **must** be set.
  - **Return type** `EC2.SecurityGroup`
  - **Returns** A SecurityGroup resource

**Snapshot** *(id)*

Creates a Snapshot resource:

```python
category = ec2.Snapshot('id')
```

- **Parameters**
  - **id** *(string)* – The Snapshot’s id identifier. This **must** be set.
  - **Return type** `EC2.Snapshot`
  - **Returns** A Snapshot resource

**Subnet** *(id)*

Creates a Subnet resource:

```python
category = ec2.Subnet('id')
```

- **Parameters**
  - **id** *(string)* – The Subnet’s id identifier. This **must** be set.
  - **Return type** `EC2.Subnet`
  - **Returns** A Subnet resource

**Tag** *(resource_id, key, value)*

Creates a Tag resource:

```python
category = ec2.Tag('resource_id','key','value')
```

- **Parameters**
  - **resource_id** *(string)* – The Tag’s resource_id identifier. This **must** be set.
  - **key** *(string)* – The Tag’s key identifier. This **must** be set.
  - **value** *(string)* – The Tag’s value identifier. This **must** be set.
  - **Return type** `EC2.Tag`
  - **Returns** A Tag resource

**Volume** *(id)*

Creates a Volume resource:

```python
category = ec2.Volume('id')
```

- **Parameters**
  - **id** *(string)* – The Volume’s id identifier. This **must** be set.
  - **Return type** `EC2.Volume`
  - **Returns** A Volume resource

**Vpc** *(id)*

Creates a Vpc resource:

```python
category = ec2.Vpc('id')
```

- **Parameters**
  - **id** *(string)* – The Vpc’s id identifier. This **must** be set.
  - **Return type** `EC2.Vpc`
  - **Returns** A Vpc resource
**VpcPeeringConnection**(*id*)

Creates a VpcPeeringConnection resource:

```python
vpc_peering_connection = ec2.VpcPeeringConnection('id')
```

**Parameters**

- **id** (*string*) – The VpcPeeringConnection’s id identifier. This must be set.

**Return type** EC2.VpcPeeringConnection

**Returns** A VpcPeeringConnection resource

---

**dhcp_options_sets**

**all()**

Creates an iterable of all DhcpOptions resources in the collection.

**Request Syntax**

```python
dhcp_options_iterator = ec2.dhcp_options_sets.all()
```

**Return type** list(ec2.DhcpOptions)

**Returns** A list of DhcpOptions resources

**filter(****kwargs**)**

Creates an iterable of all DhcpOptions resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
dhcp_options_iterator = ec2.dhcp_options_sets.filter(
    DryRun=True|False,
    DhcpOptionsIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ],
)
```

**Parameters**

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **DhcpOptionsIds** (*list*) – The IDs of one or more DHCP options sets.
  - (string)
- **Filters** (*list*) – One or more filters.
  - (string)
  - dhcp-options-id - The ID of a set of DHCP options.
- **key** - The key for one of the options (for example, `domain-name`).
- **value** - The value for one of the options.
- **tag**: `key=value` - The key/value combination of a tag assigned to the resource.
- **tag-key** - The key of a tag assigned to the resource. This filter is independent of the `tag-value` filter. For example, if you use both the filter “`tag-key=Purpose`” and the filter “`tag-value=X`”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag :key = value` filter.
- **tag-value** - The value of a tag assigned to the resource. This filter is independent of the `tag-key` filter.

- **(dict)** – A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  - **Name** *(string)* – The name of the filter. Filter names are case-sensitive.
  - **Values** *(list)* – One or more filter values. Filter values are case-sensitive.

**images**
all()

Creates an iterable of all Image resources in the collection.

Request Syntax

```python
image_iterator = ec2.images.all()
```

Return type: list(ec2.Image)

Returns: A list of Image resources

filter(**kwargs)

Creates an iterable of all Image resources in the collection filtered by kwargs passed to method.

Request Syntax

```python
image_iterator = ec2.images.filter(
    DryRun=True|False,
    ImageIds=[
        'string',
    ],
    Owners=[
        'string',
    ],
    ExecutableUsers=[
        'string',
    ],
    Filters=[
        {'Name': 'string',
         'Values': [
             'string',
         ]},
    ],
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **ImageIds** *(list)* – One or more image IDs. Default: Describes all images available to you.
  - *(string)*
- **Owners** *(list)* – Filters the images by the owner. Specify an AWS account ID, amazon (owner is Amazon), aws-marketplace (owner is AWS Marketplace), self (owner is the sender of the request). Omitting this option returns all images for which you have launch permissions, regardless of ownership.
  - *(string)*
- **ExecutableUsers** *(list)* – Scopes the images by users with explicit launch permissions. Specify an AWS account ID, self (the sender of the request), or all (public AMIs).
  - *(string)*
- **Filters** *(list)* – One or more filters.
  - architecture - The image architecture (i386|x86_64).
- `block-device-mapping.delete-on-termination` - A Boolean value that indicates whether the Amazon EBS volume is deleted on instance termination.

- `block-device-mapping.device-name` - The device name for the EBS volume (for example, /dev/sdh).

- `block-device-mapping.snapshot-id` - The ID of the snapshot used for the EBS volume.

- `block-device-mapping.volume-size` - The volume size of the EBS volume, in GiB.

- `block-device-mapping.volume-type` - The volume type of the EBS volume (gp2|standard|io1).

- `description` - The description of the image (provided during image creation).

- `hypervisor` - The hypervisor type (ovm|xen).

- `image-id` - The ID of the image.

- `image-type` - The image type (machine|kernel|ramdisk).

- `is-public` - A Boolean that indicates whether the image is public.

- `kernel-id` - The kernel ID.

- `manifest-location` - The location of the image manifest.

- `name` - The name of the AMI (provided during image creation).

- `owner-alias` - The AWS account alias (for example, amazon).

- `owner-id` - The AWS account ID of the image owner.

- `platform` - The platform. To only list Windows-based AMIs, use windows.

- `product-code` - The product code.

- `product-code.type` - The type of the product code (devpay|marketplace).

- `ramdisk-id` - The RAM disk ID.

- `root-device-name` - The name of the root device volume (for example, /dev/sdal).

- `root-device-type` - The type of the root device volume (ebs|instance-store).

- `state` - The state of the image (available|pending|failed).

- `state-reason-code` - The reason code for the state change.

- `state-reason-message` - The message for the state change.

- `tag :key =*value*` - The key/value combination of a tag assigned to the resource.

- `tag :key` - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag:key=Purpose” and the filter “tag:value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag :key =*value*` filter.

- `tag :value` - The value of a tag assigned to the resource. This filter is independent of the `tag :key` filter.

- `virtualization-type` - The virtualization type (paravirtual|hvm).

- `(dict)` - A filter name and value pair that is used to return a more specific list.
of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

- **Name** *(string)* –  
  The name of the filter. Filter names are case-sensitive.

- **Values** *(list)* –  
  One or more filter values. Filter values are case-sensitive.

  - *(string)* –

  **Return type** list(ec2.Image)  
  **Returns** A list of Image resources

- **limit** (**kwargs)**  
  Creates an iterable up to a specified amount of Image resources in the collection.

  **Request Syntax**

  ```python
  image_iterator = ec2.images.limit(
      count=123
  )
  ```

  **Parameters** count *(integer)* – The limit to the number of resources in the iterable.  
  **Return type** list(ec2.Image)  
  **Returns** A list of Image resources

- **page_size** (**kwargs)**  
  Creates an iterable of all Image resources in the collection, but limits the number of items returned by each service call by the specified amount.

  **Request Syntax**

  ```python
  image_iterator = ec2.images.page_size(
      count=123
  )
  ```

  **Parameters** count *(integer)* – The number of items returned by each service call  
  **Return type** list(ec2.Image)  
  **Returns** A list of Image resources

- **instances**

- **all()**  
  Creates an iterable of all Instance resources in the collection.

  **Request Syntax**

  ```python
  instance_iterator = ec2.instances.all()
  ```

  **Return type** list(ec2.Instance)  
  **Returns** A list of Instance resources

- **create_tags** (**kwargs)**  
  Adds or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each resource can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys must be unique per resource.

  For more information about tags, see Tagging Your Resources in the Amazon Elastic Compute Cloud User Guide.

  **Request Syntax**
response = ec2.instances.create_tags(
    DryRun=True|False,
    Tags=[
        {'Key': 'string',
         'Value': 'string'},
    ],
)

Parameters

• **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

• **Tags** *(list)* – [REQUIRED]

  One or more tags. The `value` parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.

  – *(dict)* –

    Describes a tag.

      • **Key** *(string)* –

        The key of the tag.

        Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`

      • **Value** *(string)* –

        The value of the tag.

        Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

Returns  None

**filter(****kwargs**)**

Creates an iterable of all Instance resources in the collection filtered by kwargs passed to method.

Request Syntax

```python
instance_iterator = ec2.instances.filter(
    DryRun=True|False,
    InstanceIds=[
        'string',
    ],
    Filters=[
        {'Name': 'string',
         'Values': [ 'string',
                     ]},
    ],
    NextToken='string',
    MaxResults=123
)
```
Parameters

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **InstanceIds** (*list*) – One or more instance IDs.
  
  Default: Describes all your instances.
  
  - *(string)* –

- **Filters** (*list*) – One or more filters.

  - **architecture** - The instance architecture (`i386` | `x86_64`).
  
  - **availability-zone** - The Availability Zone of the instance.
  
  - **block-device-mapping.attach-time** - The attach time for an EBS volume mapped to the instance, for example, `2010-09-15T17:15:20.000Z`.
  
  - **block-device-mapping.delete-on-termination** - A Boolean that indicates whether the EBS volume is deleted on instance termination.
  
  - **block-device-mapping.device-name** - The device name for the EBS volume (for example, `/dev/sdh` or `xvdh`).
  
  - **block-device-mapping.status** - The status for the EBS volume (attaching | attached | detaching | detached).
  
  - **block-device-mapping.volume-id** - The volume ID of the EBS volume.
  
  - **client-token** - The idempotency token you provided when you launched the instance.
  
  - **dns-name** - The public DNS name of the instance.
  
  - **group-id** - The ID of the security group for the instance. EC2-Classic only.
  
  - **group-name** - The name of the security group for the instance. EC2-Classic only.
  
  - **hypervisor** - The hypervisor type of the instance (`ovm` | `xen`).
  
  - **iam-instance-profile.arn** - The instance profile associated with the instance. Specified as an ARN.
  
  - **image-id** - The ID of the image used to launch the instance.
  
  - **instance-id** - The ID of the instance.
  
  - **instance-lifecycle** - Indicates whether this is a Spot Instance (`spot`).
  
  - **instance-state-code** - The state of the instance, as a 16-bit unsigned integer. The high byte is an opaque internal value and should be ignored. The low byte is set based on the state represented. The valid values are: 0 (pending), 16 (running), 32 (shutting-down), 48 (terminated), 64 (stopping), and 80 (stopped).
  
  - **instance-state-name** - The state of the instance (pending | running | shutting-down | terminated | stopping | stopped).
  
  - **instance-type** - The type of instance (for example, `t2.micro`).
  
  - **instance.group-id** - The ID of the security group for the instance.
  
  - **instance.group-name** - The name of the security group for the instance.
  
  - **ip-address** - The public IP address of the instance.
  
  - **kernel-id** - The kernel ID.
- **key-name** - The name of the key pair used when the instance was launched.
- **launch-index** - When launching multiple instances, this is the index for the instance in the launch group (for example, 0, 1, 2, and so on).
- **launch-time** - The time when the instance was launched.
- **monitoring-state** - Indicates whether monitoring is enabled for the instance (disabled | enabled).
- **owner-id** - The AWS account ID of the instance owner.
- **placement-group-name** - The name of the placement group for the instance.
- **platform** - The platform. Use windows if you have Windows instances; otherwise, leave blank.
- **private-dns-name** - The private DNS name of the instance.
- **private-ip-address** - The private IP address of the instance.
- **product-code** - The product code associated with the AMI used to launch the instance.
- **product-code.type** - The type of product code (devpay | marketplace).
- **ramdisk-id** - The RAM disk ID.
- **reason** - The reason for the current state of the instance (for example, shows “User Initiated [date]” when you stop or terminate the instance). Similar to the state-reason-code filter.
- **requester-id** - The ID of the entity that launched the instance on your behalf (for example, AWS Management Console, Auto Scaling, and so on).
- **reservation-id** - The ID of the instance’s reservation. A reservation ID is created any time you launch an instance. A reservation ID has a one-to-one relationship with an instance launch request, but can be associated with more than one instance if you launch multiple instances using the same launch request. For example, if you launch one instance, you’ll get one reservation ID. If you launch ten instances using the same launch request, you’ll also get one reservation ID.
- **root-device-name** - The name of the root device for the instance (for example, /dev/sda1 or /dev/xvda).
- **root-device-type** - The type of root device that the instance uses (ebs | instance-store).
- **source-dest-check** - Indicates whether the instance performs source/destination checking. A value of true means that checking is enabled, and false means checking is disabled. The value must be false for the instance to perform network address translation (NAT) in your VPC.
- **spot-instance-request-id** - The ID of the Spot Instance request.
- **state-reason-code** - The reason code for the state change.
- **state-reason-message** - A message that describes the state change.
- **subnet-id** - The ID of the subnet for the instance.
- **tag :key =*value*  - The key/value combination of a tag assigned to the resource, where tag :key is the tag’s key.
- **tag-key** - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you
get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag key = *value* filter.

- **tag-name** - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- **tenancy** - The tenancy of an instance (dedicated | default).
- **virtualization-type** - The virtualization type of the instance (paravirtual | hvm).
- **vpc-id** - The ID of the VPC that the instance is running in.
- **network-interface.description** - The description of the network interface.
- **network-interface.subnet-id** - The ID of the subnet for the network interface.
- **network-interface.vpc-id** - The ID of the VPC for the network interface.
- **network-interface.network-interface.id** - The ID of the network interface.
- **network-interface.owner-id** - The ID of the owner of the network interface.
- **network-interface.availability-zone** - The Availability Zone for the network interface.
- **network-interface.requester-id** - The requester ID for the network interface.
- **network-interface.requester-managed** - Indicates whether the network interface is being managed by AWS.
- **network-interface.status** - The status of the network interface (available | in-use).
- **network-interface.mac-address** - The MAC address of the network interface.
- **network-interface.private-dns-name** - The private DNS name of the network interface.
- **network-interface.source-dest-check** - Whether the network interface performs source/destination checking. A value of true means checking is enabled, and false means checking is disabled. The value must be false for the network interface to perform network address translation (NAT) in your VPC.
- **network-interface.group-id** - The ID of a security group associated with the network interface.
- **network-interface.group-name** - The name of a security group associated with the network interface.
- **network-interface.attachment.attachment-id** - The ID of the interface attachment.
- **network-interface.attachment.instance-id** - The ID of the instance to which the network interface is attached.
- **network-interface.attachment.instance-owner-id** - The owner ID of the instance to which the network interface is attached.
- **network-interface.addresses.private-ip-address** - The private IP address associated with the network interface.
- **network-interface.attachment.device-index** - The device index to which the network interface is attached.
- **network-interface.attachment.status** - The status
of the attachment (attaching | attached | detaching | detached).

- `network-interface.attachment.attach-time` - The time that the network interface was attached to an instance.
- `network-interface.attachment.delete-on-termination` - Specifies whether the attachment is deleted when an instance is terminated.
- `network-interface.addresses.primary` - Specifies whether the IP address of the network interface is the primary private IP address.
- `network-interface.addresses.association.public-ip` - The ID of the association of an Elastic IP address with a network interface.
- `network-interface.addresses.association.ip-owner-id` - The owner ID of the private IP address associated with the network interface.
- `association.public-ip` - The address of the Elastic IP address bound to the network interface.
- `association.ip-owner-id` - The owner of the Elastic IP address associated with the network interface.
- `association.allocation-id` - The allocation ID returned when you allocated the Elastic IP address for your network interface.
- `association.association-id` - The association ID returned when the network interface was associated with an IP address.

- `(dict)` –
  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  * **Name (string)** –
    The name of the filter. Filter names are case-sensitive.
  * **Values (list)** –
    One or more filter values. Filter values are case-sensitive.

- `(string)` –
  * **NextToken** (string) – The token to request the next page of results.
  * **MaxResults (integer)** – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned `NextToken` value. This value can be between 5 and 1000; if `MaxResults` is given a value larger than 1000, only 1000 results are returned. You cannot specify this parameter and the instance IDs parameter in the same request.

**Return type** list(ec2.Instance)

**Returns** A list of Instance resources

**limit(****kwargs**)

Creates an iterable up to a specified amount of Instance resources in the collection.

**Request Syntax**

```python
instance_iterator = ec2.instances.limit(
    count=123
)
```
Parameters count (integer) – The limit to the number of resources in the iterable.
Return type list(ec2.Instance)
Returns A list of Instance resources

monitor(**kwargs)
Enables monitoring for a running instance. For more information about monitoring instances, see Monitoring Your Instances and Volumes in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = ec2.instances.monitor(
    DryRun=True|False,
)
```

Parameters DryRun (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

Return type dict
Returns

Response Syntax

```json
{
    'InstanceMonitorings': [
        {
            'InstanceId': 'string',
            'Monitoring': {
                'State': 'disabled'|'disabling'|'enabled'|'pending'
            }
        },
    ]
}
```

Response Structure

- (dict) –
  - InstanceMonitorings (list) –
    Monitoring information for one or more instances.
      - (dict) –
        Describes the monitoring information of the instance.
          · InstanceId (string) –
            The ID of the instance.
          · Monitoring (dict) –
            The monitoring information.
          · State (string) –
            Indicates whether monitoring is enabled for the instance.

page_size(**kwargs)
Creates an iterable of all Instance resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax
instance_iterator = ec2.instances.page_size(
    count=123
)

**Parameters**

**count** *(integer)* – The number of items returned by each service call

**Return type** list(ec2.Instance)

**Returns** A list of Instance resources

**reboot** (**kwargs**)

Requests a reboot of one or more instances. This operation is asynchronous; it only queues a request to reboot the specified instances. The operation succeeds if the instances are valid and belong to you. Requests to reboot terminated instances are ignored.

If a Linux/Unix instance does not cleanly shut down within four minutes, Amazon EC2 performs a hard reboot.

For more information about troubleshooting, see Getting Console Output and Rebooting Instances in the *Amazon Elastic Compute Cloud User Guide*.

**Request Syntax**

```python
response = ec2.instances.reboot(
    DryRun=True|False,
)
```

**Parameters**

**DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

**Returns** None

**start** (**kwargs**)

Starts an Amazon EBS-backed AMI that you’ve previously stopped.

Instances that use Amazon EBS volumes as their root devices can be quickly stopped and started. When an instance is stopped, the compute resources are released and you are not billed for hourly instance usage. However, your root partition Amazon EBS volume remains, continues to persist your data, and you are charged for Amazon EBS volume usage. You can restart your instance at any time. Each time you transition an instance from stopped to started, Amazon EC2 charges a full instance hour, even if transitions happen multiple times within a single hour.

Before stopping an instance, make sure it is in a state from which it can be restarted. Stopping an instance does not preserve data stored in RAM.

Performing this operation on an instance that uses an instance store as its root device returns an error.

For more information, see Stopping Instances in the *Amazon Elastic Compute Cloud User Guide*.

**Request Syntax**

```python
response = ec2.instances.start(
    AdditionalInfo='string',
    DryRun=True|False
)
```

**Parameters**

- **AdditionalInfo** *(string)* – Reserved.
• **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Return type**  
dict

**Returns**

**Response Syntax**

```json
{
    'StartingInstances': [  
        {
            'InstanceId': 'string',
            'CurrentState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped',
            },
            'PreviousState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped',
            }
        },
    ],
}
```

**Response Structure**

• *(dict)* –  
  • **StartingInstances** *(list)* –  
    Information about one or more started instances.  
    • *(dict)* –  
      Describes an instance state change.  
      • **InstanceId** *(string)* –  
        The ID of the instance.  
      • **CurrentState** *(dict)* –  
        The current state of the instance.  
      • **Code** *(integer)* –  
        The low byte represents the state. The high byte is an opaque internal value and should be ignored.  
        • 0: pending  
        • 16: running  
        • 32: shutting-down  
        • 48: terminated  
        • 64: stopping  
        • 80: stopped  
      • **Name** *(string)* –  
        The current state of the instance.  
      • **PreviousState** *(dict)* –  
        The previous state of the instance.  
      • **Code** *(integer)* –  
        The low byte represents the state. The high byte is an opaque internal value and should be ignored.  
        • 0: pending
stop(**kwargs)

Stops an Amazon EBS-backed instance. Each time you transition an instance from stopped to started, Amazon EC2 charges a full instance hour, even if transitions happen multiple times within a single hour.

You can’t start or stop Spot Instances.

Instances that use Amazon EBS volumes as their root devices can be quickly stopped and started. When an instance is stopped, the compute resources are released and you are not billed for hourly instance usage. However, your root partition Amazon EBS volume remains, continues to persist your data, and you are charged for Amazon EBS volume usage. You can restart your instance at any time.

Before stopping an instance, make sure it is in a state from which it can be restarted. Stopping an instance does not preserve data stored in RAM.

Performing this operation on an instance that uses an instance store as its root device returns an error.

You can stop, start, and terminate EBS-backed instances. You can only terminate instance store-backed instances. What happens to an instance differs if you stop it or terminate it. For example, when you stop an instance, the root device and any other devices attached to the instance persist. When you terminate an instance, the root device and any other devices attached during the instance launch are automatically deleted. For more information about the differences between stopping and terminating instances, see Instance Lifecycle in the Amazon Elastic Compute Cloud User Guide.

For more information about troubleshooting, see Troubleshooting Stopping Your Instance in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = ec2.instances.stop(
    DryRun=True|False,
    Force=True|False
)
```

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **Force (boolean)** – Forces the instances to stop. The instances do not have an opportunity to flush file system caches or file system metadata. If you use this option, you must perform file system check and repair procedures. This option is not recommended for Windows instances.

Default: false

Return type  dict

Returns

Response Syntax
{  
    'StoppingInstances': [  
    {  
        'InstanceId': 'string',  
        'CurrentState': {  
            'Code': 123,  
            'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped'  
        },  
        'PreviousState': {  
            'Code': 123,  
            'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped'  
        }  
    },  
    ]  
}  

Response Structure  
• (dict) –  
  • StoppingInstances (list) –  
    Information about one or more stopped instances.  
    • (dict) –  
      Describes an instance state change.  
      • InstanceId (string) –  
        The ID of the instance.  
      • CurrentState (dict) –  
        The current state of the instance.  
      • Code (integer) –  
        The low byte represents the state. The high byte is an opaque internal value and should be ignored.  
        • 0: pending  
        • 16: running  
        • 32: shutting-down  
        • 48: terminated  
        • 64: stopping  
        • 80: stopped  
      • Name (string) –  
        The current state of the instance.  
      • PreviousState (dict) –  
        The previous state of the instance.  
      • Code (integer) –  
        The low byte represents the state. The high byte is an opaque internal value and should be ignored.  
        • 0: pending  
        • 16: running  
        • 32: shutting-down  
        • 48: terminated  
        • 64: stopping  
        • 80: stopped  
      • Name (string) –  
        The current state of the instance.
terminate(**kwargs)
Shuts down one or more instances. This operation is idempotent; if you terminate an instance more than once, each call succeeds.

Terminated instances remain visible after termination (for approximately one hour).

By default, Amazon EC2 deletes all EBS volumes that were attached when the instance launched. Volumes attached after instance launch continue running.

You can stop, start, and terminate EBS-backed instances. You can only terminate instance store-backed instances. What happens to an instance differs if you stop it or terminate it. For example, when you stop an instance, the root device and any other devices attached to the instance persist. When you terminate an instance, any attached EBS volumes with the DeleteOnTermination block device mapping parameter set to true are automatically deleted. For more information about the differences between stopping and terminating instances, see Instance Lifecycle in the Amazon Elastic Compute Cloud User Guide.

For more information about troubleshooting, see Troubleshooting Terminating Your Instance in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = ec2.instances.terminate(
    DryRun=True|False,
)
```

Parameters

**DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

Return type **dict**

Returns

Response Syntax

```python
{
    'TerminatingInstances': [
        {
            'InstanceId': 'string',
            'CurrentState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopped'},
            'PreviousState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopped'}},
        
    ],
}
```

Response Structure

- *(dict)*
  - **TerminatingInstances** *(list)* – Information about one or more terminated instances.
    - *(dict)*
      - Describes an instance state change.
- **InstanceId** *(string)* –
  The ID of the instance.
- **CurrentState** *(dict)* –
  The current state of the instance.
- **Code** *(integer)* –
  The low byte represents the state. The high byte is an opaque internal value and should be ignored.
  - 0: pending
  - 16: running
  - 32: shutting-down
  - 48: terminated
  - 64: stopping
  - 80: stopped
- **Name** *(string)* –
  The current state of the instance.
- **PreviousState** *(dict)* –
  The previous state of the instance.
- **Code** *(integer)* –
  The low byte represents the state. The high byte is an opaque internal value and should be ignored.
  - 0: pending
  - 16: running
  - 32: shutting-down
  - 48: terminated
  - 64: stopping
  - 80: stopped
- **Name** *(string)* –
  The current state of the instance.

```
unmonitor(**kwargs)
```

Disables monitoring for a running instance. For more information about monitoring instances, see Monitoring Your Instances and Volumes in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = ec2.instances.unmonitor(
    DryRun=True|False,
)
```

**Parameters**
- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

**Return type**
- dict

**Returns**

**Response Syntax**

```python
{
    'InstanceMonitorings': [
    ]
}
```
Response Structure

- (dict) –
  - InstanceMonitorings (list) –
    Monitoring information for one or more instances.
    - (dict) –
      Describes the monitoring information of the instance.
      - InstanceId (string) –
        The ID of the instance.
      - Monitoring (dict) –
        The monitoring information.
      - State (string) –
        Indicates whether monitoring is enabled for the instance.

internet_gateways

all()

Creates an iterable of all InternetGateway resources in the collection.

Request Syntax

internet_gateway_iterator = ec2.internet_gateways.all()

Return type  list(ec2.InternetGateway)
Returns  A list of InternetGateway resources

filter(**kwargs)

Creates an iterable of all InternetGateway resources in the collection filtered by kwargs passed to method.

Request Syntax

internet_gateway_iterator = ec2.internet_gateways.filter(
  DryRun=True|False,
  InternetGatewayIds=[
      'string',
  ],
  Filters=[
      {
          'Name': 'string',
          'Values': [ 'string',
          ],
      },
  ]
)
Parameters

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is *DryRunOperation*. Otherwise, it is *UnauthorizedOperation*.
- **InternetGatewayIds** (*list*) – One or more Internet gateway IDs.
  Default: Describes all your Internet gateways.
  - (*string*) –
- **Filters** (*list*) – One or more filters.
  - **attachment.state** - The current state of the attachment between the gateway and the VPC (*available*). Present only if a VPC is attached.
  - **attachment.vpc-id** - The ID of an attached VPC.
  - **internet-gateway-id** - The ID of the Internet gateway.
  - **tag :key =*value* - The key/value combination of a tag assigned to the resource.
  - **tag-key** - The key of a tag assigned to the resource. This filter is independent of the **tag-value** filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the **tag :key =*value* filter.
  - **tag-value** - The value of a tag assigned to the resource. This filter is independent of the **tag-key** filter.
  - (*dict*) –
    A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
    * **Name** (*string*) –
      The name of the filter. Filter names are case-sensitive.
    * **Values** (*list*) –
      One or more filter values. Filter values are case-sensitive.
        - (*string*) –

Return type: list(ec2.InternetGateway)
Returns: A list of InternetGateway resources

**limit(** **kwargs **)**
Creates an iterable up to a specified amount of InternetGateway resources in the collection.

Request Syntax

```python
internet_gateway_iterator = ec2.internet_gateways.limit(
    count=123
)
```

Parameters **count** (*integer*) – The limit to the number of resources in the iterable.
Return type: list(ec2.InternetGateway)
Returns: A list of InternetGateway resources

**page_size(** **kwargs **)**
Creates an iterable of all InternetGateway resources in the collection, but limits the number of items returned by each service call by the specified amount.
Request Syntax

internet_gateway_iterator = ec2.internet_gateways.page_size(count=123)

Parameters  **count** (integer) – The number of items returned by each service call
Return type  list(ec2.InternetGateway)
Returns  A list of InternetGateway resources

key_pairs

all()
Creates an iterable of all KeyPair resources in the collection.

Request Syntax

key_pair_iterator = ec2.key_pairs.all()

Return type  list(ec2.KeyPair)
Returns  A list of KeyPair resources

filter(**kwargs)
Creates an iterable of all KeyPair resources in the collection filtered by kwargs passed to method.

Request Syntax

key_pair_iterator = ec2.key_pairs.filter(
    DryRun=True|False,
    KeyNames=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ]
        }]
)

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **KeyNames** (list) – One or more key pair names.

  Default: Describes all your key pairs.

  - (string)

- **Filters** (list) – One or more filters.

  - fingerprint - The fingerprint of the key pair.
  - key-name - The name of the key pair.

  - (dict) –
A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

- **Name** *(string)* – The name of the filter. Filter names are case-sensitive.
- **Values** *(list)* – One or more filter values. Filter values are case-sensitive.

    * (string) –

**Return type** list(ec2.KeyPair)

**Returns** A list of KeyPair resources

#### limit(**kwargs**)

Creates an iterable up to a specified amount of KeyPair resources in the collection.

**Request Syntax**

```python
key_pair_iterator = ec2.key_pairs.limit(
    count=123
)
```

**Parameters** `count` *(integer)* – The limit to the number of resources in the iterable.

**Return type** list(ec2.KeyPair)

**Returns** A list of KeyPair resources

#### page_size(**kwargs**)

Creates an iterable of all KeyPair resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
key_pair_iterator = ec2.key_pairs.page_size(
    count=123
)
```

**Parameters** `count` *(integer)* – The number of items returned by each service call

**Return type** list(ec2.KeyPair)

**Returns** A list of KeyPair resources

#### network_acls

**all()**

Creates an iterable of all NetworkAcl resources in the collection.

**Request Syntax**

```python
network_acl_iterator = ec2.network_acls.all()
```

**Return type** list(ec2.NetworkAcl)

**Returns** A list of NetworkAcl resources

**filter(**kwargs**)

Creates an iterable of all NetworkAcl resources in the collection filtered by kwargs passed to method.

**Request Syntax**
network_acls = ec2.network_acls.filter(
    DryRun=True|False,
    NetworkAclIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ],
)

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **NetworkAclIds** *(list)* – One or more network ACL IDs.

Default: Describes all your network ACLs.
- *(string)*
- **Filters** *(list)* – One or more filters.
  - association.association-id - The ID of an association ID for the ACL.
  - association.network-acl-id - The ID of the network ACL involved in the association.
  - association.subnet-id - The ID of the subnet involved in the association.
  - default - Indicates whether the ACL is the default network ACL for the VPC.
  - entry.cidr - The CIDR range specified in the entry.
  - entry.egress - Indicates whether the entry applies to egress traffic.
  - entry.icmp.code - The ICMP code specified in the entry, if any.
  - entry.icmp.type - The ICMP type specified in the entry, if any.
  - entry.port-range.from - The start of the port range specified in the entry.
  - entry.port-range.to - The end of the port range specified in the entry.
  - entry.protocol - The protocol specified in the entry (tcp | udp | icmp or a protocol number).
  - entry.rule-action - Allows or denies the matching traffic (allow | deny).
  - entry.rule-number - The number of an entry (in other words, rule) in the ACL’s set of entries.
  - network-acl-id - The ID of the network ACL.
  - tag :key = *value* - The key/value combination of a tag assigned to the resource.
  - tag-key - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use
both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key=*value* filter.

- **tag-value** - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.

- **vpc-id** - The ID of the VPC for the network ACL.

- **(dict)** - A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  
  * **Name** (string) – The name of the filter. Filter names are case-sensitive.
  
  * **Values** (list) – One or more filter values. Filter values are case-sensitive.

**limit(****kwargs)**

Creates an iterable up to a specified amount of NetworkAcl resources in the collection.

**Request Syntax**

```python
network_acl_iterator = ec2.network_acls.limit(
    count=123
)
```

**Parameters**

- **count** (integer) – The limit to the number of resources in the iterable.

**Return type**

list(ec2.NetworkAcl)

**Returns**

A list of NetworkAcl resources

**page_size(****kwargs)**

Creates an iterable of all NetworkAcl resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
network_acl_iterator = ec2.network_acls.page_size(
    count=123
)
```

**Parameters**

- **count** (integer) – The number of items returned by each service call

**Return type**

list(ec2.NetworkAcl)

**Returns**

A list of NetworkAcl resources

**network_interfaces**

**all()**

Creates an iterable of all NetworkInterface resources in the collection.

**Request Syntax**
network_interface_iterator = ec2.network_interfaces.all()

**Return type**  list(ec2.NetworkInterface)
**Returns**  A list of NetworkInterface resources

**filter(**kwargs\**)
Creates an iterable of all NetworkInterface resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
network_interface_iterator = ec2.network_interfaces.filter(
    DryRun=True|False,
    NetworkInterfaceIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ]
)
```

**Parameters**

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **NetworkInterfaceIds** (list) – One or more network interface IDs. Default: Describes all your network interfaces.
  - (string)
- **Filters** (list) – One or more filters.
  - addresses.private-ip-address - The private IP addresses associated with the network interface.
  - addresses.primary - Whether the private IP address is the primary IP address associated with the network interface.
  - addresses.association.public-ip - The association ID returned when the network interface was associated with the Elastic IP address.
  - addresses.association.owner-id - The owner ID of the addresses associated with the network interface.
  - association.association-id - The association ID returned when the network interface was associated with an IP address.
  - association.allocation-id - The allocation ID returned when you allocated the Elastic IP address for your network interface.
  - association.ip-owner-id - The owner of the Elastic IP address associated with the network interface.
  - association.public-ip - The address of the Elastic IP address bound to the network interface.
- association.public-dns-name - The public DNS name for the network interface.
- association.attachment-id - The ID of the interface attachment.
- association.instance-id - The ID of the instance to which the network interface is attached.
- association.instance-owner-id - The owner ID of the instance to which the network interface is attached.
- association.device-index - The device index to which the network interface is attached.
- association.status - The status of the attachment (attaching | attached | detaching | detached).
- association.attach.time - The time that the network interface was attached to an instance.
- attachment.delete-on-termination - Indicates whether the attachment is deleted when an instance is terminated.
- availability-zone - The Availability Zone of the network interface.
- description - The description of the network interface.
- group-id - The ID of a security group associated with the network interface.
- group-name - The name of a security group associated with the network interface.
- mac-address - The MAC address of the network interface.
- network-interface-id - The ID of the network interface.
- owner-id - The AWS account ID of the network interface owner.
- private-ip-address - The private IP address or addresses of the network interface.
- private-dns-name - The private DNS name of the network interface.
- requester-id - The ID of the entity that launched the instance on your behalf (for example, AWS Management Console, Auto Scaling, and so on).
- requester-managed - Indicates whether the network interface is being managed by an AWS service (for example, AWS Management Console, Auto Scaling, and so on).
- source-desk-check - Indicates whether the network interface performs source/destination checking. A value of true means checking is enabled, and false means checking is disabled. The value must be false for the network interface to perform Network Address Translation (NAT) in your VPC.
- status - The status of the network interface. If the network interface is not attached to an instance, the status is available; if a network interface is attached to an instance the status is in-use.
- subnet-id - The ID of the subnet for the network interface.
- tag: key = *value* - The key/value combination of a tag assigned to the resource.
- tag-key - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter "tag-key=Purpose" and the filter "tag-value=X", you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag: key = *value* filter.
- tag-value - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- vpc-id - The ID of the VPC for the network interface.
- (dict) –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* Name (string) –
The name of the filter. Filter names are case-sensitive.

* Values (list) –
One or more filter values. Filter values are case-sensitive.

  · (string) –

**Return type** list(ec2.NetworkInterface)

**Returns** A list of NetworkInterface resources

**limit(**\*\*\textit{kwargs})**

Creates an iterable up to a specified amount of NetworkInterface resources in the collection.

**Request Syntax**

```python
network_interface_iterator = ec2.network_interfaces.limit(
    count=123
)
```

**Parameters** count (integer) – The limit to the number of resources in the iterable.

**Return type** list(ec2.NetworkInterface)

**Returns** A list of NetworkInterface resources

**page_size(**\*\*\textit{kwargs})**

Creates an iterable of all NetworkInterface resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
network_interface_iterator = ec2.network_interfaces.page_size(
    count=123
)
```

**Parameters** count (integer) – The number of items returned by each service call

**Return type** list(ec2.NetworkInterface)

**Returns** A list of NetworkInterface resources

**placement_groups**

all()

Creates an iterable of all PlacementGroup resources in the collection.

**Request Syntax**

```python
placement_group_iterator = ec2.placement_groups.all()
```

**Return type** list(ec2.PlacementGroup)

**Returns** A list of PlacementGroup resources
**filter(**kwargs**)

Creates an iterable of all PlacementGroup resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
placement_group_iterator = ec2.placement_groups.filter(
    DryRun=True|False,
    GroupNames=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ]
)
```

**Parameters**

- **DryRun** ([boolean]) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **GroupNames** ([list]) – One or more placement group names.
  - (string) – Default: Describes all your placement groups, or only those otherwise specified.
- **Filters** ([list]) – One or more filters.
  - group-name - The name of the placement group.
  - state - The state of the placement group (pending | available | deleting | deleted).
  - strategy - The strategy of the placement group (cluster).
  - (dict) – A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
    - **Name** (string) – The name of the filter. Filter names are case-sensitive.
    - **Values** (list) – One or more filter values. Filter values are case-sensitive.

**Return type**  list(ec2.PlacementGroup)

**Returns**  A list of PlacementGroup resources

**limit(**kwargs**)

Creates an iterable up to a specified amount of PlacementGroup resources in the collection.

**Request Syntax**
placement_group_iterator = ec2.placement_groups.limit(
    count=123
)

**Parameters**

- **count** *(integer)* – The limit to the number of resources in the iterable.
- **Return type** *list(ec2.PlacementGroup)*
- **Returns** *A list of PlacementGroup resources*

**page_size(****kwargs**)**

Creates an iterable of all PlacementGroup resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```
placement_group_iterator = ec2.placement_groups.page_size(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The number of items returned by each service call
- **Return type** *list(ec2.PlacementGroup)*
- **Returns** *A list of PlacementGroup resources*

**route_tables**

**all()**

Creates an iterable of all RouteTable resources in the collection.

**Request Syntax**

```
route_table_iterator = ec2.route_tables.all()
```

**Return type** *list(ec2.RouteTable)*

**Returns** *A list of RouteTable resources*

**filter(****kwargs**)**

Creates an iterable of all RouteTable resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```
route_table_iterator = ec2.route_tables.filter(
    DryRun=True|False,
    RouteTableIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ]
        },
    ]
)
```

**Parameters**
• **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

• **RouteTableIds** (*list*) – One or more route table IDs.

Default: Describes all your route tables.

– (*string*) –

• **Filters** (*list*) – One or more filters.

  – `association.route-table-association-id` - The ID of an association ID for the route table.
  – `association.route-table-id` - The ID of the route table involved in the association.
  – `association.subnet-id` - The ID of the subnet involved in the association.
  – `association.main` - Indicates whether the route table is the main route table for the VPC.
  – `route-table-id` - The ID of the route table.
  – `route.destination-cidr-block` - The CIDR range specified in a route in the table.
  – `route.destination-prefix-list-id` - The ID (prefix) of the AWS service specified in a route in the table.
  – `route.gateway-id` - The ID of a gateway specified in a route in the table.
  – `route.instance-id` - The ID of an instance specified in a route in the table.
  – `route.origin` - Describes how the route was created. CreateRouteTable indicates that the route was automatically created when the route table was created; CreateRoute indicates that the route was manually added to the route table; EnableVgwRoutePropagation indicates that the route was propagated by route propagation.
  – `route.state` - The state of a route in the route table (**active**|**blackhole**). The blackhole state indicates that the route’s target isn’t available (for example, the specified gateway isn’t attached to the VPC, the specified NAT instance has been terminated, and so on).
  – `route.vpc-peering-connection-id` - The ID of a VPC peering connection specified in a route in the table.
  – `tag :key=`*value* - The key/value combination of a tag assigned to the resource.
  – `tag-key` - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag :key=`*value* filter.
  – `tag-value` - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
  – `vpc-id` - The ID of the VPC for the route table.

– (*dict*) –

  A filter name and value pair that is used to return a more specific list
of results. Filters can be used to match a set of resources by various
criteria, such as tags, attributes, or IDs.

- **Name** (string) –
  The name of the filter. Filter names are case-sensitive.

- **Values** (list) –
  One or more filter values. Filter values are case-sensitive.
  
  - (string) –

  **Return type** list(ec2.RouteTable)
  
  **Returns** A list of RouteTable resources

**limit(**kwargs**)**

Creates an iterable up to a specified amount of RouteTable resources in the collection.

**Request Syntax**

```python
route_table_iterator = ec2.route_tables.limit(
    count=123
)
```

**Parameters**

- **count** (integer) – The limit to the number of resources in the iterable.

**Return type** list(ec2.RouteTable)

**Returns** A list of RouteTable resources

**page_size(**kwargs**)**

Creates an iterable of all RouteTable resources in the collection, but limits the number of items
returned by each service call by the specified amount.

**Request Syntax**

```python
route_table_iterator = ec2.route_tables.page_size(
    count=123
)
```

**Parameters**

- **count** (integer) – The number of items returned by each service call

**Return type** list(ec2.RouteTable)

**Returns** A list of RouteTable resources

**security_groups**

**all()**

Creates an iterable of all SecurityGroup resources in the collection.

**Request Syntax**

```python
security_group_iterator = ec2.security_groups.all()
```

**Return type** list(ec2.SecurityGroup)

**Returns** A list of SecurityGroup resources

**filter(**kwargs**)**

Creates an iterable of all SecurityGroup resources in the collection filtered by kwargs passed to
method.

**Request Syntax**

```python
```
security_group_iterator = ec2.security_groups.filter(
    DryRun=True|False,
    GroupNames=[
        'string',
    ],
    GroupIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        }
    ],
)

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **GroupNames** *(list)* – [EC2-Classic and default VPC only] One or more security group names. You can specify either the security group name or the security group ID. For security groups in a nondefault VPC, use the group-name filter to describe security groups by name.

  Default: Describes all your security groups.

  - *(string)*

- **GroupIds** *(list)* – One or more security group IDs. Required for security groups in a nondefault VPC.

  Default: Describes all your security groups.

  - *(string)*

- **Filters** *(list)* – One or more filters. If using multiple filters for rules, the results include security groups for which any combination of rules - not necessarily a single rule - match all filters.

  - description - The description of the security group.
  - egress.ip-permission.prefix-list-id - The ID (prefix) of the AWS service to which the security group allows access.
  - group-id - The ID of the security group.
  - group-name - The name of the security group.
  - ip-permission.cidr - A CIDR range that has been granted permission.
  - ip-permission.from-port - The start of port range for the TCP and UDP protocols, or an ICMP type number.
  - ip-permission.group-id - The ID of a security group that has been granted permission.
  - ip-permission.group-name - The name of a security group that has been granted permission.
  - ip-permission.protocol - The IP protocol for the permission (tcp|udp|icmp or a protocol number).
  - ip-permission.to-port - The end of port range for the TCP and UDP protocols, or an ICMP code.
  - ip-permission.user-id - The ID of an AWS account that
has been granted permission.
- **owner-id** - The AWS account ID of the owner of the security group.
- **tag-key** - The key of a tag assigned to the security group.
- **tag-value** - The value of a tag assigned to the security group.
- **vpc-id** - The ID of the VPC specified when the security group was created.

- *(dict)* - A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  * **Name (string)** – The name of the filter. Filter names are case-sensitive.
  * **Values (list)** – One or more filter values. Filter values are case-sensitive.

  - *(string)*

  **Return type** list(ec2.SecurityGroup)

  **Returns** A list of SecurityGroup resources

### limit (**kwargs**)
Creates an iterable up to a specified amount of SecurityGroup resources in the collection.

**Request Syntax**

```python
security_group_iterator = ec2.security_groups.limit(
    count=123
)
```

**Parameters**
- **count (integer)** – The limit to the number of resources in the iterable.

**Return type** list(ec2.SecurityGroup)

**Returns** A list of SecurityGroup resources

### page_size (**kwargs**)
Creates an iterable of all SecurityGroup resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
security_group_iterator = ec2.security_groups.page_size(
    count=123
)
```

**Parameters**
- **count (integer)** – The number of items returned by each service call

**Return type** list(ec2.SecurityGroup)

**Returns** A list of SecurityGroup resources

### snapshots

#### all()
Creates an iterable of all Snapshot resources in the collection.

**Request Syntax**

```python
snapshot_iterator = ec2.snapshots.all()
```
Return type  list(ec2.Snapshot)
Returns  A list of Snapshot resources

filter(**kwargs)
Creates an iterable of all Snapshot resources in the collection filtered by kwargs passed to method.

Request Syntax

```python
snapshot_iterator = ec2.snapshots.filter(
    DryRun=True|False,
    SnapshotIds=[
        'string',
    ],
    OwnerIds=[
        'string',
    ],
    RestorableByUserIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ]
        },
    ],
    NextToken='string',
    MaxResults=123
)
```

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **SnapshotIds** (list) – One or more snapshot IDs.
  - (string) –
- **OwnerIds** (list) – Returns the snapshots owned by the specified owner. Multiple owners can be specified.
  - (string) –
- **RestorableByUserIds** (list) – One or more AWS accounts IDs that can create volumes from the snapshot.
  - (string) –
- **Filters** (list) – One or more filters.
  - description - A description of the snapshot.
  - owner-alias - The AWS account alias (for example, amazon) that owns the snapshot.
  - owner-id - The ID of the AWS account that owns the snapshot.
  - progress - The progress of the snapshot, as a percentage (for example, 80%).
  - snapshot-id - The snapshot ID.
  - start-time - The time stamp when the snapshot was initiated.
  - status - The status of the snapshot (pending | completed | error).
- tag :key =*value* - The key/value combination of a tag assigned to the resource.
- tag-key - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key =*value* filter.
- tag-value - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- volume-id - The ID of the volume the snapshot is for.
- volume-size - The size of the volume, in GiB.

- (dict) –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* Name (string) –

The name of the filter. Filter names are case-sensitive.

* Values (list) –

One or more filter values. Filter values are case-sensitive.

  * NextToken (string) – The NextToken value returned from a previous paginated DescribeSnapshots request where MaxResults was used and the results exceeded the value of that parameter. Pagination continues from the end of the previous results that returned the NextToken value. This value is null when there are no more results to return.

  * MaxResults (integer) – The maximum number of snapshot results returned by DescribeSnapshots in paginated output. When this parameter is used, DescribeSnapshots only returns MaxResults results in a single page along with a NextToken response element. The remaining results of the initial request can be seen by sending another DescribeSnapshots request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. If this parameter is not used, then DescribeSnapshots returns all results. You cannot specify this parameter and the snapshot IDs parameter in the same request.

Return type list(ec2.Snapshot)

Returns A list of Snapshot resources

limit (**kwargs)

Creates an iterable up to a specified amount of Snapshot resources in the collection.

Request Syntax

```
snapshot_iterator = ec2.snapshots.limit(
    count=123
)
```

Parameters count (integer) – The limit to the number of resources in the iterable.

Return type list(ec2.Snapshot)

Returns A list of Snapshot resources
**page_size(****kwargs**)

Creates an iterable of all Snapshot resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
snapshot_iterator = ec2.snapshots.page_size(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The number of items returned by each service call

**Return type**

`list(ec2.Snapshot)`

**Returns**

A list of Snapshot resources

---

**subnets**

**all()**

Creates an iterable of all Subnet resources in the collection.

**Request Syntax**

```python
subnet_iterator = ec2.subnets.all()
```

**Return type**

`list(ec2.Subnet)`

**Returns**

A list of Subnet resources

---

**filter(****kwargs**)

Creates an iterable of all Subnet resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
subnet_iterator = ec2.subnets.filter(
    DryRun=True|False,
    SubnetIds=[
        'string',
    ],
    Filters=[
        {'Name': 'string',
         'Values': [
             'string',
         ]},
    ]
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **SubnetIds** *(list)* – One or more subnet IDs.
  
  Default: Describes all your subnets.
  
  - *(string)*
  
- **Filters** *(list)* – One or more filters.

  - *availabilityZone* - The Availability Zone for the subnet. You can also use *availability-zone* as the filter name.
- **available-ip-address-count** - The number of IP addresses in the subnet that are available.
- **cidrBlock** - The CIDR block of the subnet. The CIDR block you specify must exactly match the subnet's CIDR block for information to be returned for the subnet. You can also use `cidr` or `cidr-block` as the filter names.
- **defaultForAz** - Indicates whether this is the default subnet for the Availability Zone. You can also use `default-for-az` as the filter name.
- **state** - The state of the subnet (`pending` | `available`).
- **subnet-id** - The ID of the subnet.
- **tag**:`key=*value*` - The key/value combination of a tag assigned to the resource.
- **tag-key** - The key of a tag assigned to the resource. This filter is independent of the `tag-value` filter. For example, if you use both the filter “`tag-key=Purpose`” and the filter “`tag-value=X`”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag :key=*value*` filter.
- **tag-value** - The value of a tag assigned to the resource. This filter is independent of the `tag-key` filter.
- **vpc-id** - The ID of the VPC for the subnet.

- *(dict)* –

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* **Name (string)** –
  The name of the filter. Filter names are case-sensitive.

  * **Values (list)** –

    One or more filter values. Filter values are case-sensitive.

    * **(string)** –

  

Return type: `list(ec2.Subnet)`

Returns: A list of Subnet resources

**limit(***kwargs**)**

Creates an iterable up to a specified amount of Subnet resources in the collection.

**Request Syntax**

```python
subnet_iterator = ec2.subnets.limit(
    count=123
)
```

**Parameters**

**count (integer)** – The limit to the number of resources in the iterable.

**Return type** `list(ec2.Subnet)`

**Returns** A list of Subnet resources

**page_size(***kwargs**)**

Creates an iterable of all Subnet resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**
subnet_iterator = ec2.subnets.page_size(
    count=123
)

Parameters

- **count** *(integer)* – The number of items returned by each service call

Return type

- list(ec2.Subnet)

Returns

- A list of Subnet resources

volumes

all()

Creates an iterable of all Volume resources in the collection.

Request Syntax

volume_iterator = ec2.volumes.all()

Return type

- list(ec2.Volume)

Returns

- A list of Volume resources

filter(**kwargs)

Creates an iterable of all Volume resources in the collection filtered by kwargs passed to method.

Request Syntax

volume_iterator = ec2.volumes.filter(
    DryRun=True|False,
    VolumeIds=[
        'string',
    ],
    Filters=[
        
    ],
    NextToken='string',
    MaxResults=123
)

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **VolumeIds** *(list)* – One or more volume IDs.
  - *(string)*
- **Filters** *(list)* – One or more filters.
  - attachment.attach-time - The time stamp when the attachment initiated.
  - attachment.delete-on-termination - Whether the volume is deleted on instance termination.
  - attachment.device - The device name that is exposed to the instance (for example, /dev/sdal).
- `attachment.instance-id` - The ID of the instance the volume is attached to.
- `attachment.status` - The attachment state (attaching | attached | detaching | detached).
- `availability-zone` - The Availability Zone in which the volume was created.
- `create-time` - The time stamp when the volume was created.
- `encrypted` - The encryption status of the volume.
- `size` - The size of the volume, in GiB.
- `snapshot-id` - The snapshot from which the volume was created.
- `status` - The status of the volume (creating | available | in-use | deleting | deleted | error).
- `tag :key=*value*` - The key/value combination of a tag assigned to the resource.
- `tag-key` - The key of a tag assigned to the resource. This filter is independent of the `tag-value` filter. For example, if you use both the filter "tag-key=Purpose" and the filter "tag-value=X", you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag :key=*value*` filter.
- `tag-value` - The value of a tag assigned to the resource. This filter is independent of the `tag-key` filter.
- `volume-id` - The volume ID.
- `volume-type` - The Amazon EBS volume type. This can be `gp2` for General Purpose (SSD) volumes, `io1` for Provisioned IOPS (SSD) volumes, or `standard` for Magnetic volumes.
- `(dict)` –
  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  - `Name (string)` –
    The name of the filter. Filter names are case-sensitive.
  - `Values (list)` –
    One or more filter values. Filter values are case-sensitive.
  - `(string)` –
    - `NextToken (string)` – The `NextToken` value returned from a previous paginated `DescribeVolumes` request where `MaxResults` was used and the results exceeded the value of that parameter. Pagination continues from the end of the previous results that returned the `NextToken` value. This value is null when there are no more results to return.
    - `MaxResults (integer)` – The maximum number of volume results returned by `DescribeVolumes` in paginated output. When this parameter is used, `DescribeVolumes` only returns `MaxResults` results in a single page along with a `NextToken` response element. The remaining results of the initial request can be seen by sending another `DescribeVolumes` request with the returned `NextToken` value. This value can be between 5 and 1000; if `MaxResults` is given a value larger than 1000, only 1000 results are returned. If this parameter is not used, then `DescribeVolumes` returns all results. You cannot specify this parameter and the volume IDs parameter in the same request.

Return type `list(ec2.Volume)`
**Returns** A list of Volume resources

`limit(**kwargs)`
Creates an iterable up to a specified amount of Volume resources in the collection.

**Request Syntax**

```python
volume_iterator = ec2.volumes.limit(
    count=123
)
```

**Parameters**
- `count (integer)` – The limit to the number of resources in the iterable.
- **Return type** `list(ec2.Volume)`
- **Returns** A list of Volume resources

`page_size(**kwargs)`
Creates an iterable of all Volume resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
volume_iterator = ec2.volumes.page_size(
    count=123
)
```

**Parameters**
- `count (integer)` – The number of items returned by each service call
- **Return type** `list(ec2.Volume)`
- **Returns** A list of Volume resources

**vpc_peering_connections**

`all()`
Creates an iterable of all VpcPeeringConnection resources in the collection.

**Request Syntax**

```python
vpc_peering_connection_iterator = ec2.vpc_peering_connections.all()
```

- **Return type** `list(ec2.VpcPeeringConnection)`
- **Returns** A list of VpcPeeringConnection resources

`filter(**kwargs)`
Creates an iterable of all VpcPeeringConnection resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
vpc_peering_connection_iterator = ec2.vpc_peering_connections.filter(
    DryRun=True|False,
    VpcPeeringConnectionIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': [ 'string',
        ]
    ]
)
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **VpcPeeringConnectionIds** *(list)* – One or more VPC peering connection IDs.

  Default: Describes all your VPC peering connections.

- *(string)*

- **Filters** *(list)* – One or more filters.

  - accepter-vpc-info.cidr-block - The CIDR block of the peer VPC.
  - accepter-vpc-info.owner-id - The AWS account ID of the owner of the peer VPC.
  - accepter-vpc-info.vpc-id - The ID of the peer VPC.
  - expiration-time - The expiration date and time for the VPC peering connection.
  - requester-vpc-info.cidr-block - The CIDR block of the requester’s VPC.
  - requester-vpc-info.owner-id - The AWS account ID of the owner of the requester VPC.
  - requester-vpc-info.vpc-id - The ID of the requester VPC.
  - status-code - The status of the VPC peering connection (`pending-acceptance` | `failed` | `expired` | `provisioning` | `active` | `deleted` | `rejected`).
  - status-message - A message that provides more information about the status of the VPC peering connection, if applicable.
  - tag :key=*value* - The key/value combination of a tag assigned to the resource.
  - tag-key - The key of a tag assigned to the resource. This filter is independent of the `tag-value` filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag :key=*value*` filter.
  - tag-value - The value of a tag assigned to the resource. This filter is independent of the `tag-key` filter.
  - vpc-peering-connection-id - The ID of the VPC peering connection.

- *(dict)*

  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  - **Name** *(string)* –

    The name of the filter. Filter names are case-sensitive.

  - **Values** *(list)* –
One or more filter values. Filter values are case-sensitive.

- (string) –

**Return type** list(ec2.VpcPeeringConnection)

**Returns** A list of VpcPeeringConnection resources

**limit (kwargs)**

Creates an iterable up to a specified amount of VpcPeeringConnection resources in the collection.

**Request Syntax**

vpc_peering_connection_iterator = ec2.vpc_peering_connections.limit(
    count=123
)

**Parameters**

- count (integer) – The limit to the number of resources in the iterable.

**Return type** list(ec2.VpcPeeringConnection)

**Returns** A list of VpcPeeringConnection resources

**page_size (kwargs)**

Creates an iterable of all VpcPeeringConnection resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

vpc_peering_connection_iterator = ec2.vpc_peering_connections.page_size(
    count=123
)

**Parameters**

- count (integer) – The number of items returned by each service call

**Return type** list(ec2.VpcPeeringConnection)

**Returns** A list of VpcPeeringConnection resources

**vpcs**

**all ()**

Creates an iterable of all Vpc resources in the collection.

**Request Syntax**

vpc_iterator = ec2.vpcs.all()

**Return type** list(ec2.Vpc)

**Returns** A list of Vpc resources

**filter (kwargs)**

Creates an iterable of all Vpc resources in the collection filtered by kwargs passed to method.

**Request Syntax**

vpc_iterator = ec2.vpcs.filter(
    DryRun=True|False,
    VpcIds=[
        'string',
    ],
    Filters=[
        {
            'Name': 'string',
            'Values': ['string'],
        }
    ]
)
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **VpcIds** *(list)* – One or more VPC IDs.

Default: Describes all your VPCs.

- *(string)*

- **Filters** *(list)* – One or more filters.

  - **cidr** - The CIDR block of the VPC. The CIDR block you specify must exactly match the VPC’s CIDR block for information to be returned for the VPC. Must contain the slash followed by one or two digits (for example, `/28`).
  
  - **dhcp-options-id** - The ID of a set of DHCP options.
  
  - **isDefault** - Indicates whether the VPC is the default VPC.
  
  - **state** - The state of the VPC (`pending`|`available`).
  
  - **tag :key**=*value* - The key/value combination of a tag assigned to the resource.
  
  - **tag-key** - The key of a tag assigned to the resource. This filter is independent of the `tag-value` filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag :key`=*value* filter.
  
  - **tag-value** - The value of a tag assigned to the resource. This filter is independent of the `tag-key` filter.
  
  - **vpc-id** - The ID of the VPC.

- *(dict)* –

  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

  - **Name** *(string)* –

    The name of the filter. Filter names are case-sensitive.

  - **Values** *(list)* –

    One or more filter values. Filter values are case-sensitive.

Return type  list(ec2.Vpc)

Returns  A list of Vpc resources

**limit**(**kwargs**)

 Creates an iterable up to a specified amount of Vpc resources in the collection.

**Request Syntax**

```python
vpc_iterator = ec2.vpcs.limit(
    count=123
)```
Parameters `count (integer)` – The limit to the number of resources in the iterable.

Return type `list(ec2.Vpc)`

Returns A list of Vpc resources

**page_size(**kwargs**)**

Creates an iterable of all Vpc resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

```python
vpc_iterator = ec2.vpcs.page_size(
    count=123
)
```

Parameters `count (integer)` – The number of items returned by each service call

Return type `list(ec2.Vpc)`

Returns A list of Vpc resources

---

**DhcpOptions**

```python
class EC2.DhcpOptions(id)
```

A resource representing an Amazon Elastic Compute Cloud (EC2) DhcpOptions:

```python
import boto3

ec2 = boto3.resource('ec2')
dhcp_options = ec2.DhcpOptions('id')
```

Parameters `id (string)` – The DhcpOptions’s id identifier. This must be set.

These are the resource’s available identifiers:

- `id`

These are the resource’s available attributes:

- `dhcp_configurations`
- `dhcp_options_id`
- `tags`

These are the resource’s available actions:

- `associate_with_vpc()`
- `create_tags()`
- `delete()`
- `load()`
- `reload()`

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide*.

`id`

(string) The DhcpOptions’s id identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the *Resources Introduction Guide*. 
**dhcp_configurations**  
(list)  
One or more DHCP options in the set.

**dhcp_options_id**  
(string)  
The ID of the set of DHCP options.

**tags**  
(list)  
Any tags assigned to the DHCP options set.

**Actions**

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the [Resources Introduction Guide](#).

**associate_with_vpc(**kwargs**)**

Associates a set of DHCP options (that you’ve previously created) with the specified VPC, or associates no DHCP options with the VPC.

After you associate the options with the VPC, any existing instances and all new instances that you launch in that VPC use the options. You don’t need to restart or relaunch the instances. They automatically pick up the changes within a few hours, depending on how frequently the instance renews its DHCP lease. You can explicitly renew the lease using the operating system on the instance.

For more information, see [DHCP Options Sets](#) in the *Amazon Virtual Private Cloud User Guide*.

**Request Syntax**

```python
response = dhcp_options.associate_with_vpc(
    DryRun=True|False,
    VpcId='string'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **VpcId** *(string)* – [REQUIRED]
The ID of the VPC.

**Returns**

None

**create_tags(**kwargs**)**

Adds or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each resource can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys must be unique per resource.

For more information about tags, see [Tagging Your Resources](#) in the *Amazon Elastic Compute Cloud User Guide*.

**Request Syntax**

```python
tag = dhcp_options.create_tags(
    DryRun=True|False,
    Tags=[
        ...
    ]
)
```
'Key': 'string',
'Value': 'string'
}
]
)

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is *DryRunOperation*. Otherwise, it is *UnauthorizedOperation*.

- **Tags** *(list)* – [REQUIRED]

  One or more tags. The value parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.

  - *(dict)*

    Describes a tag.

    - **Key** *(string)* –
      
      The key of the tag.

      Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`.

    - **Value** *(string)* –
      
      The value of the tag.

      Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

  Return type list(ec2.Tag)

  Returns A list of Tag resources

del**ete** (**kwargs**)

Deletes the specified set of DHCP options. You must disassociate the set of DHCP options before you can delete it. You can disassociate the set of DHCP options by associating either a new set of options or the default set of options with the VPC.

Request Syntax

```python
response = dhcp_options.delete(
   DryRun=True|False,
)
```

Parameters  **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is *DryRunOperation*. Otherwise, it is *UnauthorizedOperation*.

Returns  None

load()  
Calls *ec2.Client.describe_dhcp_options()* to update the attributes of the DhcpOptions resource

Request Syntax

```python
dhcp_options.load()
```
**Returns** None

```python
reload()
```

Calls `ec2.Client.describe_dhcp_options()` to update the attributes of the DhcpOptions resource

**Request Syntax**

```python
dhcp_options.reload()
```

**Returns** None

### Image

**class** `EC2.Image(id)`

A resource representing an Amazon Elastic Compute Cloud (EC2) Image:

```python
import boto3

ec2 = boto3.resource('ec2')
image = ec2.Image('id')
```

**Parameters**

- **id** *(string)* – The Image’s id identifier. This **must** be set.

These are the resource’s available identifiers:

- `id`

These are the resource’s available attributes:

- `architecture`
- `block_device_mappings`
- `creation_date`
- `description`
- `hypervisor`
- `image_id`
- `image_location`
- `image_owner_alias`
- `image_type`
- `kernel_id`
- `name`
- `owner_id`
- `platform`
- `product_codes`
- `public`
- `ramdisk_id`
- `root_device_name`
- `root_device_type`
- `sriov_net_support`
- `state`
- `state_reason`
- `tags`
- `virtualization_type`

These are the resource’s available actions:

- `create_tags()`
- `deregister()`
- `describe_attribute()`
- `load()`
Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide*.

id

(string) The Image’s id identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the *Resources Introduction Guide*.

architecture

(string)

The architecture of the image.

block_device_mappings

(list)

Any block device mapping entries.

creation_date

(string)

The date and time the image was created.

description

(string)

The description of the AMI that was provided during image creation.

hypervisor

(string)

The hypervisor type of the image.

image_id

(string)

The ID of the AMI.

image_location

(string)

The location of the AMI.

image_owner_alias

(string)

The AWS account alias (for example, amazon, self) or the AWS account ID of the AMI owner.

image_type

(string)

The type of image.

kernel_id

(string)

The kernel associated with the image, if any. Only applicable for machine images.
**name**

*(string)*

The name of the AMI that was provided during image creation.

**owner_id**

*(string)*

The AWS account ID of the image owner.

**platform**

*(string)*

The value is `Windows` for Windows AMIs; otherwise blank.

**product_codes**

*(list)*

Any product codes associated with the AMI.

**public**

*(boolean)*

Indicates whether the image has public launch permissions. The value is `true` if this image has public launch permissions or `false` if it has only implicit and explicit launch permissions.

**ramdisk_id**

*(string)*

The RAM disk associated with the image, if any. Only applicable for machine images.

**root_device_name**

*(string)*

The device name of the root device (for example, `/dev/sdal` or `/dev/xvda`).

**root_device_type**

*(string)*

The type of root device used by the AMI. The AMI can use an EBS volume or an instance store volume.

**sriov_net_support**

*(string)*

Specifies whether enhanced networking is enabled.

**state**

*(string)*

The current state of the AMI. If the state is `available`, the image is successfully registered and can be used to launch an instance.

**state_reason**

*(dict)*

The reason for the state change.

**tags**

*(list)*

Any tags assigned to the image.

**virtualization_type**

*(string)*

The type of virtualization of the AMI.
Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

`create_tags (**kwargs)`

Adds or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each resource can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys must be unique per resource.

For more information about tags, see Tagging Your Resources in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
tag = image.create_tags(
    DryRun=True|False,
    Tags=[
        {'Key': 'string',
         'Value': 'string'
        },
    ]
)
```

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **Tags** (list) – [REQUIRED]

  One or more tags. The value parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.

  - (dict) –

    Describes a tag.

    - **Key** (string) –

      The key of the tag.

      Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with aws:

    - **Value** (string) –

      The value of the tag.

      Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

Return type list(ec2.Tag)

Returns A list of Tag resources

deregister (**kwargs)**

Deregisters the specified AMI. After you deregister an AMI, it can’t be used to launch new instances.

This command does not delete the AMI.

Request Syntax
response = image.deregister(
    DryRun=True|False,
)

Parameters  **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

Returns  None

```
def describe_attribute(**kwargs):
    # Describes the specified attribute of the specified AMI. You can specify only one attribute at a time.
    Response Syntax
    ```
    response = image.describe_attribute(
        DryRun=True|False,
        Attribute='description'|'kernel'|'ramdisk'|'launchPermission'|'productCodes'|'blockDeviceMapping'
    )
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.
- **Attribute** *(string)* – [REQUIRED]

    The AMI attribute.

    **Note**: Depending on your account privileges, the **blockDeviceMapping** attribute may return a **Client.AuthFailure** error. If this happens, use **DescribeImages** to get information about the block device mapping for the AMI.

Returns  **Response Syntax**

    ```
    {  
        'ImageId': 'string',  
        'LaunchPermissions': [  
            {  
                'UserId': 'string',  
                'Group': 'all'  
            },  
        ],  
        'ProductCodes': [  
            {  
                'ProductCodeId': 'string',  
                'ProductCodeType': 'devpay'|'marketplace'  
            },  
        ],  
        'KernelId': {  
            'Value': 'string'  
        },  
        'RamdiskId': {  
            'Value': 'string'  
        },  
    }
    ```

3.1. Services
'Description': {
    'Value': 'string'
},
'SriovNetSupport': {
    'Value': 'string'
},
'BlockDeviceMappings': [
    {
        'VirtualName': 'string',
        'DeviceName': 'string',
        'Ebs': {
            'SnapshotId': 'string',
            'VolumeSize': 123,
            'DeleteOnTermination': True|False,
            'VolumeType': 'standard'|'io1'|'gp2',
            'Iops': 123,
            'Encrypted': True|False
        },
        'NoDevice': 'string'
    }
]

Response Structure

- (dict) – Information about the image attribute.
  - **ImageId** *(string)* – The ID of the AMI.
  - **LaunchPermissions** *(list)* – One or more launch permissions.
    - *(dict)* – Describes a launch permission.
      - **UserId** *(string)* – The AWS account ID.
      - **Group** *(string)* – The name of the group.
  - **ProductCodes** *(list)* – One or more product codes.
    - *(dict)* – Describes a product code.
      - **ProductCodeId** *(string)* – The product code.
      - **ProductCodeType** *(string)* – The type of product code.
  - **KernelId** *(dict)* – The kernel ID.
    - **Value** *(string)* – Valid values are case-sensitive and vary by action.
- **RamdiskId** *(dict)* –
  The RAM disk ID.
  * Value *(string)* –
    Valid values are case-sensitive and vary by action.

- **Description** *(dict)* –
  A description for the AMI.
  * Value *(string)* –
    Valid values are case-sensitive and vary by action.

- **SriovNetSupport** *(dict)* –
  The value to use for a resource attribute.
  * Value *(string)* –
    Valid values are case-sensitive and vary by action.

- **BlockDeviceMappings** *(list)* –
  One or more block device mapping entries.
  * (dict) –
    Describes a block device mapping.
    - **VirtualName** *(string)* –
      The virtual device name (ephemeral N). Instance store volumes are numbered starting from 0. An instance type with 2 available instance store volumes can specify mappings for ephemeral0 and ephemeral1. The number of available instance store volumes depends on the instance type. After you connect to the instance, you must mount the volume.
    Constraints: For M3 instances, you must specify instance store volumes in the block device mapping for the instance. When you launch an M3 instance, we ignore any instance store volumes specified in the block device mapping for the AMI.
    - **DeviceName** *(string)* –
      The device name exposed to the instance (for example, /dev/sdh or xvdh ).
    - **Ebs** *(dict)* –
      Parameters used to automatically set up EBS volumes when the instance is launched.
      - **SnapshotId** *(string)* –
        The ID of the snapshot.
      - **VolumeSize** *(integer)* –
        The size of the volume, in GiB.
      Constraints: 1-1024 for standard volumes, 1-16384 for gp2 volumes, and 4-16384 for io1 volumes. If you specify a snapshot, the volume size must be equal to or larger than the snapshot size.
      Default: If you’re creating the volume from a snapshot and don’t specify a volume size, the default is the snapshot size.
    - **DeleteOnTermination** *(boolean)* –
Indicates whether the EBS volume is deleted on instance termination.

- **VolumeType** *(string)*
  The volume type. gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, and standard for Magnetic volumes.
  
  Default: standard

- **Iops** *(integer)*
  The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.
  
  Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.
  
  Condition: This parameter is required for requests to create io1 volumes; it is not used in requests to create standard or gp2 volumes.

- **Encrypted** *(boolean)*
  Indicates whether the EBS volume is encrypted. Encrypted Amazon EBS volumes may only be attached to instances that support Amazon EBS encryption.

- **NoDevice** *(string)*
  Suppresses the specified device included in the block device mapping of the AMI.

**load()**

Calls `ec2.Client.describe_images()` to update the attributes of the Image resource

**Request Syntax**

```python
image.load()
```

**Returns** None

**modify_attribute(**kwargs**)**

Modifies the specified attribute of the specified AMI. You can specify only one attribute at a time.

**Note:** AWS Marketplace product codes cannot be modified. Images with an AWS Marketplace product code cannot be made public.

**Request Syntax**

```python
response = image.modify_attribute(
    DryRun=True|False,
    Attribute='string',
    OperationType='add'|'remove',
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **Attribute** *(string)* – The name of the attribute to modify.
- **OperationType** *(string)* – The operation type.
- **UserIds** *(list)* – One or more AWS account IDs. This is only valid when modifying the `launchPermission` attribute.
  - *(string)*
- **UserGroups** *(list)* – One or more user groups. This is only valid when modifying the `launchPermission` attribute.
  - *(string)*
- **ProductCodes** *(list)* – One or more product codes. After you add a product code to an AMI, it can’t be removed. This is only valid when modifying the `productCodes` attribute.
  - *(string)*
- **Value** *(string)* – The value of the attribute being modified. This is only valid when modifying the `description` attribute.
- **LaunchPermission** *(dict)* – A launch permission modification.
  - **Add** *(list)* –
    - The AWS account ID to add to the list of launch permissions for the AMI.
      - *(dict)* –
        - **UserId** *(string)* –
          - Describes a launch permission.

Boto3 Documentation, Release 1.1.4

3.1. Services
The AWS account ID.

- **Group** *(string)*

  The name of the group.

- **Remove** *(list)*

  The AWS account ID to remove from the list of launch permissions for the AMI.

  * *(dict)*

  Describes a launch permission.

  - **UserId** *(string)*

    The AWS account ID.

  - **Group** *(string)*

    The name of the group.

- **Description** *(dict)*

  A description for the AMI.

- **Value** *(string)*

  Valid values are case-sensitive and vary by action.

**Returns** None

**reload()**

Calls `ec2.Client.describe_images()` to update the attributes of the Image resource

**Request Syntax**

```python
image.reload()
```

**Returns** None

**reset_attribute(**kwargs)**

Resets an attribute of an AMI to its default value.

**Note:** The productCodes attribute can’t be reset.

**Request Syntax**

```python
response = image.reset_attribute(
    DryRun=True|False,
    Attribute='launchPermission'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **Attribute** *(string)* – [REQUIRED]

  The attribute to reset (currently you can only reset the launch permission attribute).

**Returns** None

**Instance**

class **EC2.Instance**(id)

A resource representing an Amazon Elastic Compute Cloud (EC2) Instance:
import boto3

ec2 = boto3.resource('ec2')
instance = ec2.Instance('id')

Parameters id (string) – The Instance’s id identifier. This must be set.

These are the resource’s available identifiers:
• id

These are the resource’s available attributes:
• ami_launch_index
• architecture
• block_device_mappings
• client_token
• ebs_optimized
• hypervisor
• iam_instance_profile
• image_id
• instance_id
• instance_lifecycle
• instance_type
• kernel_id
• key_name
• launch_time
• monitoring
• network_interfaces
• placement
• platform
• private_dns_name
• private_ip_address
• product_codes
• public_dns_name
• public_ip_address
• ramdisk_id
• root_device_name
• root_device_type
• security_groups
• source_dest_check
• spot_instance_request_id
• srivnet_support
• state
• state_reason
• state_transition_reason
• subnet_id
• tags
• virtualization_type
• vpc_id

These are the resource’s available references:
• image
• key_pair
• placement_group
• subnet
• vpc

These are the resource’s available actions:
• attach_classic_link_vpc()
  • attach_volume()
  • console_output()
  • create_image()
  • create_tags()
  • describe_attribute()
  • detach_classic_link_vpc()
  • detach_volume()
  • load()
  • modify_attribute()
  • monitor()
  • password_data()
  • reboot()
  • reload()
  • report_status()
  • reset_attribute()
  • reset_kernel()
  • reset_ramdisk()
  • reset_source_dest_check()
  • start()
  • stop()
  • terminate()
  • unmonitor()

These are the resource’s available collections:
• volumes

These are the resource’s available waiters:
• wait_until_exists()
• wait_until_running()
• wait_until_stopped()
• wait_until_terminated()

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide.*

**id**

*(string)* The Instance’s id identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the *Resources Introduction Guide.*

**ami_launch_index**

*(integer)*

The AMI launch index, which can be used to find this instance in the launch group.

**architecture**

*(string)*

The architecture of the image.

**block_device_mappings**

*(list)*

Any block device mapping entries for the instance.
client_token
    (string)
    The idempotency token you provided when you launched the instance.

ebs_optimized
    (boolean)
    Indicates whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput
to Amazon EBS and an optimized configuration stack to provide optimal I/O performance. This optimization
isn’t available with all instance types. Additional usage charges apply when using an EBS Optimized
instance.

hypervisor
    (string)
    The hypervisor type of the instance.

iam_instance_profile
    (dict)
    The IAM instance profile associated with the instance.

image_id
    (string)
    The ID of the AMI used to launch the instance.

instance_id
    (string)
    The ID of the instance.

instance_lifecycle
    (string)
    Indicates whether this is a Spot Instance.

instance_type
    (string)
    The instance type.

kernel_id
    (string)
    The kernel associated with this instance.

key_name
    (string)
    The name of the key pair, if this instance was launched with an associated key pair.

launch_time
    (datetime)
    The time the instance was launched.

monitoring
    (dict)
    The monitoring information for the instance.

network_interfaces
    (list)
One or more network interfaces for the instance.

**placement**

*(dict)*

The location where the instance launched.

**platform**

*(string)*

The value is *Windows* for Windows instances; otherwise blank.

**private_dns_name**

*(string)*

The private DNS name assigned to the instance. This DNS name can only be used inside the Amazon EC2 network. This name is not available until the instance enters the running state.

**private_ip_address**

*(string)*

The private IP address assigned to the instance.

**product_codes**

*(list)*

The product codes attached to this instance.

**public_dns_name**

*(string)*

The public DNS name assigned to the instance. This name is not available until the instance enters the running state.

**public_ip_address**

*(string)*

The public IP address assigned to the instance.

**ramdisk_id**

*(string)*

The RAM disk associated with this instance.

**root_device_name**

*(string)*

The root device name (for example, /dev/sdal or /dev/xvda).

**root_device_type**

*(string)*

The root device type used by the AMI. The AMI can use an EBS volume or an instance store volume.

**security_groups**

*(list)*

One or more security groups for the instance.

**source_dest_check**

*(boolean)*

Specifies whether to enable an instance launched in a VPC to perform NAT. This controls whether source/destination checking is enabled on the instance. A value of *true* means checking is enabled, and *false* means checking is disabled. The value must be *false* for the instance to perform NAT. For more information, see NAT Instances in the Amazon Virtual Private Cloud User Guide.
spot_instance_request_id
  (string)
  The ID of the Spot Instance request.

sriov_net_support
  (string)
  Specifies whether enhanced networking is enabled.

state
  (dict)
  The current state of the instance.

state_reason
  (dict)
  The reason for the most recent state transition.

state_transition_reason
  (string)
  The reason for the most recent state transition. This might be an empty string.

subnet_id
  (string)
  The ID of the subnet in which the instance is running.

tags
  (list)
  Any tags assigned to the instance.

virtualization_type
  (string)
  The virtualization type of the instance.

vpc_id
  (string)
  The ID of the VPC in which the instance is running.

References
References are related resource instances that have a belongs-to relationship. For more information about references refer to the Resources Introduction Guide.

image
  (Image) The related image if set, otherwise None.

key_pair
  (KeyPair) The related key_pair if set, otherwise None.

placement_group
  (PlacementGroup) The related placement_group if set, otherwise None.

subnet
  (Subnet) The related subnet if set, otherwise None.

vpc
  (Vpc) The related vpc if set, otherwise None.
Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from
identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

attach_classic_link_vpc(**kwargs)

Links an EC2-Classic instance to a ClassicLink-enabled VPC through one or more of the VPC’s security
groups. You cannot link an EC2-Classic instance to more than one VPC at a time. You can only link
an instance that’s in the running state. An instance is automatically unlinked from a VPC when it’s
stopped - you can link it to the VPC again when you restart it.

After you’ve linked an instance, you cannot change the VPC security groups that are associated with it.
To change the security groups, you must first unlink the instance, and then link it again.

Linking your instance to a VPC is sometimes referred to as attaching your instance.

Request Syntax

response = instance.attach_classic_link_vpc(
    DryRun=True|False,
    VpcId='string',
    Groups=[
        'string',
    ]
)

Parameters

• DryRun (boolean) – Checks whether you have the required permissions for the
  action, without actually making the request, and provides an error response. If
  you have the required permissions, the error response is DryRunOperation.
  Otherwise, it is UnauthorizedOperation.
• VpcId (string) – [REQUIRED]
  The ID of a ClassicLink-enabled VPC.
• Groups (list) – [REQUIRED]
  The ID of one or more of the VPC’s security groups. You cannot specify security
groups from a different VPC.
    – (string) –

Return type dict

Returns

Response Syntax

{
    'Return': True|False
}

Response Structure

• (dict) –
  – Return (boolean) –
    Returns true if the request succeeds; otherwise, it returns an error.

attach_volume(**kwargs)

Attaches an EBS volume to a running or stopped instance and exposes it to the instance with the specified
device name.

Encrypted EBS volumes may only be attached to instances that support Amazon EBS encryption. For
more information, see Amazon EBS Encryption in the Amazon Elastic Compute Cloud User Guide.
For a list of supported device names, see Attaching an EBS Volume to an Instance. Any device names that aren’t reserved for instance store volumes can be used for EBS volumes. For more information, see Amazon EC2 Instance Store in the Amazon Elastic Compute Cloud User Guide.

If a volume has an AWS Marketplace product code:

• The volume can be attached only to a stopped instance.
• AWS Marketplace product codes are copied from the volume to the instance.
• You must be subscribed to the product.
• The instance type and operating system of the instance must support the product. For example, you can’t detach a volume from a Windows instance and attach it to a Linux instance.

For an overview of the AWS Marketplace, see Introducing AWS Marketplace.

For more information about EBS volumes, see Attaching Amazon EBS Volumes in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = instance.attach_volume(
    DryRun=True|False,
    VolumeId='string',
    Device='string'
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **VolumeId** *(string)* – [REQUIRED]
  The ID of the EBS volume. The volume and instance must be within the same Availability Zone.

- **Device** *(string)* – [REQUIRED]
  The device name to expose to the instance (for example, `/dev/sdh` or `xvdh`).

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'VolumeId': 'string',
    'InstanceId': 'string',
    'Device': 'string',
    'State': 'attaching'|'attached'|'detaching'|'detached',
    'AttachTime': datetime(2015, 1, 1),
    'DeleteOnTermination': True|False
}
```

**Response Structure**

- *(dict)* –

  Information about the volume attachment.

  - **VolumeId** *(string)* –
    The ID of the volume.
  
  - **InstanceId** *(string)* –
    The ID of the instance.
– **Device** *(string)* –

The device name.

– **State** *(string)* –

The attachment state of the volume.

– **AttachTime** *(datetime)* –

The time stamp when the attachment initiated.

– **DeleteOnTermination** *(boolean)* –

Indicates whether the EBS volume is deleted on instance termination.

```python
console_output(**kwargs)
```

Gets the console output for the specified instance.

Instances do not have a physical monitor through which you can view their console output. They also lack physical controls that allow you to power up, reboot, or shut them down. To allow these actions, we provide them through the Amazon EC2 API and command line interface.

Instance console output is buffered and posted shortly after instance boot, reboot, and termination. Amazon EC2 preserves the most recent 64 KB output which is available for at least one hour after the most recent post.

For Linux instances, the instance console output displays the exact console output that would normally be displayed on a physical monitor attached to a computer. This output is buffered because the instance produces it and then posts it to a store where the instance’s owner can retrieve it.

For Windows instances, the instance console output includes output from the EC2Config service.

**Request Syntax**

```python
response = instance.console_output(
    DryRun=True|False,
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'InstanceId': 'string',
    'Timestamp': datetime(2015, 1, 1),
    'Output': 'string'
}
```

**Response Structure**

- *(dict)* –
  - **InstanceId** *(string)* –
    
    The ID of the instance.
  - **Timestamp** *(datetime)* –
    
    The time the output was last updated.
Output (string)

The console output, Base64 encoded.

create_image(**kwargs)

Creates an Amazon EBS-backed AMI from an Amazon EBS-backed instance that is either running or stopped.

If you customized your instance with instance store volumes or EBS volumes in addition to the root device volume, the new AMI contains block device mapping information for those volumes. When you launch an instance from this new AMI, the instance automatically launches with those additional volumes.

For more information, see Creating Amazon EBS-Backed Linux AMIs in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
image = instance.create_image(
    DryRun=True|False,
    Name='string',
    Description='string',
    NoReboot=True|False,
    BlockDeviceMappings=[
        {'VirtualName': 'string',
         'DeviceName': 'string',
         'Ebs': {
             'SnapshotId': 'string',
             'VolumeSize': 123,
             'DeleteOnTermination': True|False,
             'VolumeType': 'standard'|'io1'|'gp2',
             'Iops': 123,
             'Encrypted': True|False
         },
         'NoDevice': 'string'
    ],
)
```

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **Name (string)** – [REQUIRED]

  A name for the new image.

  Constraints: 3-128 alphanumeric characters, parentheses (()), square brackets ([]), spaces (), periods (), slashes (/), dashes (-), single quotes (’), at-signs (@), or underscores(_)
- **Description (string)** – A description for the new image.
- **NoReboot (boolean)** – By default, this parameter is set to False, which means Amazon EC2 attempts to shut down the instance cleanly before image creation and then reboots the instance. When the parameter is set to True, Amazon EC2 doesn’t shut down the instance before creating the image. When this option is used, file system integrity on the created image can’t be guaranteed.
- **BlockDeviceMappings (list)** – Information about one or more block device mappings.
– (dict) –

Describes a block device mapping.

* **VirtualName** *(string)* –

The virtual device name *(ephemeral N)*. Instance store volumes are numbered starting from 0. An instance type with 2 available instance store volumes can specify mappings for *ephemeral0* and *ephemeral1*. The number of available instance store volumes depends on the instance type. After you connect to the instance, you must mount the volume.

Constraints: For M3 instances, you must specify instance store volumes in the block device mapping for the instance. When you launch an M3 instance, we ignore any instance store volumes specified in the block device mapping for the AMI.

* **DeviceName** *(string)* –

The device name exposed to the instance (for example, */dev/sdh* or *xvdh*).

* **Ebs** *(dict)* –

Parameters used to automatically set up EBS volumes when the instance is launched.

- **SnapshotId** *(string)* –

  The ID of the snapshot.

- **VolumeSize** *(integer)* –

  The size of the volume, in GiB.

  Constraints: 1-1024 for standard volumes, 1-16384 for gp2 volumes, and 4-16384 for io1 volumes. If you specify a snapshot, the volume size must be equal to or larger than the snapshot size.

  Default: If you’re creating the volume from a snapshot and don’t specify a volume size, the default is the snapshot size.

- **DeleteOnTermination** *(boolean)* –

  Indicates whether the EBS volume is deleted on instance termination.

- **VolumeType** *(string)* –

  The volume type. *gp2* for General Purpose (SSD) volumes, *io1* for Provisioned IOPS (SSD) volumes, and *standard* for Magnetic volumes.

  Default: *standard*

- **Iops** *(integer)* –

  The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.
Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.

Condition: This parameter is required for requests to create \texttt{io1} volumes; it is not used in requests to create \texttt{standard} or \texttt{gp2} volumes.

- \textbf{Encrypted (boolean)} –

  Indicates whether the EBS volume is encrypted. Encrypted Amazon EBS volumes may only be attached to instances that support Amazon EBS encryption.

- \textbf{NoDevice (string)} –

  Suppresses the specified device included in the block device mapping of the AMI.

\textbf{Return type} ec2.Image

\textbf{Returns} Image resource

\textbf{create\_tags(**kwargs)}

Adds or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each resource can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys must be unique per resource.

For more information about tags, see \textit{Tagging Your Resources} in the Amazon Elastic Compute Cloud User Guide.

\textbf{Request Syntax}

```python
tag = instance.create_tags(
    DryRun=True|False,
    Tags=[
        {'Key': 'string',
         'Value': 'string'},
    ]
)
```

\textbf{Parameters}

- \textbf{DryRun (boolean)} – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is \texttt{DryRunOperation}. Otherwise, it is \texttt{UnauthorizedOperation}.

- \textbf{Tags (list) – [REQUIRED]}

  One or more tags. The \textit{value} parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.

  - (dict) –

    Describes a tag.

      * \textbf{Key (string)} –

        The key of the tag.

      Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with \texttt{aws}:

      * \textbf{Value (string)} –

```
The value of the tag.

Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

Return type  list(ec2.Tag)
Returns  A list of Tag resources

`describe_attribute(**kwargs)`
Describes the specified attribute of the specified instance. You can specify only one attribute at a time. Valid attribute values are: `instanceType` | `kernel` | `ramdisk` | `userData` | `disableApiTermination` | `instanceInitiatedShutdownBehavior` | `rootDeviceName` | `blockDeviceMapping` | `productCodes` | `sourceDestCheck` | `groupSet` | `ebsOptimized` | `sriovNetSupport`

Request Syntax

```python
response = instance.describe_attribute(
    DryRun=True|False,
    Attribute='instanceType'|'kernel'|'ramdisk'|'userData'|'disableApiTermination'|'instanceInitiatedShutdownBehavior'|'rootDeviceName'|'blockDeviceMapping'|'productCodes'|'sourceDestCheck'|'groupSet'|'ebsOptimized'|'sriovNetSupport'
)
```

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **Attribute** (string) – [REQUIRED]

  The instance attribute.

Return type  dict
Returns

Response Syntax

```python
{
    'InstanceId': 'string',
    'InstanceType': { 
        'Value': 'string' 
    },
    'KernelId': { 
        'Value': 'string' 
    },
    'RamdiskId': { 
        'Value': 'string' 
    },
    'UserData': { 
        'Value': 'string' 
    },
    'DisableApiTermination': { 
        'Value': True|False 
    },
    'InstanceInitiatedShutdownBehavior': { 
        'Value': 'string' 
    },
    'RootDeviceName': { 
        'Value': 'string' 
    },
    'BlockDeviceMappings': [
```

```json
{
    'DeviceName': 'string',
    'Ebs': {
        'VolumeId': 'string',
        'Status': 'attaching'|'attached'|'detaching'|'detached',
        'AttachTime': datetime(2015, 1, 1),
        'DeleteOnTermination': True|False
    },
    'ProductCodes': [
        {
            'ProductCodeId': 'string',
            'ProductCodeType': 'devpay'|'marketplace'
        }
    ],
    'EbsOptimized': {
        'Value': True|False
    },
    'SriovNetSupport': {
        'Value': 'string'
    },
    'SourceDestCheck': {
        'Value': True|False
    },
    'Groups': [
        {
            'GroupName': 'string',
            'GroupId': 'string'
        }
    ]
}
```

**Response Structure**

- *(dict)* – Information about the instance attribute.
  - **InstanceId** *(string)* – The ID of the instance.
  - **InstanceType** *(dict)* – The instance type.
    - **Value** *(string)* – Valid values are case-sensitive and vary by action.
  - **KernelId** *(dict)* – The kernel ID.
    - **Value** *(string)* – Valid values are case-sensitive and vary by action.
  - **RamdiskId** *(dict)* – The RAM disk ID.
    - **Value** *(string)* – Valid values are case-sensitive and vary by action.
  - **UserData** *(dict)* – The Base64-encoded MIME user data.
* **Value** *(string)* –
  Valid values are case-sensitive and vary by action.

- **DisableApiTermination** *(dict)* –
  If the value is **true**, you can’t terminate the instance through the Amazon
  EC2 console, CLI, or API; otherwise, you can.
  * **Value** *(boolean)* –
    Valid values are **true** or **false**.

- **InstanceInitiatedShutdownBehavior** *(dict)* –
  Indicates whether an instance stops or terminates when you initiate shut-
  down from the instance (using the operating system command for system
  shutdown).
  * **Value** *(string)* –
    Valid values are case-sensitive and vary by action.

- **RootDeviceName** *(dict)* –
  The name of the root device (for example, `/dev/sdal` or `/dev/xvda`).
  * **Value** *(string)* –
    Valid values are case-sensitive and vary by action.

- **BlockDeviceMappings** *(list)* –
  The block device mapping of the instance.
  * *(dict)* –
    Describes a block device mapping.
    - **DeviceName** *(string)* –
      The device name exposed to the instance (for example, `/dev/sdh` or `/xvdh`).
    - **Ebs** *(dict)* –
      Parameters used to automatically set up EBS volumes when
      the instance is launched.
    - **VolumeId** *(string)* –
      The ID of the EBS volume.
    - **Status** *(string)* –
      The attachment state.
    - **AttachTime** *(datetime)* –
      The time stamp when the attachment initiated.
    - **DeleteOnTermination** *(boolean)* –
      Indicates whether the volume is deleted on instance termina-
      tion.

- **ProductCodes** *(list)* –
  A list of product codes.
  * *(dict)* –
    Describes a product code.
    - **ProductCodeId** *(string)* –
      The product code.
- **ProductCodeType**(string) –
  The type of product code.
- **EbsOptimized**(dict) –
  Indicates whether the instance is optimized for EBS I/O.
    * **Value**(boolean) –
      Valid values are **true** or **false**.
- **SriovNetSupport**(dict) –
  The value to use for a resource attribute.
    * **Value**(string) –
      Valid values are case-sensitive and vary by action.
- **SourceDestCheck**(dict) –
  Indicates whether source/destination checking is enabled. A value of **true** means checking is enabled, and **false** means checking is disabled. This value must be **false** for a NAT instance to perform NAT.
    * **Value**(boolean) –
      Valid values are **true** or **false**.
- **Groups**(list) –
  The security groups associated with the instance.
    * (dict) –
      Describes a security group.
        - **GroupName**(string) –
          The name of the security group.
        - **GroupId**(string) –
          The ID of the security group.

**detach_classic_link_vpc(****kwargs**)
Unlinks (detaches) a linked EC2-Classic instance from a VPC. After the instance has been unlinked, the VPC security groups are no longer associated with it. An instance is automatically unlinked from a VPC when it’s stopped.

**Request Syntax**

```python
response = instance.detach_classic_link_vpc(
    DryRun=True|False,
    VpcId='string'
)
```

**Parameters**

- **DryRun**(boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.
- **VpcId**(string) – [REQUIRED]
  The ID of the VPC to which the instance is linked.

**Return type**  dict

**Returns**

**Response Syntax**
detach_volume(**kwargs)

Detaches an EBS volume from an instance. Make sure to unmount any file systems on the device within your operating system before detaching the volume. Failure to do so results in the volume being stuck in a busy state while detaching.

If an Amazon EBS volume is the root device of an instance, it can’t be detached while the instance is running. To detach the root volume, stop the instance first.

When a volume with an AWS Marketplace product code is detached from an instance, the product code is no longer associated with the instance.

For more information, see Detaching an Amazon EBS Volume in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = instance.detach_volume(
    DryRun=True|False,
    VolumeId='string',
    Device='string',
    Force=True|False
)
```

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **VolumeId** (string) – [REQUIRED]

The ID of the volume.
- **Device** (string) – The device name.
- **Force** (boolean) – Forces detachment if the previous detachment attempt did not occur cleanly (for example, logging into an instance, unmounting the volume, and detaching normally). This option can lead to data loss or a corrupted file system. Use this option only as a last resort to detach a volume from a failed instance. The instance won’t have an opportunity to flush file system caches or file system metadata. If you use this option, you must perform file system check and repair procedures.

Return type: dict

Returns

Response Syntax

```json
{
    'VolumeId': 'string',
    'InstanceId': 'string',
    'Device': 'string',
}
```
"State": 'attaching'|'attached'|'detaching'|'detached',
"AttachTime": datetime(2015, 1, 1),
"DeleteOnTermination": True|False
}

Response Structure

• (dict) – Information about the volume attachment.
  – VolumeId (string) – The ID of the volume.
  – InstanceId (string) – The ID of the instance.
  – Device (string) – The device name.
  – State (string) – The attachment state of the volume.
  – AttachTime (datetime) – The time stamp when the attachment initiated.
  – DeleteOnTermination (boolean) – Indicates whether the EBS volume is deleted on instance termination.

load()
Calls ec2.Client.describe_instances() to update the attributes of the Instance resource

Request Syntax

instance.load()

Returns None

modify_attribute(**kwargs)
Modifies the specified attribute of the specified instance. You can specify only one attribute at a time.

To modify some attributes, the instance must be stopped. For more information, see Modifying Attributes of a Stopped Instance in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

response = instance.modify_attribute(
  DryRun=True|False,
  Attribute='instanceType'|'kernel'|'ramdisk'|'userData'|'disableApiTermination'|'instanceType',
  Value='string',
  BlockDeviceMappings=[
    {'DeviceName': 'string',
      'Ebs': {
        'VolumeId': 'string',
        'DeleteOnTermination': True|False
      },
      'VirtualName': 'string',
      'NoDevice': 'string'
    },
    SourceDestCheck={
  },
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **Attribute** *(string)* – The name of the attribute.

- **Value** *(string)* – A new value for the attribute. Use only with the kernel, ramdisk, userData, disableApiTermination, or instanceInitiatedShutdownBehavior attribute.

- **BlockDeviceMappings** *(list)* – Modifies the **DeleteOnTermination** attribute for volumes that are currently attached. The volume must be owned by the caller. If no value is specified for **DeleteOnTermination**, the default is **true** and the volume is deleted when the instance is terminated.

To add instance store volumes to an Amazon EBS-backed instance, you must add them when you launch the instance. For more information, see Updating the Block Device Mapping when Launching an Instance in the Amazon Elastic Compute Cloud User Guide.

- *(dict)* –

  Describes a block device mapping entry.

  * **DeviceName** *(string)* –

    The device name exposed to the instance (for example, /dev/sdh or xvdh).

  * **Ebs** *(dict)* –
Parameters used to automatically set up EBS volumes when the instance is launched.

- **VolumeId** *(string)*
  
  The ID of the EBS volume.

- **DeleteOnTermination** *(boolean)*
  
  Indicates whether the volume is deleted on instance termination.

- **VirtualName** *(string)*
  
  The virtual device name.

- **NoDevice** *(string)*
  
  Suppress the specified device included in the block device mapping.

- **SourceDestCheck** *(dict)*
  
  Specifies whether source/destination checking is enabled. A value of `true` means that checking is enabled, and `false` means checking is disabled. This value must be `false` for a NAT instance to perform NAT.

  - **Value** *(boolean)*
    
    Valid values are `true` or `false`.

- **DisableApiTermination** *(dict)*
  
  If the value is `true`, you can’t terminate the instance using the Amazon EC2 console, CLI, or API; otherwise, you can. You cannot use this parameter for Spot Instances.

  - **Value** *(boolean)*
    
    Valid values are `true` or `false`.

- **InstanceType** *(dict)*
  
  Changes the instance type to the specified value. For more information, see Instance Types. If the instance type is not valid, the error returned is `InvalidInstanceAttributeValue`.

  - **Value** *(string)*
    
    Valid values are case-sensitive and vary by action.

- **Kernel** *(dict)*
  
  Changes the instance’s kernel to the specified value. We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see PV-GRUB.

  - **Value** *(string)*
    
    Valid values are case-sensitive and vary by action.

- **Ramdisk** *(dict)*
  
  Changes the instance’s RAM disk to the specified value. We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see PV-GRUB.

  - **Value** *(string)*
    
    Valid values are case-sensitive and vary by action.

- **UserData** *(dict)*
  
  Changes the instance’s user data to the specified value.

  - **Value** *(bytes)*
    
    Valid values are case-sensitive and vary by action.

- **InstanceInitiatedShutdownBehavior** *(dict)*
  
  Specifies whether an instance stops or terminates when you initiate shutdown from the instance (using the operating system command for system shutdown).

  - **Value** *(string)*
    
    Valid values are case-sensitive and vary by action.

- **Groups** *(list)*
  
  Changes the security groups of the instance. You must specify at least one security group, even if it’s just the default security group for the VPC. You must specify the security group ID, not the security group name.

  - **(string)**
• **EbsOptimized** (*dict*) – Specifies whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal EBS I/O performance. This optimization isn’t available with all instance types. Additional usage charges apply when using an EBS Optimized instance.
  
  – **Value** (*boolean*) – 
    
    Valid values are `true` or `false`.
  
• **SriovNetSupport** (*dict*) – Set to `simple` to enable enhanced networking for the instance.

There is no way to disable enhanced networking at this time.

This option is supported only for HVM instances. Specifying this option with a PV instance can make it unreachable.

  – **Value** (*string*) – 
    
    Valid values are case-sensitive and vary by action.

Returns None

```python
monitor(**kwargs)
```

Enables monitoring for a running instance. For more information about monitoring instances, see Monitoring Your Instances and Volumes in the *Amazon Elastic Compute Cloud User Guide*.

Request Syntax

```python
response = instance.monitor(
    DryRun=True|False,
)
```

Parameters

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

Return type: dict

Returns

Response Syntax

```python
{
    'InstanceMonitorings': [
        {
            'InstanceId': 'string',
            'Monitoring': {
                'State': 'disabled'|'disabling'|'enabled'|'pending'
            }
        },
    ]
}
```

Response Structure

- (dict) –
  
  – **InstanceMonitorings** (*list*) –
    
    Monitoring information for one or more instances.
  
  – (dict) –
    
    Describes the monitoring information of the instance.
password_data(**kwargs)

Retrieves the encrypted administrator password for an instance running Windows.

The Windows password is generated at boot if the EC2Config service plugin, Ec2SetPassword, is enabled. This usually only happens the first time an AMI is launched, and then Ec2SetPassword is automatically disabled. The password is not generated for rebundled AMIs unless Ec2SetPassword is enabled before bundling.

The password is encrypted using the key pair that you specified when you launched the instance. You must provide the corresponding key pair file.

Password generation and encryption takes a few moments. We recommend that you wait up to 15 minutes after launching an instance before trying to retrieve the generated password.

Request Syntax

response = instance.password_data(
    DryRun=True|False,
)

Parameters

DryRun (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

Return type

dict

Returns

Response Syntax

{
    'InstanceId': 'string','
    'Timestamp': datetime(2015, 1, 1),
    'PasswordData': 'string'
}

Response Structure

* (dict) –

  - InstanceId (string) –
    The ID of the Windows instance.
  - Timestamp (datetime) –
    The time the data was last updated.
  - PasswordData (string) –
    The password of the instance.

reboot(**kwargs)

Requests a reboot of one or more instances. This operation is asynchronous; it only queues a request
to reboot the specified instances. The operation succeeds if the instances are valid and belong to you. Requests to reboot terminated instances are ignored.

If a Linux/Unix instance does not cleanly shut down within four minutes, Amazon EC2 performs a hard reboot.

For more information about troubleshooting, see Getting Console Output and Rebooting Instances in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = instance.reboot(
    DryRun=True|False,
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Returns**

None

**reload()**

Calls `ec2.Client.describe_instances()` to update the attributes of the Instance resource

**Request Syntax**

```python
instance.reload()
```

**Returns**

None

**report_status(**kwargs)**

Submits feedback about the status of an instance. The instance must be in the running state. If your experience with the instance differs from the instance status returned by DescribeInstanceStatus, use ReportInstanceStatus to report your experience with the instance. Amazon EC2 collects this information to improve the accuracy of status checks.

Use of this action does not change the value returned by DescribeInstanceStatus.

**Request Syntax**

```python
response = instance.report_status(
    DryRun=True|False,
    Status='ok'|'impaired',
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    ReasonCodes=[
        'instance-stuck-in-state'|'unresponsive'|'not-accepting-credentials'|'password-not-available'|'performance-network'|'performance-instance-store'|'performance-ebs-volume'|'performance-other'|'other',
    ],
    Description='string'
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **Status (string)** – [REQUIRED]

  The status of all instances listed.
• **StartTime** ([datetime](https://docs.python.org/3/library/datetime.html)) – The time at which the reported instance health state began.

• **EndTime** ([datetime](https://docs.python.org/3/library/datetime.html)) – The time at which the reported instance health state ended.

• **ReasonCodes** ([list](https://docs.python.org/3/glossary.html#term-list)) – [REQUIRED]

  One or more reason codes that describes the health state of your instance.
  - `instance-stuck-in-state`: My instance is stuck in a state.
  - `unresponsive`: My instance is unresponsive.
  - `not-accepting-credentials`: My instance is not accepting my credentials.
  - `password-not-available`: A password is not available for my instance.
  - `performance-network`: My instance is experiencing performance problems which I believe are network related.
  - `performance-instance-store`: My instance is experiencing performance problems which I believe are related to the instance stores.
  - `performance-ebs-volume`: My instance is experiencing performance problems which I believe are related to an EBS volume.
  - `performance-other`: My instance is experiencing performance problems.
  - `other`: [explain using the description parameter]
  - `(string)` –

• **Description** ([string](https://docs.python.org/3/glossary.html#term-string)) – Descriptive text about the health state of your instance.

Returns None

**reset_attribute(****kwargs**

Resets an attribute of an instance to its default value. To reset the kernel or ramdisk, the instance must be in a stopped state. To reset the SourceDestCheck, the instance can be either running or stopped.

The SourceDestCheck attribute controls whether source/destination checking is enabled. The default value is `true`, which means checking is enabled. This value must be `false` for a NAT instance to perform NAT. For more information, see NAT Instances in the `Amazon Virtual Private Cloud User Guide`.

**Request Syntax**

```python
response = instance.reset_attribute(
    DryRun=True|False,
    Attribute='instanceType'|'kernel'|'ramdisk'|'userData'|'disableApiTermination'|'instanceInitiatedShutdownBehavior'|'rootDeviceName'|'blockDeviceMapping'|'productCodes'|'sourceDestCheck'|'groupSet'|'ebsOptimized'|'sriovNetSupport'
)
```

**Parameters**

- **DryRun** ([boolean](https://docs.python.org/3/library/stdtypes.html#boolean-values)) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **Attribute** ([string](https://docs.python.org/3/glossary.html#term-string)) – [REQUIRED]

  The attribute to reset.

Returns None

**reset_kernel(****kwargs**

Resets an attribute of an instance to its default value. To reset the kernel or ramdisk, the instance must be in a stopped state. To reset the SourceDestCheck, the instance can be either running or stopped.
The `SourceDestCheck` attribute controls whether source/destination checking is enabled. The default value is `true`, which means checking is enabled. This value must be `false` for a NAT instance to perform NAT. For more information, see NAT Instances in the Amazon Virtual Private Cloud User Guide.

**Request Syntax**

```python
response = instance.reset_kernel(
    DryRun=True|False,
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Returns**

None

**reset_ramdisk(****kwargs**

Resets an attribute of an instance to its default value. To reset the kernel or ramdisk, the instance must be in a stopped state. To reset the `SourceDestCheck`, the instance can be either running or stopped.

The `SourceDestCheck` attribute controls whether source/destination checking is enabled. The default value is `true`, which means checking is enabled. This value must be `false` for a NAT instance to perform NAT. For more information, see NAT Instances in the Amazon Virtual Private Cloud User Guide.

**Request Syntax**

```python
response = instance.reset_ramdisk(
    DryRun=True|False,
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Returns**

None

**reset_source_dest_check(****kwargs**

Resets an attribute of an instance to its default value. To reset the kernel or ramdisk, the instance must be in a stopped state. To reset the `SourceDestCheck`, the instance can be either running or stopped.

The `SourceDestCheck` attribute controls whether source/destination checking is enabled. The default value is `true`, which means checking is enabled. This value must be `false` for a NAT instance to perform NAT. For more information, see NAT Instances in the Amazon Virtual Private Cloud User Guide.

**Request Syntax**

```python
response = instance.reset_source_dest_check(
    DryRun=True|False,
)
```
Parameters **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

Returns None

start(**kwargs)**

Starts an Amazon EBS-backed AMI that you’ve previously stopped.

Instances that use Amazon EBS volumes as their root devices can be quickly stopped and started. When an instance is stopped, the compute resources are released and you are not billed for hourly instance usage. However, your root partition Amazon EBS volume remains, continues to persist your data, and you are charged for Amazon EBS volume usage. You can restart your instance at any time. Each time you transition an instance from stopped to started, Amazon EC2 charges a full instance hour, even if transitions happen multiple times within a single hour.

Before stopping an instance, make sure it is in a state from which it can be restarted. Stopping an instance does not preserve data stored in RAM.

Performing this operation on an instance that uses an instance store as its root device returns an error.

For more information, see Stopping Instances in the [Amazon Elastic Compute Cloud User Guide](#).

Request Syntax

```python
response = instance.start(
    AdditionalInfo='string',
    DryRun=True|False
)
```

Parameters

- **AdditionalInfo** *(string)* – Reserved.
- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

Return type **dict**

Returns

Response Syntax

```json
{
    'StartingInstances': [
        {
            'InstanceId': 'string',
            'CurrentState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'
            },
            'PreviousState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'
            }
        }
    ]
}
```

Response Structure

- *(dict)* –
- **StartingInstances** *(list)* –

  Information about one or more started instances.

  * *(dict)* –

  Describes an instance state change.

  - **InstanceId** *(string)* –

    The ID of the instance.

  - **CurrentState** *(dict)* –

    The current state of the instance.

    - **Code** *(integer)* –

      The low byte represents the state. The high byte is an opaque internal value and should be ignored.

      - 0: pending
      - 16: running
      - 32: shutting-down
      - 48: terminated
      - 64: stopping
      - 80: stopped

    - **Name** *(string)* –

      The current state of the instance.

  - **PreviousState** *(dict)* –

    The previous state of the instance.

    - **Code** *(integer)* –

      The low byte represents the state. The high byte is an opaque internal value and should be ignored.

      - 0: pending
      - 16: running
      - 32: shutting-down
      - 48: terminated
      - 64: stopping
      - 80: stopped

    - **Name** *(string)* –

      The current state of the instance.

**stop**( **kwargs**)

Stops an Amazon EBS-backed instance. Each time you transition an instance from stopped to started, Amazon EC2 charges a full instance hour, even if transitions happen multiple times within a single hour.

You can’t start or stop Spot Instances.

Instances that use Amazon EBS volumes as their root devices can be quickly stopped and started. When an instance is stopped, the compute resources are released and you are not billed for hourly instance usage. However, your root partition Amazon EBS volume remains, continues to persist your data, and you are charged for Amazon EBS volume usage. You can restart your instance at any time.

Before stopping an instance, make sure it is in a state from which it can be restarted. Stopping an instance does not preserve data stored in RAM.

Performing this operation on an instance that uses an instance store as its root device returns an error.

You can stop, start, and terminate EBS-backed instances. You can only terminate instance store-backed instances. What happens to an instance differs if you stop it or terminate it. For example, when you stop an instance, the root device and any other devices attached to the instance persist. When you terminate
an instance, the root device and any other devices attached during the instance launch are automatically
deleted. For more information about the differences between stopping and terminating instances, see
Instance Lifecycle in the Amazon Elastic Compute Cloud User Guide.

For more information about troubleshooting, see Troubleshooting Stopping Your Instance in the Amazon
Elastic Compute Cloud User Guide.

Request Syntax

```python
response = instance.stop(
    DryRun=True|False,
    Force=True|False
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the
  action, without actually making the request, and provides an error response. If
  you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **Force** *(boolean)* – Forces the instances to stop. The instances do not have an
  opportunity to flush file system caches or file system metadata. If you use this
  option, you must perform file system check and repair procedures. This option
  is not recommended for Windows instances.

Default: false

Return type: dict

Returns

Response Syntax

```json
{
    'StoppingInstances': [  
        {  
            'InstanceId': 'string',  
            'CurrentState': {  
                'Code': 123,  
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping',  
            },  
            'PreviousState': {  
                'Code': 123,  
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping',  
            }  
        }  
    ]
}
```

Response Structure

- *(dict)* –
  - **StoppingInstances** *(list)* – Information about one or more stopped instances.

    - *(dict)* – Describes an instance state change.
      - **InstanceId** *(string)* – The ID of the instance.
      - **CurrentState** *(dict)* – The current state of the instance.
- **Code (integer)** –
  The low byte represents the state. The high byte is an opaque internal value and should be ignored.
  - 0: pending
  - 16: running
  - 32: shutting-down
  - 48: terminated
  - 64: stopping
  - 80: stopped
- **Name (string)** –
  The current state of the instance.

- **PreviousState (dict)** –
  The previous state of the instance.

- **Code (integer)** –
  The low byte represents the state. The high byte is an opaque internal value and should be ignored.
  - 0: pending
  - 16: running
  - 32: shutting-down
  - 48: terminated
  - 64: stopping
  - 80: stopped
- **Name (string)** –
  The current state of the instance.

**terminate (**kwargs**)**

Shuts down one or more instances. This operation is idempotent; if you terminate an instance more than once, each call succeeds.

Terminated instances remain visible after termination (for approximately one hour).

By default, Amazon EC2 deletes all EBS volumes that were attached when the instance launched. Volumes attached after instance launch continue running.

You can stop, start, and terminate EBS-backed instances. You can only terminate instance store-backed instances. What happens to an instance differs if you stop it or terminate it. For example, when you stop an instance, the root device and any other devices attached to the instance persist. When you terminate an instance, any attached EBS volumes with the `DeleteOnTermination` block device mapping parameter set to `true` are automatically deleted. For more information about the differences between stopping and terminating instances, see Instance Lifecycle in the Amazon Elastic Compute Cloud User Guide.

For more information about troubleshooting, see Troubleshooting Terminating Your Instance in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = instance.terminate(
    DryRun=True|False,
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
Return type  dict

Returns

Response Syntax

```json
{
   'TerminatingInstances': [
      {
         'InstanceId': 'string',
         'CurrentState': {
            'Code': 123,
            'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'
         },
         'PreviousState': {
            'Code': 123,
            'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'
         }
      }
   ]
}
```

Response Structure

* (dict) –
  – TerminatingInstances (list) –

Information about one or more terminated instances.

* (dict) –

  Describes an instance state change.

  - InstanceId (string) –

    The ID of the instance.

  - CurrentState (dict) –

    The current state of the instance.

  - Code (integer) –

    The low byte represents the state. The high byte is an opaque internal value and should be ignored.

    - 0: pending
    - 16: running
    - 32: shutting-down
    - 48: terminated
    - 64: stopping
    - 80: stopped

  - Name (string) –

    The current state of the instance.

  - PreviousState (dict) –

    The previous state of the instance.

  - Code (integer) –

    The low byte represents the state. The high byte is an opaque internal value and should be ignored.

    - 0: pending
    - 16: running
    - 32: shutting-down
    - 48: terminated
    - 64: stopping
· **Name (string)** – The current state of the instance.

**unmonitor(****kwargs**

Disables monitoring for a running instance. For more information about monitoring instances, see Monitoring Your Instances and Volumes in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = instance.unmonitor(
    DryRun=True|False,
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunException. Otherwise, it is UnauthorizedOperation.

**Return type**

- **dict**

**Returns**

**Response Syntax**

```python
{
    'InstanceMonitorings': [
        {
            'InstanceId': 'string',
            'Monitoring': {
                'State': 'disabled'|'disabling'|'enabled'|'pending'
            }
        },
    ]
}
```

**Response Structure**

- **(dict)**
  - **InstanceMonitorings (list)** – Monitoring information for one or more instances.
    - **(dict)**
      - **InstanceMonitorings (list)** – Describes the monitoring information of the instance.
        - **InstanceId (string)** – The ID of the instance.
        - **Monitoring (dict)** – The monitoring information.
          - **State (string)** – Indicates whether monitoring is enabled for the instance.

**Collections**

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the Resources Introduction Guide.

**volumes**
all()
Creates an iterable of all Volume resources in the collection.

Request Syntax

```python
volume_iterator = instance.volumes.all()
```

Return type list(ec2.Volume)
Returns A list of Volume resources

filter(**kwargs)
Creates an iterable of all Volume resources in the collection filtered by kwargs passed to method.

Request Syntax

```python
volume_iterator = instance.volumes.filter(
    DryRun=True|False,
    VolumeIds=[
        'string',
    ],
    NextToken='string',
    MaxResults=123
)
```

Parameters
- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **VolumeIds** (list) – One or more volume IDs.
  - (string)
- **NextToken** (string) – The NextToken value returned from a previous paginated DescribeVolumes request where MaxResults was used and the results exceeded the value of that parameter. Pagination continues from the end of the previous results that returned the NextToken value. This value is null when there are no more results to return.
- **MaxResults** (integer) – The maximum number of volume results returned by DescribeVolumes in paginated output. When this parameter is used, DescribeVolumes only returns MaxResults results in a single page along with a NextToken response element. The remaining results of the initial request can be seen by sending another DescribeVolumes request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. If this parameter is not used, then DescribeVolumes returns all results. You cannot specify this parameter and the volume IDs parameter in the same request.

Return type list(ec2.Volume)
Returns A list of Volume resources

limit(**kwargs)
Creates an iterable up to a specified amount of Volume resources in the collection.

Request Syntax

```python
volume_iterator = instance.volumes.limit(
    count=123
)
```
Parameters count (integer) – The limit to the number of resources in the iterable.
Return type list(ec2.Volume)
Returns A list of Volume resources

page_size (**kwargs)
Creates an iterable of all Volume resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

```python
volume_iterator = instance.volumes.page_size(
    count=123
)
```

Parameters count (integer) – The number of items returned by each service call
Return type list(ec2.Volume)
Returns A list of Volume resources

Waiters

Waiters provide an interface to wait for a resource to reach a specific state. For more information about waiters refer to the Resources Introduction Guide.

wait_until_exists (**kwargs)
Waits until this Instance is exists. This method calls EC2.Waiter.instance_exists.wait() which polls. EC2.Client.describe_instances().wait() every 5 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

```python
instance.wait_until_exists(
    DryRun=True|False,
    Filters=[
        
            'Name': 'string',
            'Values': [
                'string',
            ]
        ),
    NextToken='string',
    MaxResults=123
)
```

Parameters

- DryRun (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- Filters (list) – One or more filters.
  - architecture - The instance architecture (i386|x86_64).
  - availability-zone - The Availability Zone of the instance.
  - block-device-mapping.attach-time - The attach time for an EBS volume mapped to the instance, for example, 2010-09-15T17:15:20.000Z.
  - block-device-mapping.delete-on-termination - A Boolean that indicates whether the EBS volume is deleted on instance termination.
- **block-device-mapping.device-name** - The device name for the EBS volume (for example, /dev/sdh or xvdh).
- **block-device-mapping.status** - The status for the EBS volume (attaching|attached|detaching|detached).
- **block-device-mapping.volume-id** - The volume ID of the EBS volume.
- **client-token** - The idempotency token you provided when you launched the instance.
- **dns-name** - The public DNS name of the instance.
- **group-id** - The ID of the security group for the instance. EC2-Classic only.
- **group-name** - The name of the security group for the instance. EC2-Classic only.
- **hypervisor** - The hypervisor type of the instance (ovm|xen).
- **iam-instance-profile.arn** - The instance profile associated with the instance. Specified as an ARN.
- **image-id** - The ID of the image used to launch the instance.
- **instance-id** - The ID of the instance.
- **instance-lifecycle** - Indicates whether this is a Spot Instance (spot).
- **instance-state-code** - The state of the instance, as a 16-bit unsigned integer. The high byte is an opaque internal value and should be ignored. The low byte is set based on the state represented. The valid values are: 0 (pending), 16 (running), 32 (shutting-down), 48 (terminated), 64 (stopping), and 80 (stopped).
- **instance-state-name** - The state of the instance (pending|running|shutting-down|terminated|stopping|stopped).
- **instance-type** - The type of instance (for example, t2.micro).
- **instance.group-id** - The ID of the security group for the instance.
- **instance.group-name** - The name of the security group for the instance.
- **ip-address** - The public IP address of the instance.
- **kernel-id** - The kernel ID.
- **key-name** - The name of the key pair used when the instance was launched.
- **launch-index** - When launching multiple instances, this is the index for the instance in the launch group (for example, 0, 1, 2, and so on).
- **launch-time** - The time when the instance was launched.
- **monitoring-state** - Indicates whether monitoring is enabled for the instance (disabled|enabled).
- **owner-id** - The AWS account ID of the instance owner.
- **placement-group-name** - The name of the placement group for the instance.
- **platform** - The platform. Use windows if you have Windows instances; otherwise, leave blank.
- **private-dns-name** - The private DNS name of the instance.
- **private-ip-address** - The private IP address of the instance.
- **product-code** - The product code associated with the AMI used to launch the instance.
- **product-code.type** - The type of product code (devpay|marketplace).
- **ramdisk-id** - The RAM disk ID.
- **reason** - The reason for the current state of the instance (for example,
shows “User Initiated [date]” when you stop or terminate the instance). Similar to the state-reason-code filter.

- requester-id - The ID of the entity that launched the instance on your behalf (for example, AWS Management Console, Auto Scaling, and so on).

- reservation-id - The ID of the instance’s reservation. A reservation ID is created any time you launch an instance. A reservation ID has a one-to-one relationship with an instance launch request, but can be associated with more than one instance if you launch multiple instances using the same launch request. For example, if you launch one instance, you’ll get one reservation ID. If you launch ten instances using the same launch request, you’ll also get one reservation ID.

- root-device-name - The name of the root device for the instance (for example, /dev/sda1 or /dev/xvda).

- root-device-type - The type of root device that the instance uses (ebs | instance-store).

- source-dest-check - Indicates whether the instance performs source/destination checking. A value of true means that checking is enabled, and false means checking is disabled. The value must be false for the instance to perform network address translation (NAT) in your VPC.

- spot-instance-request-id - The ID of the Spot Instance request.

- state-reason-code - The reason code for the state change.

- state-reason-message - A message that describes the state change.

- subnet-id - The ID of the subnet for the instance.

- tag : key = value* - The key/value combination of a tag assigned to the resource, where tag : key is the tag’s key.

- tag-key - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag : key = value* filter.

- tag-value - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.

- tenancy - The tenancy of an instance (dedicated | default).

- virtualization-type - The virtualization type of the instance (paravirtual | hvm).

- vpc-id - The ID of the VPC that the instance is running in.

- network-interface.description - The description of the network interface.

- network-interface.subnet-id - The ID of the subnet for the network interface.

- network-interface.vpc-id - The ID of the VPC for the network interface.

- network-interface.network-interface.id - The ID of the network interface.

- network-interface.owner-id - The ID of the owner of the network interface.

- network-interface.availability-zone - The Availability Zone for the network interface.

- network-interface.requester-id - The requester ID for the network interface.

- network-interface.requester-managed - Indicates whether
the network interface is being managed by AWS.

- **network-interface.status** - The status of the network interface (available) | in-use).
- **network-interface.mac-address** - The MAC address of the network interface.
- **network-interface.private-dns-name** - The private DNS name of the network interface.
- **network-interface.source-dest-check** - Whether the network interface performs source/destination checking. A value of true means checking is enabled, and false means checking is disabled. The value must be false for the network interface to perform network address translation (NAT) in your VPC.
- **network-interface.group-id** - The ID of a security group associated with the network interface.
- **network-interface.group-name** - The name of a security group associated with the network interface.
- **network-interface.attachment.attachment-id** - The ID of the interface attachment.
- **network-interface.attachment.instance-id** - The ID of the instance to which the network interface is attached.
- **network-interface.attachment.instance-owner-id** - The owner ID of the instance to which the network interface is attached.
- **network-interface.addresses.private-ip-address** - The private IP address associated with the network interface.
- **network-interface.attachment.device-index** - The device index to which the network interface is attached.
- **network-interface.attachment.status** - The status of the attachment (attaching | attached | detaching | detached).
- **network-interface.attachment.attach-time** - The time that the network interface was attached to an instance.
- **network-interface.attachment.delete-on-termination** - Specifies whether the attachment is deleted when an instance is terminated.
- **network-interface.addresses.primary** - Specifies whether the IP address of the network interface is the primary private IP address.
- **network-interface.addresses.association.public-ip** - The ID of the association of an Elastic IP address with a network interface.
- **network-interface.addresses.association.ip-owner-id** - The owner ID of the private IP address associated with the network interface.
- **association.public-ip** - The address of the Elastic IP address bound to the network interface.
- **association.ip-owner-id** - The owner of the Elastic IP address associated with the network interface.
- **association.allocation-id** - The allocation ID returned when you allocated the Elastic IP address for your network interface.
- **association.association-id** - The association ID returned when the network interface was associated with an IP address.

- **(dict)** -

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
* Name *(string)* —
  The name of the filter. Filter names are case-sensitive.
* Values *(list)* —
  One or more filter values. Filter values are case-sensitive.
  · *(string)* —
  · NextToken *(string)* — The token to request the next page of results.
  · MaxResults *(integer)* — The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. You cannot specify this parameter and the instance IDs parameter in the same request.

Returns None

**wait_until_running(****kwargs**

Waits until this Instance is running. This method calls EC2.Waiter.instance_running.wait() which polls EC2.Client.describe_instances() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

```
instance.wait_until_running(
    DryRun=True|False,
    Filters=[
        {
            'Name': 'string',
            'Values': [ 'string',
            ]
        },
    ],
    NextToken='string',
    MaxResults=123
)
```

Parameters

• **DryRun** *(boolean)* — Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

• **Filters** *(list)* — One or more filters.
  — architecture - The instance architecture (i386|x86_64).
  — availability-zone - The Availability Zone of the instance.
  — block-device-mapping.attach-time - The attach time for an EBS volume mapped to the instance, for example, 2010-09-15T17:15:20.000Z.
  — block-device-mapping.delete-on-termination - A Boolean that indicates whether the EBS volume is deleted on instance termination.
  — block-device-mapping.device-name - The device name for the EBS volume (for example, /dev/sdh or xvdh).
  — block-device-mapping.status - The status for the EBS volume (attaching|attached|detaching|detached).
  — block-device-mapping.volume-id - The volume ID of the EBS volume.
ID is created any time you launch an instance. A reservation ID has a one-to-one relationship with an instance launch request, but can be associated with more than one instance if you launch multiple instances using the same launch request. For example, if you launch one instance, you’ll get one reservation ID. If you launch ten instances using the same launch request, you’ll also get one reservation ID.

- **root-device-name** - The name of the root device for the instance (for example, /dev/sda1 or /dev/xvda).
- **root-device-type** - The type of root device that the instance uses (ebs | instance-store).
- **source-dest-check** - Indicates whether the instance performs source/destination checking. A value of true means that checking is enabled, and false means checking is disabled. The value must be false for the instance to perform network address translation (NAT) in your VPC.
- **spot-instance-request-id** - The ID of the Spot Instance request.
- **state-reason-code** - The reason code for the state change.
- **state-reason-message** - A message that describes the state change.
- **subnet-id** - The ID of the subnet for the instance.
- **tag :key =*value* - The key/value combination of a tag assigned to the resource, where tag :key is the tag’s key.
- **tag-key** - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key =*value* filter.
- **tag-value** - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- **tenancy** - The tenancy of an instance (dedicated | default).
- **virtualization-type** - The virtualization type of the instance (paravirtual | hvm).
- **vpc-id** - The ID of the VPC that the instance is running in.
- **network-interface.description** - The description of the network interface.
- **network-interface.subnet-id** - The ID of the subnet for the network interface.
- **network-interface.vpc-id** - The ID of the VPC for the network interface.
- **network-interface.network-interface.id** - The ID of the network interface.
- **network-interface.owner-id** - The ID of the owner of the network interface.
- **network-interface.availability-zone** - The Availability Zone for the network interface.
- **network-interface.requester-id** - The requester ID for the network interface.
- **network-interface.requester-managed** - Indicates whether the network interface is being managed by AWS.
- **network-interface.status** - The status of the network interface (available | in-use).
- **network-interface.mac-address** - The MAC address of the network interface.
- **network-interface-private-dns-name** - The private DNS
name of the network interface.

- `network-interface.source-dest-check` - Whether the network interface performs source/destination checking. A value of `true` means checking is enabled, and `false` means checking is disabled. The value must be `false` for the network interface to perform network address translation (NAT) in your VPC.

- `network-interface.group-id` - The ID of a security group associated with the network interface.

- `network-interface.group-name` - The name of a security group associated with the network interface.

- `network-interface.attachment.attachment-id` - The ID of the interface attachment.

- `network-interface.attachment.instance-id` - The ID of the instance to which the network interface is attached.

- `network-interface.attachment.instance-owner-id` - The owner ID of the instance to which the network interface is attached.

- `network-interface.addresses.private-ip-address` - The private IP address associated with the network interface.

- `network-interface.attachment.device-index` - The device index to which the network interface is attached.

- `network-interface.attachment.status` - The status of the attachment (`attaching` | `attached` | `detaching` | `detached`).

- `network-interface.attachment.attach-time` - The time that the network interface was attached to an instance.

- `network-interface.attachment.delete-on-termination` - Specifies whether the attachment is deleted when an instance is terminated.

- `network-interface.addresses.primary` - Specifies whether the IP address of the network interface is the primary private IP address.

- `network-interface.addresses.association.public-ip` - The ID of the association of an Elastic IP address with a network interface.

- `network-interface.addresses.association.ip-owner-id` - The owner ID of the private IP address associated with the network interface.

- `association.public-ip` - The address of the Elastic IP address bound to the network interface.

- `association.ip-owner-id` - The owner of the Elastic IP address associated with the network interface.

- `association.allocation-id` - The allocation ID returned when you allocated the Elastic IP address for your network interface.

- `association.association-id` - The association ID returned when the network interface was associated with an IP address.

- `(dict)` -

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

- `Name (string)` -
  The name of the filter. Filter names are case-sensitive.

- `Values (list)` -
  One or more filter values. Filter values are case-sensitive.

  - `(string)` -
**NextToken (string)** – The token to request the next page of results.

**MaxResults (integer)** – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned **NextToken** value. This value can be between 5 and 1000; if **MaxResults** is given a value larger than 1000, only 1000 results are returned. You cannot specify this parameter and the instance IDs parameter in the same request.

**Returns** None

**wait_until_stopped(**kwargs**)**

Waits until this Instance is stopped. This method calls EC2.Waiter.instance_stopped.wait() which polls. EC2.Client.describe_instances() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

**Request Syntax**

```python
instance.wait_until_stopped(
    DryRun=True|False,
    Filters=[
        
        'Name': 'string',
        'Values': [ 'string',
                    ],
        ],
    NextToken='string',
    MaxResults=123
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **Filters (list)** – One or more filters.
  - architecture - The instance architecture (i386|x86_64).
  - availability-zone - The Availability Zone of the instance.
  - block-device-mapping.attach-time - The attach time for an EBS volume mapped to the instance, for example, 2010-09-15T17:15:20.000Z.
  - block-device-mapping.delete-on-termination - A Boolean that indicates whether the EBS volume is deleted on instance termination.
  - block-device-mapping.device-name - The device name for the EBS volume (for example, /dev/sdh or xvdh).
  - block-device-mapping.status - The status for the EBS volume (attaching|attached|detaching|detached).
  - block-device-mapping.volume-id - The volume ID of the EBS volume.
  - client-token - The idempotency token you provided when you launched the instance.
  - dns-name - The public DNS name of the instance.
  - group-id - The ID of the security group for the instance. EC2-Classic only.
- **group-name** - The name of the security group for the instance. EC2-
  Classic only.
- **hypervisor** - The hypervisor type of the instance (ovm | xen).
- **iam-instance-profile.arn** - The instance profile associated with
  the instance. Specified as an ARN.
- **image-id** - The ID of the image used to launch the instance.
- **instance-id** - The ID of the instance.
- **instance-lifecycle** - Indicates whether this is a Spot Instance
  (spot).
- **instance-state-code** - The state of the instance, as a 16-bit un-
  signed integer. The high byte is an opaque internal value and should be
  ignored. The low byte is set based on the state represented. The valid val-
  ues are: 0 (pending), 16 (running), 32 (shutting-down), 48 (terminated),
  64 (stopping), and 80 (stopped).
- **instance-state-name** - The state of the instance (pending | run-
  ning | shutting-down | terminated | stopping | stopped).
- **instance-type** - The type of instance (for example, t2.micro).
- **instance.group-id** - The ID of the security group for the instance.
- **instance.group-name** - The name of the security group for the in-
  stance.
- **ip-address** - The public IP address of the instance.
- **kernel-id** - The kernel ID.
- **key-name** - The name of the key pair used when the instance was
  launched.
- **launch-index** - When launching multiple instances, this is the index
  for the instance in the launch group (for example, 0, 1, 2, and so on).
- **launch-time** - The time when the instance was launched.
- **monitoring-state** - Indicates whether monitoring is enabled for the
  instance (disabled | enabled).
- **owner-id** - The AWS account ID of the instance owner.
- **placement-group-name** - The name of the placement group for the
  instance.
- **platform** - The platform. Use windows if you have Windows in-
  stances; otherwise, leave blank.
- **private-dns-name** - The private DNS name of the instance.
- **private-ip-address** - The private IP address of the instance.
- **product-code** - The product code associated with the AMI used to
  launch the instance.
- **product-code.type** - The type of product code (devpay | mark
  etspace).
- **ramdisk-id** - The RAM disk ID.
- **reason** - The reason for the current state of the instance (for example,
  shows “User Initiated [date]” when you stop or terminate the instance).
  Similar to the state-reason-code filter.
- **requester-id** - The ID of the entity that launched the instance on
  your behalf (for example, AWS Management Console, Auto Scaling, and
  so on).
- **reservation-id** - The ID of the instance’s reservation. A reservation
  ID is created any time you launch an instance. A reservation ID has a
  one-to-one relationship with an instance launch request, but can be asso-
  ciated with more than one instance if you launch multiple instances using
  the same launch request. For example, if you launch one instance, you’ll
  get one reservation ID. If you launch ten instances using the same launch
request, you’ll also get one reservation ID.

- **root-device-name** - The name of the root device for the instance (for example, `/dev/sdal` or `/dev/xvda`).
- **root-device-type** - The type of root device that the instance uses (ebs|instance-store).
- **source-dest-check** - Indicates whether the instance performs source/destination checking. A value of `true` means that checking is enabled, and `false` means checking is disabled. The value must be `false` for the instance to perform network address translation (NAT) in your VPC.
- **spot-instance-request-id** - The ID of the Spot Instance request.
- **state-reason-code** - The reason code for the state change.
- **state-reason-message** - A message that describes the state change.
- **subnet-id** - The ID of the subnet for the instance.
- **tag :key ="value"** - The key/value combination of a tag assigned to the resource, where `tag :key` is the tag’s key.
- **tag-key** - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key ="value" filter.
- **tag-value** - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- **tenancy** - The tenancy of an instance (dedicated|default).
- **virtualization-type** - The virtualization type of the instance (paravirtual|hvm).
- **vpc-id** - The ID of the VPC that the instance is running in.
- **network-interface.description** - The description of the network interface.
- **network-interface.subnet-id** - The ID of the subnet for the network interface.
- **network-interface.vpc-id** - The ID of the VPC for the network interface.
- **network-interface.network-interface.id** - The ID of the network interface.
- **network-interface.owner-id** - The ID of the owner of the network interface.
- **network-interface.availability-zone** - The Availability Zone for the network interface.
- **network-interface.requester-id** - The requester ID for the network interface.
- **network-interface.requester-managed** - Indicates whether the network interface is being managed by AWS.
- **network-interface.status** - The status of the network interface (available|in-use).
- **network-interface.mac-address** - The MAC address of the network interface.
- **network-interface-private-dns-name** - The private DNS name of the network interface.
- **network-interface.source-dest-check** - Whether the network interface performs source/destination checking. A value of `true` means checking is enabled, and `false` means checking is disabled. The value must be `false` for the network interface to perform network ad-
dress translation (NAT) in your VPC.

- `network-interface.group-id` - The ID of a security group associated with the network interface.
- `network-interface.group-name` - The name of a security group associated with the network interface.
- `network-interface.attachment.attachment-id` - The ID of the interface attachment.
- `network-interface.attachment.instance-id` - The ID of the instance to which the network interface is attached.
- `network-interface.attachment.instance-owner-id` - The owner ID of the instance to which the network interface is attached.
- `network-interface.addresses.private-ip-address` - The private IP address associated with the network interface.
- `network-interface.attachment.device-index` - The device index to which the network interface is attached.
- `network-interface.attachment.status` - The status of the attachment (attaching | attached | detaching | detached).
- `network-interface.attachment.attach-time` - The time that the network interface was attached to an instance.
- `network-interface.attachment.delete-on-termination` - Specifies whether the attachment is deleted when an instance is terminated.
- `network-interface.addresses.primary` - Specifies whether the IP address of the network interface is the primary private IP address.
- `network-interface.addresses.association.public-ip` - The ID of the association of an Elastic IP address with a network interface.
- `network-interface.addresses.association.ip-owner-id` - The owner ID of the private IP address associated with the network interface.
- `association.public-ip` - The address of the Elastic IP address bound to the network interface.
- `association.ip-owner-id` - The owner of the Elastic IP address associated with the network interface.
- `associationallocation-id` - The allocation ID returned when you allocated the Elastic IP address for your network interface.
- `association.association-id` - The association ID returned when the network interface was associated with an IP address.

- `(dict)`

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* **Name** *(string)* –
  The name of the filter. Filter names are case-sensitive.

* **Values** *(list)* –
  One or more filter values. Filter values are case-sensitive.

  - *(string)*

• **NextToken** *(string)* – The token to request the next page of results.
• **MaxResults** *(integer)* – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only
1000 results are returned. You cannot specify this parameter and the instance IDs parameter in the same request.

Returns None

```python
wait_until_terminated(**kwargs)
```

Waits until this Instance is terminated. This method calls EC2.Waiter.instance_terminated.wait() which polls EC2.Client.describe_instances() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

```python
instance.wait_until_terminated(
    DryRun=True|False,
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ],
    NextToken='string',
    MaxResults=123
)
```

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **Filters** (list) – One or more filters.
  - architecture - The instance architecture (i386|x86_64).
  - availability-zone - The Availability Zone of the instance.
  - block-device-mapping.attach-time - The attach time for an EBS volume mapped to the instance, for example, 2010-09-15T17:15:20.000Z.
  - block-device-mapping.delete-on-termination - A Boolean that indicates whether the EBS volume is deleted on instance termination.
  - block-device-mapping.device-name - The device name for the EBS volume (for example, /dev/sdh or xvdh).
  - block-device-mapping.status - The status for the EBS volume (attaching|attached|detaching|detached).
  - block-device-mapping.volume-id - The volume ID of the EBS volume.
  - client-token - The idempotency token you provided when you launched the instance.
  - dns-name - The public DNS name of the instance.
  - group-id - The ID of the security group for the instance. EC2-Classic only.
  - group-name - The name of the security group for the instance. EC2-Classic only.
  - hypervisor - The hypervisor type of the instance (ovm|xen).
  - iam-instance-profile.arn - The instance profile associated with the instance. Specified as an ARN.
  - image-id - The ID of the image used to launch the instance.
- **instance-id** - The ID of the instance.
- **instance-lifecycle** - Indicates whether this is a Spot Instance (spot).
- **instance-state-code** - The state of the instance, as a 16-bit unsigned integer. The high byte is an opaque internal value and should be ignored. The low byte is set based on the state represented. The valid values are: 0 (pending), 16 (running), 32 (shutting-down), 48 (terminated), 64 (stopping), and 80 (stopped).
- **instance-state-name** - The state of the instance (pending | running | shutting-down | terminated | stopping | stopped).
- **instance-type** - The type of instance (for example, t2.micro).
- **instance.group-id** - The ID of the security group for the instance.
- **instance.group-name** - The name of the security group for the instance.
- **ip-address** - The public IP address of the instance.
- **kernel-id** - The kernel ID.
- **key-name** - The name of the key pair used when the instance was launched.
- **launch-index** - When launching multiple instances, this is the index for the instance in the launch group (for example, 0, 1, 2, and so on).
- **launch-time** - The time when the instance was launched.
- **monitoring-state** - Indicates whether monitoring is enabled for the instance (disabled | enabled).
- **owner-id** - The AWS account ID of the instance owner.
- **placement-group-name** - The name of the placement group for the instance.
- **platform** - The platform. Use windows if you have Windows instances; otherwise, leave blank.
- **private-dns-name** - The private DNS name of the instance.
- **private-ip-address** - The private IP address of the instance.
- **product-code** - The product code associated with the AMI used to launch the instance.
- **product-code.type** - The type of product code (devpay | marketplace).
- **ramdisk-id** - The RAM disk ID.
- **reason** - The reason for the current state of the instance (for example, shows “User Initiated [date]” when you stop or terminate the instance). Similar to the state-reason-code filter.
- **requester-id** - The ID of the entity that launched the instance on your behalf (for example, AWS Management Console, Auto Scaling, and so on).
- **reservation-id** - The ID of the instance’s reservation. A reservation ID is created any time you launch an instance. A reservation ID has a one-to-one relationship with an instance launch request, but can be associated with more than one instance if you launch multiple instances using the same launch request. For example, if you launch one instance, you’ll get one reservation ID. If you launch ten instances using the same launch request, you’ll also get one reservation ID.
- **root-device-name** - The name of the root device for the instance (for example, /dev/sda1 or /dev/xvda).
- **root-device-type** - The type of root device that the instance uses (ebs | instance-store).
- **source-dest-check** - Indicates whether the instance performs
source/destination checking. A value of true means that checking is enabled, and false means checking is disabled. The value must be false for the instance to perform network address translation (NAT) in your VPC.

- spot-instance-request-id - The ID of the Spot Instance request.
- state-reason-code - The reason code for the state change.
- state-reason-message - A message that describes the state change.
- subnet-id - The ID of the subnet for the instance.
- tag :key = "value" - The key/value combination of a tag assigned to the resource, where tag :key is the tag’s key.
- tag-key - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the tag :key = "value" filter.
- tag-value - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
- tenancy - The tenancy of an instance (dedicated | default).
- virtualization-type - The virtualization type of the instance (paravirtual | hvm).
- vpc-id - The ID of the VPC that the instance is running in.
- network-interface.description - The description of the network interface.
- network-interface.subnet-id - The ID of the subnet for the network interface.
- network-interface.vpc-id - The ID of the VPC for the network interface.
- network-interface.network-interface.id - The ID of the network interface.
- network-interface.owner-id - The ID of the owner of the network interface.
- network-interface.availability-zone - The Availability Zone for the network interface.
- network-interface.requester-id - The requester ID for the network interface.
- network-interface.requester-managed - Indicates whether the network interface is being managed by AWS.
- network-interface.status - The status of the network interface (available | in-use).
- network-interface.mac-address - The MAC address of the network interface.
- network-interface-private-dns-name - The private DNS name of the network interface.
- network-interface-source-dest-check - Whether the network interface performs source/destination checking. A value of true means checking is enabled, and false means checking is disabled. The value must be false for the network interface to perform network address translation (NAT) in your VPC.
- network-interface-group-id - The ID of a security group associated with the network interface.
- network-interface-group-name - The name of a security group associated with the network interface.
- network-interface-attachment.attachment-id - The ID
of the interface attachment.

- `network-interface.attachment.instance-id` - The ID of the instance to which the network interface is attached.

- `network-interface.attachment.instance-owner-id` - The owner ID of the instance to which the network interface is attached.

- `network-interface.addresses.private-ip-address` - The private IP address associated with the network interface.

- `network-interface.attachment.device-index` - The device index to which the network interface is attached.

- `network-interface.attachment.status` - The status of the attachment (`attaching` | `attached` | `detaching` | `detached`).

- `network-interface.attachment.attach-time` - The time that the network interface was attached to an instance.

- `network-interface.attachment.delete-on-termination` - Specifies whether the attachment is deleted when an instance is terminated.

- `network-interface.addresses.primary` - Specifies whether the IP address of the network interface is the primary private IP address.

- `network-interface.addresses.association.public-ip` - The ID of the association of an Elastic IP address with a network interface.

- `network-interface.addresses.association.ip-owner-id` - The owner ID of the private IP address associated with the network interface.

- `association.public-ip` - The address of the Elastic IP address bound to the network interface.

- `association.ip-owner-id` - The owner of the Elastic IP address associated with the network interface.

- `association.allocation-id` - The allocation ID returned when you allocated the Elastic IP address for your network interface.

- `association.association-id` - The association ID returned when the network interface was associated with an IP address.

- `(dict)` —

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* **Name** *(string)* –

  The name of the filter. Filter names are case-sensitive.

* **Values** *(list)* –

  One or more filter values. Filter values are case-sensitive.

  - *(string)* –

  * **NextToken** *(string)* – The token to request the next page of results.

  * **MaxResults** *(integer)* – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned `NextToken` value. This value can be between 5 and 1000; if `MaxResults` is given a value larger than 1000, only 1000 results are returned. You cannot specify this parameter and the instance IDs parameter in the same request.

**Returns** None
InternetGateway

class EC2.InternetGateway(id)
A resource representing an Amazon Elastic Compute Cloud (EC2) InternetGateway:

    import boto3

ec2 = boto3.resource('ec2')
internet_gateway = ec2.InternetGateway('id')

Parameters id (string) – The InternetGateway’s id identifier. This must be set.

These are the resource’s available identifiers:
    • id
These are the resource’s available attributes:
    • attachments
    • internet_gateway_id
    • tags
These are the resource’s available actions:
    • attach_to_vpc()
    • create_tags()
    • delete()
    • detach_from_vpc()
    • load()
    • reload()

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

id
    (string) The InternetGateway’s id identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

attachments
    (list)
Any VPCs attached to the Internet gateway.

internet_gateway_id
    (string)
The ID of the Internet gateway.

tags
    (list)
Any tags assigned to the Internet gateway.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

attach_to_vpc(**kwargs)
Attaches an Internet gateway to a VPC, enabling connectivity between the Internet and the VPC. For more information about your VPC and Internet gateway, see the Amazon Virtual Private Cloud User Guide.
Request Syntax

```python
response = internet_gateway.attach_to_vpc(
    DryRun=True|False,
    VpcId='string'
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **VpcId** *(string)* – [REQUIRED]
  
  The ID of the VPC.

Returns

None

create_tags(**kwargs)**

Adds or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each resource can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys must be unique per resource.

For more information about tags, see Tagging Your Resources in the *Amazon Elastic Compute Cloud User Guide*.

Request Syntax

```python
tag = internet_gateway.create_tags(
    DryRun=True|False,
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **Tags** *(list)* – [REQUIRED]
  
  One or more tags. The `value` parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.

  - *(dict)* – Describes a tag.

    - **Key** *(string)* – The key of the tag.

      Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws`:

    - **Value** *(string)* – The value of the tag.
Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

Return type list(ec2.Tag)

Returns A list of Tag resources

delete(**kwargs)

Deletes the specified Internet gateway. You must detach the Internet gateway from the VPC before you can delete it.

Request Syntax

def delete(**kwargs):
    return ec2.InternetGateway().delete(**kwargs)

Parameters

- DryRun (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

Returns None

detach_from_vpc(**kwargs)

Detaches an Internet gateway from a VPC, disabling connectivity between the Internet and the VPC. The VPC must not contain any running instances with Elastic IP addresses.

Request Syntax

def detach_from_vpc(**kwargs):
    return ec2.InternetGateway().detach_from_vpc(**kwargs)

Parameters

- DryRun (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- VpcId (string) – [REQUIRED]

Returns None

load()

Calls ec2.Client.describe_internet_gateways() to update the attributes of the Internet-Gateway resource

Request Syntax

internet_gateway.load()

Returns None

reload()

Calls ec2.Client.describe_internet_gateways() to update the attributes of the Internet-Gateway resource

Request Syntax
internet_gateway.reload()

Returns None

KeyPair
class EC2.KeyPair(name)
    A resource representing an Amazon Elastic Compute Cloud (EC2) KeyPair:

    import boto3

    ec2 = boto3.resource('ec2')
    key_pair = ec2.KeyPair('name')

    Parameters name (string) -- The KeyPair's name identifier. This must be set.

These are the resource's available identifiers:
    *name
These are the resource's available attributes:
    *key_fingerprint
    *key_name
These are the resource's available actions:
    *delete()
    *load()
    *reload()

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

name  
(string) The KeyPair's name identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

key_fingerprint
    (string)

    If you used CreateKeyPair to create the key pair, this is the SHA-1 digest of the DER encoded private key. If you used ImportKeyPair to provide AWS the public key, this is the MD5 public key fingerprint as specified in section 4 of RFC4716.

key_name
    (string)

    The name of the key pair.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

delete (**kwargs)
    Deletes the specified key pair, by removing the public key from Amazon EC2.

Request Syntax
response = key_pair.delete(
    DryRun=True|False,
)

**Parameters**  
**DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Returns**  
None

### load()
Calls `ec2.Client.describe_key_pairs()` to update the attributes of the KeyPair resource.

**Request Syntax**

```python
key_pair.load()
```

**Returns**  
None

### reload()
Calls `ec2.Client.describe_key_pairs()` to update the attributes of the KeyPair resource.

**Request Syntax**

```python
key_pair.reload()
```

**Returns**  
None

### NetworkAcl
class EC2.NetworkAcl(id)

A resource representing an Amazon Elastic Compute Cloud (EC2) NetworkAcl:

```python
import boto3

ec2 = boto3.resource('ec2')
network_acl = ec2.NetworkAcl('id')
```

**Parameters**  
**id** *(string)* – The NetworkAcl’s id identifier. This must be set.

These are the resource’s available identifiers:

• **id**

These are the resource’s available attributes:

• **associations**
• **entries**
• **is_default**
• **network_acl_id**
• **tags**
• **vpc_id**

These are the resource’s available references:

• **vpc**

These are the resource’s available actions:

• **create_entry()**
• **create_tags()**
• **delete()**
Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide*.

**id**
(string) The NetworkAcl's id identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the *Resources Introduction Guide*.

**associations**
(list)
Any associations between the network ACL and one or more subnets

**entries**
(list)
One or more entries (rules) in the network ACL.

**is_default**
(boolean)
Indicates whether this is the default network ACL for the VPC.

**network_acl_id**
(string)
The ID of the network ACL.

**tags**
(list)
Any tags assigned to the network ACL.

**vpc_id**
(string)
The ID of the VPC for the network ACL.

References

References are related resource instances that have a belongs-to relationship. For more information about references refer to the *Resources Introduction Guide*.

**vpc**
(Vpc) The related vpc if set, otherwise **None**.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide*.

**create_entry**(**kwargs**)
Creates an entry (a rule) in a network ACL with the specified rule number. Each network ACL has a set of numbered ingress rules and a separate set of numbered egress rules. When determining whether a packet should be allowed in or out of a subnet associated with the ACL, we process the entries in the
ACL according to the rule numbers, in ascending order. Each network ACL has a set of ingress rules and a separate set of egress rules.

We recommend that you leave room between the rule numbers (for example, 100, 110, 120, ...), and not number them one right after the other (for example, 101, 102, 103, ...). This makes it easier to add a rule between existing ones without having to renumber the rules.

After you add an entry, you can’t modify it; you must either replace it, or create an entry and delete the old one.

For more information about network ACLs, see Network ACLs in the Amazon Virtual Private Cloud User Guide.

Request Syntax

```python
response = network_acl.create_entry(
    DryRun=True|False,
    RuleNumber=123,
    Protocol='string',
    RuleAction='allow'|'deny',
    Egress=True|False,
    CidrBlock='string',
    IcmpTypeCode={
        'Type': 123,
        'Code': 123
    },
    PortRange={
        'From': 123,
        'To': 123
    }
)
```

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **RuleNumber (integer)** – [REQUIRED]

  The rule number for the entry (for example, 100). ACL entries are processed in ascending order by rule number.

  Constraints: Positive integer from 1 to 32766
- **Protocol (string)** – [REQUIRED]

  The protocol. A value of -1 means all protocols.
- **RuleAction (string)** – [REQUIRED]

  Indicates whether to allow or deny the traffic that matches the rule.
- **Egress (boolean)** – [REQUIRED]

  Indicates whether this is an egress rule (rule is applied to traffic leaving the subnet).
- **CidrBlock (string)** – [REQUIRED]

  The network range to allow or deny, in CIDR notation (for example 172.16.0.0/24).
- **IcmpTypeCode (dict)** – ICMP protocol: The ICMP type and code. Required if specifying ICMP for the protocol.
- **Type** (integer) –
  The ICMP code. A value of -1 means all codes for the specified ICMP type.
- **Code** (integer) –
  The ICMP type. A value of -1 means all types.

- **PortRange** (dict) – TCP or UDP protocols: The range of ports the rule applies to.
  - **From** (integer) –
    The first port in the range.
  - **To** (integer) –
    The last port in the range.

**Returns** None

**create_tags** (**kwargs)**

Add or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each resource can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys must be unique per resource.

For more information about tags, see Tagging Your Resources in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
tag = network_acl.create_tags(
    DryRun=True|False,
    Tags=[
        {'Key': 'string',
         'Value': 'string'}
    ]
)
```

**Parameters**

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.
- **Tags** ([list]) – [REQUIRED]

  One or more tags. The **value** parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.

  - **(dict)** –

    Describes a tag.
    - **Key** (string) –
      The key of the tag.

      Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws`:
    - **Value** (string) –
      The value of the tag.
Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

**Return type** list(ec2.Tag)

**Returns** A list of Tag resources

### delete (**kwargs)

Deletes the specified network ACL. You can’t delete the ACL if it’s associated with any subnets. You can’t delete the default network ACL.

**Request Syntax**

```python
response = network_acl.delete(
    DryRun=True|False,
)
```

**Parameters**

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

**Returns** None

### delete_entry (**kwargs)

Deletes the specified ingress or egress entry (rule) from the specified network ACL.

**Request Syntax**

```python
response = network_acl.delete_entry(
    DryRun=True|False,
    RuleNumber=123,
    Egress=True|False
)
```

**Parameters**

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **RuleNumber** (integer) – [REQUIRED]
  
  The rule number of the entry to delete.

- **Egress** (boolean) – [REQUIRED]
  
  Indicates whether the rule is an egress rule.

**Returns** None

### load()

Calls ec2.Client.describe_network_acls() to update the attributes of the NetworkAcl resource.

**Request Syntax**

```python
network_acl.load()
```

**Returns** None

### reload()

Calls ec2.Client.describe_network_acls() to update the attributes of the NetworkAcl resource.
replace_association(**kwargs)
Changes which network ACL a subnet is associated with. By default when you create a subnet, it’s automatically associated with the default network ACL. For more information about network ACLs, see Network ACLs in the Amazon Virtual Private Cloud User Guide.

Request Syntax

response = network_acl.replace_association(
    DryRun=True|False,
    AssociationId='string',
)

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **AssociationId** *(string)* – [REQUIRED]
The ID of the current association between the original network ACL and the subnet.

Return type: dict

Returns

Response Syntax

{
    'NewAssociationId': 'string'
}

Response Structure

- *(dict)* –
  - **NewAssociationId** *(string)* –
    The ID of the new association.

replace_entry(**kwargs)
Replaces an entry (rule) in a network ACL. For more information about network ACLs, see Network ACLs in the Amazon Virtual Private Cloud User Guide.

Request Syntax

response = network_acl.replace_entry(
    DryRun=True|False,
    RuleNumber=123,
    Protocol='string',
    RuleAction='allow'|'deny',
    Egress=True|False,
    CidrBlock='string',
    IcmpTypeCode={
        'Type': 123,
        'Code': 123
    }
)
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **RuleNumber** *(integer)* – [REQUIRED]
  The rule number of the entry to replace.
- **Protocol** *(string)* – [REQUIRED]
  The IP protocol. You can specify `all` or `-1` to mean all protocols.
- **RuleAction** *(string)* – [REQUIRED]
  Indicates whether to allow or deny the traffic that matches the rule.
- **Egress** *(boolean)* – [REQUIRED]
  Indicates whether to replace the egress rule.
  Default: If no value is specified, we replace the ingress rule.
- **CidrBlock** *(string)* – [REQUIRED]
  The network range to allow or deny, in CIDR notation.
- **IcmpTypeCode** *(dict)* – ICMP protocol: The ICMP type and code. Required if specifying 1 (ICMP) for the protocol.
  - **Type** *(integer)* –
    The ICMP code. A value of -1 means all codes for the specified ICMP type.
  - **Code** *(integer)* –
    The ICMP type. A value of -1 means all types.
- **PortRange** *(dict)* – TCP or UDP protocols: The range of ports the rule applies to. Required if specifying 6 (TCP) or 17 (UDP) for the protocol.
  - **From** *(integer)* –
    The first port in the range.
  - **To** *(integer)* –
    The last port in the range.

Returns None

NetworkInterface

class **EC2.NetworkInterface**(id)

A resource representing an Amazon Elastic Compute Cloud (EC2) NetworkInterface:

```python
import boto3

ec2 = boto3.resource('ec2')
network_interface = ec2.NetworkInterface('id')
```

Parameters **id** *(string)* – The NetworkInterface’s id identifier. This must be set.
These are the resource’s available identifiers:

• **id**

These are the resource’s available attributes:

• **association**
• **attachment**
• **availability_zone**
• **description**
• **groups**
• **mac_address**
• **network_interface_id**
• **owner_id**
• **private_dns_name**
• **private_ip_address**
• **private_ip_addresses**
• **requester_id**
• **requester_managed**
• **source_dest_check**
• **status**
• **subnet_id**
• **tag_set**
• **vpc_id**

These are the resource’s available references:

• **subnet**
• **vpc**

These are the resource’s available actions:

• **assign_private_ip_addresses()**
• **attach()**
• **create_tags()**
• **delete()**
• **describe_attribute()**
• **detach()**
• **load()**
• **modify_attribute()**
• **reload()**
• **reset_attribute()**
• **unassign_private_ip_addresses()**

**Identifiers**

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide*.

**id**

*string* The NetworkInterface’s id identifier. This **must** be set.

**Attributes**

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the **load()** method. For more information about attributes refer to the *Resources Introduction Guide*.

**association**

*dict*

The association information for an Elastic IP associated with the network interface.

**attachment**

*dict*

The network interface attachment.
availability_zone
  (string)
  The Availability Zone.

description
  (string)
  A description.

groups
  (list)
  Any security groups for the network interface.

mac_address
  (string)
  The MAC address.

network_interface_id
  (string)
  The ID of the network interface.

owner_id
  (string)
  The AWS account ID of the owner of the network interface.

private_dns_name
  (string)
  The private DNS name.

private_ip_address
  (string)
  The IP address of the network interface within the subnet.

private_ip_addresses
  (list)
  The private IP addresses associated with the network interface.

requester_id
  (string)
  The ID of the entity that launched the instance on your behalf (for example, AWS Management Console or Auto Scaling).

requester_managed
  (boolean)
  Indicates whether the network interface is being managed by AWS.

source_dest_check
  (boolean)
  Indicates whether traffic to or from the instance is validated.

status
  (string)
  The status of the network interface.
subnet_id
(string)
The ID of the subnet.

tag_set
(list)
Any tags assigned to the network interface.
vpc_id
(string)
The ID of the VPC.

References
References are related resource instances that have a belongs-to relationship. For more information about references refer to the Resources Introduction Guide.

subnet
(Subnet) The related subnet if set, otherwise None.
vpc
(Vpc) The related vpc if set, otherwise None.

Actions
Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

assign_private_ip_addresses(**kwargs)
Assigns one or more secondary private IP addresses to the specified network interface. You can specify one or more specific secondary IP addresses, or you can specify the number of secondary IP addresses to be automatically assigned within the subnet’s CIDR block range. The number of secondary IP addresses that you can assign to an instance varies by instance type. For information about instance types, see Instance Types in the Amazon Elastic Compute Cloud User Guide. For more information about Elastic IP addresses, see Elastic IP Addresses in the Amazon Elastic Compute Cloud User Guide.

AssignPrivateIpAddresses is available only in EC2-VPC.

Request Syntax
response = network_interface.assign_private_ip_addresses(
    PrivateIpAddresses=[
        'string',
    ],
    SecondaryPrivateIpAddressCount=123,
    AllowReassignment=True|False
)

Parameters
- PrivateIpAddresses (list) – One or more IP addresses to be assigned as a secondary private IP address to the network interface. You can’t specify this parameter when also specifying a number of secondary IP addresses.

  If you don’t specify an IP address, Amazon EC2 automatically selects an IP address within the subnet range.
  
  - (string) –

- SecondaryPrivateIpAddressCount (integer) – The number of secondary IP addresses to assign to the network interface. You can’t specify this parameter when also specifying private IP addresses.
• **AllowReassignment** (*boolean*) – Indicates whether to allow an IP address that is already assigned to another network interface or instance to be reassigned to the specified network interface.

Returns None

**attach** (**kwargs**)
Attaches a network interface to an instance.

Request Syntax

```python
response = network_interface.attach(
    DryRun=True|False,
    InstanceId='string',
    DeviceIndex=123
)
```

Parameters

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.
- **InstanceId** (*string*) – [REQUIRED]
The ID of the instance.
- **DeviceIndex** (*integer*) – [REQUIRED]
The index of the device for the network interface attachment.

Return type dict

Returns

Response Syntax

```python
{
    'AttachmentId': 'string'
}
```

Response Structure

- *(dict)* –
  - **AttachmentId** (*string*) –
    The ID of the network interface attachment.

**create_tags** (**kwargs**)
Adds or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each resource can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys must be unique per resource.

For more information about tags, see Tagging Your Resources in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
tag = network_interface.create_tags(
    DryRun=True|False,
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        }
    ]
)
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **Tags** *(list)* – [REQUIRED]

  One or more tags. The `value` parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.

  - *(dict)* –

    Describes a tag.
    
    * **Key** *(string)* –
      
      The key of the tag.
      
      Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`
    
    * **Value** *(string)* –
      
      The value of the tag.
      
      Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

**Return type**  list(ec2.Tag)

**Returns**  A list of Tag resources

**delete**(**kwargs**)

Deletes the specified network interface. You must detach the network interface before you can delete it.

**Request Syntax**

```python
response = network_interface.delete(
    DryRun=True|False,
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Returns**  None

**describe_attribute**(**kwargs**)

Describes a network interface attribute. You can specify only one attribute at a time.

**Request Syntax**

```python
response = network_interface.describe_attribute(
    DryRun=True|False,
    Attribute='description'|'groupSet'|'sourceDestCheck'|'attachment'
)
```

**Parameters**
- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **Attribute** (*string*) – The attribute of the network interface.

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'NetworkInterfaceId': 'string',
    'Description': {
        'Value': 'string'
    },
    'SourceDestCheck': {
        'Value': True|False
    },
    'Groups': [
        {
            'GroupName': 'string',
            'GroupId': 'string'
        }
    ],
    'Attachment': {
        'AttachmentId': 'string',
        'InstanceId': 'string',
        'InstanceOwnerId': 'string',
        'DeviceIndex': 123,
        'Status': 'attaching'|'attached'|'detaching'|'detached',
        'AttachTime': datetime(2015, 1, 1),
        'DeleteOnTermination': True|False
    }
}
```

**Response Structure**

- (*dict*)
  - **NetworkInterfaceId** (*string*) – The ID of the network interface.
  - **Description** (*dict*) – The description of the network interface.
    * **Value** (*string*) – Valid values are case-sensitive and vary by action.
  - **SourceDestCheck** (*dict*) – Indicates whether source/destination checking is enabled.
    * **Value** (*boolean*) – Valid values are true or false.
  - **Groups** (*list*) – The security groups associated with the network interface.
    * (*dict*)
      - Describes a security group.
        - **GroupName** (*string*) –
The name of the security group.

- **GroupId** *(string)* –
  The ID of the security group.

- **Attachment** *(dict)* –
  The attachment (if any) of the network interface.
  - **AttachmentId** *(string)* –
    The ID of the network interface attachment.
  - **InstanceId** *(string)* –
    The ID of the instance.
  - **InstanceOwnerId** *(string)* –
    The AWS account ID of the owner of the instance.
  - **DeviceIndex** *(integer)* –
    The device index of the network interface attachment on the instance.
  - **Status** *(string)* –
    The attachment state.
  - **AttachTime** *(datetime)* –
    The timestamp indicating when the attachment initiated.
  - **DeleteOnTermination** *(boolean)* –
    Indicates whether the network interface is deleted when the instance is terminated.

**detach** (**kwargs**)
Detaches a network interface from an instance.

**Request Syntax**

```python
response = network_interface.detach(
    DryRun=True|False,
    Force=True|False
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **Force** *(boolean)* – Specifies whether to force a detachment.

**Returns** None

**load** ()
Calls ec2.Client.describe_network_interfaces() to update the attributes of the Network-Interface resource

**Request Syntax**

```python
network_interface.load()
```

**Returns** None

**modify_attribute** (**kwargs**)
Modifies the specified network interface attribute. You can specify only one attribute at a time.
**Request Syntax**

```python
response = network_interface.modify_attribute(
    DryRun=True|False,
    Description={
        'Value': 'string'
    },
    SourceDestCheck={
        'Value': True|False
    },
    Groups=[
        'string',
    ],
    Attachment={
        'AttachmentId': 'string',
        'DeleteOnTermination': True|False
    }
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **Description** *(dict)* – A description for the network interface.
  - **Value** *(string)* – Valid values are case-sensitive and vary by action.
- **SourceDestCheck** *(dict)* – Indicates whether source/destination checking is enabled. A value of true means checking is enabled, and false means checking is disabled. This value must be false for a NAT instance to perform NAT. For more information, see NAT Instances in the Amazon Virtual Private Cloud User Guide.
  - **Value** *(boolean)* – Valid values are true or false.
- **Groups** *(list)* – Changes the security groups for the network interface. The new set of groups you specify replaces the current set. You must specify at least one group, even if it’s just the default security group in the VPC. You must specify the ID of the security group, not the name.
  - *(string)*
- **Attachment** *(dict)* – Information about the interface attachment. If modifying the ‘delete on termination’ attribute, you must specify the ID of the interface attachment.
  - **AttachmentId** *(string)* – The ID of the network interface attachment.
  - **DeleteOnTermination** *(boolean)* – Indicates whether the network interface is deleted when the instance is terminated.

**Returns** None

**reload()**

Calls `ec2.Client.describe_network_interfaces()` to update the attributes of the Network-Interface resource

**Request Syntax**
network_interface.reload()

Returns None

reset_attribute(**kwargs)
Resets a network interface attribute. You can specify only one attribute at a time.

Request Syntax

response = network_interface.reset_attribute(
    DryRun=True|False,
    SourceDestCheck='string'
)

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **SourceDestCheck (string)** – The source/destination checking attribute. Resets the value to true.

Returns None

unassign_private_ip_addresses(**kwargs)
Unassigns one or more secondary private IP addresses from a network interface.

Request Syntax

response = network_interface.unassign_private_ip_addresses(
    PrivateIpAddresses=[
        'string',
    ]
)

Parameters PrivateIpAddresses (list) – [REQUIRED]
The secondary private IP addresses to unassign from the network interface. You can specify this option multiple times to unassign more than one IP address.

Returns None

PlacementGroup

class EC2.PlacementGroup(name)
A resource representing an Amazon Elastic Compute Cloud (EC2) PlacementGroup:

import boto3

ec2 = boto3.resource('ec2')
placement_group = ec2.PlacementGroup('name')

Parameters name (string) – The PlacementGroup’s name identifier. This must be set.

These are the resource’s available identifiers:
- **name**

These are the resource’s available attributes:
- **group_name**
These are the resource’s available actions:

- `delete()`
- `load()`
- `reload()`

These are the resource’s available collections:

- `instances`

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide.*

- `name` *(string)* The PlacementGroup’s name identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the *Resources Introduction Guide.*

- `group_name` *(string)* The name of the placement group.
- `state` *(string)* The state of the placement group.
- `strategy` *(string)* The placement strategy.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide.*

- `delete(**kwargs)` Deletes the specified placement group. You must terminate all instances in the placement group before you can delete the placement group. For more information about placement groups and cluster instances, see Cluster Instances in the *Amazon Elastic Compute Cloud User Guide.*

Request Syntax

```python
response = placement_group.delete(
    DryRun=True|False,
)
```

**Parameters**  
`DryRun` *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

**Returns**  
None

- `load()`  
  Calls `ec2.Client.describe_placement_groups()` to update the attributes of the Placement-Group resource.
Request Syntax

placement_group.load()

Returns None

reload()

Calls ec2.Client.describe_placement_groups() to update the attributes of the Placement-Group resource

Request Syntax

placement_group.reload()

Returns None

Collections

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the *Resources Introduction Guide*.

instances

all()

Creates an iterable of all Instance resources in the collection.

Request Syntax

instance_iterator = placement_group.instances.all()

Return type list(ec2.Instance)

Returns A list of Instance resources

create_tags(**kwargs)

Adds or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each resource can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys must be unique per resource.

For more information about tags, see *Tagging Your Resources* in the *Amazon Elastic Compute Cloud User Guide*.

Request Syntax

response = placement_group.instances.create_tags(
    DryRun=True|False,
    Tags=[
        {'Key': 'string',
         'Value': 'string' },
    ]
)

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
• **Tags** *(list)* – [REQUIRED]

One or more tags. The *value* parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.

– *(dict)* –

  Describes a tag.

  * **Key** *(string)* –
    
    The key of the tag.
    
    Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with *aws:*.

  * **Value** *(string)* –
    
    The value of the tag.
    
    Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

**Returns** None

**filter** (**kwargs**)

Creates an iterable of all Instance resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
instance_iterator = placement_group.instances.filter(
    DryRun=True|False,
    InstanceIds=[
        'string',
    ],
    NextToken='string',
    MaxResults=123
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is *DryRunOperation*. Otherwise, it is *UnauthorizedOperation*.
- **InstanceIds** *(list)* – One or more instance IDs.

  Default: Describes all your instances.

  – *(string)* –

- **NextToken** *(string)* – The token to request the next page of results.
- **MaxResults** *(integer)* – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned *NextToken* value. This value can be between 5 and 1000; if *MaxResults* is given a value larger than 1000, only 1000 results are returned. You cannot specify this parameter and the instance IDs parameter in the same request.

**Return type** list(*ec2.Instance*)

**Returns** A list of Instance resources

**limit** (**kwargs**)

Creates an iterable up to a specified amount of Instance resources in the collection.

**Request Syntax**
instance_iterator = placement_group.instances.limit(
    count=123
)

**Parameters**

- **count** (*integer*) – The limit to the number of resources in the iterable.
- **Return type** *list(ec2.Instance)*
- **Returns** A list of Instance resources

**monitor**(**kwargs**)

 Enables monitoring for a running instance. For more information about monitoring instances, see Monitoring Your Instances and Volumes in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = placement_group.instances.monitor(
    DryRun=True|False,
)
```

**Parameters**

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

**Return type** *dict*

**Returns**

**Response Syntax**

```json
{
    'InstanceMonitorings': [  
    {  
        'InstanceId': 'string',  
        'Monitoring': {  
            'State': 'disabled'|'disabling'|'enabled'|'pending'
        }
    },
    
    }
}
```

**Response Structure**

- *(dict)* –
  - **InstanceMonitorings** (*list*) –
    Monitoring information for one or more instances.
  - *(dict)* –
    Describes the monitoring information of the instance.
    - **InstanceId** (*string*) –
      The ID of the instance.
    - **Monitoring** (*dict*) –
      The monitoring information.
    - **State** (*string*) –
      Indicates whether monitoring is enabled for the instance.
**page_size(****kwargs**

Creates an iterable of all Instance resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
instance_iterator = placement_group.instances.page_size(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The number of items returned by each service call

**Return type**

list(ec2.Instance)

**Returns**

A list of Instance resources

**reboot(****kwargs**

Requests a reboot of one or more instances. This operation is asynchronous; it only queues a request to reboot the specified instances. The operation succeeds if the instances are valid and belong to you. Requests to reboot terminated instances are ignored.

If a Linux/Unix instance does not cleanly shut down within four minutes, Amazon EC2 performs a hard reboot.

For more information about troubleshooting, see Getting Console Output and Rebooting Instances in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = placement_group.instances.reboot(
    DryRun=True|False,
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

**Returns**

None

**start(****kwargs**

Starts an Amazon EBS-backed AMI that you’ve previously stopped.

Instances that use Amazon EBS volumes as their root devices can be quickly stopped and started. When an instance is stopped, the compute resources are released and you are not billed for hourly instance usage. However, your root partition Amazon EBS volume remains, continues to persist your data, and you are charged for Amazon EBS volume usage. You can restart your instance at any time. Each time you transition an instance from stopped to started, Amazon EC2 charges a full instance hour, even if transitions happen multiple times within a single hour.

Before stopping an instance, make sure it is in a state from which it can be restarted. Stopping an instance does not preserve data stored in RAM.

Performing this operation on an instance that uses an instance store as its root device returns an error.

For more information, see Stopping Instances in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**
response = placement_group.instances.start(
    AdditionalInfo='string',
    DryRun=True|False
)

Parameters
- **AdditionalInfo** *(string)* – Reserved.
- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

Returns
- **dict**

Response Syntax
- {  
  'StartingInstances': [  
    {  
      'InstanceId': 'string',  
      'CurrentState': {  
        'Code': 123,  
        'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped'  
      },  
      'PreviousState': {  
        'Code': 123,  
        'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped'  
      }  
    },  
  ];
}

Response Structure
- *(dict)* –
  - **StartingInstances** *(list)* –
    Information about one or more started instances.
    - *(dict)* –
      Describes an instance state change.
      - **InstanceId** *(string)* –
        The ID of the instance.
      - **CurrentState** *(dict)* –
        The current state of the instance.
      - **Code** *(integer)* –
        The low byte represents the state. The high byte is an opaque internal value and should be ignored.
        - 0: pending
        - 16: running
        - 32: shutting-down
        - 48: terminated
        - 64: stopping
        - 80: stopped
      - **Name** *(string)* –
        The current state of the instance.
- **PreviousState (dict)** –
  The previous state of the instance.
- **Code (integer)** –
  The low byte represents the state. The high byte is an opaque internal value and should be ignored.
  - 0: pending
  - 16: running
  - 32: shutting-down
  - 48: terminated
  - 64: stopping
  - 80: stopped
- **Name (string)** –
  The current state of the instance.

**stop(**kwargs**)

Stops an Amazon EBS-backed instance. Each time you transition an instance from stopped to started, Amazon EC2 charges a full instance hour, even if transitions happen multiple times within a single hour.

You can’t start or stop Spot Instances.

Instances that use Amazon EBS volumes as their root devices can be quickly stopped and started. When an instance is stopped, the compute resources are released and you are not billed for hourly instance usage. However, your root partition Amazon EBS volume remains, continues to persist your data, and you are charged for Amazon EBS volume usage. You can restart your instance at any time.

Before stopping an instance, make sure it is in a state from which it can be restarted. Stopping an instance does not preserve data stored in RAM.

Performing this operation on an instance that uses an instance store as its root device returns an error.

You can stop, start, and terminate EBS-backed instances. You can only terminate instance store-backed instances. What happens to an instance differs if you stop it or terminate it. For example, when you stop an instance, the root device and any other devices attached to the instance persist.

When you terminate an instance, the root device and any other devices attached during the instance launch are automatically deleted. For more information about the differences between stopping and terminating instances, see Instance Lifecycle in the *Amazon Elastic Compute Cloud User Guide*.

For more information about troubleshooting, see *Troubleshooting Stopping Your Instance* in the *Amazon Elastic Compute Cloud User Guide*.

**Request Syntax**

```python
response = placement_group.instances.stop(
    DryRun=True|False,
    Force=True|False
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **Force (boolean)** – Forces the instances to stop. The instances do not have an opportunity to flush file system caches or file system metadata. If you
use this option, you must perform file system check and repair procedures. This option is not recommended for Windows instances.

Default: false

Return type  dict

Returns

Response Syntax

```
{
    'StoppingInstances': [
        {
            'InstanceId': 'string',
            'CurrentState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped',
            },
            'PreviousState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped',
            }
        }
    ],
}
```

Response Structure

- **(dict)** –
  - **StoppingInstances (list)** –

  Information about one or more stopped instances.

  - **(dict)** –

    Describes an instance state change.

    - **InstanceId (string)** –

      The ID of the instance.

    - **CurrentState (dict)** –

      The current state of the instance.

    - **Code (integer)** –

      The low byte represents the state. The high byte is an opaque internal value and should be ignored.

      - 0: pending
      - 16: running
      - 32: shutting-down
      - 48: terminated
      - 64: stopping
      - 80: stopped

    - **Name (string)** –

      The current state of the instance.

    - **PreviousState (dict)** –

      The previous state of the instance.

    - **Code (integer)** –

      The low byte represents the state. The high byte is an opaque internal value and should be ignored.

      - 0: pending
terminate(**kwargs)
Shuts down one or more instances. This operation is idempotent; if you terminate an instance more
than once, each call succeeds.

Terminated instances remain visible after termination (for approximately one hour).

By default, Amazon EC2 deletes all EBS volumes that were attached when the instance launched.
Volumes attached after instance launch continue running.

You can stop, start, and terminate EBS-backed instances. You can only terminate instance store-
backed instances. What happens to an instance differs if you stop it or terminate it. For example,
when you stop an instance, the root device and any other devices attached to the instance persist.
When you terminate an instance, any attached EBS volumes with the DeleteOnTermination
block device mapping parameter set to true are automatically deleted. For more information about
the differences between stopping and terminating instances, see Instance Lifecycle in the Amazon
Elastic Compute Cloud User Guide .

For more information about troubleshooting, see Troubleshooting Terminating Your Instance in the
Amazon Elastic Compute Cloud User Guide .

Request Syntax

response = placement_group.instances.terminate(
    DryRun=True|False,
)

Parameters
DryRun (boolean) – Checks whether you have the required permis-
sions for the action, without actually making the request, and provides an
error response. If you have the required permissions, the error response is
DryRunOperation. Otherwise, it is UnauthorizedOperation.

Return type dict
Returns

Response Syntax

```python
{
    'TerminatingInstances': [
        {
            'InstanceId': 'string',
            'CurrentState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped'
            },
            'PreviousState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped'
            }
        }
    ]
}
```
Response Structure

- (dict) –
  - TerminatingInstances (list) –
    Information about one or more terminated instances.
      * (dict) –
        Describes an instance state change.
          - InstanceId (string) –
            The ID of the instance.
          - CurrentState (dict) –
            The current state of the instance.
            - Code (integer) –
              The low byte represents the state. The high byte is an opaque internal value and should be ignored.
              - 0: pending
              - 16: running
              - 32: shutting-down
              - 48: terminated
              - 64: stopping
              - 80: stopped
          - Name (string) –
            The current state of the instance.
          - PreviousState (dict) –
            The previous state of the instance.
            - Code (integer) –
              The low byte represents the state. The high byte is an opaque internal value and should be ignored.
              - 0: pending
              - 16: running
              - 32: shutting-down
              - 48: terminated
              - 64: stopping
              - 80: stopped
          - Name (string) –
            The current state of the instance.

unmonitor(**kwargs)

Disables monitoring for a running instance. For more information about monitoring instances, see Monitoring Your Instances and Volumes in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = placement_group.instances.unmonitor(
    DryRun=True|False,
)
```

**Parameters**

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an
error response. If you have the required permissions, the error response is
DryRunOperation. Otherwise, it is UnauthorizedOperation.

Return type  dict

Returns

Response Syntax

```{  'InstanceMonitorings': [  {  'InstanceId': 'string',  'Monitoring': {  'State': 'disabled'|'disabling'|'enabled'|'pending'  }  },  ]  }```

Response Structure

- (dict) –
  - InstanceMonitorings (list) –
    Monitoring information for one or more instances.
    - (dict) –
      Describes the monitoring information of the instance.
      - InstanceId (string) –
        The ID of the instance.
      - Monitoring (dict) –
        The monitoring information.
      - State (string) –
        Indicates whether monitoring is enabled for the instance.

RouteTable

class EC2.RouteTable (id)

A resource representing an Amazon Elastic Compute Cloud (EC2) RouteTable:

```import boto3

ec2 = boto3.resource('ec2')
route_table = ec2.RouteTable('id')
```

Parameters id (string) – The RouteTable’s id identifier. This must be set.

These are the resource’s available identifiers:

- id

These are the resource’s available attributes:

- associations_attribute
- propagating_vgws
- route_table_id
- routes
- tags
- vpc_id
These are the resource’s available references:
  • vpc

These are the resource’s available actions:
  • associate_with_subnet()
  • create_route()
  • create_tags()
  • delete()
  • load()
  • reload()

These are the resource’s available collections:
  • associations

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

id
  (string) The RouteTable’s id identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

associations_attribute
  (list)
  The associations between the route table and one or more subnets.

propagating_vgws
  (list)
  Any virtual private gateway (VGW) propagating routes.

route_table_id
  (string)
  The ID of the route table.

routes
  (list)
  The routes in the route table.

tags
  (list)
  Any tags assigned to the route table.

vpc_id
  (string)
  The ID of the VPC.

References

References are related resource instances that have a belongs-to relationship. For more information about references refer to the Resources Introduction Guide.

vpc
  (Vpc) The related vpc if set, otherwise None.

Actions

3.1. Services
Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

**associate_with_subnet(**kwargs**)**

Associates a subnet with a route table. The subnet and route table must be in the same VPC. This association causes traffic originating from the subnet to be routed according to the routes in the route table. The action returns an association ID, which you need in order to disassociate the route table from the subnet later. A route table can be associated with multiple subnets.

For more information about route tables, see Route Tables in the Amazon Virtual Private Cloud User Guide.

**Request Syntax**

```python
route_table_association = route_table.associate_with_subnet(
    DryRun=True|False,
    SubnetId='string',
)
```

**Parameters**

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **SubnetId** (string) – [REQUIRED]

  The ID of the subnet.

**Return type** ec2.RouteTableAssociation

**Returns** RouteTableAssociation resource

**create_route(**kwargs**)**

Creates a route in a route table within a VPC.

You must specify one of the following targets: Internet gateway or virtual private gateway, NAT instance, VPC peering connection, or network interface.

When determining how to route traffic, we use the route with the most specific match. For example, let’s say the traffic is destined for 192.0.2.3 and the route table includes the following two routes:

- 192.0.2.0/24 (goes to some target A)
- 192.0.2.0/28 (goes to some target B)

Both routes apply to the traffic destined for 192.0.2.3. However, the second route in the list covers a smaller number of IP addresses and is therefore more specific, so we use that route to determine where to target the traffic.

For more information about route tables, see Route Tables in the Amazon Virtual Private Cloud User Guide.

**Request Syntax**

```python
response = route_table.create_route(
    DryRun=True|False,
    DestinationCidrBlock='string',
    GatewayId='string',
    InstanceId='string',
    NetworkInterfaceId='string',
    VpcPeeringConnectionId='string'
)
```

**Parameters**
• **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

• **DestinationCidrBlock** (string) – [REQUIRED]
  
  The CIDR address block used for the destination match. Routing decisions are based on the most specific match.

• **GatewayId** (string) – The ID of an Internet gateway or virtual private gateway attached to your VPC.

• **InstanceId** (string) – The ID of a NAT instance in your VPC. The operation fails if you specify an instance ID unless exactly one network interface is attached.

• **NetworkInterfaceId** (string) – The ID of a network interface.

• **VpcPeeringConnectionId** (string) – The ID of a VPC peering connection.

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
   'Return': True|False
}
```

**Response Structure**

• (dict) –
  
  • **Return** (boolean) –
    
    Returns `true` if the request succeeds; otherwise, it returns an error.

### create_tags(**kwargs)**

Adds or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each resource can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys must be unique per resource.

For more information about tags, see [Tagging Your Resources](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/TaggingYourResources.html) in the *Amazon Elastic Compute Cloud User Guide*.

**Request Syntax**

```python
tag = route_table.create_tags(
    DryRun=True|False,
    Tags=[
        
        
        {'Key': 'string',
         'Value': 'string'}
    ]
)
```

**Parameters**

• **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

• **Tags** (list) – [REQUIRED]

  One or more tags. The `value` parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.
- (dict) –

Describes a tag.

* Key (string) –

  The key of the tag.

  Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with aws:

* Value (string) –

  The value of the tag.

  Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

  **Return type** list(ec2.Tag)

  **Returns** A list of Tag resources

**delete(**kwargs)**

Deletes the specified route table. You must disassociate the route table from any subnets before you can delete it. You can’t delete the main route table.

**Request Syntax**

```python
response = route_table.delete(
    DryRun=True|False,
)
```

**Parameters**  

**DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

**Returns** None

**load()**

Calls `ec2.Client.describe_route_tables()` to update the attributes of the RouteTable resource

**Request Syntax**

```python
route_table.load()
```

**Returns** None

**reload()**

Calls `ec2.Client.describe_route_tables()` to update the attributes of the RouteTable resource

**Request Syntax**

```python
route_table.reload()
```

**Returns** None

**Collections**

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the Resources Introduction Guide.
all()
Creates an iterable of all RouteTableAssociation resources in the collection.

Request Syntax

```python
route_table_association_iterator = route_table.associations.all()
```

Return type list(ec2.RouteTableAssociation)
Returns A list of RouteTableAssociation resources

filter(**kwargs)
Creates an iterable of all RouteTableAssociation resources in the collection filtered by kwargs passed to method.

Request Syntax

```python
route_table_association_iterator = route_table.associations.filter(
    DryRun=True|False,
    Filters=[
        {
            'Name': 'string',
            'Values': [
                'string',
            ],
        },
    ]
)
```

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **Filters (list)** – One or more filters.
  - association.route-table-association-id - The ID of an association ID for the route table.
  - association.route-table-id - The ID of the route table involved in the association.
  - association.subnet-id - The ID of the subnet involved in the association.
  - association.main - Indicates whether the route table is the main route table for the VPC.
  - route-table-id - The ID of the route table.
  - route.destination-cidr-block - The CIDR range specified in a route in the table.
  - route.destination-prefix-list-id - The ID (prefix) of the AWS service specified in a route in the table.
  - route.gateway-id - The ID of a gateway specified in a route in the table.
  - route.instance-id - The ID of an instance specified in a route in the table.
  - route.origin - Describes how the route was created. CreateRouteTable indicates that the route was automatically created when the route table was created; CreateRoute indicates that the route was manually added to the route table; EnableVgwRoutePropagation indicates that the route was propagated by route propagation.
- `route.state` - The state of a route in the route table (active | blackhole). The blackhole state indicates that the route’s target isn’t available (for example, the specified gateway isn’t attached to the VPC, the specified NAT instance has been terminated, and so on).
- `route.vpc-peering-connection-id` - The ID of a VPC peering connection specified in a route in the table.
- `tag :key=*value*` - The key/value combination of a tag assigned to the resource.
- `tag-key` - The key of a tag assigned to the resource. This filter is independent of the `tag-value` filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the `tag :key=*value*` filter.
- `tag-value` - The value of a tag assigned to the resource. This filter is independent of the `tag-key` filter.
- `vpc-id` - The ID of the VPC for the route table.

- `(dict)` –
  A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.
  
  * Name (string) –
    The name of the filter. Filter names are case-sensitive.
  * Values (list) –
    One or more filter values. Filter values are case-sensitive.
    · (string) –

  Return type list(ec2.RouteTableAssociation)
  Returns A list of RouteTableAssociation resources

`limit(**kwargs)`

Creates an iterable up to a specified amount of RouteTableAssociation resources in the collection.

Request Syntax

```python
route_table_association_iterator = route_table.associations.limit(
    count=123
)
```

Parameters count (integer) – The limit to the number of resources in the iterable.

Return type list(ec2.RouteTableAssociation)

Returns A list of RouteTableAssociation resources

`page_size(**kwargs)`

Creates an iterable of all RouteTableAssociation resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

```python
route_table_association_iterator = route_table.associations.page_size(
    count=123
)
```

Parameters count (integer) – The number of items returned by each service call
Return type  list(ec2.RouteTableAssociation)
Returns  A list of RouteTableAssociation resources

RouteTableAssociation
class EC2.RouteTableAssociation(id)
A resource representing an Amazon Elastic Compute Cloud (EC2) RouteTableAssociation:

import boto3
e2 = boto3.resource('ec2')
route_table_association = ec2.RouteTableAssociation('id')

Parameters id (string) – The RouteTableAssociation’s id identifier. This must be set.

These are the resource’s available identifiers:
• id

These are the resource’s available attributes:
• main
• route_table_association_id
• route_table_id
• subnet_id

These are the resource’s available references:
• route_table
• subnet

These are the resource’s available actions:
• delete()
• replace_subnet()

Identifiers
Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

id
(string) The RouteTableAssociation’s id identifier. This must be set.

Attributes
Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

main
(boolean)
Indicates whether this is the main route table.

route_table_association_id
(string)
The ID of the association between a route table and a subnet.

route_table_id
(string)
The ID of the route table.

subnet_id
(string)
The ID of the subnet. A subnet ID is not returned for an implicit association.
References

References are related resource instances that have a belongs-to relationship. For more information about references refer to the Resources Introduction Guide.

route_table

(RouteTable) The related route_table if set, otherwise None.

subnet

(Subnet) The related subnet if set, otherwise None.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

delete (**kwargs)

Disassociates a subnet from a route table.

After you perform this action, the subnet no longer uses the routes in the route table. Instead, it uses the routes in the VPC’s main route table. For more information about route tables, see Route Tables in the Amazon Virtual Private Cloud User Guide.

Request Syntax

response = route_table_association.delete(
    DryRun=True|False,
)

Parameters

DryRun (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

Returns

None

replace_subnet (**kwargs)

Changes the route table associated with a given subnet in a VPC. After the operation completes, the subnet uses the routes in the new route table it’s associated with. For more information about route tables, see Route Tables in the Amazon Virtual Private Cloud User Guide.

You can also use ReplaceRouteTableAssociation to change which table is the main route table in the VPC. You just specify the main route table’s association ID and the route table to be the new main route table.

Request Syntax

route_table_association = route_table_association.replace_subnet(
    DryRun=True|False,
    RouteTableId='string'
)

Parameters

- DryRun (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- RouteTableId (string) – [REQUIRED]

The ID of the new route table to associate with the subnet.

Return type

ec2.RouteTableAssociation

Returns

RouteTableAssociation resource
SecurityGroup

class `EC2.SecurityGroup(id)`
A resource representing an Amazon Elastic Compute Cloud (EC2) SecurityGroup:

```python
import boto3
ec2 = boto3.resource('ec2')
security_group = ec2.SecurityGroup('id')
```

**Parameters**

id *(string)* – The SecurityGroup’s id identifier. This must be set.

These are the resource’s available identifiers:

- **id**

These are the resource’s available attributes:

- `description`
- `group_id`
- `group_name`
- `ip_permissions`
- `ip_permissions_egress`
- `owner_id`
- `tags`
- `vpc_id`

These are the resource’s available actions:

- `authorize_egress()`
- `authorize_ingress()`
- `create_tags()`
- `delete()`
- `load()`
- `reload()`
- `revoke_egress()`
- `revoke_ingress()`

**Identifiers**

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide*.

id *(string)* – The SecurityGroup’s id identifier. This must be set.

**Attributes**

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the *Resources Introduction Guide*.

**description** *(string)*

A description of the security group.

**group_id** *(string)*

The ID of the security group.

**group_name** *(string)*

The name of the security group.
ip_permissions
  (list)
   One or more inbound rules associated with the security group.

ip_permissions_egress
  (list)
   [EC2-VPC] One or more outbound rules associated with the security group.

owner_id
  (string)
   The AWS account ID of the owner of the security group.

tags
  (list)
   Any tags assigned to the security group.

vpc_id
  (string)
   [EC2-VPC] The ID of the VPC for the security group.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

authorize_egress(**kwargs)

    Adds one or more egress rules to a security group for use with a VPC. Specifically, this action permits instances to send traffic to one or more destination CIDR IP address ranges, or to one or more destination security groups for the same VPC.

    Warning: You can have up to 50 rules per security group (covering both ingress and egress rules).

A security group is for use with instances either in the EC2-Classic platform or in a specific VPC. This action doesn’t apply to security groups for use in EC2-Classic. For more information, see Security Groups for Your VPC in the Amazon Virtual Private Cloud User Guide.

Each rule consists of the protocol (for example, TCP), plus either a CIDR range or a source group. For the TCP and UDP protocols, you must also specify the destination port or port range. For the ICMP protocol, you must also specify the ICMP type and code. You can use -1 for the type or code to mean all types or all codes.

Rule changes are propagated to affected instances as quickly as possible. However, a small delay might occur.

Request Syntax

response = security_group.authorize_egress(
    DryRun=True|False,
    SourceSecurityGroupName='string',
    SourceSecurityGroupOwnerId='string',
    IpProtocol='string',
    FromPort=123,
    ToPort=123,
    CidrIp='string',
    IpPermissions=[
    ]
)
'IpProtocol': 'string',
'FromPort': 123,
'ToPort': 123,
'UserIdGroupPairs': [
    {'UserId': 'string',
     'GroupName': 'string',
     'GroupId': 'string'}
],
'IpRanges': [
    {'CidrIp': 'string'}
],
'PrefixListIds': [
    {'PrefixListId': 'string'}
]
)

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **SourceSecurityGroupName** *(string)* – The name of a destination security group. To authorize outbound access to a destination security group, we recommend that you use a set of IP permissions instead.

- **SourceSecurityGroupOwnerId** *(string)* – The AWS account number for a destination security group. To authorize outbound access to a destination security group, we recommend that you use a set of IP permissions instead.

- **IpProtocol** *(string)* – The IP protocol name (*tcp*, *udp*, *icmp*) or number (see Protocol Numbers). Use `-1` to specify all.

- **FromPort** *(integer)* – The start of port range for the TCP and UDP protocols, or an ICMP type number. For the ICMP type number, use `-1` to specify all ICMP types.

- **ToPort** *(integer)* – The end of port range for the TCP and UDP protocols, or an ICMP code number. For the ICMP code number, use `-1` to specify all ICMP codes for the ICMP type.

- **CidrIp** *(string)* – The CIDR IP address range. You can’t specify this parameter when specifying a source security group.

- **IpPermissions** *(list)* – A set of IP permissions. You can’t specify a destination security group and a CIDR IP address range.

  - *(dict)* –

    Describes a security group rule.

    * **IpProtocol** *(string)* –

      The protocol.

      When you call `DescribeSecurityGroups`, the protocol value returned is the name. Exception: For TCP, UDP, and ICMP, the value returned is the name (for example, `tcp`, `udp`, or `icmp`). For a list
of protocol numbers, see Protocol Numbers. (VPC only) When you call AuthorizeSecurityGroupIngress, you can use –1 to specify all.

* FromPort (integer) –

The start of port range for the TCP and UDP protocols, or an ICMP type number. A value of –1 indicates all ICMP types.

* ToPort (integer) –

The end of port range for the TCP and UDP protocols, or an ICMP code. A value of –1 indicates all ICMP codes for the specified ICMP type.

* UserIdGroupPairs (list) –

One or more security group and AWS account ID pairs.

- (dict) –
  Describes a security group and AWS account ID pair.
  - UserId (string) –
    The ID of an AWS account. EC2-Classic only.
  - GroupName (string) –
    The name of the security group. In a request, use this parameter for a security group in EC2-Classic or a default VPC only. For a security group in a nondefault VPC, use GroupId.
  - GroupId (string) –
    The ID of the security group.

* IpRanges (list) –

One or more IP ranges.

- (dict) –
  Describes an IP range.
  - CidrIp (string) –
    The CIDR range. You can either specify a CIDR range or a source security group, not both.

* PrefixListIds (list) –

(Valid for AuthorizeSecurityGroupEgress, RevokeSecurityGroupEgress and DescribeSecurityGroups only) One or more prefix list IDs for an AWS service. In an AuthorizeSecurityGroupEgress request, this is the AWS service that you want to access through a VPC endpoint from instances associated with the security group.

- (dict) –
  The ID of the prefix.
  - PrefixListId (string) –
    The ID of the prefix.

**Returns** None

authorize_ingress (**kwargs)

Adds one or more ingress rules to a security group.

**Warning:** EC2-Classic: You can have up to 100 rules per group. EC2-VPC: You can have up to 50 rules per group (covering both ingress and egress rules).
Rule changes are propagated to instances within the security group as quickly as possible. However, a small delay might occur.

[EC2-Classic] This action gives one or more CIDR IP address ranges permission to access a security group in your account, or gives one or more security groups (called the source groups) permission to access a security group for your account. A source group can be for your own AWS account, or another.

[EC2-VPC] This action gives one or more CIDR IP address ranges permission to access a security group in your VPC, or gives one or more other security groups (called the source groups) permission to access a security group for your VPC. The security groups must all be for the same VPC.

Request Syntax

```python
response = security_group.authorize_ingress(
    DryRun=True|False,
    GroupName='string',
    SourceSecurityGroupName='string',
    SourceSecurityGroupOwnerId='string',
    IpProtocol='string',
    FromPort=123,
    ToPort=123,
    CidrIp='string',
    IpPermissions=[
        {'IpProtocol': 'string',
         'FromPort': 123,
         'ToPort': 123,
         'UserIdGroupPairs': [
             {'UserId': 'string',
              'GroupName': 'string',
              'GroupId': 'string',
             ],
         'IpRanges': [
             {'CidrIp': 'string'}
         ],
         'PrefixListIds': [
             {'PrefixListId': 'string'}
         ]
        }]
)
```

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **GroupName (string)** – [EC2-Classic, default VPC] The name of the security group.
- **SourceSecurityGroupName (string)** – [EC2-Classic, default VPC] The name of the source security group. You can’t specify this parameter in combination with the following parameters: the CIDR IP address range, the start of the port range.
- **SourceSecurityGroupOwnerId (string)** – [EC2-Classic, default VPC] The owner ID of the source security group.
- **IpProtocol (string)** – The protocol to use for incoming traffic (e.g., `tcp` or `udp`).
- **FromPort (integer)** – The start of the port range for incoming traffic.
- **ToPort (integer)** – The end of the port range for incoming traffic.
- **CidrIp (string)** – The CIDR IP address range of the inbound source CIDR.
- **IpPermissions (list of dictionaries)** – A list of dictionaries that define the permissions for the inbound traffic.
range, the IP protocol, and the end of the port range. For EC2-VPC, the source security group must be in the same VPC.

- **SourceSecurityGroupOwnerId** *(string)* – [EC2-Classic, default VPC] The AWS account number for the source security group. For EC2-VPC, the source security group must be in the same VPC. You can’t specify this parameter in combination with the following parameters: the CIDR IP address range, the IP protocol, the start of the port range, and the end of the port range. Creates rules that grant full ICMP, UDP, and TCP access. To create a rule with a specific IP protocol and port range, use a set of IP permissions instead.

- **IpProtocol** *(string)* – The IP protocol name (tcp, udp, icmp) or number (see Protocol Numbers). (VPC only) Use -1 to specify all.

- **FromPort** *(integer)* – The start of port range for the TCP and UDP protocols, or an ICMP type number. For the ICMP type number, use -1 to specify all ICMP types.

- **ToPort** *(integer)* – The end of port range for the TCP and UDP protocols, or an ICMP code number. For the ICMP code number, use -1 to specify all ICMP codes for the ICMP type.

- **CidrIp** *(string)* – The CIDR IP address range. You can’t specify this parameter when specifying a source security group.

- **IpPermissions** *(list)* – A set of IP permissions. Can be used to specify multiple rules in a single command.

  - *(dict)* –

    Describes a security group rule.

    - **IpProtocol** *(string)* –

      The protocol.

      When you call DescribeSecurityGroups, the protocol value returned is the number. Exception: For TCP, UDP, and ICMP, the value returned is the name (for example, tcp, udp, or icmp). For a list of protocol numbers, see Protocol Numbers. (VPC only) When you call AuthorizeSecurityGroupIngress, you can use -1 to specify all.

    - **FromPort** *(integer)* –

      The start of port range for the TCP and UDP protocols, or an ICMP type number. A value of -1 indicates all ICMP types.

    - **ToPort** *(integer)* –

      The end of port range for the TCP and UDP protocols, or an ICMP code. A value of -1 indicates all ICMP codes for the specified ICMP type.

- **UserIdGroupPairs** *(list)* –

  One or more security group and AWS account ID pairs.

  - *(dict)* –

    Describes a security group and AWS account ID pair.

    - **UserId** *(string)* –

      The ID of an AWS account. EC2-Classic only.

    - **GroupName** *(string)* –

      The name of the security group. In a request, use this parameter for a security group in EC2-Classic or a default VPC only. For a security group in a nondefault VPC, use GroupId.

    - **GroupId** *(string)* –

      The ID of the security group.
**IpRanges** *(list)* –
One or more IP ranges.
  · *(dict)* –
    Describes an IP range.
  · **CidrIp** *(string)* –
    The CIDR range. You can either specify a CIDR range or a source security group, not both.

**PrefixListIds** *(list)* –
(Valid for AuthorizeSecurityGroupEgress, RevokeSecurityGroupEgress and DescribeSecurityGroups only) One or more prefix list IDs for an AWS service. In an AuthorizeSecurityGroupEgress request, this is the AWS service that you want to access through a VPC endpoint from instances associated with the security group.
  · *(dict)* –
    The ID of the prefix.
  · **PrefixListId** *(string)* –
    The ID of the prefix.

Returns
None

create_tags(**kwars)**
Adds or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each resource can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys must be unique per resource.

For more information about tags, see Tagging Your Resources in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
tag = security_group.create_tags(
    DryRun=True|False,
    Tags=[
        {'Key': 'string',
         'Value': 'string'},
    ],
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **Tags** *(list)* – [REQUIRED]
  One or more tags. The value parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.
  · *(dict)* –
    Describes a tag.
Key (string) –
The key of the tag.
Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with aws:

Value (string) –
The value of the tag.
Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

Return type  list(ec2.Tag)
Returns  A list of Tag resources

delete (**kwargs)
Deletes a security group.
If you attempt to delete a security group that is associated with an instance, or is referenced by another security group, the operation fails with InvalidGroup.InUse in EC2-Classic or DependencyViolation in EC2-VPC.

Request Syntax

response = security_group.delete(
    DryRun=True|False,
    GroupName='string',
)

Parameters

- DryRun (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- GroupName (string) – [EC2-Classic, default VPC] The name of the security group. You can specify either the security group name or the security group ID.

Returns  None

load()
Calls ec2.Client.describe_security_groups() to update the attributes of the Security-Group resource

Request Syntax

security_group.load()

Returns  None

reload()
Calls ec2.Client.describe_security_groups() to update the attributes of the Security-Group resource

Request Syntax

security_group.reload()

Returns  None
**revoke_egress(****kwargs**

Removes one or more egress rules from a security group for EC2-VPC. The values that you specify in the revoke request (for example, ports) must match the existing rule’s values for the rule to be revoked.

Each rule consists of the protocol and the CIDR range or source security group. For the TCP and UDP protocols, you must also specify the destination port or range of ports. For the ICMP protocol, you must also specify the ICMP type and code.

Rule changes are propagated to instances within the security group as quickly as possible. However, a small delay might occur.

**Request Syntax**

```python
response = security_group.revoke_egress(
    DryRun=True|False,
    SourceSecurityGroupName='string',
    SourceSecurityGroupOwnerId='string',
    IpProtocol='string',
    FromPort=123,
    ToPort=123,
    CidrIp='string',
    IpPermissions=[
        {
            'IpProtocol': 'string',
            'FromPort': 123,
            'ToPort': 123,
            'UserIdGroupPairs': [
                {
                    'UserId': 'string',
                    'GroupName': 'string',
                    'GroupId': 'string'
                },
            ],
            'IpRanges': [
                {
                    'CidrIp': 'string'
                },
            ],
            'PrefixListIds': [
                {
                    'PrefixListId': 'string'
                },
            ]
        },
    ]
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **SourceSecurityGroupName** *(string)* – The name of a destination security group. To revoke outbound access to a destination security group, we recommend that you use a set of IP permissions instead.

- **SourceSecurityGroupOwnerId** *(string)* – The AWS account number for a destination security group. To revoke outbound access to a destination security group, we recommend that you use a set of IP permissions instead.

3.1. Services 1705
• **IpProtocol** *(string)* – The IP protocol name (tcp, udp, icmp) or number (see Protocol Numbers). Use -1 to specify all.
• **FromPort** *(integer)* – The start of port range for the TCP and UDP protocols, or an ICMP type number. For the ICMP type number, use -1 to specify all ICMP types.
• **ToPort** *(integer)* – The end of port range for the TCP and UDP protocols, or an ICMP code number. For the ICMP code number, use -1 to specify all ICMP codes for the ICMP type.
• **CidrIp** *(string)* – The CIDR IP address range. You can’t specify this parameter when specifying a source security group.
• **IpPermissions** *(list)* – A set of IP permissions. You can’t specify a destination security group and a CIDR IP address range.
  - *(dict)* – Describes a security group rule.
      When you call DescribeSecurityGroups, the protocol value returned is the number. Exception: For TCP, UDP, and ICMP, the value returned is the name (for example, tcp, udp, or icmp). For a list of protocol numbers, see Protocol Numbers. (VPC only) When you call AuthorizeSecurityGroupIngress, you can use -1 to specify all.
    * **FromPort** *(integer)* – The start of port range for the TCP and UDP protocols, or an ICMP type number. A value of -1 indicates all ICMP types.
    * **ToPort** *(integer)* – The end of port range for the TCP and UDP protocols, or an ICMP code. A value of -1 indicates all ICMP codes for the specified ICMP type.
    * **UserIdGroupPairs** *(list)* – One or more security group and AWS account ID pairs.
      - *(dict)* – Describes a security group and AWS account ID pair.
        * **UserId** *(string)* – The ID of an AWS account. EC2-Classic only.
        * **GroupName** *(string)* – The name of the security group. In a request, use this parameter for a security group in EC2-Classic or a default VPC only. For a security group in a nondefault VPC, use GroupId.
        * **GroupId** *(string)* – The ID of the security group.
    * **IpRanges** *(list)* – One or more IP ranges.
      - *(dict)* – Describes an IP range.
        * **CidrIp** *(string)* – The CIDR range. You can either specify a CIDR range or a source security group, not both.
* **PrefixListIds** *(list)* –

(Valid for AuthorizeSecurityGroupEgress, RevokeSecurityGroupEgress, and DescribeSecurityGroups only) One or more prefix list IDs for an AWS service. In an AuthorizeSecurityGroupEgress request, this is the AWS service that you want to access through a VPC endpoint from instances associated with the security group.

- *(dict)* –
  The ID of the prefix.

- **PrefixListId** *(string)* –
  The ID of the prefix.

**Returns** None

**revoke_ingress** (**kwargs**)

Removes one or more ingress rules from a security group. The values that you specify in the revoke request (for example, ports) must match the existing rule’s values for the rule to be removed.

Each rule consists of the protocol and the CIDR range or source security group. For the TCP and UDP protocols, you must also specify the destination port or range of ports. For the ICMP protocol, you must also specify the ICMP type and code.

Rule changes are propagated to instances within the security group as quickly as possible. However, a small delay might occur.

**Request Syntax**

```python
response = security_group.revoke_ingress(
    DryRun=True|False,
    GroupName='string',
    SourceSecurityGroupName='string',
    SourceSecurityGroupOwnerId='string',
    IpProtocol='string',
    FromPort=123,
    ToPort=123,
    CidrIp='string',
    IpPermissions=[
        {
            'IpProtocol': 'string',
            'FromPort': 123,
            'ToPort': 123,
            'UserIdGroupPairs': []
        },
        {
            'IpRanges': [
                { 'CidrIp': 'string' }
            ],
        },
        { 'PrefixListIds': [ }]
    ]
)
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **GroupName** *(string)* – [EC2-Classic, default VPC] The name of the security group.

- **SourceSecurityGroupName** *(string)* – [EC2-Classic, default VPC] The name of the source security group. You can’t specify this parameter in combination with the following parameters: the CIDR IP address range, the start of the port range, the IP protocol, and the end of the port range. For EC2-VPC, the source security group must be in the same VPC.

- **SourceSecurityGroupOwnerId** *(string)* – [EC2-Classic, default VPC] The AWS account ID of the source security group. For EC2-VPC, the source security group must be in the same VPC. You can’t specify this parameter in combination with the following parameters: the CIDR IP address range, the IP protocol, the start of the port range, and the end of the port range. To revoke a specific rule for an IP protocol and port range, use a set of IP permissions instead.

- **IpProtocol** *(string)* – The IP protocol name (tcp, udp, icmp) or number (see Protocol Numbers). Use -1 to specify all.

- **FromPort** *(integer)* – The start of port range for the TCP and UDP protocols, or an ICMP type number. For the ICMP type number, use -1 to specify all ICMP types.

- **ToPort** *(integer)* – The end of port range for the TCP and UDP protocols, or an ICMP code number. For the ICMP code number, use -1 to specify all ICMP codes for the ICMP type.

- **CidrIp** *(string)* – The CIDR IP address range. You can’t specify this parameter when specifying a source security group.

- **IpPermissions** *(list)* – A set of IP permissions. You can’t specify a source security group and a CIDR IP address range.

  - *(dict)* – Describes a security group rule.

    - **IpProtocol** *(string)* –
      
      The protocol.

      When you call DescribeSecurityGroups, the protocol value returned is the number. Exception: For TCP, UDP, and ICMP, the value returned is the name (for example, tcp, udp, or icmp). For a list of protocol numbers, see Protocol Numbers. (VPC only) When you call AuthorizeSecurityGroupIngress, you can use -1 to specify all.

    - **FromPort** *(integer)* –
      
      The start of port range for the TCP and UDP protocols, or an ICMP type number. A value of -1 indicates all ICMP types.

    - **ToPort** *(integer)* –
      
      The end of port range for the TCP and UDP protocols, or an ICMP code. A value of -1 indicates all ICMP codes for the specified ICMP type.

    - **UserIdGroupPairs** *(list)* –
One or more security group and AWS account ID pairs.
· (dict) –
  Describes a security group and AWS account ID pair.
· **UserId** *(string)* –
  The ID of an AWS account. EC2-Classic only.
· **GroupName** *(string)* –
  The name of the security group. In a request, use this parameter for a security group in EC2-Classic or a default VPC only.
  For a security group in a nondefault VPC, use **GroupId**.
· **GroupId** *(string)* –
  The ID of the security group.

* **IpRanges** *(list)* –
  One or more IP ranges.
· (dict) –
  Describes an IP range.
· **CidrIp** *(string)* –
  The CIDR range. You can either specify a CIDR range or a source security group, not both.

* **PrefixListIds** *(list)* –
  (Valid for AuthorizeSecurityGroupEgress, RevokeSecurityGroupEgress and DescribeSecurityGroups only) One or more prefix list IDs for an AWS service. In an AuthorizeSecurityGroupEgress request, this is the AWS service that you want to access through a VPC endpoint from instances associated with the security group.
· (dict) –
  The ID of the prefix.
· **PrefixListId** *(string)* –
  The ID of the prefix.

**Returns** None

---

**Snapshot**

class **EC2 . Snapshot** *(id)*

A resource representing an Amazon Elastic Compute Cloud (EC2) Snapshot:

```python
import boto3

ec2 = boto3.resource('ec2')
snapshot = ec2.Snapshot('id')
```

**Parameters**

- **id** *(string)* – The Snapshot’s id identifier. This **must** be set.

These are the resource’s available identifiers:
- **id**

These are the resource’s available attributes:
- **data_encryption_key_id**
- **description**
- **encrypted**
Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

id

(string) The Snapshot’s id identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

data_encryption_key_id

(string)

The data encryption key identifier for the snapshot. This value is a unique identifier that corresponds to the data encryption key that was used to encrypt the original volume or snapshot copy. Because data encryption keys are inherited by volumes created from snapshots, and vice versa, if snapshots share the same data encryption key identifier, then they belong to the same volume/snapshot lineage. This parameter is only returned by the DescribeSnapshots API operation.

description

(string)

The description for the snapshot.

encrypted

(bolean)

Indicates whether the snapshot is encrypted.

kms_key_id

(string)
The full ARN of the AWS Key Management Service (AWS KMS) customer master key (CMK) that was used to protect the volume encryption key for the parent volume.

**owner_alias**

*(string)*

The AWS account alias (for example, `amazon`, `self`) or AWS account ID that owns the snapshot.

**owner_id**

*(string)*

The AWS account ID of the EBS snapshot owner.

**progress**

*(string)*

The progress of the snapshot, as a percentage.

**snapshot_id**

*(string)*

The ID of the snapshot. Each snapshot receives a unique identifier when it is created.

**start_time**

*(datetime)*

The time stamp when the snapshot was initiated.

**state**

*(string)*

The snapshot state.

**state_message**

*(string)*

Encrypted Amazon EBS snapshots are copied asynchronously. If a snapshot copy operation fails (for example, if the proper AWS Key Management Service (AWS KMS) permissions are not obtained) this field displays error state details to help you diagnose why the error occurred. This parameter is only returned by the DescribeSnapshots API operation.

**tags**

*(list)*

Any tags assigned to the snapshot.

**volume_id**

*(string)*

The ID of the volume that was used to create the snapshot.

**volume_size**

*(integer)*

The size of the volume, in GiB.

References

References are related resource instances that have a belongs-to relationship. For more information about references refer to the *Resources Introduction Guide*.

**volume**

*(Volume)* The related volume if set, otherwise *None*. 

---

3.1. Services
Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

copy(**kwargs)

Copies a point-in-time snapshot of an EBS volume and stores it in Amazon S3. You can copy the snapshot within the same region or from one region to another. You can use the snapshot to create EBS volumes or Amazon Machine Images (AMIs). The snapshot is copied to the regional endpoint that you send the HTTP request to.

Copies of encrypted EBS snapshots remain encrypted. Copies of unencrypted snapshots remain unencrypted, unless the Encrypted flag is specified during the snapshot copy operation. By default, encrypted snapshot copies use the default AWS Key Management Service (AWS KMS) customer master key (CMK); however, you can specify a non-default CMK with the KmsKeyId parameter.

For more information, see Copying an Amazon EBS Snapshot in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = snapshot.copy(
    DryRun=True|False,
    SourceRegion='string',
    Description='string',
    Encrypted=True|False,
    KmsKeyId='string'
)
```

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **SourceRegion (string)** – [REQUIRED]

  The ID of the region that contains the snapshot to be copied.

- **Description (string)** – A description for the EBS snapshot.

- **DestinationRegion (string)** – The destination region to use in the PresignedUrl parameter of a snapshot copy operation. This parameter is only valid for specifying the destination region in a PresignedUrl parameter, where it is required.

  Note: CopySnapshot sends the snapshot copy to the regional endpoint that you send the HTTP request to, such as ec2.us-east-1.amazonaws.com (in the AWS CLI, this is specified with the --region parameter or the default region in your AWS configuration file).

  Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.

- **PresignedUrl (string)** – The pre-signed URL that facilitates copying an encrypted snapshot. This parameter is only required when copying an encrypted snapshot with the Amazon EC2 Query API; it is available as an optional parameter in all other cases. The PresignedUrl should use the snapshot source endpoint, the CopySnapshot action, and include the SourceRegion, SourceSnapshotId, and DestinationRegion parameters. The PresignedUrl must be signed using AWS Signature Version 4. Because EBS snapshots are stored in Amazon S3, the signing algorithm for this parameter uses
the same logic that is described in Authenticating Requests by Using Query Parameters (AWS Signature Version 4) in the Amazon Simple Storage Service API Reference. An invalid or improperly signed PresignedUrl will cause the copy operation to fail asynchronously, and the snapshot will move to an error state.

Please note that this parameter is automatically populated if it is not provided. Including this parameter is not required.

- **Encrypted** *(boolean)* – Specifies whether the destination snapshot should be encrypted. There is no way to create an unencrypted snapshot copy from an encrypted snapshot; however, you can encrypt a copy of an unencrypted snapshot with this flag. The default CMK for EBS is used unless a non-default AWS Key Management Service (AWS KMS) CMK is specified with **KmsKeyId**. For more information, see Amazon EBS Encryption in the Amazon Elastic Compute Cloud User Guide.

- **KmsKeyId** *(string)* – The full ARN of the AWS Key Management Service (AWS KMS) CMK to use when creating the snapshot copy. This parameter is only required if you want to use a non-default CMK; if this parameter is not specified, the default CMK for EBS is used. The ARN contains the `arn:aws:kms` namespace, followed by the region of the CMK, the AWS account ID of the CMK owner, the `key` namespace, and then the CMK ID. For example, `arn:aws:kms:us-east-1:012345678910:key/abcd1234-a123-456a-a12b-a123b4cd56ef`. The specified CMK must exist in the region that the snapshot is being copied to. If a **KmsKeyId** is specified, the **Encrypted** flag must also be set.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'SnapshotId': 'string'
}
```

**Response Structure**

- *(dict)* –
  - **SnapshotId** *(string)* – The ID of the new snapshot.

**create_tags** *(**kwargs**)*

Adds or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each resource can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys must be unique per resource.

For more information about tags, see Tagging Your Resources in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
tag = snapshot.create_tags(
    DryRun=True|False,
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **Tags** *(list)* – `[REQUIRED]`

  One or more tags. The `value` parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.

    - *(dict)* – Describes a tag.
      - **Key** *(string)* – The key of the tag.

        Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws`.

      - **Value** *(string)* – The value of the tag.

        Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

Return type: `list(CloudFormation.Tag)`

Returns A list of Tag resources

delete(**kwargs)**

Deletes the specified snapshot.

When you make periodic snapshots of a volume, the snapshots are incremental, and only the blocks on the device that have changed since your last snapshot are saved in the new snapshot. When you delete a snapshot, only the data not needed for any other snapshot is removed. So regardless of which prior snapshots have been deleted, all active snapshots will have access to all the information needed to restore the volume.

You cannot delete a snapshot of the root device of an EBS volume used by a registered AMI. You must first de-register the AMI before you can delete the snapshot.

For more information, see Deleting an Amazon EBS Snapshot in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = snapshot.delete(
    DryRun=True|False,
)
```

Parameters **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

Returns None
**describe_attribute(**kwargs)**

Describes the specified attribute of the specified snapshot. You can specify only one attribute at a time.

For more information about EBS snapshots, see Amazon EBS Snapshots in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = snapshot.describe_attribute(
    DryRun=True|False,
    Attribute='productCodes'|'createVolumePermission'
)
```

**Parameters**

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **Attribute** (*string*) – [REQUIRED]

  The snapshot attribute you would like to view.

**Return type** dict

**Response Syntax**

```python
{
    'SnapshotId': 'string',
    'CreateVolumePermissions': [
        {
            'UserId': 'string',
            'Group': 'all'
        },
    ],
    'ProductCodes': [
        {
            'ProductCodeId': 'string',
            'ProductCodeType': 'devpay'|'marketplace'
        },
    ]
}
```

**Response Structure**

- *(dict)* –
  - **SnapshotId** (*string*) –
    
    The ID of the EBS snapshot.
  - **CreateVolumePermissions** (*list*) –
    
    A list of permissions for creating volumes from the snapshot.
    * *(dict)* –
      
      Describes the user or group to be added or removed from the permissions for a volume.
      - **UserId** (*string*) –
        
        The specific AWS account ID that is to be added or removed from a volume’s list of create volume permissions.
· **Group** *(string)* –
  The specific group that is to be added or removed from a volume’s list of create volume permissions.

  **ProductCodes** *(list)* –
  A list of product codes.
  *
  **ProductCodeId** *(string)* –
  The product code.
  **ProductCodeType** *(string)* –
  The type of product code.

`load()`
Calls `ec2.Client.describe_snapshots()` to update the attributes of the Snapshot resource

**Request Syntax**

```python
snapshot.load()
```

**Returns** None

`modify_attribute(**kwargs)`
Adds or removes permission settings for the specified snapshot. You may add or remove specified AWS account IDs from a snapshot’s list of create volume permissions, but you cannot do both in a single API call. If you need to both add and remove account IDs for a snapshot, you must use multiple API calls.

For more information on modifying snapshot permissions, see Sharing Snapshots in the Amazon Elastic Compute Cloud User Guide.

**Note:** Snapshots with AWS Marketplace product codes cannot be made public.

**Request Syntax**

```python
response = snapshot.modify_attribute(
    DryRun=True|False,
    Attribute='productCodes'|'createVolumePermission',
    OperationType='add'|'remove',
    UserIds=[
        'string',
    ],
    GroupNames=[
        'string',
    ],
    CreateVolumePermission={
        'Add': [  
            {'UserId': 'string',  
            'Group': 'all'
            },
        ],
        'Remove': [
            {'UserId': 'string',  
            'Group': 'all'
            }
        ],
    }
)
```
Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **Attribute** (string) – The snapshot attribute to modify.

**Note:** Only volume creation permissions may be modified at the customer level.

- **OperationType** (string) – The type of operation to perform to the attribute.
- **UserIds** (list) – The account ID to modify for the snapshot.
  - (string)
- **GroupNames** (list) – The group to modify for the snapshot.
  - (string)
- **CreateVolumePermission** (dict) – A JSON representation of the snapshot attribute modification.
  - **Add** (list) –
    Adds a specific AWS account ID or group to a volume’s list of create volume permissions.
    * (dict) –
      Describes the user or group to be added or removed from the permissions for a volume.
      - **UserId** (string) –
        The specific AWS account ID that is to be added or removed from a volume’s list of create volume permissions.
      - **Group** (string) –
        The specific group that is to be added or removed from a volume’s list of create volume permissions.
  - **Remove** (list) –
    Removes a specific AWS account ID or group from a volume’s list of create volume permissions.
    * (dict) –
      Describes the user or group to be added or removed from the permissions for a volume.
      - **UserId** (string) –
        The specific AWS account ID that is to be added or removed from a volume’s list of create volume permissions.
      - **Group** (string) –
        The specific group that is to be added or removed from a volume’s list of create volume permissions.

**Returns** None

**reload()**

Calls `ec2.Client.describe_snapshots()` to update the attributes of the Snapshot resource.

**Request Syntax**
snapshot.reload()

Returns None
reset_attribute(**kwargs)
Resets permission settings for the specified snapshot.
For more information on modifying snapshot permissions, see Sharing Snapshots in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

response = snapshot.reset_attribute(
    DryRun=True|False,
    Attribute='productCodes'|'createVolumePermission'
)

Parameters

• **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
• **Attribute (string)** – [REQUIRED]
The attribute to reset. Currently, only the attribute for permission to create volumes can be reset.

Returns None

Waiters

Waiters provide an interface to wait for a resource to reach a specific state. For more information about waiters refer to the Resources Introduction Guide.

wait_until_completed(**kwargs)

Waits until this Snapshot is completed. This method calls EC2.Waiter.snapshot_completed.wait() which polls EC2.Client.describe_snapshots() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

snapshot.wait_until_completed(
    DryRun=True|False,
    OwnerIds=['string'],
    RestorableByUserIds=['string'],
    Filters=[
        {'Name': 'string',
         'Values': ['string',
            ]},
    ],
    NextToken='string',
    MaxResults=123
)
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **OwnerIds** *(list)* – Returns the snapshots owned by the specified owner. Multiple owners can be specified.
  - *(string)*

- **RestorableByUserIds** *(list)* – One or more AWS accounts IDs that can create volumes from the snapshot.
  - *(string)*

- **Filters** *(list)* – One or more filters.
  - description - A description of the snapshot.
  - owner-alias - The AWS account alias (for example, `amazon`) that owns the snapshot.
  - owner-id - The ID of the AWS account that owns the snapshot.
  - progress - The progress of the snapshot, as a percentage (for example, 80%).
  - snapshot-id - The snapshot ID.
  - start-time - The time stamp when the snapshot was initiated.
  - status - The status of the snapshot (`pending` | `completed` | `error`).
  - tag :key =*value* - The key/value combination of a tag assigned to the resource.
  - tag-key - The key of a tag assigned to the resource. This filter is independent of the tag-value filter. For example, if you use both the filter “tag-key=Purpose” and the filter “tag-value=X”, you get any resources assigned both the tag key Purpose (regardless of what the tag’s value is), and the tag value X (regardless of what the tag’s key is). If you want to list only resources where Purpose is X, see the **tag :key =*value* filter.
  - tag-value - The value of a tag assigned to the resource. This filter is independent of the tag-key filter.
  - volume-id - The ID of the volume the snapshot is for.
  - volume-size - The size of the volume, in GiB.
  - *(dict)*

A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

- **Name** *(string)* –
  
The name of the filter. Filter names are case-sensitive.

- **Values** *(list)* –
  
  One or more filter values. Filter values are case-sensitive.

- **NextToken** *(string)* – The `NextToken` value returned from a previous paginated `DescribeSnapshots` request where `MaxResults` was used and the results exceeded the value of that parameter. Pagination continues from the end of the previous results that returned the `NextToken` value. This value is null when there are no more results to return.

- **MaxResults** *(integer)* – The maximum number of snapshot results returned by `DescribeSnapshots` in paginated output. When this parameter is used, `DescribeSnapshots` only returns `MaxResults` results in a single page along with a `NextToken` response element. The remaining results of the initi-
tial request can be seen by sending another DescribeSnapshots request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. If this parameter is not used, then DescribeSnapshots returns all results. You cannot specify this parameter and the snapshot IDs parameter in the same request.

Returns None

Subnet

class EC2.Subnet (id)
A resource representing an Amazon Elastic Compute Cloud (EC2) Subnet:

import boto3

e2 = boto3.resource('ec2')
senet = ec2.Subnet('id')

Parameters id (string) – The Subnet’s id identifier. This must be set.

These are the resource’s available identifiers:
• id

These are the resource’s available attributes:
• availability_zone
• available_ip_address_count
• cidr_block
• default_for_az
• map_public_ip_on_launch
• state
• subnet_id
• tags
• vpc_id

These are the resource’s available references:
• vpc

These are the resource’s available actions:
• create_instances()
• create_network_interface()
• create_tags()
• delete()
• load()
• reload()

These are the resource’s available collections:
• instances
• network_interfaces

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

id

(string) The Subnet’s id identifier. This must be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.
**availability_zone**
*(string)*

The Availability Zone of the subnet.

**available_ip_address_count**
*(integer)*

The number of unused IP addresses in the subnet. Note that the IP addresses for any stopped instances are considered unavailable.

**cidr_block**
*(string)*

The CIDR block assigned to the subnet.

**default_for_az**
*(boolean)*

Indicates whether this is the default subnet for the Availability Zone.

**map_public_ip_on_launch**
*(boolean)*

Indicates whether instances launched in this subnet receive a public IP address.

**state**
*(string)*

The current state of the subnet.

**subnet_id**
*(string)*

The ID of the subnet.

**tags**
*(list)*

Any tags assigned to the subnet.

**vpc_id**
*(string)*

The ID of the VPC the subnet is in.

References

References are related resource instances that have a belongs-to relationship. For more information about references refer to the Resources Introduction Guide.

**vpc**
*(Vpc)* The related vpc if set, otherwise None.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

**create_instances(**kwargs**)**

Launches the specified number of instances using an AMI for which you have permissions.

When you launch an instance, it enters the pending state. After the instance is ready for you, it enters the running state. To check the state of your instance, call DescribeInstances.
If you don’t specify a security group when launching an instance, Amazon EC2 uses the default security group. For more information, see Security Groups in the Amazon Elastic Compute Cloud User Guide.

[EC2-VPC only accounts] If you don’t specify a subnet in the request, we choose a default subnet from your default VPC for you.

[EC2-Classic accounts] If you’re launching into EC2-Classic and you don’t specify an Availability Zone, we choose one for you.

Linux instances have access to the public key of the key pair at boot. You can use this key to provide secure access to the instance. Amazon EC2 public images use this feature to provide secure access without passwords. For more information, see Key Pairs in the Amazon Elastic Compute Cloud User Guide.

You can provide optional user data when launching an instance. For more information, see Instance Metadata in the Amazon Elastic Compute Cloud User Guide.

If any of the AMIs have a product code attached for which the user has not subscribed, RunInstances fails.

T2 instance types can only be launched into a VPC. If you do not have a default VPC, or if you do not specify a subnet ID in the request, RunInstances fails.

For more information about troubleshooting, see What To Do If An Instance Immediately Terminates, and Troubleshooting Connecting to Your Instance in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
instance = subnet.create_instances(
    DryRun=True|False,
    ImageId='string',
    MinCount=123,
    MaxCount=123,
    KeyName='string',
    SecurityGroups=[
        'string',
    ],
    SecurityGroupIds=[
        'string',
    ],
    UserData='string',
    InstanceType='t1.micro'|'m1.small'|'m1.medium'|'m1.large'|'m1.xlarge'|'m3.medium'|'m3.large'|'m3.xlarge'|'m3.2xlarge'|'m4.16xlarge'|'m4.4xlarge'|'m4.8xlarge'|'r3.large'|'r3.xlarge'|'r3.2xlarge'|'r3.4xlarge'|'r3.8xlarge'|'d2.xlarge'|'d2.2xlarge'|'d2.4xlarge'|'d2.8xlarge',
    Placement={
        'AvailabilityZone': 'string',
        'GroupName': 'string',
        'Tenancy': 'default'|'dedicated',
    },
    KernelId='string',
    RamdiskId='string',
    BlockDeviceMappings=[
        {
            'VirtualName': 'string',
            'DeviceName': 'string',
            'Ebs': {
                'SnapshotId': 'string',
                'VolumeSize': 123,
                'DeleteOnTermination': True|False,
                'VolumeType': 'standard'|'io1'|'gp2',
                'Iops': 123,
                'Encrypted': True|False
            }
        }
    ]
)
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **ImageId** *(string)* – **[REQUIRED]**

  The ID of the AMI, which you can get by calling `DescribeImages`.

- **MinCount** *(integer)* – **[REQUIRED]**

  The minimum number of instances to launch. If you specify a minimum that is more instances than Amazon EC2 can launch in the target Availability Zone, Amazon EC2 launches no instances.

  **Constraints:** Between 1 and the maximum number you’re allowed for the specified instance type. For more information about the default limits, and how to request an increase, see How many instances can I run in Amazon EC2 in the Amazon EC2 General FAQ.
• **MaxCount** *(integer) – [REQUIRED]*

The maximum number of instances to launch. If you specify more instances than Amazon EC2 can launch in the target Availability Zone, Amazon EC2 launches the largest possible number of instances above **MinCount**.

Constraints: Between 1 and the maximum number you’re allowed for the specified instance type. For more information about the default limits, and how to request an increase, see How many instances can I run in Amazon EC2 in the Amazon EC2 General FAQ.

• **KeyName** *(string)* – The name of the key pair. You can create a key pair using CreateKeyPair or ImportKeyPair.

**Warning:** If you do not specify a key pair, you can’t connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

• **SecurityGroups** *(list)* – [EC2-Classic, default VPC] One or more security group names. For a nondefault VPC, you must use security group IDs instead.

Default: Amazon EC2 uses the default security group.

  – *(string)*

• **SecurityGroupIds** *(list)* – One or more security group IDs. You can create a security group using CreateSecurityGroup.

Default: Amazon EC2 uses the default security group.

  – *(string)*

• **UserData** *(string)* – The Base64-encoded MIME user data for the instances.

  This value will be base64 encoded automatically. Do not base64 encode this value prior to performing the operation.

• **InstanceType** *(string)* – The instance type. For more information, see Instance Types in the Amazon Elastic Compute Cloud User Guide.

Default: **m1.small**

• **Placement** *(dict)* – The placement for the instance.

  – **AvailabilityZone** *(string)*

  The Availability Zone of the instance.

  – **GroupName** *(string)*

  The name of the placement group the instance is in (for cluster compute instances).

  – **Tenancy** *(string)*

  The tenancy of the instance (if the instance is running in a VPC). An instance with a tenancy of dedicated runs on single-tenant hardware.

• **KernelId** *(string)* – The ID of the kernel.

  **Warning:** We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see PV-GRUB in the Amazon Elastic Compute Cloud User Guide.

• **RamdiskId** *(string)* – The ID of the RAM disk.

  **Warning:** We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see PV-GRUB in the Amazon Elastic Compute Cloud User Guide.

• **BlockDeviceMappings** *(list)* – The block device mapping.
Describes a block device mapping.

* VirtualName (string) –

  The virtual device name (ephemeral N). Instance store volumes are numbered starting from 0. An instance type with 2 available instance store volumes can specify mappings for ephemeral0 and ephemeral1. The number of available instance store volumes depends on the instance type. After you connect to the instance, you must mount the volume.

Constraints: For M3 instances, you must specify instance store volumes in the block device mapping for the instance. When you launch an M3 instance, we ignore any instance store volumes specified in the block device mapping for the AMI.

* DeviceName (string) –

  The device name exposed to the instance (for example, /dev/sdh or xvdh).

* Ebs (dict) –

  Parameters used to automatically set up EBS volumes when the instance is launched.

  - SnapshotId (string) –
    The ID of the snapshot.

  - VolumeSize (integer) –
    The size of the volume, in GiB.

    Constraints: 1-1024 for standard volumes, 1-16384 for gp2 volumes, and 4-16384 for io1 volumes. If you specify a snapshot, the volume size must be equal to or larger than the snapshot size.

    Default: If you’re creating the volume from a snapshot and don’t specify a volume size, the default is the snapshot size.

  - DeleteOnTermination (boolean) –
    Indicates whether the EBS volume is deleted on instance termination.

  - VolumeType (string) –
    The volume type. gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, and standard for Magnetic volumes.

    Default: standard

  - Iops (integer) –
    The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.
Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.

Condition: This parameter is required for requests to create io1 volumes; it is not used in requests to create standard or gp2 volumes.

- **Encrypted** *(boolean)*

  Indicates whether the EBS volume is encrypted. Encrypted Amazon EBS volumes may only be attached to instances that support Amazon EBS encryption.

- **NoDevice** *(string)*

  Suppresses the specified device included in the block device mapping of the AMI.

- **Monitoring** *(dict)* – The monitoring for the instance.

  - **Enabled** *(boolean)* – [REQUIRED]

    Indicates whether monitoring is enabled for the instance.

- **DisableApiTermination** *(boolean)* – If you set this parameter to true, you can’t terminate the instance using the Amazon EC2 console, CLI, or API; otherwise, you can. If you set this parameter to true and then later want to be able to terminate the instance, you must first change the value of the disableApiTermination attribute to false using ModifyInstanceAttribute. Alternatively, if you set InstanceInitiatedShutdownBehavior to terminate, you can terminate the instance by running the shutdown command from the instance.

  Default: false

- **InstanceInitiatedShutdownBehavior** *(string)* – Indicates whether an instance stops or terminates when you initiate shutdown from the instance (using the operating system command for system shutdown).

  Default: stop

- **PrivateIpAddress** *(string)* – [EC2-VPC] The primary IP address. You must specify a value from the IP address range of the subnet.

  Only one private IP address can be designated as primary. Therefore, you can’t specify this parameter if PrivateIpAddresses.n.Primary is set to true and PrivateIpAddresses.n.PrivateIpAddress is set to an IP address.

  Default: We select an IP address from the IP address range of the subnet.

- **ClientToken** *(string)* – Unique, case-sensitive identifier you provide to ensure the idempotency of the request. For more information, see Ensuring Idempotency.

  Constraints: Maximum 64 ASCII characters

- **AdditionalInfo** *(string)* – Reserved.

- **NetworkInterfaces** *(list)* – One or more network interfaces.

  - *(dict)*

    Describes a network interface.

      - **NetworkInterfaceId** *(string)*

        The ID of the network interface.

      - **DeviceIndex** *(integer)*
The index of the device on the instance for the network interface attachment. If you are specifying a network interface in a RunInstances request, you must provide the device index.

* **SubnetId (string)** –

  The ID of the subnet associated with the network string. Applies only if creating a network interface when launching an instance.

* **Description (string)** –

  The description of the network interface. Applies only if creating a network interface when launching an instance.

* **PrivateIpAddress (string)** –

  The private IP address of the network interface. Applies only if creating a network interface when launching an instance.

* **Groups (list)** –

  The IDs of the security groups for the network interface. Applies only if creating a network interface when launching an instance.

  · **(string)** –

* **DeleteOnTermination (boolean)** –

  If set to true, the interface is deleted when the instance is terminated. You can specify true only if creating a new network interface when launching an instance.

* **PrivateIpAddresses (list)** –

  One or more private IP addresses to assign to the network interface. Only one private IP address can be designated as primary.

  · **(dict)** –

    Describes a secondary private IP address for a network interface.

    · **PrivateIpAddress (string)** – [REQUIRED]

      The private IP addresses.

    · **Primary (boolean)** –

      Indicates whether the private IP address is the primary private IP address. Only one IP address can be designated as primary.

* **SecondaryPrivateIpAddressCount (integer)** –

  The number of secondary private IP addresses. You can’t specify this option and specify more than one private IP address using the private IP addresses option.

* **AssociatePublicIpAddress (boolean)** –

  Indicates whether to assign a public IP address to an instance you launch in a VPC. The public IP address can only be assigned to a network interface for eth0, and can only be assigned to a new network interface, not an existing one. You cannot specify more than one network interface in the request. If launching into a default subnet, the default value is true.

  · **IamInstanceProfile (dict)** – The IAM instance profile.

    – **Arn (string)** –

      The Amazon Resource Name (ARN) of the instance profile.

    – **Name (string)** –

      The name of the instance profile.
- **EbsOptimized** *(boolean)* – Indicates whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal EBS I/O performance. This optimization isn’t available with all instance types. Additional usage charges apply when using an EBS-optimized instance.

  Default: false

**Return type** list(ec2.Instance)

**Returns** A list of Instance resources

```python
create_network_interface(**kwargs)
```

Creates a network interface in the specified subnet.

For more information about network interfaces, see Elastic Network Interfaces in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
network_interface = subnet.create_network_interface(
    Description='string',
    PrivateIpAddress='string',
    Groups=[
        'string',
    ],
    PrivateIpAddresses=[
        {
            'PrivateIpAddress': 'string',
            'Primary': True|False
        },
    ],
    SecondaryPrivateIpAddressCount=123,
    DryRun=True|False
)
```

**Parameters**

- **Description** *(string)* – A description for the network interface.
- **PrivateIpAddress** *(string)* – The primary private IP address of the network interface. If you don’t specify an IP address, Amazon EC2 selects one for you from the subnet range. If you specify an IP address, you cannot indicate any IP addresses specified in privateIpAddresses as primary (only one IP address can be designated as primary).
- **Groups** *(list)* – The IDs of one or more security groups.
  - *(string)* –
- **PrivateIpAddresses** *(list)* – One or more private IP addresses.
  - *(dict)* –
    Describes a secondary private IP address for a network interface.
    - **Primary** *(boolean)* – Indicates whether the private IP address is the primary private IP address. Only one IP address can be designated as primary.
- **SecondaryPrivateIpAddressCount** *(integer)* – The number of secondary private IP addresses to assign to a network interface. When you specify a number of secondary IP addresses, Amazon EC2 selects these IP addresses within the subnet range. You can’t specify this option and specify more than one private IP address using privateIpAddresses.
The number of IP addresses you can assign to a network interface varies by instance type. For more information, see Private IP Addresses Per ENI Per Instance Type in the Amazon Elastic Compute Cloud User Guide.

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

**Return type** `ec2.NetworkInterface`

**Returns** NetworkInterface resource

create_tags(**kwargs)**

Adds or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each resource can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys must be unique per resource.

For more information about tags, see Tagging Your Resources in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
    tag = subnet.create_tags(
        DryRun=True|False,
        Tags=[
            {'Key': 'string',
             'Value': 'string'},
        ]
    )
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **Tags (list)** – [REQUIRED]

    One or more tags. The `value` parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.

        - (dict) –

      Describes a tag.

        - **Key (string)** –

          The key of the tag.

          Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:

        - **Value (string)** –

          The value of the tag.

          Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

**Return type** `list(ec2.Tag)`

**Returns** A list of Tag resources
**delete(****kwargs**)
Deletes the specified subnet. You must terminate all running instances in the subnet before you can delete
the subnet.

**Request Syntax**

```python
response = subnet.delete(
    DryRun=True|False,
)
```

**Parameters**

**DryRun** *(boolean)* – Checks whether you have the required permissions for the
action, without actually making the request, and provides an error response. If you have
the required permissions, the error response is **DryRunOperation**. Otherwise, it is
**UnauthorizedOperation**.

**Returns**

**None**

**load()**
Calls **ec2.Client.describe_subnets()** to update the attributes of the Subnet resource

**Request Syntax**

```python
subnet.load()
```

**Returns**

**None**

**reload()**
Calls **ec2.Client.describe_subnets()** to update the attributes of the Subnet resource

**Request Syntax**

```python
subnet.reload()
```

**Returns**

**None**

**Collections**

Collections provide an interface to iterate over and manipulate groups of resources. For more information about
collections refer to the **Resources Introduction Guide**.

**instances**

**all()**
Creates an iterable of all Instance resources in the collection.

**Request Syntax**

```python
instance_iterator = subnet.instances.all()
```

**Return type**

**list(ec2.Instance)**

**Returns**

A list of Instance resources

**create_tags(****kwargs**)**
Adds or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each
resource can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys
must be unique per resource.

For more information about tags, see **Tagging Your Resources** in the **Amazon Elastic Compute
Cloud User Guide**.
Request Syntax

response = subnet.instances.create_tags(
    DryRun=True|False,
    Tags=[
        {'Key': 'string',
         'Value': 'string'},
    ],
)

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **Tags** *(list)* – [REQUIRED]
  One or more tags. The value parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.
  - *(dict)* –
    Describes a tag.
    - **Key** *(string)* –
      The key of the tag.
      Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`
    - **Value** *(string)* –
      The value of the tag.
      Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

Returns  None

**filter**(**kwargs**)
Creates an iterable of all Instance resources in the collection filtered by kwargs passed to method.

Request Syntax

instance_iterator = subnet.instances.filter(
    DryRun=True|False,
    InstanceIds=['string'],
    NextToken='string',
    MaxResults=123
)

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
• **InstanceIds** (*list*) – One or more instance IDs.
  
  Default: Describes all your instances.
  
  – (*string*) –

• **NextToken** (*string*) – The token to request the next page of results.

• **MaxResults** (*integer*) – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. You cannot specify this parameter and the instance IDs parameter in the same request.

  **Return type** list(ec2.Instance)
  **Returns** A list of Instance resources

**limit(** **kwargs)**

Creates an iterable up to a specified amount of Instance resources in the collection.

**Request Syntax**

```python
instance_iterator = subnet.instances.limit(
    count=123
)
```

**Parameters** count (*integer*) – The limit to the number of resources in the iterable.

**Return type** list(ec2.Instance)

**Returns** A list of Instance resources

**monitor(** **kwargs)**

**Request Syntax**

```python
response = subnet.instances.monitor(
    DryRun=True|False,
)
```

**Parameters** DryRun (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'InstanceMonitorings': [
        {
            'InstanceId': 'string',
            'Monitoring': {
                'State': 'disabled'|'disabling'|'enabled'|'pending'
            }
        },
    ]
}
```

**Response Structure**
• (dict) –
  • **InstanceMonitorings** (list) –
    Monitoring information for one or more instances.
    * (dict) –
      Describes the monitoring information of the instance.
      • **InstanceId** (string) –
        The ID of the instance.
      • **Monitoring** (dict) –
        The monitoring information.
      • **State** (string) –
        Indicates whether monitoring is enabled for the instance.

**page_size(**kwargs)**

Creates an iterable of all Instance resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```
instance_iterator = subnet.instances.page_size(
    count=123
)
```

**Parameters**

`count (integer)` – The number of items returned by each service call

**Return type**

`list(ec2.Instance)`

**Returns**

A list of Instance resources

**reboot(**kwargs)**

Requests a reboot of one or more instances. This operation is asynchronous; it only queues a request to reboot the specified instances. The operation succeeds if the instances are valid and belong to you. Requests to reboot terminated instances are ignored.

If a Linux/Unix instance does not cleanly shut down within four minutes, Amazon EC2 performs a hard reboot.

For more information about troubleshooting, see Getting Console Output and Rebooting Instances in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```
response = subnet.instances.reboot(
    DryRun=True|False,
)
```

**Parameters**

`DryRun (boolean)` – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Returns**

None

**start(**kwargs)**

Starts an Amazon EBS-backed AMI that you’ve previously stopped.

Instances that use Amazon EBS volumes as their root devices can be quickly stopped and started. When an instance is stopped, the compute resources are released and you are not billed for hourly

3.1. Services
instance usage. However, your root partition Amazon EBS volume remains, continues to persist your data, and you are charged for Amazon EBS volume usage. You can restart your instance at any time. Each time you transition an instance from stopped to started, Amazon EC2 charges a full instance hour, even if transitions happen multiple times within a single hour.

Before stopping an instance, make sure it is in a state from which it can be restarted. Stopping an instance does not preserve data stored in RAM.

Performing this operation on an instance that uses an instance store as its root device returns an error.

For more information, see Stopping Instances in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = subnet.instances.start(
    AdditionalInfo='string',
    DryRun=True|False
)
```

Parameters

- **AdditionalInfo** *(string)* – Reserved.
- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

Return type **dict**

Returns

Response Syntax

```json
{
    'StartingInstances': [
        {
            'InstanceId': 'string',
            'CurrentState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped'
            },
            'PreviousState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped'
            }
        }
    ]
}
```

Response Structure

- *(dict)*
  - **StartingInstances** *(list)* – Information about one or more started instances.
    - *(dict)*
      - **InstanceId** *(string)* – Describes an instance state change.
        - **InstanceId** *(string)* – The ID of the instance.
· **CurrentState** (dict) –
  The current state of the instance.
· **Code** (integer) –
  The low byte represents the state. The high byte is an opaque internal value and should be ignored.
  · 0: pending
  · 16: running
  · 32: shutting-down
  · 48: terminated
  · 64: stopping
  · 80: stopped
· **Name** (string) –
  The current state of the instance.

· **PreviousState** (dict) –
  The previous state of the instance.
· **Code** (integer) –
  The low byte represents the state. The high byte is an opaque internal value and should be ignored.
  · 0: pending
  · 16: running
  · 32: shutting-down
  · 48: terminated
  · 64: stopping
  · 80: stopped
· **Name** (string) –
  The current state of the instance.

**stop(** **kwargs **)**
Stops an Amazon EBS-backed instance. Each time you transition an instance from stopped to started, Amazon EC2 charges a full instance hour, even if transitions happen multiple times within a single hour.

You can’t start or stop Spot Instances.

Instances that use Amazon EBS volumes as their root devices can be quickly stopped and started. When an instance is stopped, the compute resources are released and you are not billed for hourly instance usage. However, your root partition Amazon EBS volume remains, continues to persist your data, and you are charged for Amazon EBS volume usage. You can restart your instance at any time.

Before stopping an instance, make sure it is in a state from which it can be restarted. Stopping an instance does not preserve data stored in RAM.

Performing this operation on an instance that uses an instance store as its root device returns an error.

You can stop, start, and terminate EBS-backed instances. You can only terminate instance store-backed instances. What happens to an instance differs if you stop it or terminate it. For example, when you stop an instance, the root device and any other devices attached to the instance persist. When you terminate an instance, the root device and any other devices attached during the instance launch are automatically deleted. For more information about the differences between stopping and terminating instances, see Instance Lifecycle in the Amazon Elastic Compute Cloud User Guide.
For more information about troubleshooting, see Troubleshooting Stopping Your Instance in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = subnet.instances.stop(
    DryRun=True|False,
    Force=True|False
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **Force (boolean)** – Forces the instances to stop. The instances do not have an opportunity to flush file system caches or file system metadata. If you use this option, you must perform file system check and repair procedures. This option is not recommended for Windows instances.

Default: false

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'StoppingInstances': [
        {
            'InstanceId': 'string',
            'CurrentState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped'
            },
            'PreviousState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped'
            }
        }
    ]
}
```

**Response Structure**

- **(dict)** –
  - **StoppingInstances (list)** –
    Information about one or more stopped instances.
    - **(dict)** –
      Describes an instance state change.
      - **InstanceId (string)** –
        The ID of the instance.
      - **CurrentState (dict)** –
        The current state of the instance.
      - **Code (integer)** –
        The low byte represents the state. The high byte is an opaque internal value and should be ignored.
The current state of the instance.

- **Name (string)** –

The current state of the instance.

- **PreviousState (dict)** –

The previous state of the instance.

- **Code (integer)** –

The low byte represents the state. The high byte is an opaque internal value and should be ignored.

- 0: pending
- 16: running
- 32: shutting-down
- 48: terminated
- 64: stopping
- 80: stopped

Parameters **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

Return type **dict**
Returns

Response Syntax

```json
{
  'TerminatingInstances': [
    {
      'InstanceId': 'string',
      'CurrentState': {
        'Code': 123,
        'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped'
      },
      'PreviousState': {
        'Code': 123,
        'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped'
      }
    },
  ],
}
```

Response Structure

- (dict) –
  - TerminatingInstances (list) –
    Information about one or more terminated instances.
      - (dict) –
        Describes an instance state change.
          - InstanceId (string) –
            The ID of the instance.
          - CurrentState (dict) –
            The current state of the instance.
            - Code (integer) –
              The low byte represents the state. The high byte is an opaque internal value and should be ignored.
              - 0: pending
              - 16: running
              - 32: shutting-down
              - 48: terminated
              - 64: stopping
              - 80: stopped
            - Name (string) –
              The current state of the instance.
          - PreviousState (dict) –
            The previous state of the instance.
            - Code (integer) –
              The low byte represents the state. The high byte is an opaque internal value and should be ignored.
              - 0: pending
              - 16: running
              - 32: shutting-down
              - 48: terminated
              - 64: stopping
              - 80: stopped
unmonitor(**kwargs)

Disables monitoring for a running instance. For more information about monitoring instances, see Monitoring Your Instances and Volumes in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = subnet.instances.unmonitor(
    DryRun=True|False,
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

**Return type**

dict

**Returns**

**Response Syntax**

```
{
    'InstanceMonitorings': [
        {'InstanceId': 'string',
         'Monitoring': {
             'State': 'disabled'|'disabling'|'enabled'|'pending'
         }
    ],
}
```

**Response Structure**

- *(dict)* –
  - **InstanceMonitorings (list)** –
    Monitoring information for one or more instances.
  - *(dict)* –
    Describes the monitoring information of the instance.
      - **InstanceId (string)** –
        The ID of the instance.
      - **Monitoring (dict)** –
        The monitoring information.
      - **State (string)** –
        Indicates whether monitoring is enabled for the instance.

`network_interfaces

all()

Creates an iterable of all NetworkInterface resources in the collection.

**Request Syntax**
network_interface_iterator = subnet.network_interfaces.all()

    Return type  list(ec2.NetworkInterface)
    Returns    A list of NetworkInterface resources

**filter(**kwargs)**

Creates an iterable of all NetworkInterface resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
network_interface_iterator = subnet.network_interfaces.filter(
    DryRun=True|False,
    NetworkInterfaceIds=[
        'string',
    ],
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **NetworkInterfaceIds** *(list)* – One or more network interface IDs.

- Default: Describes all your network interfaces.

**Return type**  list(ec2.NetworkInterface)
**Returns**    A list of NetworkInterface resources

**limit(**kwargs)**

Creates an iterable up to a specified amount of NetworkInterface resources in the collection.

**Request Syntax**

```python
network_interface_iterator = subnet.network_interfaces.limit(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The limit to the number of resources in the iterable.

**Return type**  list(ec2.NetworkInterface)
**Returns**    A list of NetworkInterface resources

**page_size(**kwargs)**

Creates an iterable of all NetworkInterface resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
network_interface_iterator = subnet.network_interfaces.page_size(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The number of items returned by each service call

**Return type**  list(ec2.NetworkInterface)
**Returns**    A list of NetworkInterface resources
Tag

```python
class EC2.Tag(resource_id, key, value)
    A resource representing an Amazon Elastic Compute Cloud (EC2) Tag:

import boto3

ec2 = boto3.resource('ec2')
tag = ec2.Tag('resource_id', 'key', 'value')
```

Parameters

- **resource_id** *(string)* – The Tag’s resource_id identifier. This **must** be set.
- **key** *(string)* – The Tag’s key identifier. This **must** be set.
- **value** *(string)* – The Tag’s value identifier. This **must** be set.

These are the resource’s available identifiers:
- `resource_id`
- `key`
- `value`

These are the resource’s available attributes:
- `resource_type`

These are the resource’s available actions:
- `delete()`
- `load()`
- `reload()`

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide*.

resource_id *(string)* – The Tag’s resource_id identifier. This **must** be set.

key *(string)* – The Tag’s key identifier. This **must** be set.

value *(string)* – The Tag’s value identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the *Resources Introduction Guide*.

resource_type *(string)*

The resource type.

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the *Resources Introduction Guide*.

delete (**kwargs)**

Deletes the specified set of tags from the specified set of resources. This call is designed to follow a DescribeTags request.

For more information about tags, see Tagging Your Resources in the *Amazon Elastic Compute Cloud User Guide*.
Request Syntax

```python
response = tag.delete(
    DryRun=True|False,
)
```

**Parameters**  
**DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Returns**  
None

`load()`  
Calls `ec2.Client.describe_tags()` to update the attributes of the Tag resource

**Request Syntax**

```python
tag.load()
```

**Returns**  
None

`reload()`  
Calls `ec2.Client.describe_tags()` to update the attributes of the Tag resource

**Request Syntax**

```python
tag.reload()
```

**Returns**  
None

---

**Volume**

**class**  
`EC2.Volume(id)`

A resource representing an Amazon Elastic Compute Cloud (EC2) Volume:

```python
import boto3

e2 = boto3.resource('ec2')
volume = e2.Volume('id')
```

**Parameters**  
**id** *(string)* – The Volume’s id identifier. This must be set.

These are the resource’s available identifiers:

- `id`

These are the resource’s available attributes:

- `attachments`
- `availability_zone`
- `create_time`
- `encrypted`
- `iops`
- `kms_key_id`
- `size`
- `snapshot_id`
- `state`
- `tags`
These are the resource’s available actions:

- attach_to_instance()
- create_snapshot()
- create_tags()
- delete()
- describe_attribute()
- describe_status()
- detach_from_instance()
- enable_io()
- load()
- modify_attribute()
- reload()

These are the resource’s available collections:

- snapshots

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

**id**

(string) The Volume’s id identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

**attachments**

(list)

Information about the volume attachments.

**availability_zone**

(string)

The Availability Zone for the volume.

**create_time**

(datetime)

The time stamp when volume creation was initiated.

**encrypted**

(boolean)

Indicates whether the volume will be encrypted.

**iops**

(integer)

The number of I/O operations per second (IOPS) that the volume supports. For Provisioned IOPS (SSD) volumes, this represents the number of IOPS that are provisioned for the volume. For General Purpose (SSD) volumes, this represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information on General Purpose (SSD) baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the Amazon Elastic Compute Cloud User Guide.

Constraint: Range is 100 to 20000 for Provisioned IOPS (SSD) volumes and 3 to 10000 for General Purpose (SSD) volumes.
Condition: This parameter is required for requests to create io1 volumes; it is not used in requests to create standard or gp2 volumes.

**kms_key_id**

*(string)*

The full ARN of the AWS Key Management Service (AWS KMS) customer master key (CMK) that was used to protect the volume encryption key for the volume.

**size**

*(integer)*

The size of the volume, in GiBs.

**snapshot_id**

*(string)*

The snapshot from which the volume was created, if applicable.

**state**

*(string)*

The volume state.

**tags**

*(list)*

Any tags assigned to the volume.

**volume_id**

*(string)*

The ID of the volume.

**volume_type**

*(string)*

The volume type. This can be gp2 for General Purpose (SSD) volumes, io1 for Provisioned IOPS (SSD) volumes, or standard for Magnetic volumes.

## Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the [Resources Introduction Guide](#).

**attach_to_instance(** **kwargs**

Attaches an EBS volume to a running or stopped instance and exposes it to the instance with the specified device name.

Encrypted EBS volumes may only be attached to instances that support Amazon EBS encryption. For more information, see Amazon EBS Encryption in the [Amazon Elastic Compute Cloud User Guide](#).

For a list of supported device names, see Attaching an EBS Volume to an Instance. Any device names that aren’t reserved for instance store volumes can be used for EBS volumes. For more information, see Amazon EC2 Instance Store in the [Amazon Elastic Compute Cloud User Guide](#).

If a volume has an AWS Marketplace product code:

- The volume can be attached only to a stopped instance.
- AWS Marketplace product codes are copied from the volume to the instance.
- You must be subscribed to the product.
- The instance type and operating system of the instance must support the product. For example, you can’t detach a volume from a Windows instance and attach it to a Linux instance.
For an overview of the AWS Marketplace, see Introducing AWS Marketplace.

For more information about EBS volumes, see Attaching Amazon EBS Volumes in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = volume.attach_to_instance(
    DryRun=True|False,
    InstanceId='string',
    Device='string'
)
```

Parameters

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **InstanceId** (*string*) – [REQUIRED]
  The ID of the instance.
- **Device** (*string*) – [REQUIRED]
  The device name to expose to the instance (for example, /dev/sdh or xvdh).

Return type  dict

Returns

Response Syntax

```python
{
    'VolumeId': 'string',
    'InstanceId': 'string',
    'Device': 'string',
    'State': 'attaching'|'attached'|'detaching'|'detached',
    'AttachTime': datetime(2015, 1, 1),
    'DeleteOnTermination': True|False
}
```

Response Structure

- (*dict*) – Information about the volume attachment.
  - **VolumeId** (*string*) – The ID of the volume.
  - **InstanceId** (*string*) – The ID of the instance.
  - **Device** (*string*) – The device name.
  - **State** (*string*) – The attachment state of the volume.
  - **AttachTime** (*datetime*) – The time stamp when the attachment initiated.
  - **DeleteOnTermination** (*boolean*) – Indicates whether the EBS volume is deleted on instance termination.
**create_snapshot** (**kwargs**)

Creates a snapshot of an EBS volume and stores it in Amazon S3. You can use snapshots for backups, to make copies of EBS volumes, and to save data before shutting down an instance.

When a snapshot is created, any AWS Marketplace product codes that are associated with the source volume are propagated to the snapshot.

You can take a snapshot of an attached volume that is in use. However, snapshots only capture data that has been written to your EBS volume at the time the snapshot command is issued; this may exclude any data that has been cached by any applications or the operating system. If you can pause any file systems on the volume long enough to take a snapshot, your snapshot should be complete. However, if you cannot pause all file writes to the volume, you should unmount the volume from within the instance, issue the snapshot command, and then remount the volume to ensure a consistent and complete snapshot. You may remount and use your volume while the snapshot status is **pending**.

To create a snapshot for EBS volumes that serve as root devices, you should stop the instance before taking the snapshot.

Snapshots that are taken from encrypted volumes are automatically encrypted. Volumes that are created from encrypted snapshots are also automatically encrypted. Your encrypted volumes and any associated snapshots always remain protected.

For more information, see Amazon Elastic Block Store and Amazon EBS Encryption in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
snapshot = volume.create_snapshot(
    DryRun=True|False,
    Description='string'
)
```

**Parameters**

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **Description** (string) – A description for the snapshot.

**Return type** ec2.Snapshot

**Returns** Snapshot resource

**create_tags** (**kwargs**)

Adds or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each resource can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys must be unique per resource.

For more information about tags, see Tagging Your Resources in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
tag = volume.create_tags(
    DryRun=True|False,
    Tags=[
        {'Key': 'string',
         'Value': 'string'}
    ],
```
Parameters

- **DryRun** *(boolean)* — Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **Tags** *(list)* — [REQUIRED] One or more tags. The `value` parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.

  - *(dict)* — Describes a tag.
    - **Key** *(string)* — The key of the tag.
      - Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws`:
    - **Value** *(string)* — The value of the tag.
      - Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

**Return type** list(ec2.Tag)

**Returns** A list of Tag resources

### delete(**kwargs)**

Deletes the specified EBS volume. The volume must be in the available state (not attached to an instance).

**Note:** The volume may remain in the deleting state for several minutes.

For more information, see Deleting an Amazon EBS Volume in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = volume.delete(
    DryRun=True|False,
)
```

**Parameters** **DryRun** *(boolean)* — Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Returns** None

### describe_attribute(**kwargs)**

Describes the specified attribute of the specified volume. You can specify only one attribute at a time.

For more information about EBS volumes, see Amazon EBS Volumes in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**
response = volume.describe_attribute(
    DryRun=True|False,
    Attribute='autoEnableIO'|'productCodes'
)

Parameters
- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **Attribute** (string) – The instance attribute.

Return type  dict

Returns

Response Syntax

```python
{
    'VolumeId': 'string',
    'AutoEnableIO': {
        'Value': True|False
    },
    'ProductCodes': [
    {
        'ProductCodeId': 'string',
        'ProductCodeType': 'devpay'|'marketplace'
    }
]
}
```

Response Structure
- **(dict)** –
  - **VolumeId** (string) – The ID of the volume.
  - **AutoEnableIO** (dict) – The state of `autoEnableIO` attribute.
    - **Value** (boolean) – Valid values are `true` or `false`.
  - **ProductCodes** (list) – A list of product codes.
    - **(dict)** – Describes a product code.
      - **ProductCodeId** (string) – The product code.
      - **ProductCodeType** (string) – The type of product code.

**describe_status** (**kwargs**) Describes the status of the specified volumes. Volume status provides the result of the checks performed on your volumes to determine events that can impair the performance of your volumes. The performance of a volume can be affected if an issue occurs on the volume’s underlying host. If the volume’s underlying host experiences a power outage or system issue, after the system is restored, there could be data
inconsistencies on the volume. Volume events notify you if this occurs. Volume actions notify you if any action needs to be taken in response to the event.

The `DescribeVolumeStatus` operation provides the following information about the specified volumes:

**Status**: Reflects the current status of the volume. The possible values are `ok`, `impaired`, `warning`, or `insufficient-data`. If all checks pass, the overall status of the volume is `ok`. If the check fails, the overall status is `impaired`. If the status is `insufficient-data`, then the checks may still be taking place on your volume at the time. We recommend that you retry the request. For more information on volume status, see Monitoring the Status of Your Volumes.

**Events**: Reflect the cause of a volume status and may require you to take action. For example, if your volume returns an `impaired` status, then the volume event might be `potential-data-inconsistency`. This means that your volume has been affected by an issue with the underlying host, has all I/O operations disabled, and may have inconsistent data.

**Actions**: Reflect the actions you may have to take in response to an event. For example, if the status of the volume is `impaired` and the volume event shows `potential-data-inconsistency`, then the action shows `enable-volume-io`. This means that you may want to enable the I/O operations for the volume by calling the `EnableVolumeIO` action and then check the volume for data consistency.

**Note**: Volume status is based on the volume status checks, and does not reflect the volume state. Therefore, volume status does not indicate volumes in the `error` state (for example, when a volume is incapable of accepting I/O.)

### Request Syntax

```python
response = volume.describe_status(
    DryRun=True|False,
    Filters=[
        {'Name': 'string',
         'Values': ['string',
                    ]},
    ],
    NextToken='string',
    MaxResults=123
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **Filters** *(list)* – One or more filters.
  - **action.code** – The action code for the event (for example, `enable-volume-io`).
  - **action.description** – A description of the action.
  - **action.event-id** – The event ID associated with the action.
  - **availability-zone** – The Availability Zone of the instance.
  - **event.description** – A description of the event.
  - **event.event-id** – The event ID.
  - **event.event-type** – The event type (for `io-enabled`: `passed` or `failed`; for `io-performance`: `io-performance:degraded`
– event.not-after - The latest end time for the event.
– event.not-before - The earliest start time for the event.
– volume-status.status - The status of the volume (ok | impaired | warning | insufficient-data).

– (dict) –
A filter name and value pair that is used to return a more specific list of results. Filters can be used to match a set of resources by various criteria, such as tags, attributes, or IDs.

* Name (string) –
The name of the filter. Filter names are case-sensitive.

* Values (list) –
One or more filter values. Filter values are case-sensitive.

* NextToken (string) – The NextToken value to include in a future DescribeVolumeStatus request. When the results of the request exceed MaxResults, this value can be used to retrieve the next page of results. This value is null when there are no more results to return.

* MaxResults (integer) – The maximum number of volume results returned by DescribeVolumeStatus in paginated output. When this parameter is used, the request only returns MaxResults results in a single page along with a NextToken response element. The remaining results of the initial request can be seen by sending another request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. If this parameter is not used, then DescribeVolumeStatus returns all results. You cannot specify this parameter and the volume IDs parameter in the same request.

Return type: dict

Returns

Response Syntax

```json
{
    'VolumeStatuses': [
        {
            'VolumeId': 'string',
            'AvailabilityZone': 'string',
            'VolumeStatus': {
                'Status': 'ok' | 'impaired' | 'insufficient-data',
                'Details': [
                    {
                        'Name': 'io-enabled' | 'io-performance',
                        'Status': 'string'
                    }
                ]
            }
        }
    ]
}
```

',
'Events': [
{
'EventType': 'string',
'Description': 'string',
'NotBefore': datetime(2015, 1, 1),
'NotAfter': datetime(2015, 1, 1),
'EventId': 'string'
},
],
'Actions': [
{
'Code': 'string',
'Description': 'string',
'EventType': 'string',
'EventId': 'string'
},
]
],

'NextToken': 'string'

Response Structure

- (dict) –
  - VolumeStatuses (list) –
    A list of volumes.
      * (dict) –

Describes the volume status.
  - VolumeId (string) –
    The volume ID.
  - AvailabilityZone (string) –
    The Availability Zone of the volume.
  - VolumeStatus (dict) –
    The volume status.
  - Status (string) –
    The status of the volume.
  - Details (list) –
    The details of the volume status.
      * (dict) –

Describes a volume status.
  - Name (string) –
    The name of the volume status.
  - Status (string) –
    The intended status of the volume status.
  - Events (list) –
    A list of events associated with the volume.
      * (dict) –

Describes a volume status event.
- **EventType** *(string)* –
  The type of this event.
- **Description** *(string)* –
  A description of the event.
- **NotBefore** *(datetime)* –
  The earliest start time of the event.
- **NotAfter** *(datetime)* –
  The latest end time of the event.
- **EventId** *(string)* –
  The ID of this event.
- **Actions** *(list)* –
  The details of the operation.
  *(dict)* –
  Describes a volume status operation code.
  - **Code** *(string)* –
    The code identifying the operation, for example, `enable-volume-io`.
  - **Description** *(string)* –
    A description of the operation.
  - **EventType** *(string)* –
    The event type associated with this operation.
  - **EventId** *(string)* –
    The ID of the event associated with this operation.
- **NextToken** *(string)* –
  The token to use to retrieve the next page of results. This value is `null` when there are no more results to return.

**detach_from_instance** (**kwargs**)
Detaches an EBS volume from an instance. Make sure to unmount any file systems on the device within your operating system before detaching the volume. Failure to do so results in the volume being stuck in a busy state while detaching.

If an Amazon EBS volume is the root device of an instance, it can’t be detached while the instance is running. To detach the root volume, stop the instance first.

When a volume with an AWS Marketplace product code is detached from an instance, the product code is no longer associated with the instance.

For more information, see Detaching an Amazon EBS Volume in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = volume.detach_from_instance(
    DryRun=True|False,
    InstanceId='string',
    Device='string',
    Force=True|False
)
```

**Parameters**
• **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

• **InstanceId** *(string)* – The ID of the instance.

• **Device** *(string)* – The device name.

• **Force** *(boolean)* – Forces detachment if the previous detachment attempt did not occur cleanly (for example, logging into an instance, unmounting the volume, and detaching normally). This option can lead to data loss or a corrupted file system. Use this option only as a last resort to detach a volume from a failed instance. The instance won’t have an opportunity to flush file system caches or file system metadata. If you use this option, you must perform file system check and repair procedures.

**Return type** - dict

**Returns**

**Response Syntax**

```python
{
    'VolumeId': 'string',
    'InstanceId': 'string',
    'Device': 'string',
    'State': 'attaching'|'attached'|'detaching'|'detached',
    'AttachTime': datetime(2015, 1, 1),
    'DeleteOnTermination': True|False
}
```

**Response Structure**

• *(dict)* –

  Information about the volume attachment.
  
  • **VolumeId** *(string)* –
    
    The ID of the volume.
  
  • **InstanceId** *(string)* –
    
    The ID of the instance.
  
  • **Device** *(string)* –
    
    The device name.
  
  • **State** *(string)* –
    
    The attachment state of the volume.
  
  • **AttachTime** *(datetime)* –
    
    The time stamp when the attachment initiated.
  
  • **DeleteOnTermination** *(boolean)* –
    
    Indicates whether the EBS volume is deleted on instance termination.

**enable_io(***kwargs**)

Enables I/O operations for a volume that had I/O operations disabled because the data on the volume was potentially inconsistent.

**Request Syntax**

```python
response = volume.enable_io(
    DryRun=True|False,
)
```
**Parameters**  
**DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Returns**  
None

**load()**  
Calls `ec2.Client.describe_volumes()` to update the attributes of the Volume resource

**Request Syntax**

```python
volume.load()
```

**Returns**  
None

**modify_attribute(**kwargs**)**  
Modifies a volume attribute.

By default, all I/O operations for the volume are suspended when the data on the volume is determined to be potentially inconsistent, to prevent undetectable, latent data corruption. The I/O access to the volume can be resumed by first enabling I/O access and then checking the data consistency on your volume.

You can change the default behavior to resume I/O operations. We recommend that you change this only for boot volumes or for volumes that are stateless or disposable.

**Request Syntax**

```python
response = volume.modify_attribute(
    DryRun=True|False,
    AutoEnableIO={
        'Value': True|False
    }
)
```

**Parameters**

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **AutoEnableIO** (*dict*) – Indicates whether the volume should be auto-enabled for I/O operations.
  - **Value** (*boolean*) –
    - Valid values are `true` or `false`.

**Returns**  
None

**reload()**  
Calls `ec2.Client.describe_volumes()` to update the attributes of the Volume resource

**Request Syntax**

```python
volume.reload()
```

**Returns**  
None

**Collections**

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the *Resources Introduction Guide*. 

---

**Boto3 Documentation, Release 1.1.4**
snapshots

all()
Creates an iterable of all Snapshot resources in the collection.

Request Syntax

```python
snapshot_iterator = volume.snapshots.all()
```

Return type list(ec2.Snapshot)
Returns A list of Snapshot resources

filter(**kwargs)
Creates an iterable of all Snapshot resources in the collection filtered by kwargs passed to method.

Request Syntax

```python
snapshot_iterator = volume.snapshots.filter(
    DryRun=True|False,
    SnapshotIds=[
        'string',
    ],
    OwnerIds=[
        'string',
    ],
    RestorableByUserIds=[
        'string',
    ],
    NextToken='string',
    MaxResults=123
)
```

Parameters

- **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **SnapshotIds** (list) – One or more snapshot IDs. Default: Describes snapshots for which you have launch permissions.
  - (string) –
- **OwnerIds** (list) – Returns the snapshots owned by the specified owner. Multiple owners can be specified.
  - (string) –
- **RestorableByUserIds** (list) – One or more AWS accounts IDs that can create volumes from the snapshot.
  - (string) –
- **NextToken** (string) – The NextToken value returned from a previous paginated DescribeSnapshots request where MaxResults was used and the results exceeded the value of that parameter. Pagination continues from the end of the previous results that returned the NextToken value. This value is null when there are no more results to return.
- **MaxResults** (integer) – The maximum number of snapshot results returned by DescribeSnapshots in paginated output. When this parameter is used, DescribeSnapshots only returns MaxResults results in a single page along with a NextToken response element. The remaining results of the initial request can be seen by sending another
DescribeSnapshots request with the returned NextToken value. This value can be between 5 and 1000; if MaxResults is given a value larger than 1000, only 1000 results are returned. If this parameter is not used, then DescribeSnapshots returns all results. You cannot specify this parameter and the snapshot IDs parameter in the same request.

**Return type**  list(ec2.Snapshot)

**Returns**  A list of Snapshot resources

**limit(**kwargs)**

Creates an iterable up to a specified amount of Snapshot resources in the collection.

**Request Syntax**

```python
snapshot_iterator = volume.snapshots.limit(
    count=123
)
```

**Parameters**  count (integer) – The limit to the number of resources in the iterable.

**Return type**  list(ec2.Snapshot)

**Returns**  A list of Snapshot resources

**page_size(**kwargs)**

Creates an iterable of all Snapshot resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
snapshot_iterator = volume.snapshots.page_size(
    count=123
)
```

**Parameters**  count (integer) – The number of items returned by each service call

**Return type**  list(ec2.Snapshot)

**Returns**  A list of Snapshot resources

**Vpc**

**class EC2.Vpc(id)**

A resource representing an Amazon Elastic Compute Cloud (EC2) Vpc:

```python
import boto3

ec2 = boto3.resource('ec2')
vpc = ec2.Vpc('id')
```

**Parameters**  id (string) – The Vpc’s id identifier. This must be set.

These are the resource’s available identifiers:

• id

These are the resource’s available attributes:

• cidr_block
• dhcp_options_id
• instance_tenancy
• is_default
• state
• tags
• **vpc_id**

These are the resource’s available references:

• **dhcp_options**

These are the resource’s available actions:

• `associate_dhcp_options()`
• `attach_classic_link_instance()`
• `attach_internet_gateway()`
• `create_network_acl()`
• `create_route_table()`
• `create_security_group()`
• `create_subnet()`
• `create_tags()`
• `delete()`
• `describe_attribute()`
• `detach_classic_link_instance()`
• `detach_internet_gateway()`
• `disable_classic_link()`
• `enable_classic_link()`
• `load()`
• `modify_attribute()`
• `reload()`
• `request_vpc_peering_connection()`

These are the resource’s available collections:

• `accepted_vpc_peering_connections`
• `instances`
• `internet_gateways`
• `network_acls`
• `network_interfaces`
• `requested_vpc_peering_connections`
• `route_tables`
• `security_groups`
• `subnets`

Identifiers

Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the *Resources Introduction Guide*.

**id**

*(string)* The Vpc’s id identifier. This **must** be set.

Attributes

Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the `load()` method. For more information about attributes refer to the *Resources Introduction Guide*.

**cidr_block**

*(string)*

The CIDR block for the VPC.

**dhcp_options_id**

*(string)*

The ID of the set of DHCP options you’ve associated with the VPC (or `default` if the default options are associated with the VPC).
The allowed tenancy of instances launched into the VPC.

```
is_default
    (boolean)
    Indicates whether the VPC is the default VPC.
```

```
state
    (string)
    The current state of the VPC.
```

```
tags
    (list)
    Any tags assigned to the VPC.
```

```
vpc_id
    (string)
    The ID of the VPC.
```

References

References are related resource instances that have a belongs-to relationship. For more information about references refer to the Resources Introduction Guide.

```
dhcp_options
    (DhcpOptions) The related dhcp_options if set, otherwise None.
```

Actions

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the Resources Introduction Guide.

```
associate_dhcp_options (**kwargs)
    Associates a set of DHCP options (that you’ve previously created) with the specified VPC, or associates no DHCP options with the VPC.
```

After you associate the options with the VPC, any existing instances and all new instances that you launch in that VPC use the options. You don’t need to restart or relaunch the instances. They automatically pick up the changes within a few hours, depending on how frequently the instance renews its DHCP lease. You can explicitly renew the lease using the operating system on the instance.

For more information, see DHCP Options Sets in the Amazon Virtual Private Cloud User Guide.

Request Syntax

```
response = vpc.associate_dhcp_options(
    DryRun=True|False,
    DhcpOptionsId='string',
)
```

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **DhcpOptionsId (string)** – [REQUIRED]

The ID of the DHCP options set, or default to associate no DHCP options with the VPC.
Returns None

attach_classic_link_instance(**kwargs)

Links an EC2-Classic instance to a ClassicLink-enabled VPC through one or more of the VPC’s security groups. You cannot link an EC2-Classic instance to more than one VPC at a time. You can only link an instance that’s in the running state. An instance is automatically unlinked from a VPC when it's stopped - you can link it to the VPC again when you restart it.

After you’ve linked an instance, you cannot change the VPC security groups that are associated with it. To change the security groups, you must first unlink the instance, and then link it again.

Linking your instance to a VPC is sometimes referred to as attaching your instance.

Request Syntax

response = vpc.attach_classic_link_instance(
    DryRun=True|False,
    InstanceId='string',
    Groups=[
        'string',
    ],
)

Parameters

• **DryRun**(boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

• **InstanceId**(string) – [REQUIRED]
The ID of an EC2-Classic instance to link to the ClassicLink-enabled VPC.

• **Groups**(list) – [REQUIRED]
The ID of one or more of the VPC’s security groups. You cannot specify security groups from a different VPC.

Return type dict

Returns

Response Syntax

{
    'Return': True|False
}

Response Structure

• (dict) –
  • Return (boolean) –
    Returns true if the request succeeds; otherwise, it returns an error.

attach_internet_gateway(**kwargs)

Attaches an Internet gateway to a VPC, enabling connectivity between the Internet and the VPC. For more information about your VPC and Internet gateway, see the Amazon Virtual Private Cloud User Guide.

Request Syntax

response = vpc.attach_internet_gateway(
    DryRun=True|False,
    InternetGatewayId='string',
)
Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
- **InternetGatewayId (string)** – [REQUIRED]

The ID of the Internet gateway.

Returns None

### create_network_acl(**kwargs**)

Creates a network ACL in a VPC. Network ACLs provide an optional layer of security (in addition to security groups) for the instances in your VPC.

For more information about network ACLs, see Network ACLs in the Amazon Virtual Private Cloud User Guide.

Request Syntax

```python
network_acl = vpc.create_network_acl(
    DryRun=True|False,
)
```

### Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

### Return type

`ec2.NetworkAcl`

### Returns

NetworkAcl resource

### create_route_table(**kwargs**)

Creates a route table for the specified VPC. After you create a route table, you can add routes and associate the table with a subnet.

For more information about route tables, see Route Tables in the Amazon Virtual Private Cloud User Guide.

Request Syntax

```python
route_table = vpc.create_route_table(
    DryRun=True|False,
)
```

### Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

### Return type

`ec2.RouteTable`

### Returns

RouteTable resource

### create_security_group(**kwargs**)

Creates a security group.
A security group is for use with instances either in the EC2-Classic platform or in a specific VPC. For more information, see Amazon EC2 Security Groups in the Amazon Elastic Compute Cloud User Guide and Security Groups for Your VPC in the Amazon Virtual Private Cloud User Guide.

**Warning:**
EC2-Classic: You can have up to 500 security groups.
EC2-VPC: You can create up to 100 security groups per VPC.

When you create a security group, you specify a friendly name of your choice. You can have a security group for use in EC2-Classic with the same name as a security group for use in a VPC. However, you can’t have two security groups for use in EC2-Classic with the same name or two security groups for use in a VPC with the same name.

You have a default security group for use in EC2-Classic and a default security group for use in your VPC. If you don’t specify a security group when you launch an instance, the instance is launched into the appropriate default security group. A default security group includes a default rule that grants instances unrestricted network access to each other.

You can add or remove rules from your security groups using AuthorizeSecurityGroupIngress, AuthorizeSecurityGroupEgress, RevokeSecurityGroupIngress, and RevokeSecurityGroupEgress.

**Request Syntax**

```python
def create_security_group(vpc, **kwargs):
    DryRun=True|False,
    GroupName='string',
    Description='string',
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **GroupName (string)** – [REQUIRED]
  
  The name of the security group.
  
  Constraints: Up to 255 characters in length
  
  Constraints for EC2-Classic: ASCII characters
  
  Constraints for EC2-VPC: a-z, A-Z, 0-9, spaces, and `_:-/@[]+=;{}!$*

- **Description (string)** – [REQUIRED]
  
  A description for the security group. This is informational only.
  
  Constraints: Up to 255 characters in length
  
  Constraints for EC2-Classic: ASCII characters
  
  Constraints for EC2-VPC: a-z, A-Z, 0-9, spaces, and `_:-/@[]+=;{}!$*

**Return type** ec2.SecurityGroup

**Returns** SecurityGroup resource

**create_subnet(**kwargs**)

Creates a subnet in an existing VPC.

When you create each subnet, you provide the VPC ID and the CIDR block you want for the subnet. After you create a subnet, you can’t change its CIDR block. The subnet’s CIDR block can be the same as the VPC’s CIDR block (assuming you want only a single subnet in the VPC), or a subset of the VPC’s CIDR
block. If you create more than one subnet in a VPC, the subnets’ CIDR blocks must not overlap. The
smallest subnet (and VPC) you can create uses a /28 netmask (16 IP addresses), and the largest uses a /16
netmask (65,536 IP addresses).

Warning: AWS reserves both the first four and the last IP address in each subnet’s CIDR block.
They’re not available for use.

If you add more than one subnet to a VPC, they’re set up in a star topology with a logical router in the
middle.

If you launch an instance in a VPC using an Amazon EBS-backed AMI, the IP address doesn’t change
if you stop and restart the instance (unlike a similar instance launched outside a VPC, which gets a new
IP address when restarted). It’s therefore possible to have a subnet with no running instances (they’re all
stopped), but no remaining IP addresses available.

For more information about subnets, see Your VPC and Subnets in the Amazon Virtual Private Cloud
User Guide.

Request Syntax

```python
subnet = vpc.create_subnet(
    DryRun=True|False,
    CidrBlock='string',
    AvailabilityZone='string'
)
```

Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the
  action, without actually making the request, and provides an error response. If
  you have the required permissions, the error response is DryRunOperation.
  Otherwise, it is UnauthorizedOperation.
- **CidrBlock** *(string)* – [REQUIRED]
  The network range for the subnet, in CIDR notation. For example, 10.0.0.0/24.
- **AvailabilityZone** *(string)* – The Availability Zone for the subnet.
  Default: Amazon EC2 selects one for you (recommended).

Return type **ec2.Subnet**

Returns Subnet resource

create_tags(**kwargs)

Adds or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each resource
can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys must be unique
per resource.

For more information about tags, see Tagging Your Resources in the Amazon Elastic Compute Cloud User
Guide.

Request Syntax

```python
tag = vpc.create_tags(
    DryRun=True|False,
    Tags=[
        {'Key': 'string',
         'Value': 'string'}
    ],
)
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **Tags** *(list)* – *(REQUIRED)*

  One or more tags. The value parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.

  - *(dict)* –

    Describes a tag.

    * **Key** *(string)* –

      The key of the tag.

      Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with aws:

    * **Value** *(string)* –

      The value of the tag.

      Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

  Returns A list of Tag resources

**delete(** **kwargs**

Deletes the specified VPC. You must detach or delete all gateways and resources that are associated with the VPC before you can delete it. For example, you must terminate all instances running in the VPC, delete all security groups associated with the VPC (except the default one), delete all route tables associated with the VPC (except the default one), and so on.

**Request Syntax**

```python
response = vpc.delete(
    DryRun=True|False,
)
```

**Parameters** **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

**Returns** None

**describe_attribute**(**kwargs**

Describes the specified attribute of the specified VPC. You can specify only one attribute at a time.

**Request Syntax**

```python
response = vpc.describe_attribute(
    DryRun=True|False,
    Attribute='enableDnsSupport'|'enableDnsHostnames'
)
```
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is **DryRunOperation**. Otherwise, it is **UnauthorizedOperation**.

- **Attribute** *(string)* – The VPC attribute.

Return type  **dict**

Returns

**Response Syntax**

```python
{
    'VpcId': 'string',
    'EnableDnsSupport': {
        'Value': True|False
    },
    'EnableDnsHostnames': {
        'Value': True|False
    }
}
```

**Response Structure**

- *(dict)* –
  - **VpcId** *(string)* –
    - The ID of the VPC.
  - **EnableDnsSupport** *(dict)* –
    - Indicates whether DNS resolution is enabled for the VPC. If this attribute is **true**, the Amazon DNS server resolves DNS hostnames for your instances to their corresponding IP addresses; otherwise, it does not.
      - **Value** *(boolean)* –
        - Valid values are **true** or **false**.
    - **EnableDnsHostnames** *(dict)* –
      - Indicates whether the instances launched in the VPC get DNS hostnames. If this attribute is **true**, instances in the VPC get DNS hostnames; otherwise, they do not.
        - **Value** *(boolean)* –
          - Valid values are **true** or **false**.

**detach_classic_link_instance** (**kwargs**)

Unlinks (detaches) a linked EC2-Classic instance from a VPC. After the instance has been unlinked, the VPC security groups are no longer associated with it. An instance is automatically unlinked from a VPC when it’s stopped.

**Request Syntax**

```python
response = vpc.detach_classic_link_instance(
    DryRun=True|False,
    InstanceId='string',
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If
you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **InstanceId** *(string) – [REQUIRED]*

  The ID of the instance to unlink from the VPC.

**Return type**  `dict`

**Returns**

**Response Syntax**

```python
{
   'Return': True|False
}
```

**Response Structure**

- *(dict)*
  - **Return** *(boolean)*
    
    Returns `true` if the request succeeds; otherwise, it returns an error.

**detach_internet_gateway** *(**kwargs)*

Detaches an Internet gateway from a VPC, disabling connectivity between the Internet and the VPC. The VPC must not contain any running instances with Elastic IP addresses.

**Request Syntax**

```python
response = vpc.detach_internet_gateway(
    DryRun=True|False,
    InternetGatewayId='string',
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **InternetGatewayId** *(string) – [REQUIRED]*

  The ID of the Internet gateway.

**Return type**  `None`

**disable_classic_link** *(**kwargs)*

Disables ClassicLink for a VPC. You cannot disable ClassicLink for a VPC that has EC2-Classic instances linked to it.

**Request Syntax**

```python
response = vpc.disable_classic_link(
    DryRun=True|False,
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Return type**  `dict`
Returns

Response Syntax

```python
{
    'Return': True|False
}
```

Response Structure
- `(dict)`
- `Return (boolean)`

Returns `true` if the request succeeds; otherwise, it returns an error.

**enable_classic_link(**kwargs)**

Enables a VPC for ClassicLink. You can then link EC2-Classic instances to your ClassicLink-enabled VPC to allow communication over private IP addresses. You cannot enable your VPC for ClassicLink if any of your VPC’s route tables have existing routes for address ranges within the `10.0.0.0/8` IP address range, excluding local routes for VPCs in the `10.0.0.0/16` and `10.1.0.0/16` IP address ranges. For more information, see ClassicLink in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```python
response = vpc.enable_classic_link(
    DryRun=True|False,
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Return type**

- `dict`

**Returns**

Response Syntax

```python
{
    'Return': True|False
}
```

Response Structure
- `(dict)`
- `Return (boolean)`

Returns `true` if the request succeeds; otherwise, it returns an error.

**load()**

Calls `ec2.Client.describe_vpcs()` to update the attributes of the Vpc resource

Request Syntax

```python
vpc.load()
```

**Returns**

- `None`

**modify_attribute(**kwargs)**

Modifies the specified attribute of the specified VPC.

Request Syntax
response = vpc.modify_attribute(
    EnableDnsSupport={
        'Value': True|False
    },
    EnableDnsHostnames={
        'Value': True|False
    }
)

**Parameters**

- **EnableDnsSupport (dict)** – Indicates whether the DNS resolution is supported for the VPC. If enabled, queries to the Amazon provided DNS server at the 169.254.169.253 IP address, or the reserved IP address at the base of the VPC network range “plus two” will succeed. If disabled, the Amazon provided DNS service in the VPC that resolves public DNS hostnames to IP addresses is not enabled.
  - **Value (boolean)** – Valid values are `true` or `false`.

- **EnableDnsHostnames (dict)** – Indicates whether the instances launched in the VPC get DNS hostnames. If enabled, instances in the VPC get DNS hostnames; otherwise, they do not.
  You can only enable DNS hostnames if you also enable DNS support.
  - **Value (boolean)** – Valid values are `true` or `false`.

**Returns** None

`reload()`

Calls `ec2.Client.describe_vpcs()` to update the attributes of the Vpc resource

**Request Syntax**

vpc.reload()

**Returns** None

`request_vpc_peering_connection(**kwargs)`

Requests a VPC peering connection between two VPCs: a requester VPC that you own and a peer VPC with which to create the connection. The peer VPC can belong to another AWS account. The requester VPC and peer VPC cannot have overlapping CIDR blocks.

The owner of the peer VPC must accept the peering request to activate the peering connection. The VPC peering connection request expires after 7 days, after which it cannot be accepted or rejected.

A `CreateVpcPeeringConnection` request between VPCs with overlapping CIDR blocks results in the VPC peering connection having a status of `failed`.

**Request Syntax**

```python
vpc_peering_connection = vpc.request_vpc_peering_connection(
    DryRun=True|False,
    PeerVpcId='string',
    PeerOwnerId='string'
)
```

**Parameters**
• **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

• **PeerVpcId (string)** – The ID of the VPC with which you are creating the VPC peering connection.

• **PeerOwnerId (string)** – The AWS account ID of the owner of the peer VPC.

  Default: Your AWS account ID

**Return type**  
`ec2.VpcPeeringConnection`  
**Returns**  
VpcPeeringConnection resource

**Collections**

Collections provide an interface to iterate over and manipulate groups of resources. For more information about collections refer to the *Resources Introduction Guide.*

**accepted_vpc_peering_connections**

**all()**

Creates an iterable of all VpcPeeringConnection resources in the collection.

**Request Syntax**

```python
vpc_peering_connection_iterator = vpc.accepted_vpc_peering_connections.all()
```

**Return type**  
`list(ec2.VpcPeeringConnection)`  
**Returns**  
A list of VpcPeeringConnection resources

**filter(**kwargs**)**

Creates an iterable of all VpcPeeringConnection resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
vpc_peering_connection_iterator = vpc.accepted_vpc_peering_connections.filter(
    DryRun=True|False,
    VpcPeeringConnectionIds=['string'],
)
```

**Parameters**

• **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

• **VpcPeeringConnectionIds (list)** – One or more VPC peering connection IDs.

  Default: Describes all your VPC peering connections.

  – (string) –

**Return type**  
`list(ec2.VpcPeeringConnection)`  
**Returns**  
A list of VpcPeeringConnection resources

**limit(**kwargs**)**

Creates an iterable up to a specified amount of VpcPeeringConnection resources in the collection.
Request Syntax

```
vpc_peering_connection_iterator = vpc.accepted_vpc_peering_connections.limit(
    count=123
)
```

**Parameters**

*count* *(integer)* – The limit to the number of resources in the iterable.

**Return type**

`list(ec2.VpcPeeringConnection)`

**Returns**

A list of VpcPeeringConnection resources

---

**page_size** *(**kwargs)**

Creates an iterable of all VpcPeeringConnection resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

```
vpc_peering_connection_iterator = vpc.accepted_vpc_peering_connections.page_size(
    count=123
)
```

**Parameters**

*count* *(integer)* – The number of items returned by each service call

**Return type**

`list(ec2.VpcPeeringConnection)`

**Returns**

A list of VpcPeeringConnection resources

---

**instances**

**all()**

Creates an iterable of all Instance resources in the collection.

Request Syntax

```
instance_iterator = vpc.instances.all()
```

**Return type**

`list(ec2.Instance)`

**Returns**

A list of Instance resources

---

**create_tags** *(**kwargs)**

Adds or overwrites one or more tags for the specified Amazon EC2 resource or resources. Each resource can have a maximum of 10 tags. Each tag consists of a key and optional value. Tag keys must be unique per resource.

For more information about tags, see *Tagging Your Resources* in the *Amazon Elastic Compute Cloud User Guide*.

Request Syntax

```
response = vpc.instances.create_tags(
    DryRun=True|False,
    Tags=[
        
    
    
```

**Parameters**
• **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

• **Tags** *(list)* – [REQUIRED]

  One or more tags. The `value` parameter is required, but if you don’t want the tag to have a value, specify the parameter with no value, and we set the value to an empty string.

  – *(dict)* –

    Describes a tag.

    * **Key** *(string)* –

      The key of the tag.

      Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws:`

    * **Value** *(string)* –

      The value of the tag.

      Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.

  **Returns** None

**filter**(**kwargs**)

Creates an iterable of all Instance resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
instance_iterator = vpc.instances.filter(
    DryRun=True|False,
    InstanceIds=[
        'string',
    ],
    NextToken='string',
    MaxResults=123
)
```

**Parameters**

• **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

• **InstanceIds** *(list)* – One or more instance IDs. Default: Describes all your instances.

  – *(string)* –

  • **NextToken** *(string)* – The token to request the next page of results.

  • **MaxResults** *(integer)* – The maximum number of results to return for the request in a single page. The remaining results of the initial request can be seen by sending another request with the returned `NextToken` value. This value can be between 5 and 1000; if `MaxResults` is given a value larger than 1000, only 1000 results are returned. You cannot specify this parameter and the instance IDs parameter in the same request.

  **Return type** list(EC2.Instance)

  **Returns** A list of Instance resources
**limit(**kwargs**)

Creates an iterable up to a specified amount of Instance resources in the collection.

**Request Syntax**

```python
instance_iterator = vpc.instances.limit(
    count=123
)
```

- **Parameters**
  - `count (integer)` – The limit to the number of resources in the iterable.
  - **Return type**
    - `list(ec2.Instance)`
  - **Returns**
    - A list of Instance resources

**monitor(**kwargs**)

Enables monitoring for a running instance. For more information about monitoring instances, see Monitoring Your Instances and Volumes in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = vpc.instances.monitor(
    DryRun=True|False,
)
```

- **Parameters**
  - `DryRun (boolean)` – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.
  - **Return type**
    - `dict`
  - **Returns**
    - Response Syntax
      ```python
      {
        'InstanceMonitorings': [
          {
            'InstanceId': 'string',
            'Monitoring': {
              'State': 'disabled'|'disabling'|'enabled'|'pending'
            }
          },
        ]
      }
      ```

- **Response Structure**
  - *(dict)* –
    - **InstanceMonitorings (list)** –
      Monitoring information for one or more instances.
      - *(dict)* –
        - **InstanceId (string)** –
          The ID of the instance.
        - **Monitoring (dict)** –
          The monitoring information.
· **State (string)** – Indicates whether monitoring is enabled for the instance.

**page_size (**kwargs **)**

Creates an iterable of all Instance resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
def instance_iterator = vpc.instances.page_size(count=123)
```

**Parameters**

- **count (integer)** – The number of items returned by each service call

**Return type**

`list(ec2.Instance)`

**Returns**

A list of Instance resources

**reboot (**kwargs **)**

Requests a reboot of one or more instances. This operation is asynchronous; it only queues a request to reboot the specified instances. The operation succeeds if the instances are valid and belong to you. Requests to reboot terminated instances are ignored.

If a Linux/Unix instance does not cleanly shut down within four minutes, Amazon EC2 performs a hard reboot.

For more information about troubleshooting, see Getting Console Output and Rebooting Instances in the *Amazon Elastic Compute Cloud User Guide*.

**Request Syntax**

```python
def response = vpc.instances.reboot(DryRun=True|False)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Returns**

None

**start (**kwargs **)**

Starts an Amazon EBS-backed AMI that you’ve previously stopped.

Instances that use Amazon EBS volumes as their root devices can be quickly stopped and started. When an instance is stopped, the compute resources are released and you are not billed for hourly instance usage. However, your root partition Amazon EBS volume remains, continues to persist your data, and you are charged for Amazon EBS volume usage. You can restart your instance at any time. Each time you transition an instance from stopped to started, Amazon EC2 charges a full instance hour, even if transitions happen multiple times within a single hour.

Before stopping an instance, make sure it is in a state from which it can be restarted. Stopping an instance does not preserve data stored in RAM.

Performing this operation on an instance that uses an instance store as its root device returns an error.

For more information, see Stopping Instances in the *Amazon Elastic Compute Cloud User Guide*.
Request Syntax

```python
response = vpc.instances.start(
    AdditionalInfo='string',
    DryRun=True|False
)
```

Parameters

- **AdditionalInfo** *(string)* – Reserved.
- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

Return type  `dict`

Returns

Response Syntax

```python
{
    'StartingInstances': [
        {
            'InstanceId': 'string',
            'CurrentState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped',
            },
            'PreviousState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped',
            }
        }
    ]
}
```

Response Structure

- *(dict)* –
  - **StartingInstances** *(list)* – Information about one or more started instances.
    - *(dict)* –
      - **InstanceId** *(string)* – The ID of the instance.
      - **CurrentState** *(dict)* – The current state of the instance.
        - **Code** *(integer)* – The low byte represents the state. The high byte is an opaque internal value and should be ignored.
          - 0: pending
          - 16: running
          - 32: shutting-down
          - 48: terminated
          - 64: stopping
          - 80: stopped
· **Name** *(string)* –
  The current state of the instance.

· **PreviousState** *(dict)* –
  The previous state of the instance.

· **Code** *(integer)* –
  The low byte represents the state. The high byte is an opaque internal value and should be ignored.
  · 0: *pending*
  · 16: *running*
  · 32: *shutting-down*
  · 48: *terminated*
  · 64: *stopping*
  · 80: *stopped*

· **Name** *(string)* –
  The current state of the instance.

### `stop(**kwargs)`

Stops an Amazon EBS-backed instance. Each time you transition an instance from stopped to started, Amazon EC2 charges a full instance hour, even if transitions happen multiple times within a single hour.

You can’t start or stop Spot Instances.

Instances that use Amazon EBS volumes as their root devices can be quickly stopped and started. When an instance is stopped, the compute resources are released and you are not billed for hourly instance usage. However, your root partition Amazon EBS volume remains, continues to persist your data, and you are charged for Amazon EBS volume usage. You can restart your instance at any time.

Before stopping an instance, make sure it is in a state from which it can be restarted. Stopping an instance does not preserve data stored in RAM.

Performing this operation on an instance that uses an instance store as its root device returns an error.

You can stop, start, and terminate EBS-backed instances. You can only terminate instance store-backed instances. What happens to an instance differs if you stop it or terminate it. For example, when you stop an instance, the root device and any other devices attached to the instance persist. When you terminate an instance, the root device and any other devices attached during the instance launch are automatically deleted. For more information about the differences between stopping and terminating instances, see Instance Lifecycle in the *Amazon Elastic Compute Cloud User Guide*.

For more information about troubleshooting, see Troubleshooting Stopping Your Instance in the *Amazon Elastic Compute Cloud User Guide*.

**Request Syntax**

```python
response = vpc.instances.stop(
    DryRun=True|False,
    Force=True|False
)
```

**Parameters**

· **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an er-
ror response. If you have the required permissions, the error response is
DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **Force (boolean)** – Forces the instances to stop. The instances do not have
an opportunity to flush file system caches or file system metadata. If you
use this option, you must perform file system check and repair procedures.
This option is not recommended for Windows instances.

Default: false

**Return type**: dict

**Returns**

**Response Syntax**

```json
{
    'StoppingInstances': [
        {
            'InstanceId': 'string',
            'CurrentState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped'
            },
            'PreviousState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped'
            }
        },
    ]
}
```

**Response Structure**

- *(dict)* –
  - **StoppingInstances (list)** –
    Information about one or more stopped instances.
    *(dict)* –
    
    Describes an instance state change.
    - **InstanceId (string)** –
      The ID of the instance.
    - **CurrentState (dict)** –
      The current state of the instance.
    - **Code (integer)** –
      The low byte represents the state. The high byte is an
      opaque internal value and should be ignored.
      - 0: pending
      - 16: running
      - 32: shutting-down
      - 48: terminated
      - 64: stopping
      - 80: stopped
    - **Name (string)** –
      The current state of the instance.
    - **PreviousState (dict)** –
      The previous state of the instance.
**Code (integer)** –

The low byte represents the state. The high byte is an opaque internal value and should be ignored.

- 0: pending
- 16: running
- 32: shutting-down
- 48: terminated
- 64: stopping
- 80: stopped

**Name (string)** –

The current state of the instance.

**terminate(**kwargs**)

Shuts down one or more instances. This operation is idempotent; if you terminate an instance more than once, each call succeeds.

Terminated instances remain visible after termination (for approximately one hour).

By default, Amazon EC2 deletes all EBS volumes that were attached when the instance launched. Volumes attached after instance launch continue running.

You can stop, start, and terminate EBS-backed instances. You can only terminate instance store-backed instances. What happens to an instance differs if you stop it or terminate it. For example, when you stop an instance, the root device and any other devices attached to the instance persist. When you terminate an instance, any attached EBS volumes with the DeleteOnTermination block device mapping parameter set to true are automatically deleted. For more information about the differences between stopping and terminating instances, see Instance Lifecycle in the Amazon Elastic Compute Cloud User Guide.

For more information about troubleshooting, see Troubleshooting Terminating Your Instance in the Amazon Elastic Compute Cloud User Guide.

**Request Syntax**

```python
response = vpc.instances.terminate(
    DryRun=True|False,
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

**Return type**

dict

**Response Syntax**

```python
{
    'TerminatingInstances': [
        {
            'InstanceId': 'string',
            'CurrentState': {
                'Code': 123,
                'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped',
            },
            'PreviousState': {
            },
        },
    ]
}
```
'Code': 123,
'Name': 'pending'|'running'|'shutting-down'|'terminated'|'stopping'|'stopped'}

Response Structure

• (dict) –
  – TerminatingInstances (list) –
    Information about one or more terminated instances.
    • (dict) –
      Describes an instance state change.
      • InstanceId (string) –
        The ID of the instance.
      • CurrentState (dict) –
        The current state of the instance.
      • Code (integer) –
        The low byte represents the state. The high byte is an opaque internal value and should be ignored.
        • 0: pending
        • 16: running
        • 32: shutting-down
        • 48: terminated
        • 64: stopping
        • 80: stopped
      • Name (string) –
        The current state of the instance.
      • PreviousState (dict) –
        The previous state of the instance.
      • Code (integer) –
        The low byte represents the state. The high byte is an opaque internal value and should be ignored.
        • 0: pending
        • 16: running
        • 32: shutting-down
        • 48: terminated
        • 64: stopping
        • 80: stopped
      • Name (string) –
        The current state of the instance.

**unmonitor(**kwargs**)

Disables monitoring for a running instance. For more information about monitoring instances, see Monitoring Your Instances and Volumes in the Amazon Elastic Compute Cloud User Guide.

Request Syntax

```
response = vpc.instances.unmonitor(
    DryRun=True|False,
```
Parameters **DryRun** (boolean) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

Return type **dict**

Returns

Response Syntax

```
{
    'InstanceMonitorings': [
        {
            'InstanceId': 'string',
            'Monitoring': {
                'State': 'disabled'|'disabling'|'enabled'|'pending'
            }
        },
    ]
}
```

Response Structure

* (dict) –
  - **InstanceMonitorings** (list) –
    Monitoring information for one or more instances.

    * (dict) –
      Describes the monitoring information of the instance.

      - **InstanceId** (string) –
        The ID of the instance.
      - **Monitoring** (dict) –
        The monitoring information.
      - **State** (string) –
        Indicates whether monitoring is enabled for the instance.

**internet_gateways**

**all()**

Creates an iterable of all InternetGateway resources in the collection.

Request Syntax

```
internet_gateway_iterator = vpc.internet_gateways.all()
```

Return type list(ec2.InternetGateway)

Returns A list of InternetGateway resources

**filter(****kwargs**)**

Creates an iterable of all InternetGateway resources in the collection filtered by kwargs passed to method.

Request Syntax
Parameters

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

- **InternetGatewayIds** *(list)* – One or more Internet gateway IDs.
  
  Default: Describes all your Internet gateways.

**Return type** `list(ec2.InternetGateway)`
**Returns** A list of InternetGateway resources

### limit(**kwargs)**

Creates an iterable up to a specified amount of InternetGateway resources in the collection.

**Request Syntax**

```python
internet_gateway_iterator = vpc.internet_gateways.limit(
    count=123
)
```

**Parameters** `count` *(integer)* – The limit to the number of resources in the iterable.

**Return type** `list(ec2.InternetGateway)`

**Returns** A list of InternetGateway resources

### page_size(**kwargs)**

Creates an iterable of all InternetGateway resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
internet_gateway_iterator = vpc.internet_gateways.page_size(
    count=123
)
```

**Parameters** `count` *(integer)* – The number of items returned by each service call

**Return type** `list(ec2.InternetGateway)`

**Returns** A list of InternetGateway resources

### network_acls

**all()**

Creates an iterable of all NetworkAcl resources in the collection.

**Request Syntax**

```python
network_acl_iterator = vpc.network_acls.all()
```

**Return type** `list(ec2.NetworkAcl)`
Returns A list of NetworkAcl resources

**filter(**kwargs)**

Creates an iterable of all NetworkAcl resources in the collection filtered by kwargs passed to method.

Request Syntax

```python
network_acl_iterato = vpc.network_acls.filter(
    DryRun=True|False,
    NetworkAclIds=[
        'string',
    ],
)
```

**Parameters**

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **NetworkAclIds (list)** – One or more network ACL IDs.
  
  Default: Describes all your network ACLs.

**Return type** list(ec2.NetworkAcl)

**Returns** A list of NetworkAcl resources

**limit(**kwargs)**

Creates an iterable up to a specified amount of NetworkAcl resources in the collection.

Request Syntax

```python
network_acl_iterator = vpc.network_acls.limit(
    count=123
)
```

**Parameters** count (integer) – The limit to the number of resources in the iterable.

**Return type** list(ec2.NetworkAcl)

**Returns** A list of NetworkAcl resources

**page_size(**kwargs)**

Creates an iterable of all NetworkAcl resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

```python
network_acl_iterator = vpc.network_acls.page_size(
    count=123
)
```

**Parameters** count (integer) – The number of items returned by each service call

**Return type** list(ec2.NetworkAcl)

**Returns** A list of NetworkAcl resources

**network_interfaces**
**all()**

Creates an iterable of all NetworkInterface resources in the collection.

**Request Syntax**

```python
network_interface_iterator = vpc.network_interfaces.all()
```

**Return type**  
`list(ec2.NetworkInterface)`

**Returns**  
A list of NetworkInterface resources

**filter(**kwargs**)**

Creates an iterable of all NetworkInterface resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
network_interface_iterator = vpc.network_interfaces.filter(
    DryRun=True|False,
    NetworkInterfaceIds=[
        'string',
    ],
)
```

**Parameters**

- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

- **NetworkInterfaceIds** *(list)* – One or more network interface IDs.

  Default: Describes all your network interfaces.

**Return type**  
`list(ec2.NetworkInterface)`

**Returns**  
A list of NetworkInterface resources

**limit(**kwargs**)**

Creates an iterable up to a specified amount of NetworkInterface resources in the collection.

**Request Syntax**

```python
network_interface_iterator = vpc.network_interfaces.limit(
    count=123
)
```

**Parameters**

- **count** *(integer)* – The limit to the number of resources in the iterable.

**Return type**  
`list(ec2.NetworkInterface)`

**Returns**  
A list of NetworkInterface resources

**page_size(**kwargs**)**

Creates an iterable of all NetworkInterface resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
network_interface_iterator = vpc.network_interfaces.page_size(
    count=123
)
```
Parameters **count** (**integer**) – The number of items returned by each service call

Return type list(ec2.NetworkInterface)

Returns A list of NetworkInterface resources

**requested_vpc_peering_connections**

- **all**()
  - Creates an iterable of all VpcPeeringConnection resources in the collection.

  Request Syntax

  ```python
  vpc_peering_connection_iterator = vpc.requested_vpc_peering_connections.all()
  ```

  Return type list(ec2.VpcPeeringConnection)

  Returns A list of VpcPeeringConnection resources

- **filter(**kwargs)
  - Creates an iterable of all VpcPeeringConnection resources in the collection filtered by kwargs passed to method.

  Request Syntax

  ```python
  vpc_peering_connection_iterator = vpc.requested_vpc_peering_connections.filter(
      DryRun=True|False,
      VpcPeeringConnectionIds=[
          'string',
      ],
  )
  ```

  Parameters

  - **DryRun** (**boolean**) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.

  - **VpcPeeringConnectionIds** (**list**) – One or more VPC peering connection IDs.

    Default: Describes all your VPC peering connections.

    - (string)

  Return type list(ec2.VpcPeeringConnection)

  Returns A list of VpcPeeringConnection resources

- **limit(**kwargs)
  - Creates an iterable up to a specified amount of VpcPeeringConnection resources in the collection.

  Request Syntax

  ```python
  vpc_peering_connection_iterator = vpc.requested_vpc_peering_connections.limit(
      count=123
  )
  ```

  Parameters **count** (**integer**) – The limit to the number of resources in the iterable.

  Return type list(ec2.VpcPeeringConnection)

  Returns A list of VpcPeeringConnection resources

- **page_size(**kwargs)
  - Creates an iterable of all VpcPeeringConnection resources in the collection, but limits the number of items returned by each service call by the specified amount.
Request Syntax

```python
vpc_peering_connection_iterator = vpc.requested_vpc_peering_connections.page_size(
count=123
)
```

**Parameters**
- `count` *(integer)* – The number of items returned by each service call

**Return type**
`list(ec2.VpcPeeringConnection)`

**Returns**
A list of VpcPeeringConnection resources

### route_tables

#### all()
Creates an iterable of all RouteTable resources in the collection.

**Request Syntax**

```python
route_table_iterator = vpc.route_tables.all()
```

**Return type**
`list(ec2.RouteTable)`

**Returns**
A list of RouteTable resources

#### filter(**kwargs)**
Creates an iterable of all RouteTable resources in the collection filtered by kwargs passed to method.

**Request Syntax**

```python
route_table_iterator = vpc.route_tables.filter(
    DryRun=True|False,
    RouteTableIds=[
        'string',
    ],
)
```

**Parameters**
- **DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **RouteTableIds** *(list)* – One or more route table IDs.
  
  Default: Describes all your route tables.

**Return type**
`list(ec2.RouteTable)`

**Returns**
A list of RouteTable resources

#### limit(**kwargs)**
Creates an iterable up to a specified amount of RouteTable resources in the collection.

**Request Syntax**

```python
route_table_iterator = vpc.route_tables.limit(
    count=123
)
```

**Parameters**
- `count` *(integer)* – The limit to the number of resources in the iterable.

**Return type**
`list(ec2.RouteTable)`

**Returns**
A list of RouteTable resources
Returns A list of RouteTable resources

page_size(**kwargs)

Creates an iterable of all RouteTable resources in the collection, but limits the number of items returned by each service call by the specified amount.

Request Syntax

```python
route_table_iterator = vpc.route_tables.page_size(count=123)
```

Parameters count (integer) – The number of items returned by each service call

Return type list(ec2.RouteTable)

Returns A list of RouteTable resources

security_groups

all()

Creates an iterable of all SecurityGroup resources in the collection.

Request Syntax

```python
security_group_iterator = vpc.security_groups.all()
```

Return type list(ec2.SecurityGroup)

Returns A list of SecurityGroup resources

filter(**kwargs)

Creates an iterable of all SecurityGroup resources in the collection filtered by kwargs passed to method.

Request Syntax

```python
security_group_iterator = vpc.security_groups.filter(
    DryRun=True|False,
    GroupNames=[
        'string',
    ],
    GroupIds=[
        'string',
    ],
)
```

Parameters

- **DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is DryRunOperation. Otherwise, it is UnauthorizedOperation.
- **GroupNames (list)** – [EC2-Classic and default VPC only] One or more security group names. You can specify either the security group name or the security group ID. For security groups in a nondefault VPC, use the group-name filter to describe security groups by name.

Default: Describes all your security groups.

- `(string)`
- **GroupIds (list)** – One or more security group IDs. Required for security
groups in a nondefault VPC.

  Default: Describes all your security groups.
  
  - *(string)* –
    
    **Return type** list(ec2.SecurityGroup)
    
    **Returns** A list of SecurityGroup resources

**limit(**kwargs)**

Creates an iterable up to a specified amount of SecurityGroup resources in the collection.

**Request Syntax**

```python
security_group_iterator = vpc.security_groups.limit(count=123)
```

**Parameters**

- **count (integer)** – The limit to the number of resources in the iterable.

  **Return type** list(ec2.SecurityGroup)

  **Returns** A list of SecurityGroup resources

**page_size(**kwargs)**

Creates an iterable of all SecurityGroup resources in the collection, but limits the number of items
returned by each service call by the specified amount.

**Request Syntax**

```python
security_group_iterator = vpc.security_groups.page_size(count=123)
```

**Parameters**

- **count (integer)** – The number of items returned by each service call

  **Return type** list(ec2.SecurityGroup)

  **Returns** A list of SecurityGroup resources

**subnets**

- **all()**

  Creates an iterable of all Subnet resources in the collection.

  **Request Syntax**

  ```python
  subnet_iterator = vpc.subnets.all()
  ```

  **Return type** list(ec2.Subnet)

  **Returns** A list of Subnet resources

**filter(**kwargs)**

Creates an iterable of all Subnet resources in the collection filtered by **kwargs** passed to method.

**Request Syntax**

```python
subnet_iterator = vpc.subnets.filter(
    DryRun=True|False,
    SubnetIds=[
        'string',
    ],
)
```
Parameters

- **DryRun** (*boolean*) – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is *DryRunOperation*. Otherwise, it is *UnauthorizedOperation*.
- **SubnetIds** (*list*) – One or more subnet IDs.

Default: Describes all your subnets.

- **Return type** list(ec2.Subnet)
- **Returns** A list of Subnet resources

**limit** (***kwargs**)

Creates an iterable up to a specified amount of Subnet resources in the collection.

**Request Syntax**

```python
subnet_iterator = vpc.subnets.limit(
    count=123
)
```

- **Parameters** count (*integer*) – The limit to the number of resources in the iterable.
- **Return type** list(ec2.Subnet)
- **Returns** A list of Subnet resources

**page_size** (***kwargs**)

Creates an iterable of all Subnet resources in the collection, but limits the number of items returned by each service call by the specified amount.

**Request Syntax**

```python
subnet_iterator = vpc.subnets.page_size(
    count=123
)
```

- **Parameters** count (*integer*) – The number of items returned by each service call
- **Return type** list(ec2.Subnet)
- **Returns** A list of Subnet resources

**VpcPeeringConnection**

**class** `EC2.VpcPeeringConnection(id)`

A resource representing an Amazon Elastic Compute Cloud (EC2) VpcPeeringConnection:

```python
import boto3
ec2 = boto3.resource('ec2')
vpc_peering_connection = ec2.VpcPeeringConnection('id')
```

- **Parameters** id (*string*) – The VpcPeeringConnection’s id identifier. This must be set.

These are the resource’s available identifiers:
- **id**

These are the resource’s available attributes:
- **accepter_vpc_info**
- **expiration_time**
- **requester_vpc_info**
These are the resource’s available references:
• accepter_vpc
• requester_vpc

These are the resource’s available actions:
• accept()
• delete()
• load()
• reject()
• reload()

Identifiers
Identifiers are properties of a resource that are set upon instantiation of the resource. For more information about identifiers refer to the Resources Introduction Guide.

id
(string) The VpcPeeringConnection’s id identifier. This must be set.

Attributes
Attributes provide access to the properties of a resource. Attributes are lazy-loaded the first time one is accessed via the load() method. For more information about attributes refer to the Resources Introduction Guide.

accepter_vpc_info
(dict)
The information of the peer VPC.

expiration_time
(datetime)
The time that an unaccepted VPC peering connection will expire.

requester_vpc_info
(dict)
The information of the requester VPC.

status
(dict)
The status of the VPC peering connection.

tags
(list)
Any tags assigned to the resource.

tags
(string)
The ID of the VPC peering connection.

References
References are related resource instances that have a belongs-to relationship. For more information about references refer to the Resources Introduction Guide.

accepter_vpc
(Vpc) The related accepter_vpc if set, otherwise None.
**requester_vpc**

(Vpc) The related requester_vpc if set, otherwise None.

**Actions**

Actions call operations on resources. They may automatically handle the passing in of arguments set from identifiers and some attributes. For more information about actions refer to the `Resources Introduction Guide`.

**accept(**kwargs**)**

Accept a VPC peering connection request. To accept a request, the VPC peering connection must be in the `pending-acceptance` state, and you must be the owner of the peer VPC. Use the `DescribeVpcPeeringConnections` request to view your outstanding VPC peering connection requests.

**Request Syntax**

```python
response = vpc_peering_connection.accept(
    DryRun=True|False,
)
```

**Parameters**

**DryRun** *(boolean)* – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'VpcPeeringConnection': {
        'AccepterVpcInfo': {
            'CidrBlock': 'string',
            'OwnerId': 'string',
            'VpcId': 'string'
        },
        'ExpirationTime': datetime(2015, 1, 1),
        'RequesterVpcInfo': {
            'CidrBlock': 'string',
            'OwnerId': 'string',
            'VpcId': 'string'
        },
        'Status': {
            'Code': 'initiating-request'|'pending-acceptance'|'active'|'deleted'|'rejected'|'failed'|'expired'|'provisioning'|'deleting',
            'Message': 'string'
        },
        'Tags': [
            {'Key': 'string',
            'Value': 'string'},
        ],
        'VpcPeeringConnectionId': 'string'
    }
}
```

**Response Structure**

- (dict) –
- **VpcPeeringConnection (dict)** –
  Information about the VPC peering connection.
  * **AccepterVpcInfo (dict)** –
    The information of the peer VPC.
    - **CidrBlock (string)** –
      The CIDR block for the VPC.
    - **OwnerId (string)** –
      The AWS account ID of the VPC owner.
    - **VpcId (string)** –
      The ID of the VPC.
  * **ExpirationTime (datetime)** –
    The time that an unaccepted VPC peering connection will expire.
  * **RequesterVpcInfo (dict)** –
    The information of the requester VPC.
    - **CidrBlock (string)** –
      The CIDR block for the VPC.
    - **OwnerId (string)** –
      The AWS account ID of the VPC owner.
    - **VpcId (string)** –
      The ID of the VPC.
  * **Status (dict)** –
    The status of the VPC peering connection.
    - **Code (string)** –
      The status of the VPC peering connection.
    - **Message (string)** –
      A message that provides more information about the status, if applicable.
  * **Tags (list)** –
    Any tags assigned to the resource.
    - (dict) –
      Describes a tag.
    - **Key (string)** –
      The key of the tag.
      Constraints: Tag keys are case-sensitive and accept a maximum of 127 Unicode characters. May not begin with `aws`:
    - **Value (string)** –
      The value of the tag.
      Constraints: Tag values are case-sensitive and accept a maximum of 255 Unicode characters.
  * **VpcPeeringConnectionId (string)** –
    The ID of the VPC peering connection.

**delete (**kwargs**)**

Deletes a VPC peering connection. Either the owner of the requester VPC or the owner of the peer VPC.
can delete the VPC peering connection if it's in the active state. The owner of the requester VPC can delete a VPC peering connection in the pending-acceptance state.

**Request Syntax**

```python
response = vpc_peering_connection.delete(
    DryRun=True|False,
)
```

**Parameters**

**DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Return type**

dict

**Returns**

**Response Syntax**

```python
{
    'Return': True|False
}
```

**Response Structure**

- (dict) –
  - **Return (boolean)** – Returns true if the request succeeds; otherwise, it returns an error.

**load()**

Calls `ec2.Client.describe_vpc_peering_connections()` to update the attributes of the VpcPeeringConnection resource.

**Request Syntax**

```python
vpc_peering_connection.load()
```

**Returns**

None

**reject(**kwargs**)**

Rejects a VPC peering connection request. The VPC peering connection must be in the pending-acceptance state. Use the `DescribeVpcPeeringConnections` request to view your outstanding VPC peering connection requests. To delete an active VPC peering connection, or to delete a VPC peering connection request that you initiated, use `DeleteVpcPeeringConnection`.

**Request Syntax**

```python
response = vpc_peering_connection.reject(
    DryRun=True|False,
)
```

**Parameters**

**DryRun (boolean)** – Checks whether you have the required permissions for the action, without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

**Return type**

dict
Returns

Response Syntax

    {
        'Return': True|False
    }

Response Structure

• (dict) –
  – Return (boolean) –

    Returns true if the request succeeds; otherwise, it returns an error.

reload()

Calls ec2.Client.describe_vpc_peering_connections() to update the attributes of the VpcPeeringConnection resource

Request Syntax

vpc_peering_connection.reload()

Returns None

ECS

Table of Contents

• ECS
  – Client
  – Paginators
  – Waiters

Client

class ECS.Client

A low-level client representing Amazon EC2 Container Service (ECS):

import boto3

client = boto3.client('ecs')

These are the available methods:

• can_paginate()
• create_cluster()
• create_service()
• delete_cluster()
• delete_service()
• deregister_container_instance()
• deregister_task_definition()
• describe_clusters()
• describe_container_instances()
• describe_services()
• describe_task_definition()
• `describe_tasks()`
• `discover_poll_endpoint()`
• `generate_presigned_url()`
• `get_paginate()`
• `get_waiter()`
• `list_clusters()`
• `list_container_instances()`
• `list_services()`
• `list_task_definition_families()`
• `list_task_definitions()`
• `list_tasks()`
• `register_container_instance()`
• `register_task_definition()`
• `run_task()`
• `start_task()`
• `stop_task()`
• `submit_container_state_change()`
• `submit_task_state_change()`
• `update_container_agent()`
• `update_service()`

`can_paginate(operation_name)`
Check if an operation can be paginated.

**Parameters**

- `operation_name` *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginate("create_foo")`.

**Returns**

- `True` if the operation can be paginated, `False` otherwise.

`create_cluster(**kwargs)`
Creates a new Amazon ECS cluster. By default, your account will receive a default cluster when you launch your first container instance. However, you can create your own cluster with a unique name with the `CreateCluster` action.

**Request Syntax**

```python
response = client.create_cluster(
    clusterName='string'
)
```

**Parameters**

- `clusterName` *(string)* – The name of your cluster. If you do not specify a name for your cluster, you will create a cluster named `default`. Up to 255 letters (uppercase and lowercase), numbers, hyphens, and underscores are allowed.

**Return type**

dict

**Returns**

**Response Syntax**

```python
{
    'cluster': {
        'clusterArn': 'string',
        'clusterName': 'string',
        'status': 'string',
        'registeredContainerInstancesCount': 123,
        'runningTasksCount': 123,
        'pendingTasksCount': 123,
```
'activeServicesCount': 123
}
}

**Response Structure**

- (dict) –
  - cluster (dict) –
    - The full description of your new cluster.
      - **clusterArn** (string) –
        The Amazon Resource Name (ARN) that identifies the cluster. The ARN contains the `arn:aws:ecs` namespace, followed by the region of the cluster, the AWS account ID of the cluster owner, the `cluster` namespace, and then the cluster name. For example, `arn:aws:ecs:region:0123456789:cluster/test`.
      - **clusterName** (string) –
        A user-generated string that you can use to identify your cluster.
      - **status** (string) –
        The status of the cluster. The valid values are `ACTIVE` or `INACTIVE`. `ACTIVE` indicates that you can register container instances with the cluster and the associated instances can accept tasks.
      - **registeredContainerInstancesCount** (integer) –
        The number of container instances registered into the cluster.
      - **runningTasksCount** (integer) –
        The number of tasks in the cluster that are in the `RUNNING` state.
      - **pendingTasksCount** (integer) –
        The number of tasks in the cluster that are in the `PENDING` state.
      - **activeServicesCount** (integer) –
        The number of services that are running on the cluster in an `ACTIVE` state. You can view these services with `ListServices`.

**create_service(**kwargs**)**

Runs and maintains a desired number of tasks from a specified task definition. If the number of tasks running in a service drops below `desiredCount`, Amazon ECS will spawn another instantiation of the task in the specified cluster.

**Request Syntax**

```python
response = client.create_service(
    cluster='string',
    serviceName='string',
    taskDefinition='string',
    loadBalancers=[
        {
            'loadBalancerName': 'string',
            'containerName': 'string',
            'containerPort': 123
        },
    ],
    desiredCount=123,
    clientToken='string',
```
Parameters

- **cluster (string)** – The short name or full Amazon Resource Name (ARN) of the cluster that you want to run your service on. If you do not specify a cluster, the default cluster is assumed.
- **serviceName (string)** – [REQUIRED]

  The name of your service. Up to 255 letters (uppercase and lowercase), numbers, hyphens, and underscores are allowed. Service names must be unique within a cluster, but you can have similarly named services in multiple clusters within a region or across multiple regions.
- **taskDefinition (string)** – [REQUIRED]

  The family and revision (family:revision) or full Amazon Resource Name (ARN) of the task definition that you want to run in your service. If a revision is not specified, the latest ACTIVE revision is used.
- **loadBalancers (list)** – A list of load balancer objects, containing the load balancer name, the container name (as it appears in a container definition), and the container port to access from the load balancer.
  - (dict) –
    - **loadBalancerName (string)** – The name of the load balancer.
    - **containerName (string)** – The name of the container to associate with the load balancer.
    - **containerPort (integer)** – The port on the container to associate with the load balancer. This port must correspond to a containerPort in the service's task definition. Your container instances must allow ingress traffic on the hostPort of the port mapping.
- **desiredCount (integer)** – [REQUIRED]

  The number of instantiations of the specified task definition that you would like to place and keep running on your cluster.
- **clientToken (string)** – Unique, case-sensitive identifier you provide to ensure the idempotency of the request. Up to 32 ASCII characters are allowed.
- **role (string)** – The name or full Amazon Resource Name (ARN) of the IAM role that allows your Amazon ECS container agent to make calls to your load balancer on your behalf. This parameter is only required if you are using a load balancer with your service.

Return type dict

Returns

Response Syntax

```python
{
    'service': {
        'serviceArn': 'string',
        'serviceName': 'string',
        'clusterArn': 'string',
        'loadBalancers': [ ]
    }
}
```
Response Structure

- **service** *(dict)*

  The full description of your service following the create call.
  
  * **serviceArn** *(string)*
    
    The Amazon Resource Name (ARN) that identifies the service. The ARN contains the `arn:aws:ecs` namespace, followed by the region of the service, the AWS account ID of the service owner, the service namespace, and then the service name. For example, `arn:aws:ecs:region:012345678910:service/my-service`.
  
  * **serviceName** *(string)*
    
    A user-generated string that you can use to identify your service.
  
  * **clusterArn** *(string)*
    
    The Amazon Resource Name (ARN) of the of the cluster that hosts the service.
  
  * **loadBalancers** *(list)*
    
    A list of load balancer objects, containing the load balancer name, the container name (as it appears in a container definition), and the container port to access from the load balancer.
  
  - *(dict)*
Details on a load balancer that is used with a service.

- **loadBalancerName** *(string)* –
  The name of the load balancer.

- **containerName** *(string)* –
  The name of the container to associate with the load balancer.

- **containerPort** *(integer)* –
  The port on the container to associate with the load balancer. This port must correspond to a `containerPort` in the service’s task definition. Your container instances must allow ingress traffic on the `hostPort` of the port mapping.

- **status** *(string)* –
  The status of the service. The valid values are `ACTIVE`, `DRAINING`, or `INACTIVE`.

- **desiredCount** *(integer)* –
  The desired number of instantiations of the task definition to keep running on the service. This value is specified when the service is created with `CreateService`, and it can be modified with `UpdateService`.

- **runningCount** *(integer)* –
  The number of tasks in the cluster that are in the `RUNNING` state.

- **pendingCount** *(integer)* –
  The number of tasks in the cluster that are in the `PENDING` state.

- **taskDefinition** *(string)* –
  The task definition to use for tasks in the service. This value is specified when the service is created with `CreateService`, and it can be modified with `UpdateService`.

- **deployments** *(list)* –
  The current state of deployments for the service.
  - *(dict)* –
    The details of an Amazon ECS service deployment.
    - **id** *(string)* –
      The ID of the deployment.
    - **status** *(string)* –
      The status of the deployment. Valid values are `PRIMARY` (for the most recent deployment), `ACTIVE` (for previous deployments that still have tasks running, but are being replaced with the primary deployment), and `INACTIVE` (for deployments that have been completely replaced).
    - **taskDefinition** *(string)* –
      The most recent task definition that was specified for the service to use.
    - **desiredCount** *(integer)* –
      The most recent desired count of tasks that was specified for the service to deploy and/or maintain.
    - **pendingCount** *(integer)* –
The number of tasks in the deployment that are in the **PENDING** status.

- **runningCount** *(integer)* —

The number of tasks in the deployment that are in the **RUNNING** status.

- **createdAt** *(datetime)* —

The Unix time in seconds and milliseconds when the service was created.

- **updatedAt** *(datetime)* —

The Unix time in seconds and milliseconds when the service was last updated.

- **roleArn** *(string)* —

The Amazon Resource Name (ARN) of the IAM role associated with the service that allows the Amazon ECS container agent to register container instances with a load balancer.

- **events** *(list)* —

The event stream for your service. A maximum of 100 of the latest events are displayed.

  - *(dict)* —

    Details on an event associated with a service.

    - **id** *(string)* —

      The ID string of the event.

    - **createdAt** *(datetime)* —

      The Unix time in seconds and milliseconds when the event was triggered.

    - **message** *(string)* —

      The event message.

### delete_cluster(**kwargs**)

Deletes the specified cluster. You must deregister all container instances from this cluster before you may delete it. You can list the container instances in a cluster with ListContainerInstances and deregister them with DeregisterContainerInstance.

**Request Syntax**

```python
response = client.delete_cluster(
    cluster='string'
)
```

**Parameters**

- **cluster** *(string)* — [REQUIRED]

  The short name or full Amazon Resource Name (ARN) of the cluster that you want to delete.

**Return type**
dict

**Response Syntax**

```json
{
    'cluster': {
        'clusterArn': 'string',
        'clusterName': 'string',
```
{'status': 'string',
'registeredContainerInstancesCount': 123,
'runningTasksCount': 123,
'pendingTasksCount': 123,
'activeServicesCount': 123}
}

Response Structure

- (dict) –
  - cluster (dict) –
    The full description of the deleted cluster.
      * clusterArn (string) –
        The Amazon Resource Name (ARN) that identifies the cluster. The ARN contains the arn:aws:ecs namespace, followed by the region of the cluster, the AWS account ID of the cluster owner, the cluster namespace, and then the cluster name. For example, arn:aws:ecs:region:012345678910:cluster/test.
      * clusterName (string) –
        A user-generated string that you can use to identify your cluster.
      * status (string) –
        The status of the cluster. The valid values are ACTIVE or INACTIVE. ACTIVE indicates that you can register container instances with the cluster and the associated instances can accept tasks.
      * registeredContainerInstancesCount (integer) –
        The number of container instances registered into the cluster.
      * runningTasksCount (integer) –
        The number of tasks in the cluster that are in the RUNNING state.
      * pendingTasksCount (integer) –
        The number of tasks in the cluster that are in the PENDING state.
      * activeServicesCount (integer) –
        The number of services that are running on the cluster in an ACTIVE state. You can view these services with ListServices.

delete_service(**kwargs)
Deletes a specified service within a cluster.

Request Syntax

response = client.delete_service(
    cluster='string',
    service='string'
)

Parameters

- cluster (string) – The name of the cluster that hosts the service you want to delete.
- service (string) – [REQUIRED]
  The name of the service you want to delete.

Return type  dict
Returns

Response Syntax

```python
{
    'service': {
        'serviceArn': 'string',
        'serviceName': 'string',
        'clusterArn': 'string',
        'loadBalancers': [
            {
                'loadBalancerName': 'string',
                'containerName': 'string',
                'containerPort': 123
            }
        ],
        'status': 'string',
        'desiredCount': 123,
        'runningCount': 123,
        'pendingCount': 123,
        'taskDefinition': 'string',
        'deployments': [
            {
                'id': 'string',
                'status': 'string',
                'taskDefinition': 'string',
                'desiredCount': 123,
                'pendingCount': 123,
                'runningCount': 123,
                'createdAt': datetime(2015, 1, 1),
                'updatedAt': datetime(2015, 1, 1)
            }
        ],
        'roleArn': 'string',
        'events': [
            {
                'id': 'string',
                'createdAt': datetime(2015, 1, 1),
                'message': 'string'
            }
        ]
    }
}
```

Response Structure

- *(dict)* –
  - **service (dict)** –
    - Details on a service within a cluster
      * **serviceArn (string)** –
        The Amazon Resource Name (ARN) that identifies the service. The ARN contains the arn:aws:ecs namespace, followed by the region of the service, the AWS account ID of the service owner, the service namespace, and then the service name. For example, arn:aws:ecs:region:012345678910:service/my-service.
      * **serviceName (string)** –
        A user-generated string that you can use to identify your service.
* **clusterArn** *(string)* –
  The Amazon Resource Name (ARN) of the cluster that hosts the service.

* **loadBalancers** *(list)* –
  A list of load balancer objects, containing the load balancer name, the container name (as it appears in a container definition), and the container port to access from the load balancer.
  · *(dict)* –
    Details on a load balancer that is used with a service.
    · **loadBalancerName** *(string)* –
      The name of the load balancer.
    · **containerName** *(string)* –
      The name of the container to associate with the load balancer.
    · **containerPort** *(integer)* –
      The port on the container to associate with the load balancer.
      This port must correspond to a *containerPort* in the service’s task definition. Your container instances must allow ingress traffic on the *hostPort* of the port mapping.

* **status** *(string)* –
  The status of the service. The valid values are **ACTIVE** , **DRAINING** , or **INACTIVE** .

* **desiredCount** *(integer)* –
  The desired number of instantiations of the task definition to keep running on the service. This value is specified when the service is created with CreateService , and it can be modified with UpdateService .

* **runningCount** *(integer)* –
  The number of tasks in the cluster that are in the **RUNNING** state.

* **pendingCount** *(integer)* –
  The number of tasks in the cluster that are in the **PENDING** state.

* **taskDefinition** *(string)* –
  The task definition to use for tasks in the service. This value is specified when the service is created with CreateService , and it can be modified with UpdateService .

* **deployments** *(list)* –
  The current state of deployments for the service.
  · *(dict)* –
    The details of an Amazon ECS service deployment.
    · **id** *(string)* –
      The ID of the deployment.
    · **status** *(string)* –
      The status of the deployment. Valid values are **PRIMARY** (for the most recent deployment), **ACTIVE** (for previous deployments that still have tasks running, but are being replaced with the **PRIMARY** deployment), and **INACTIVE** (for deployments that have been completely replaced).
· **taskDefinition** *(string)* –
  The most recent task definition that was specified for the service to use.

· **desiredCount** *(integer)* –
  The most recent desired count of tasks that was specified for the service to deploy and/or maintain.

· **pendingCount** *(integer)* –
  The number of tasks in the deployment that are in the PENDING status.

· **runningCount** *(integer)* –
  The number of tasks in the deployment that are in the RUNNING status.

· **createdAt** *(datetime)* –
  The Unix time in seconds and milliseconds when the service was created.

· **updatedAt** *(datetime)* –
  The Unix time in seconds and milliseconds when the service was last updated.

* **roleArn** *(string)* –
  The Amazon Resource Name (ARN) of the IAM role associated with the service that allows the Amazon ECS container agent to register container instances with a load balancer.

* **events** *(list)* –
  The event stream for your service. A maximum of 100 of the latest events are displayed.

  · **(dict)** –
  Details on an event associated with a service.

  · **id** *(string)* –
  The ID string of the event.

  · **createdAt** *(datetime)* –
  The Unix time in seconds and milliseconds when the event was triggered.

  · **message** *(string)* –
  The event message.

### deregister_container_instance(**kwargs)**

Deregisters an Amazon ECS container instance from the specified cluster. This instance will no longer be available to run tasks.

If you intend to use the container instance for some other purpose after deregistration, you should stop all of the tasks running on the container instance before deregistration to avoid any orphaned tasks from consuming resources.

Deregistering a container instance removes the instance from a cluster, but it does not terminate the EC2 instance; if you are finished using the instance, be sure to terminate it in the Amazon EC2 console to stop billing.

**Note:** When you terminate a container instance, it is automatically deregistered from your cluster.
Request Syntax

```python
response = client.deregister_container_instance(
    cluster='string',
    containerInstance='string',
    force=True|False
)
```

Parameters

- **cluster** *(string)* – The short name or full Amazon Resource Name (ARN) of the cluster that hosts the container instance you want to deregister. If you do not specify a cluster, the default cluster is assumed.

- **containerInstance** *(string)* – [REQUIRED]
  The container instance UUID or full Amazon Resource Name (ARN) of the container instance you want to deregister. The ARN contains the `arn:aws:ecs` namespace, followed by the region of the container instance, the AWS account ID of the container instance owner, the `container-instance` namespace, and then the container instance UUID. For example, `arn:aws:ecs:region:aws_account_id:container-instance/container_instance_UUID`.

- **force** *(boolean)* – Force the deregistration of the container instance. If you have tasks running on the container instance when you deregister it with the `force` option, these tasks remain running and they will continue to pass Elastic Load Balancing load balancer health checks until you terminate the instance or the tasks stop through some other means, but they are orphaned (no longer monitored or accounted for by Amazon ECS). If an orphaned task on your container instance is part of an Amazon ECS service, then the service scheduler will start another copy of that task on a different container instance if possible.

Return type  dict

Returns

Response Syntax

```json
{
    'containerInstance': {
        'containerInstanceArn': 'string',
        'ec2InstanceId': 'string',
        'versionInfo': {
            'agentVersion': 'string',
            'agentHash': 'string',
            'dockerVersion': 'string'
        },
        'remainingResources': [
            {
                'name': 'string',
                'type': 'string',
                'doubleValue': 123.0,
                'longValue': 123,
                'integerValue': 123,
                'stringSetValue': ['string'],
            }
        ],
        'registeredResources': [
            {
                'name': 'string',
            }
        ],
    }
}
```
Response Structure

- **containerInstance (dict)** –

  An Amazon EC2 instance that is running the Amazon ECS agent and has been registered with a cluster.

  - **containerInstanceArn (string)** –
    
    The Amazon Resource Name (ARN) of the container instance. The ARN contains the `arn:aws:ecs` namespace, followed by the region of the container instance, the AWS account ID of the container instance owner, the `container-instance` namespace, and then the container instance UUID. For example, `arn:aws:ecs:region:aws_account_id:container-instance/container_instance_UUID`.

  - **ec2InstanceId (string)** –
    
    The Amazon EC2 instance ID of the container instance.

  - **versionInfo (dict)** –
    
    The version information for the Amazon ECS container agent and Docker daemon running on the container instance.

      - **agentVersion (string)** –
        
        The version number of the Amazon ECS container agent.

      - **agentHash (string)** –
        
        The Git commit hash for the Amazon ECS container agent build on the `amazon-ecs-agent` GitHub repository.

      - **dockerVersion (string)** –
        
        The Docker version running on the container instance.

  - **remainingResources (list)** –

    The remaining resources of the container instance that are available for new tasks.

      - **(dict)** –

        Describes the resources available for a container instance.

        - **name (string)** –

          The name of the resource, such as `CPU`, `MEMORY`, `PORTS`, or a user-defined resource.

        - **type (string)** –
The type of the resource, such as INTEGER, DOUBLE, LONG, or STRINGSET.

- **doubleValue (float)** –
  
  When the `doubleValue` type is set, the value of the resource must be a double precision floating-point type.

- **longValue (integer)** –
  
  When the `longValue` type is set, the value of the resource must be an extended precision floating-point type.

- **integerValue (integer)** –
  
  When the `integerValue` type is set, the value of the resource must be an integer.

- **stringSetValue (list)** –
  
  When the `stringSetValue` type is set, the value of the resource must be a string type.

- **(string)** –

  - **registeredResources (list)** –
    
    The registered resources on the container instance that are in use by current tasks.
    
    - **(dict)** –
      
      Describes the resources available for a container instance.
      
      - **name (string)** –
        
        The name of the resource, such as CPU, MEMORY, PORTS, or a user-defined resource.
      
      - **type (string)** –
        
        The type of the resource, such as INTEGER, DOUBLE, LONG, or STRINGSET.
      
      - **doubleValue (float)** –
        
        When the `doubleValue` type is set, the value of the resource must be a double precision floating-point type.
      
      - **longValue (integer)** –
        
        When the `longValue` type is set, the value of the resource must be an extended precision floating-point type.
      
      - **integerValue (integer)** –
        
        When the `integerValue` type is set, the value of the resource must be an integer.
      
      - **stringSetValue (list)** –
        
        When the `stringSetValue` type is set, the value of the resource must be a string type.
      
      - **(string)** –

  - **status (string)** –

    The status of the container instance. The valid values are ACTIVE or INACTIVE. ACTIVE indicates that the container instance can accept tasks.

  - **agentConnected (boolean)** –

    This parameter returns `true` if the agent is actually connected to Amazon ECS. Registered instances with an agent that may be un-
healthy or stopped will return false, and instances without a connected agent cannot accept placement request.

* runningTasksCount (integer) –

The number of tasks on the container instance that are in the RUNNING status.

* pendingTasksCount (integer) –

The number of tasks on the container instance that are in the PENDING status.

* agentUpdateStatus (string) –

The status of the most recent agent update. If an update has never been requested, this value is NULL.

deregister_task_definition(**kwargs)

Deregisters the specified task definition by family and revision. Upon deregistration, the task definition is marked as INACTIVE. Existing tasks and services that reference an INACTIVE task definition continue to run without disruption. Existing services that reference an INACTIVE task definition can still scale up or down by modifying the service’s desired count.

You cannot use an INACTIVE task definition to run new tasks or create new services, and you cannot update an existing service to reference an INACTIVE task definition (although there may be up to a 10 minute window following deregistration where these restrictions have not yet taken effect).

Request Syntax

response = client.deregister_task_definition(
    taskDefinition='string'
)

Parameters  taskDefinition (string) – [REQUIRED]

The family and revision (family:revision) or full Amazon Resource Name (ARN) of the task definition that you want to deregister. You must specify a revision.

Return type  dict

Response Syntax

```python
{
    'taskDefinition': {
        'taskDefinitionArn': 'string',
        'containerDefinitions': [ {
            'name': 'string',
            'image': 'string',
            'cpu': 123,
            'memory': 123,
            'links': [ {
                'string',
            },
            'portMappings': [ {
                'containerPort': 123,
                'hostPort': 123,
                'protocol': 'tcp'|'udp'
            },
```
Response Structure

* (dict) –

  taskDefinition (dict) –

  The full description of the deregistered task.

  * taskDefinitionArn (string) –

    The full Amazon Resource Name (ARN) of the of the task definition.

  * containerDefinitions (list) –

    A list of container definitions in JSON format that describe the different containers that make up your task. For more information on container definition parameters and defaults, see Amazon ECS Task Definitions in the Amazon EC2 Container Service Developer Guide.
· (dict) –

Container definitions are used in task definitions to describe the different containers that are launched as part of a task.

· name (string) –

The name of a container. If you are linking multiple containers together in a task definition, the name of one container can be entered in the links of another container to connect the containers.

· image (string) –

The image used to start a container. This string is passed directly to the Docker daemon. Images in the Docker Hub registry are available by default. Other repositories are specified with *repository-url* /*image* :*tag*.

· cpu (integer) –

The number of cpu units reserved for the container. A container instance has 1,024 cpu units for every CPU core. This parameter specifies the minimum amount of CPU to reserve for a container, and containers share unallocated CPU units with other containers on the instance with the same ratio as their allocated amount.

For example, if you run a single-container task on a single-core instance type with 512 CPU units specified for that container, and that is the only task running on the container instance, that container could use the full 1,024 CPU unit share at any given time. However, if you launched another copy of the same task on that container instance, each task would be guaranteed a minimum of 512 CPU units when needed, and each container could float to higher CPU usage if the other container was not using it, but if both tasks were 100% active all of the time, they would be limited to 512 CPU units.

The Docker daemon on the container instance uses the CPU value to calculate the relative CPU share ratios for running containers. For more information, see CPU share constraint in the Docker documentation. The minimum valid CPU share value that the Linux kernel will allow is 2; however, the CPU parameter is not required, and you can use CPU values below 2 in your container definitions. For CPU values below 2 (including null), the behavior varies based on your Amazon ECS container agent version:

· Agent versions less than or equal to 1.1.0: Null and zero CPU values are passed to Docker as 0, which Docker then converts to 1,024 CPU shares. CPU values of 1 are passed to Docker as 1, which the Linux kernel converts to 2 CPU shares.

· Agent versions greater than or equal to 1.2.0: Null, zero, and CPU values of 1 are passed to Docker as 2.

· memory (integer) –

The number of MiB of memory reserved for the container. If your container attempts to exceed the memory allocated here, the container is killed.
The link parameter allows containers to communicate with each other without the need for port mappings, using the name parameter. The name:internalName construct is analogous to name:alias in Docker links. For more information on linking Docker containers, see https://docs.docker.com/userguide/dockerlinks/.

Warning: Containers that are collocated on a single container instance may be able to communicate with each other without requiring links or host port mappings. Network isolation is achieved on the container instance using security groups and VPC settings.

The list of port mappings for the container.

Port mappings allow containers to access ports on the host container instance to send or receive traffic. Port mappings are specified as part of the container definition.

The port number on the container that is bound to the user-specified or automatically assigned host port. If you specify a container port and not a host port, your container will automatically receive a host port in the ephemeral port range (for more information, see hostPort).

The port number on the container instance to reserve for your container. You can specify a non-reserved host port for your container port mapping, or you can omit the hostPort (or set it to 0) while specifying a containerPort and your container will automatically receive a port in the ephemeral port range for your container instance operating system and Docker version.

The default ephemeral port range is 49153 to 65535, and this range is used for Docker versions prior to 1.6.0. For Docker version 1.6.0 and later, the Docker daemon tries to read the ephemeral port range from /proc/sys/net/ipv4/ip_local_port_range; if this kernel parameter is unavailable, the default ephemeral port range is used. You should not attempt to specify a host port in the ephemeral port range, since these are reserved for automatic assignment. In general, ports below 32768 are outside of the ephemeral port range.

The default reserved ports are 22 for SSH, the Docker ports 2375 and 2376, and the Amazon ECS Container Agent port 51678. Any host port that was previously specified in a running task is also reserved while the task is running (once a task stops, the host port is released). The current reserved ports are displayed in the remainingResources of DescribeCon-
ContainerInstances output, and a container instance may have up to 50 reserved ports at a time, including the default reserved ports (automatically assigned ports do not count toward this limit).

- **protocol (string)** –
  The protocol used for the port mapping. Valid values are `tcp` and `udp`. The default is `tcp`.

- **essential (boolean)** –
  If the essential parameter of a container is marked as `true`, the failure of that container will stop the task. If the essential parameter of a container is marked as `false`, then its failure will not affect the rest of the containers in a task. If this parameter is omitted, a container is assumed to be essential.

  **Note:** All tasks must have at least one essential container.

- **entryPoint (list)** –

  **Warning:** Early versions of the Amazon ECS container agent do not properly handle `entryPoint` parameters. If you have problems using `entryPoint`, update your container agent or enter your commands and arguments as `command` array items instead.

  The `ENTRYPOINT` that is passed to the container. For more information on the Docker `ENTRYPOINT` parameter, see [https://docs.docker.com/reference/builder/#entrypoint](https://docs.docker.com/reference/builder/#entrypoint).

- **command (list)** –

  The `CMD` that is passed to the container. For more information on the Docker `CMD` parameter, see [https://docs.docker.com/reference/builder/#cmd](https://docs.docker.com/reference/builder/#cmd).

- **environment (list)** –

  The environment variables to pass to a container.

  - **(dict)** –
    A key and value pair object.

    - **name (string)** –
      The name of the key value pair. For environment variables, this is the name of the environment variable.

    - **value (string)** –
      The value of the key value pair. For environment variables, this is the value of the environment variable.

  - **mountPoints (list)** –

    The mount points for data volumes in your container.

    - **(dict)** –
      Details on a volume mount point that is used in a container definition.
- **sourceVolume** *(string)* –
  The name of the volume to mount.

- **containerPath** *(string)* –
  The path on the container to mount the host volume at.

- **readOnly** *(boolean)* –
  If this value is `true`, the container has read-only access to the volume. If this value is `false`, then the container can write to the volume. The default value is `false`.

- **volumesFrom** *(list)* –
  Data volumes to mount from another container.
  *(dict)* –
  Details on a data volume from another container.

- **sourceContainer** *(string)* –
  The name of the container to mount volumes from.

- **readOnly** *(boolean)* –
  If this value is `true`, the container has read-only access to the volume. If this value is `false`, then the container can write to the volume. The default value is `false`.

- **family** *(string)* –
  The family of your task definition. You can think of the `family` as the name of your task definition.

- **revision** *(integer)* –
  The revision of the task in a particular family. You can think of the revision as a version number of a task definition in a family. When you register a task definition for the first time, the revision is 1, and each time you register a new revision of a task definition in the same family, the revision value always increases by one (even if you have deregistered previous revisions in this family).

- **volumes** *(list)* –
  The list of volumes in a task. For more information on volume definition parameters and defaults, see Amazon ECS Task Definitions in the Amazon EC2 Container Service Developer Guide.

  *(dict)* –
  A data volume used in a task definition.

  - **name** *(string)* –
    The name of the volume. This name is referenced in the `sourceVolume` parameter of container definition `mountPoints`.

  - **host** *(dict)* –
    The path on the host container instance that is presented to the containers which access the volume. If this parameter is empty, then the Docker daemon assigns a host path for you.

  - **sourcePath** *(string)* –
    The path on the host container instance that is presented to the container. If this parameter is empty, then the Docker daemon has assigned a host path for you.
* status (string) –

The status of the task definition.

**describe_clusters** (**kwargs**)

Describes one or more of your clusters.

**Request Syntax**

```python
response = client.describe_clusters(
    clusters=[
        'string',
    ]
)
```

**Parameters**

clusters (list) – A space-separated list of cluster names or full cluster Amazon Resource Name (ARN) entries. If you do not specify a cluster, the default cluster is assumed.

**Return type**

dict

**Response Syntax**

```python
{
    'clusters': [
        {
            'clusterArn': 'string',
            'clusterName': 'string',
            'status': 'string',
            'registeredContainerInstancesCount': 123,
            'runningTasksCount': 123,
            'pendingTasksCount': 123,
            'activeServicesCount': 123
        },
    ],
    'failures': [
        {
            'arn': 'string',
            'reason': 'string'
        },
    ]
}
```

**Response Structure**

* (dict) –
  
  clusters (list) –

  The list of clusters.

* (dict) –

  A regional grouping of one or more container instances on which you can run task requests. Each account receives a default cluster the first time you use the Amazon ECS service, but you may also create other clusters. Clusters may contain more than one instance type simultaneously.

  * clusterArn (string) –
The Amazon Resource Name (ARN) that identifies the cluster. The ARN contains the `arn:aws:ecs` namespace, followed by the region of the cluster, the AWS account ID of the cluster owner, the `cluster` namespace, and then the cluster name. For example, `arn:aws:ecs:region:012345678910:cluster/test`.

- **clusterName (string)** –
  A user-generated string that you can use to identify your cluster.

- **status (string)** –
  The status of the cluster. The valid values are `ACTIVE` or `INACTIVE`. `ACTIVE` indicates that you can register container instances with the cluster and the associated instances can accept tasks.

- **registeredContainerInstancesCount (integer)** –
  The number of container instances registered into the cluster.

- **runningTasksCount (integer)** –
  The number of tasks in the cluster that are in the `RUNNING` state.

- **pendingTasksCount (integer)** –
  The number of tasks in the cluster that are in the `PENDING` state.

- **activeServicesCount (integer)** –
  The number of services that are running on the cluster in an `ACTIVE` state. You can view these services with `ListServices`.

- **failures (list)** –
  A failed resource.

  - **arn (string)** –
    The Amazon Resource Name (ARN) of the failed resource.

  - **reason (string)** –
    The reason for the failure.

---

**describe_container_instances (**kwargs**)

Describes Amazon EC2 Container Service container instances. Returns metadata about registered and remaining resources on each container instance requested.

**Request Syntax**

```python
response = client.describe_container_instances(
    cluster='string',
    containerInstances=['string',
    ]
)
```

**Parameters**

- **cluster (string)** – The short name or full Amazon Resource Name (ARN) of the cluster that hosts the container instances you want to describe. If you do not specify a cluster, the default cluster is assumed.
• **containerInstances** *(list)* – [REQUIRED]

A space-separated list of container instance UUIDs or full Amazon Resource Name (ARN) entries.

- *(string)* –

Returns

**Response Syntax**

```python
{
    'containerInstances': [
        {
            'containerInstanceArn': 'string',
            'ec2InstanceId': 'string',
            'versionInfo': {
                'agentVersion': 'string',
                'agentHash': 'string',
                'dockerVersion': 'string'
            },
            'remainingResources': [
                {
                    'name': 'string',
                    'type': 'string',
                    'doubleValue': 123.0,
                    'longValue': 123,
                    'integerValue': 123,
                    'stringSetValue': [
                        'string',
                    ]
                },
                ...
            ],
            'registeredResources': [
                {
                    'name': 'string',
                    'type': 'string',
                    'doubleValue': 123.0,
                    'longValue': 123,
                    'integerValue': 123,
                    'stringSetValue': [
                        'string',
                    ]
                },
                ...
            ],
            'status': 'string',
            'agentConnected': True|False,
            'runningTasksCount': 123,
            'pendingTasksCount': 123,
            'agentUpdateStatus': 'PENDING'|'STAGING'|'STAGED'|'UPDATING'|'UPDATED'|'FAILED',
        },
        ...
    ],
    'failures': [
        {
            'arn': 'string',
            'reason': 'string'
        },
        ...
    ]
}
```
Response Structure
• (dict) –
  – containerInstances (list) –

The list of container instances.
  ∗ (dict) –

An Amazon EC2 instance that is running the Amazon ECS agent and has been registered with a cluster.
  ∗ containerInstanceArn (string) –

The Amazon Resource Name (ARN) of the container instance. The ARN contains the arn:aws:ecs namespace, followed by the region of the container instance, the AWS account ID of the container instance owner, the container-instance namespace, and then the container instance UUID. For example, arn:aws:ecs:region:aws_account_id:container-instance/container_instance_UUID.
  ∗ ec2InstanceId (string) –

The Amazon EC2 instance ID of the container instance.
  ∗ versionInfo (dict) –

The version information for the Amazon ECS container agent and Docker daemon running on the container instance.
  ∗ agentVersion (string) –

The version number of the Amazon ECS container agent.
  ∗ agentHash (string) –

The Git commit hash for the Amazon ECS container agent build on the amazon-ecs-agent GitHub repository.
  ∗ dockerVersion (string) –

The Docker version running on the container instance.
  ∗ remainingResources (list) –

The remaining resources of the container instance that are available for new tasks.
  ∗ (dict) –

Describes the resources available for a container instance.
  ∗ name (string) –

The name of the resource, such as CPU, MEMORY, PORTS, or a user-defined resource.
  ∗ type (string) –

The type of the resource, such as INTEGER, DOUBLE, LONG, or STRINGSET.
  ∗ doubleValue (float) –

When the doubleValue type is set, the value of the resource must be a double precision floating-point type.
  ∗ longValue (integer) –

When the longValue type is set, the value of the resource must be an extended precision floating-point type.
  ∗ integerValue (integer) –
When the `integerValue` type is set, the value of the resource must be an integer.

- **stringSetValue (list)** –

  When the `stringSetValue` type is set, the value of the resource must be a string type.

- (string) –

- **registeredResources (list)** –

  The registered resources on the container instance that are in use by current tasks.

- (dict) –

  Describes the resources available for a container instance.

- **name (string)** –

  The name of the resource, such as `CPU`, `MEMORY`, `PORTS`, or a user-defined resource.

- **type (string)** –

  The type of the resource, such as `INTEGER`, `DOUBLE`, `LONG`, or `STRINGSET`.

- **doubleValue (float)** –

  When the `doubleValue` type is set, the value of the resource must be a double precision floating-point type.

- **longValue (integer)** –

  When the `longValue` type is set, the value of the resource must be an extended precision floating-point type.

- **integerValue (integer)** –

  When the `integerValue` type is set, the value of the resource must be an integer.

- **stringSetValue (list)** –

  When the `stringSetValue` type is set, the value of the resource must be a string type.

- (string) –

- **status (string)** –

  The status of the container instance. The valid values are `ACTIVE` or `INACTIVE`. `ACTIVE` indicates that the container instance can accept tasks.

- **agentConnected (boolean)** –

  This parameter returns `true` if the agent is actually connected to Amazon ECS. Registered instances with an agent that may be unhealthy or stopped will return `false`, and instances without a connected agent cannot accept placement request.

- **runningTasksCount (integer)** –

  The number of tasks on the container instance that are in the `RUNNING` status.

- **pendingTasksCount (integer)** –

  The number of tasks on the container instance that are in the `PENDING` status.

- **agentUpdateStatus (string)** –
The status of the most recent agent update. If an update has never been requested, this value is NULL.

- **failures (list)** –
  - *(dict)* –
    A failed resource.
    - **arn (string)** –
      The Amazon Resource Name (ARN) of the failed resource.
    - **reason (string)** –
      The reason for the failure.

**describe_services (**kwargs**)**

Describes the specified services running in your cluster.

**Request Syntax**

```python
response = client.describe_services(
    cluster='string',
    services=[
        'string',
    ]
)
```

**Parameters**

- **cluster (string)** – The name of the cluster that hosts the service you want to describe.
- **services (list)** – [REQUIRED]
  A list of services you want to describe.

**Return type** *dict*

**Response Syntax**

```json
{
    'services': [
        {
            'serviceArn': 'string',
            'serviceName': 'string',
            'clusterArn': 'string',
            'loadBalancers': [
                {
                    'loadBalancerName': 'string',
                    'containerName': 'string',
                    'containerPort': 123
                },
            ],
            'status': 'string',
            'desiredCount': 123,
            'runningCount': 123,
            'pendingCount': 123,
            'taskDefinition': 'string',
            'deployments': [
                {
                    'id': 'string',
                    'status': 'string',
                },
            ],
        },
    ]
}
```
'taskDefinition': 'string',
'desiredCount': 123,
'pendingCount': 123,
'runningCount': 123,
'createdAt': datetime(2015, 1, 1),
'updatedAt': datetime(2015, 1, 1)
},

'roleArn': 'string',
'events': [
  {
    'id': 'string',
    'createdAt': datetime(2015, 1, 1),
    'message': 'string'
  }
],

'failures': [
  {
    'arn': 'string',
    'reason': 'string'
  }
}

Response Structure

- (dict) –
  - services (list) –

The list of services described.

  * (dict) –

Details on a service within a cluster

  - serviceArn (string) –

    The Amazon Resource Name (ARN) that identifies the service. The ARN contains the arn:aws:ecs namespace, followed by the region of the service, the AWS account ID of the service owner, the service namespace, and then the service name. For example, arn:aws:ecs:region:012345678910:service/my-service.

  - serviceName (string) –

    A user-generated string that you can use to identify your service.

  - clusterArn (string) –

    The Amazon Resource Name (ARN) of the of the cluster that hosts the service.

  - loadBalancers (list) –

    A list of load balancer objects, containing the load balancer name, the container name (as it appears in a container definition), and the container port to access from the load balancer.

  * (dict) –

Details on a load balancer that is used with a service.

  - loadBalancerName (string) –
The name of the load balancer.

- **containerName (string)** –

The name of the container to associate with the load balancer.

- **containerPort (integer)** –

The port on the container to associate with the load balancer. This port must correspond to a `containerPort` in the service’s task definition. Your container instances must allow ingress traffic on the `hostPort` of the port mapping.

- **status (string)** –

The status of the service. The valid values are `ACTIVE`, `DRAINING`, or `INACTIVE`.

- **desiredCount (integer)** –

The desired number of instantiations of the task definition to keep running on the service. This value is specified when the service is created with `CreateService`, and it can be modified with `UpdateService`.

- **runningCount (integer)** –

The number of tasks in the cluster that are in the `RUNNING` state.

- **pendingCount (integer)** –

The number of tasks in the cluster that are in the `PENDING` state.

- **taskDefinition (string)** –

The task definition to use for tasks in the service. This value is specified when the service is created with `CreateService`, and it can be modified with `UpdateService`.

- **deployments (list)** –

The current state of deployments for the service.

- **(dict)** –

The details of an Amazon ECS service deployment.

- **id (string)** –

The ID of the deployment.

- **status (string)** –

The status of the deployment. Valid values are `PRIMARY` (for the most recent deployment), `ACTIVE` (for previous deployments that still have tasks running, but are being replaced with the `PRIMARY` deployment), and `INACTIVE` (for deployments that have been completely replaced).

- **taskDefinition (string)** –

The most recent task definition that was specified for the service to use.

- **desiredCount (integer)** –

The most recent desired count of tasks that was specified for the service to deploy and/or maintain.

- **pendingCount (integer)** –

The number of tasks in the deployment that are in the `PENDING` status.
- **runningCount** *(integer)* –
  The number of tasks in the deployment that are in the **RUNNING** status.
- **createdAt** *(datetime)* –
  The Unix time in seconds and milliseconds when the service was created.
- **updatedAt** *(datetime)* –
  The Unix time in seconds and milliseconds when the service was last updated.
- **roleArn** *(string)* –
  The Amazon Resource Name (ARN) of the IAM role associated with the service that allows the Amazon ECS container agent to register container instances with a load balancer.
- **events** *(list)* –
  The event stream for your service. A maximum of 100 of the latest events are displayed.
  - *(dict)* –
    Details on an event associated with a service.
    - **id** *(string)* –
      The ID string of the event.
    - **createdAt** *(datetime)* –
      The Unix time in seconds and milliseconds when the event was triggered.
    - **message** *(string)* –
      The event message.
    - **failures** *(list)* –
      Any failures associated with the call.
      - *(dict)* –
        A failed resource.
        - **arn** *(string)* –
          The Amazon Resource Name (ARN) of the failed resource.
        - **reason** *(string)* –
          The reason for the failure.

**describe_task_definition(****kwargs)**
Describes a task definition. You can specify a family and revision to find information on a specific task definition, or you can simply specify the family to find the latest **ACTIVE** revision in that family.

**Note:** You can only describe **INACTIVE** task definitions while an active task or service references them.

**Request Syntax**

```python
response = client.describe_task_definition(
    taskDefinition='string'
)
```

**Parameters**

- **taskDefinition** *(string)* – [REQUIRED]
The family for the latest ACTIVE revision, family and revision (family:revision) for a specific revision in the family, or full Amazon Resource Name (ARN) of the task definition that you want to describe.

Return type  dict

Returns

Response Syntax

```python
{
    'taskDefinition': {
        'taskDefinitionArn': 'string',
        'containerDefinitions': [
            {
                'name': 'string',
                'image': 'string',
                'cpu': 123,
                'memory': 123,
                'links': [
                    'string',
                ],
                'portMappings': [
                    {
                        'containerPort': 123,
                        'hostPort': 123,
                        'protocol': 'tcp'|'udp'
                    },
                ],
                'essential': True|False,
                'entryPoint': [
                    'string',
                ],
                'command': [
                    'string',
                ],
                'environment': [
                    {
                        'name': 'string',
                        'value': 'string'
                    },
                ],
                'mountPoints': [
                    {
                        'sourceVolume': 'string',
                        'containerPath': 'string',
                        'readOnly': True|False
                    },
                ],
                'volumesFrom': [
                    {
                        'sourceContainer': 'string',
                        'readOnly': True|False
                    },
                ],
                'family': 'string',
                'revision': 123,
                'volumes': [
                ]
            },
        ],
        'family': 'string',
        'revision': 123,
    }
}
```
Response Structure

- (dict) –
  - taskDefinition (dict) –

  The full task definition description.

  * taskDefinitionArn (string) –

    The full Amazon Resource Name (ARN) of the task definition.

  * containerDefinitions (list) –

    A list of container definitions in JSON format that describe the different containers that make up your task. For more information on container definition parameters and defaults, see Amazon ECS Task Definitions in the Amazon EC2 Container Service Developer Guide.

    - (dict) –

      Container definitions are used in task definitions to describe the different containers that are launched as part of a task.

      * name (string) –

        The name of a container. If you are linking multiple containers together in a task definition, the name of one container can be entered in the links of another container to connect the containers.

      * image (string) –

        The image used to start a container. This string is passed directly to the Docker daemon. Images in the Docker Hub registry are available by default. Other repositories are specified with *repository-url* /*image* :*tag*.

      * cpu (integer) –

        The number of cpu units reserved for the container. A container instance has 1,024 cpu units for every CPU core. This parameter specifies the minimum amount of CPU to reserve for a container, and containers share unallocated CPU units with other containers on the instance with the same ratio as their allocated amount.

      For example, if you run a single-container task on a single-core instance type with 512 CPU units specified for that container, and that is the only task running on the container instance, that container could use the full 1,024 CPU unit share at any given time. However, if you launched another copy of the same task on that container instance, each task would be...
guaranteed a minimum of 512 CPU units when needed, and each container could float to higher CPU usage if the other container was not using it, but if both tasks were 100% active all of the time, they would be limited to 512 CPU units.

The Docker daemon on the container instance uses the CPU value to calculate the relative CPU share ratios for running containers. For more information, see CPU share constraint in the Docker documentation. The minimum valid CPU share value that the Linux kernel will allow is 2; however, the CPU parameter is not required, and you can use CPU values below 2 in your container definitions. For CPU values below 2 (including null), the behavior varies based on your Amazon ECS container agent version:

- **Agent versions less than or equal to 1.1.0**: Null and zero CPU values are passed to Docker as 0, which Docker then converts to 1,024 CPU shares. CPU values of 1 are passed to Docker as 1, which the Linux kernel converts to 2 CPU shares.

- **Agent versions greater than or equal to 1.2.0**: Null, zero, and CPU values of 1 are passed to Docker as 2.

- **memory (integer)** –

  The number of MiB of memory reserved for the container. If your container attempts to exceed the memory allocated here, the container is killed.

- **links (list)** –

  The link parameter allows containers to communicate with each other without the need for port mappings, using the name parameter. The name:internalName construct is analogous to name:alias in Docker links. For more information on linking Docker containers, see https://docs.docker.com/userguide/dockerlinks/.

**Warning**: Containers that are collocated on a single container instance may be able to communicate with each other without requiring links or host port mappings. Network isolation is achieved on the container instance using security groups and VPC settings.

- **portMappings (list)** –

  The list of port mappings for the container.

- **containerPort (integer)** –

  The port number on the container that is bound to the user-specified or automatically assigned host port. If you specify a container port and not a host port, your container will automatically receive a host port in the ephemeral port range (for more information, see hostPort).

- **hostPort (integer)** –
The port number on the container instance to reserve for your container. You can specify a non-reserved host port for your container port mapping, or you can omit the `hostPort` (or set it to 0) while specifying a `containerPort` and your container will automatically receive a port in the ephemeral port range for your container instance operating system and Docker version.

The default ephemeral port range is 49153 to 65535, and this range is used for Docker versions prior to 1.6.0. For Docker version 1.6.0 and later, the Docker daemon tries to read the ephemeral port range from `/proc/sys/net/ipv4/ip_local_port_range`; if this kernel parameter is unavailable, the default ephemeral port range is used. You should not attempt to specify a host port in the ephemeral port range, since these are reserved for automatic assignment. In general, ports below 32768 are outside of the ephemeral port range.

The default reserved ports are 22 for SSH, the Docker ports 2375 and 2376, and the Amazon ECS Container Agent port 51678. Any host port that was previously specified in a running task is also reserved while the task is running (once a task stops, the host port is released). The current reserved ports are displayed in the `remainingResources` of `DescribeContainerInstances` output, and a container instance may have up to 50 reserved ports at a time, including the default reserved ports (automatically assigned ports do not count toward this limit).

- `protocol (string)` –
  The protocol used for the port mapping. Valid values are `tcp` and `udp`. The default is `tcp`.

- `essential (boolean)` –
  If the `essential` parameter of a container is marked as `true`, the failure of that container will stop the task. If the `essential` parameter of a container is marked as `false`, then its failure will not affect the rest of the containers in a task. If this parameter is omitted, a container is assumed to be essential.

**Note:** All tasks must have at least one essential container.

- `entryPoint (list)` –

  **Warning:** Early versions of the Amazon ECS container agent do not properly handle `entryPoint` parameters. If you have problems using `entryPoint`, update your container agent or enter your commands and arguments as `command` array items instead.

  The `ENTRYPOINT` that is passed to the container. For more information on the Docker `ENTRYPOINT` parameter, see [https://docs.docker.com/reference/builder/#entrypoint](https://docs.docker.com/reference/builder/#entrypoint).
- **command** *(list)* –
  The `CMD` that is passed to the container. For more information on the Docker `CMD` parameter, see https://docs.docker.com/reference/builder/#cmd.

- **(string)** –
- **environment** *(list)* –
  The environment variables to pass to a container.

- **(dict)** –
  A key and value pair object.
  - **name** *(string)* –
    The name of the key value pair. For environment variables, this is the name of the environment variable.
  - **value** *(string)* –
    The value of the key value pair. For environment variables, this is the value of the environment variable.

- **mountPoints** *(list)* –
  The mount points for data volumes in your container.

- **(dict)** –
  Details on a volume mount point that is used in a container definition.
  - **sourceVolume** *(string)* –
    The name of the volume to mount.
  - **containerPath** *(string)* –
    The path on the container to mount the host volume at.
  - **readOnly** *(boolean)* –
    If this value is `true`, the container has read-only access to the volume. If this value is `false`, then the container can write to the volume. The default value is `false`.

- **volumesFrom** *(list)* –
  Data volumes to mount from another container.

- **(dict)** –
  Details on a data volume from another container.
  - **sourceContainer** *(string)* –
    The name of the container to mount volumes from.
  - **readOnly** *(boolean)* –
    If this value is `true`, the container has read-only access to the volume. If this value is `false`, then the container can write to the volume. The default value is `false`.

* **family** *(string)* –
  The family of your task definition. You can think of the `family` as the name of your task definition.

* **revision** *(integer)* –
  The revision of the task in a particular family. You can think of the revision as a version number of a task definition in a family. When you register a task definition for the first time, the revision is 1, and each time you register a new revision of a task definition in the same
family, the revision value always increases by one (even if you have
deregistered previous revisions in this family).

* **volumes** *(list)* –

The list of volumes in a task. For more information on volume def-
inition parameters and defaults, see Amazon ECS Task Definitions
in the *Amazon EC2 Container Service Developer Guide* .

  · **(dict)** –

    A data volume used in a task definition.

  · **name** *(string)* –

    The name of the volume. This name is referenced in the *sourceVolume*
    parameter of container definition *mountPoints* .

  · **host** *(dict)* –

    The path on the host container instance that is presented to the
    containers which access the volume. If this parameter is empty, then
    the Docker daemon assigns a host path for you.

  · **sourcePath** *(string)* –

    The path on the host container instance that is presented to the
    container. If this parameter is empty, then the Docker daemon
    has assigned a host path for you.

* **status** *(string)* –

The status of the task definition.

**describe_tasks** (**kwargs)**

Describes a specified task or tasks.

**Request Syntax**

```
response = client.describe_tasks(
    cluster='string',
    tasks=[
        'string',
    ],
)
```

**Parameters**

- **cluster** *(string)* – The short name or full Amazon Resource Name (ARN) of the
  cluster that hosts the task you want to describe. If you do not specify a cluster,
  the default cluster is assumed.

- **tasks** *(list)* – [REQUIRED]

  A space-separated list of task UUIDs or full Amazon Resource Name (ARN)
  entries.

**Return type**  **dict**

**Returns**

**Response Syntax**

```
{
    'tasks': [
        {
            'taskArn': 'string',
        },
    ],
```

3.1. Services
Response Structure

- (dict) –
  - tasks (list) –

The list of tasks.

  - (dict) –

Details on a task in a cluster.

  - taskArn (string) –
The Amazon Resource Name (ARN) of the task.

- **clusterArn (string)** –
  The Amazon Resource Name (ARN) of the cluster that hosts the task.

- **taskDefinitionArn (string)** –
  The Amazon Resource Name (ARN) of the task definition that creates the task.

- **containerInstanceArn (string)** –
  The Amazon Resource Name (ARN) of the container instances that host the task.

- **overrides (dict)** –
  One or more container overrides.

- **containerOverrides (list)** –
  One or more container overrides sent to a task.

- **name (string)** –
  The name of the container that receives the override.

- **command (list)** –
  The command to send to the container that overrides the default command from the Docker image or the task definition.

- **environment (list)** –
  The environment variables to send to the container. You can add new environment variables, which are added to the container at launch, or you can override the existing environment variables from the Docker image or the task definition.

- **name (string)** –
  The name of the key value pair. For environment variables, this is the name of the environment variable.

- **value (string)** –
  The value of the key value pair. For environment variables, this is the value of the environment variable.

- **lastStatus (string)** –
  The last known status of the task.

- **desiredStatus (string)** –
  The desired status of the task.

- **containers (list)** –
  The containers associated with the task.

- **containerArn (string)** –
  The Amazon Resource Name (ARN) of the container.
· taskArn (string) –  
The Amazon Resource Name (ARN) of the task.
· name (string) –  
The name of the container.
· lastStatus (string) –  
The last known status of the container.
· exitCode (integer) –  
The exit code returned from the container.
· reason (string) –  
A short (255 max characters) human-readable string to pro-
vide additional detail about a running or stopped container.
· networkBindings (list) –  
The network bindings associated with the container.
  · (dict) –  
  Details on the network bindings between a container and its
  host container instance.
· bindIP (string) –  
The IP address that the container is bound to on the container
instance.
· containerPort (integer) –  
The port number on the container that is be used with the
network binding.
· hostPort (integer) –  
The port number on the host that is used with the network
binding.
· protocol (string) –  
The protocol used for the network binding.
· startedBy (string) –  
The tag specified when a task is started. If the task is started
by an Amazon ECS service, then the startedBy parameter
contains the deployment ID of the service that starts it.

  – failures (list) –  
  * (dict) –  
  A failed resource.
    · arn (string) –  
      The Amazon Resource Name (ARN) of the failed resource.
    · reason (string) –  
      The reason for the failure.

discover_poll_endpoint (**kwargs)

Note: This action is only used by the Amazon EC2 Container Service agent, and it is not intended for
use outside of the agent.

Returns an endpoint for the Amazon EC2 Container Service agent to poll for updates.
Request Syntax

```python
response = client.discover_poll_endpoint(
    containerInstance='string',
    cluster='string'
)
```

Parameters

- **containerInstance** *(string)* – The container instance UUID or full Amazon Resource Name (ARN) of the container instance. The ARN contains the `arn:aws:ecs` namespace, followed by the region of the container instance, the AWS account ID of the container instance owner, the `container-instance` namespace, and then the container instance UUID. For example, `arn:aws:ecs:region:aws_account_id:container-instance/container_instance_UUID`.

- **cluster** *(string)* – The cluster that the container instance belongs to.

Return type  *dict*

Returns

Response Syntax

```json
{
    'endpoint': 'string',
    'telemetryEndpoint': 'string'
}
```

Response Structure

- *(dict)*
  - **endpoint** *(string)* – The endpoint for the Amazon ECS agent to poll.
  - **telemetryEndpoint** *(string)* – The telemetry endpoint for the Amazon ECS agent.

`generate_presigned_url` *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*

Generate a presigned url given a client, its method, and arguments

Parameters

- **ClientMethod** *(string)* – The client method to presign for
- **Params** *(dict)* – The parameters normally passed to `ClientMethod`.
- **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
- **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

Returns The presigned url

`get Paginator` *(operation_name)*

Create a paginator for an operation.

Parameters **operation_name** *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you’d normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginator("create_foo").`

Raises **OperationNotPageableError** Raised if the operation is not pageable. You can use the `client.can_paginate` method to check if an operation is pageable.

Return type  *L{botocore.paginate.Paginator}*

Returns A paginator object.
get_waiter(waiter_name)

list_clusters(**kwargs)
Returns a list of existing clusters.

Request Syntax

```python
response = client.list_clusters(
    nextToken='string',
    maxResults=123
)
```

Parameters

- **nextToken** *(string)* – The nextToken value returned from a previous paginated ListClusters request where maxResults was used and the results exceeded the value of that parameter. Pagination continues from the end of the previous results that returned the nextToken value. This value is null when there are no more results to return.

- **maxResults** *(integer)* – The maximum number of cluster results returned by ListClusters in paginated output. When this parameter is used, ListClusters only returns maxResults results in a single page along with a nextToken response element. The remaining results of the initial request can be seen by sending another ListClusters request with the returned nextToken value. This value can be between 1 and 100. If this parameter is not used, then ListClusters returns up to 100 results and a nextToken value if applicable.

Return type dict

Returns

Response Syntax

```python
{
    'clusterArns': [
        'string',
    ],
    'nextToken': 'string'
}
```

Response Structure

- *(dict)* –
  - **clusterArns** *(list)* –
    The list of full Amazon Resource Name (ARN) entries for each cluster associated with your account.
    - *(string)* –
  - **nextToken** *(string)* –
    The nextToken value to include in a future ListClusters request. When the results of a ListClusters request exceed maxResults, this value can be used to retrieve the next page of results. This value is null when there are no more results to return.

list_container_instances(**kwargs)
Returns a list of container instances in a specified cluster.

Request Syntax
response = client.list_container_instances(
    cluster='string',
    nextToken='string',
    maxResults=123
)

Parameters

- **cluster** *(string)* – The short name or full Amazon Resource Name (ARN) of the cluster that hosts the container instances you want to list. If you do not specify a cluster, the default cluster is assumed.
- **nextToken** *(string)* – The nextToken value returned from a previous paginated ListContainerInstances request where maxResults was used and the results exceeded the value of that parameter. Pagination continues from the end of the previous results that returned the nextToken value. This value is null when there are no more results to return.
- **maxResults** *(integer)* – The maximum number of container instance results returned by ListContainerInstances in paginated output. When this parameter is used, ListContainerInstances only returns maxResults results in a single page along with a nextToken response element. The remaining results of the initial request can be seen by sending another ListContainerInstances request with the returned nextToken value. This value can be between 1 and 100. If this parameter is not used, then ListContainerInstances returns up to 100 results and a nextToken value if applicable.

Return type  dict

Returns

**Response Syntax**

```python
{
    'containerInstanceArns': [ 'string', ]
    'nextToken': 'string'
}
```

**Response Structure**

- *(dict)* –
  - **containerInstanceArns** *(list)* –
    The list of container instance full Amazon Resource Name (ARN) entries for each container instance associated with the specified cluster.
    - *(string)* –
  - **nextToken** *(string)* –
    The nextToken value to include in a future ListContainerInstances request. When the results of a ListContainerInstances request exceed maxResults, this value can be used to retrieve the next page of results. This value is null when there are no more results to return.

**list_services(** **kwargs** **)**

Lists the services that are running in a specified cluster.

**Request Syntax**

3.1. Services
response = client.list_services(
    cluster='string',
    nextToken='string',
    maxResults=123
)

Parameters

- **cluster** *(string)* – The short name or full Amazon Resource Name (ARN) of the
  cluster that hosts the services you want to list. If you do not specify a cluster, the
default cluster is assumed..

- **nextToken** *(string)* – The *nextToken* value returned from a previous pagi-
nated *ListServices* request where *maxResults* was used and the results
exceeded the value of that parameter. Pagination continues from the end of the
previous results that returned the *nextToken* value. This value is *null* when
there are no more results to return.

- **maxResults** *(integer)* – The maximum number of container instance results re-
turned by *ListServices* in paginated output. When this parameter is used,
*ListServices* only returns *maxResults* results in a single page along with
a *nextToken* response element. The remaining results of the initial request
can be seen by sending another *ListServices* request with the returned
*nextToken* value. This value can be between 1 and 100. If this parameter
is not used, then *ListServices* returns up to 100 results and a *nextToken*
value if applicable.

Return type  **dict**

Returns

Response Syntax

```
{
    'serviceArns': [],
    'nextToken': 'string'
}
```

Response Structure

- *(dict)* –
  - **serviceArns** *(list)* –
    The list of full Amazon Resource Name (ARN) entries for each service
    associated with the specified cluster.
  - *(string)* –
  - **nextToken** *(string)* –
    The *nextToken* value to include in a future *ListServices* request.
    When the results of a *ListServices* request exceed *maxResults*, this
    value can be used to retrieve the next page of results. This value is
    *null* when there are no more results to return.

`list_task_definition_families(**kwargs)`

Returns a list of task definition families that are registered to your account (which may include task
definition families that no longer have any ACTIVE task definitions). You can filter the results with the
*familyPrefix* parameter.

Request Syntax
response = client.list_task_definition_families(
    familyPrefix='string',
    nextToken='string',
    maxResults=123
)

Parameters

- **familyPrefix** *(string)* – The familyPrefix is a string that is used to filter the results of ListTaskDefinitionFamilies. If you specify a familyPrefix, only task definition family names that begin with the familyPrefix string are returned.

- **nextToken** *(string)* – The nextToken value returned from a previous paginated ListTaskDefinitionFamilies request where maxResults was used and the results exceeded the value of that parameter. Pagination continues from the end of the previous results that returned the nextToken value. This value is null when there are no more results to return.

- **maxResults** *(integer)* – The maximum number of task definition family results returned by ListTaskDefinitionFamilies in paginated output. When this parameter is used, ListTaskDefinitions only returns maxResults results in a single page along with a nextToken response element. The remaining results of the initial request can be seen by sending another ListTaskDefinitionFamilies request with the returned nextToken value. This value can be between 1 and 100. If this parameter is not used, then ListTaskDefinitionFamilies returns up to 100 results and a nextToken value if applicable.

Return type  **dict**

Returns

Response Syntax

```python
{
    'families': [  
        'string',
    ],
    'nextToken': 'string'
}
```

Response Structure

- *(dict)* –
  - **families** *(list)* –
    The list of task definition family names that match the ListTaskDefinitionFamilies request.
  - *(string)* –
  - **nextToken** *(string)* –
    The nextToken value to include in a future ListTaskDefinitionFamilies request. When the results of a ListTaskDefinitionFamilies request exceed maxResults, this value can be used to retrieve the next page of results. This value is null when there are no more results to return.

list_task_definitions(**kwargs)**

Returns a list of task definitions that are registered to your account. You can filter the results by family name with the familyPrefix parameter or by status with the status parameter.

Request Syntax
response = client.list_task_definitions(
    familyPrefix='string',
    status='ACTIVE'|'INACTIVE',
    sort='ASC'|'DESC',
    nextToken='string',
    maxResults=123
)

Parameters

• familyPrefix (string) – The full family name that you want to filter the ListTaskDefinitions results with. Specifying a familyPrefix will limit the listed task definitions to task definition revisions that belong to that family.

• status (string) – The task definition status that you want to filter the ListTaskDefinitions results with. By default, only ACTIVE task definitions are listed. By setting this parameter to INACTIVE, you can view task definitions that are INACTIVE as long as an active task or service still references them. If you paginate the resulting output, be sure to keep the status value constant in each subsequent request.

• sort (string) – The order in which to sort the results. Valid values are ASC and DESC. By default (ASC), task definitions are listed lexicographically by family name and in ascending numerical order by revision so that the newest task definitions in a family are listed last. Setting this parameter to DESC reverses the sort order on family name and revision so that the newest task definitions in a family are listed first.

• nextToken (string) – The nextToken value returned from a previous paginated ListTaskDefinitions request where maxResults was used and the results exceeded the value of that parameter. Pagination continues from the end of the previous results that returned the nextToken value. This value is null when there are no more results to return.

• maxResults (integer) – The maximum number of task definition results returned by ListTaskDefinitions in paginated output. When this parameter is used, ListTaskDefinitions only returns maxResults results in a single page along with a nextToken response element. The remaining results of the initial request can be seen by sending another ListTaskDefinitions request with the returned nextToken value. This value can be between 1 and 100. If this parameter is not used, then ListTaskDefinitions returns up to 100 results and a nextToken value if applicable.

Return type  dict

Returns

Response Syntax

```python
{
    'taskDefinitionArns': [
        'string',
    ],
    'nextToken': 'string'
}
```

Response Structure

• (dict) –
  • taskDefinitionArns (list) –
    The list of task definition Amazon Resource Name (ARN) entries for the
ListTaskDefinitions request.
* (string) –
  - nextToken (string) –

The `nextToken` value to include in a future `ListTaskDefinitions` request. When the results of a `ListTaskDefinitions` request exceed `maxResults`, this value can be used to retrieve the next page of results. This value is null when there are no more results to return.

`list_tasks(**kwargs)`

Returns a list of tasks for a specified cluster. You can filter the results by family name, by a particular container instance, or by the desired status of the task with the family, containerInstance, and desiredStatus parameters.

Request Syntax

```python
response = client.list_tasks(
    cluster='string',
    containerInstance='string',
    family='string',
    nextToken='string',
    maxResults=123,
    startedBy='string',
    serviceName='string',
    desiredStatus='RUNNING'|'PENDING'|'STOPPED'
)
```

Parameters

- **cluster (string)** – The short name or full Amazon Resource Name (ARN) of the cluster that hosts the tasks you want to list. If you do not specify a cluster, the default cluster is assumed.
- **containerInstance (string)** – The container instance UUID or full Amazon Resource Name (ARN) of the container instance that you want to filter the `ListTasks` results with. Specifying a `containerInstance` will limit the results to tasks that belong to that container instance.
- **family (string)** – The name of the family that you want to filter the `ListTasks` results with. Specifying a `family` will limit the results to tasks that belong to that family.
- **nextToken (string)** – The `nextToken` value returned from a previous paginated `ListTasks` request where `maxResults` was used and the results exceeded the value of that parameter. Pagination continues from the end of the previous results that returned the `nextToken` value. This value is null when there are no more results to return.
- **maxResults (integer)** – The maximum number of task results returned by `ListTasks` in paginated output. When this parameter is used, `ListTasks` only returns `maxResults` results in a single page along with a `nextToken` response element. The remaining results of the initial request can be seen by sending another `ListTasks` request with the returned `nextToken` value. This value can be between 1 and 100. If this parameter is not used, then `ListTasks` returns up to 100 results and a `nextToken` value if applicable.
- **startedBy (string)** – The `startedBy` value that you want to filter the task results with. Specifying a `startedBy` value will limit the results to tasks that were started with that value.
- **serviceName (string)** – The name of the service that you want to filter the `ListTasks` results with. Specifying a `serviceName` will limit the results to tasks that belong to that service.
• **desiredStatus** *(string)* – The task status that you want to filter the ListTasks results with. Specifying a desiredStatus of STOPPED will limit the results to tasks that are in the STOPPED status, which can be useful for debugging tasks that are not starting properly or have died or finished. The default status filter is RUNNING.

**Return type** dict

**Returns**

**Response Syntax**

```python
{
    'taskArns': [
        'string',
    ],
    'nextToken': 'string'
}
```

**Response Structure**

• *(dict)* –
  – **taskArns** *(list)* –
    The list of task Amazon Resource Name (ARN) entries for the ListTasks request.
  • *(string)* –
  – **nextToken** *(string)* –
    The nextToken value to include in a future ListTasks request. When the results of a ListTasks request exceed maxResults, this value can be used to retrieve the next page of results. This value is null when there are no more results to return.

**register_container_instance**(**kwargs**)  

**Note:** This action is only used by the Amazon EC2 Container Service agent, and it is not intended for use outside of the agent.

Registers an Amazon EC2 instance into the specified cluster. This instance will become available to place containers on.

**Request Syntax**

```python
response = client.register_container_instance(
    cluster='string',
    instanceIdentityDocument='string',
    instanceIdentityDocumentSignature='string',
    totalResources=[
        {
            'name': 'string',
            'type': 'string',
            'doubleValue': 123.0,
            'longValue': 123,
            'integerValue': 123,
            'stringSetValue': [
                'string',
            ],
        },
    ],
)
```
versionInfo={
    'agentVersion': 'string',
    'agentHash': 'string',
    'dockerVersion': 'string'
},
containerInstanceArn='string'
}

Parameters

- **cluster** *(string)* – The short name or full Amazon Resource Name (ARN) of the cluster that you want to register your container instance with. If you do not specify a cluster, the default cluster is assumed.

- **instanceIdentityDocument** *(string)* – The instance identity document for the Amazon EC2 instance to register. This document can be found by running the following command from the instance: `curl http://169.254.169.254/latest/dynamic/instance-identity/document/`

- **instanceIdentityDocumentSignature** *(string)* – The instance identity document signature for the Amazon EC2 instance to register. This signature can be found by running the following command from the instance: `curl http://169.254.169.254/latest/dynamic/instance-identity/signature/`

- **totalResources** *(list)* – The resources available on the instance.
  - *(dict)* –
    
    Describes the resources available for a container instance.

    - **name** *(string)* –
      
      The name of the resource, such as CPU, MEMORY, PORTS, or a user-defined resource.

    - **type** *(string)* –
      
      The type of the resource, such as INTEGER, DOUBLE, LONG, or STRINGSET.

    - **doubleValue** *(float)* –
      
      When the doubleValue type is set, the value of the resource must be a double precision floating-point type.

    - **longValue** *(integer)* –
      
      When the longValue type is set, the value of the resource must be an extended precision floating-point type.

    - **integerValue** *(integer)* –
      
      When the integerValue type is set, the value of the resource must be an integer.

    - **stringSetValue** *(list)* –
      
      When the stringSetValue type is set, the value of the resource must be a string type.

- **versionInfo** *(dict)* – The version information for the Amazon ECS container agent and Docker daemon running on the container instance.
  - **agentVersion** *(string)* –
    
    The version number of the Amazon ECS container agent.

  - **agentHash** *(string)* –
    
    The Git commit hash for the Amazon ECS container agent build on the `amazon-ecs-agent` GitHub repository.
– **dockerVersion** *(string)* –

The Docker version running on the container instance.

• **containerInstanceArn** *(string)* – The Amazon Resource Name (ARN) of the container instance (if it was previously registered).

**Return type** `dict`

**Response Syntax**

```
{
    'containerInstance': {
        'containerInstanceArn': 'string',
        'ec2InstanceId': 'string',
        'versionInfo': {
            'agentVersion': 'string',
            'agentHash': 'string',
            'dockerVersion': 'string'
        },
        'remainingResources': [
            {
                'name': 'string',
                'type': 'string',
                'doubleValue': 123.0,
                'longValue': 123,
                'integerValue': 123,
                'stringSetValue': ['string']
            }
        ],
        'registeredResources': [
            {
                'name': 'string',
                'type': 'string',
                'doubleValue': 123.0,
                'longValue': 123,
                'integerValue': 123,
                'stringSetValue': ['string']
            }
        ],
        'status': 'string',
        'agentConnected': True|False,
        'runningTasksCount': 123,
        'pendingTasksCount': 123,
        'agentUpdateStatus': 'PENDING'|'STAGING'|'STAGED'|'UPDATING'|'UPDATED'|'FAILED'
    }
}
```

**Response Structure**

• *(dict)* –

  – **containerInstance** *(dict)* –

    An Amazon EC2 instance that is running the Amazon ECS agent and has been registered with a cluster.

    • **containerInstanceArn** *(string)* –
The Amazon Resource Name (ARN) of the container instance. The ARN contains the `arn:aws:ecs` namespace, followed by the region of the container instance, the AWS account ID of the container instance owner, the `container-instance` namespace, and then the container instance UUID. For example, `arn:aws:ecs:region:aws_account_id:container-instance/container_instance_UUID`.

* `ec2InstanceId (string)` –
  The Amazon EC2 instance ID of the container instance.

* `versionInfo (dict)` –
  The version information for the Amazon ECS container agent and Docker daemon running on the container instance.
    - `agentVersion (string)` –
      The version number of the Amazon ECS container agent.
    - `agentHash (string)` –
      The Git commit hash for the Amazon ECS container agent build on the `amazon-ecs-agent` GitHub repository.
    - `dockerVersion (string)` –
      The Docker version running on the container instance.

* `remainingResources (list)` –
  The remaining resources of the container instance that are available for new tasks.
    - `(dict)` –
      Describes the resources available for a container instance.
    - `name (string)` –
      The name of the resource, such as `CPU`, `MEMORY`, `PORTS`, or a user-defined resource.
    - `type (string)` –
      The type of the resource, such as `INTEGER`, `DOUBLE`, `LONG`, or `STRINGSET`.
    - `doubleValue (float)` –
      When the `doubleValue` type is set, the value of the resource must be a double precision floating-point type.
    - `longValue (integer)` –
      When the `longValue` type is set, the value of the resource must be an extended precision floating-point type.
    - `integerValue (integer)` –
      When the `integerValue` type is set, the value of the resource must be an integer.
    - `stringSetValue (list)` –
      When the `stringSetValue` type is set, the value of the resource must be a string type.
    - `(string)` –

* `registeredResources (list)` –
  The registered resources on the container instance that are in use by current tasks.
    - `(dict)` –
Describes the resources available for a container instance.

- **name** *(string)*
  
  The name of the resource, such as `CPU`, `MEMORY`, `PORTS`, or a user-defined resource.

- **type** *(string)*
  
  The type of the resource, such as `INTEGER`, `DOUBLE`, `LONG`, or `STRINGSET`.

- **doubleValue** *(float)*
  
  When the `doubleValue` type is set, the value of the resource must be a double precision floating-point type.

- **longValue** *(integer)*
  
  When the `longValue` type is set, the value of the resource must be an extended precision floating-point type.

- **integerValue** *(integer)*
  
  When the `integerValue` type is set, the value of the resource must be an integer.

- **stringSetValue** *(list)*
  
  When the `stringSetValue` type is set, the value of the resource must be a string type.

- **status** *(string)*
  
  The status of the container instance. The valid values are `ACTIVE` or `INACTIVE`. `ACTIVE` indicates that the container instance can accept tasks.

- **agentConnected** *(boolean)*
  
  This parameter returns `true` if the agent is actually connected to Amazon ECS. Registered instances with an agent that may be unhealthy or stopped will return `false`, and instances without a connected agent cannot accept placement request.

- **runningTasksCount** *(integer)*
  
  The number of tasks on the container instance that are in the `RUNNING` status.

- **pendingTasksCount** *(integer)*
  
  The number of tasks on the container instance that are in the `PENDING` status.

- **agentUpdateStatus** *(string)*
  
  The status of the most recent agent update. If an update has never been requested, this value is `NULL`.

### register_task_definition(**kwargs)

Registers a new task definition from the supplied `family` and `containerDefinitions`. Optionally, you can add data volumes to your containers with the `volumes` parameter. For more information on task definition parameters and defaults, see Amazon ECS Task Definitions in the Amazon EC2 Container Service Developer Guide.

#### Request Syntax

```python
response = client.register_task_definition(
    family='string',
```
containerDefinitions=[
    {
        'name': 'string',
        'image': 'string',
        'cpu': 123,
        'memory': 123,
        'links': [
            'string',
        ],
        'portMappings': [
            {
                'containerPort': 123,
                'hostPort': 123,
                'protocol': 'tcp'|'udp'
            },
        ],
        'essential': True|False,
        'entryPoint': ['string'],
        'command': ['string'],
        'environment': [
            {
                'name': 'string',
                'value': 'string'
            },
        ],
        'mountPoints': [
            {
                'sourceVolume': 'string',
                'containerPath': 'string',
                'readOnly': True|False
            },
        ],
        'volumesFrom': [
            {
                'sourceContainer': 'string',
                'readOnly': True|False
            },
        ]
    },
],
volumes=[
    {
        'name': 'string',
        'host': {
            'sourcePath': 'string'
        }
    },
]

Parameters

- **family (string)** – [REQUIRED]

You must specify a family for a task definition, which allows you to track multiple versions of the same task definition. You can think of the family as
a name for your task definition. Up to 255 letters (uppercase and lowercase),
numbers, hyphens, and underscores are allowed.

- **containerDefinitions (list)** – [REQUIRED]

A list of container definitions in JSON format that describe the different contain-
ers that make up your task.

- **(dict)** –

  Container definitions are used in task definitions to describe the different
containers that are launched as part of a task.

  - **name (string)** –

    The name of a container. If you are linking multiple containers to-
gether in a task definition, the name of one container can be entered
in the links of another container to connect the containers.

  - **image (string)** –

    The image used to start a container. This string is passed di-
rectly to the Docker daemon. Images in the Docker Hub reg-
istry are available by default. Other repositories are specified with
*repository-url* /*image* :*tag*.

  - **cpu (integer)** –

    The number of cpu units reserved for the container. A container
instance has 1,024 cpu units for every CPU core. This parameter
specifies the minimum amount of CPU to reserve for a container,
and containers share unallocated CPU units with other containers
on the instance with the same ratio as their allocated amount.

    For example, if you run a single-container task on a single-core in-
stance type with 512 CPU units specified for that container, and that
is the only task running on the container instance, that container
could use the full 1,024 CPU unit share at any given time. However,
if you launched another copy of the same task on that container in-
stance, each task would be guaranteed a minimum of 512 CPU units
when needed, and each container could float to higher CPU usage
if the other container was not using it, but if both tasks were 100%
active all of the time, they would be limited to 512 CPU units.

    The Docker daemon on the container instance uses the CPU value
to calculate the relative CPU share ratios for running containers.
For more information, see CPU share constraint in the Docker doc-
mentation. The minimum valid CPU share value that the Linux
kernel will allow is 2; however, the CPU parameter is not required,
and you can use CPU values below 2 in your container definitions.
For CPU values below 2 (including null), the behavior varies based
on your Amazon ECS container agent version:

  - **Agent versions less than or equal to 1.1.0**: Null and zero
    CPU values are passed to Docker as 0, which Docker then
    converts to 1,024 CPU shares. CPU values of 1 are passed
to Docker as 1, which the Linux kernel converts to 2 CPU
    shares.

  - **Agent versions greater than or equal to 1.2.0**: Null, zero,
    and CPU values of 1 are passed to Docker as 2.

  - **memory (integer)** –

    The number of MiB of memory reserved for the container. If your
container attempts to exceed the memory allocated here, the con-
tainer is killed.

* links (list) –

The link parameter allows containers to communicate with each other without the need for port mappings, using the name parameter. The name:internalName construct is analogous to name:alias in Docker links. For more information on linking Docker containers, see https://docs.docker.com/userguide/dockerlinks/.

**Warning:** Containers that are collocated on a single container instance may be able to communicate with each other without requiring links or host port mappings. Network isolation is achieved on the container instance using security groups and VPC settings.

* (string) –

* portMappings (list) –

The list of port mappings for the container.

* (dict) –

Port mappings allow containers to access ports on the host container instance to send or receive traffic. Port mappings are specified as part of the container definition.

* containerPort (integer) –

The port number on the container that is bound to the user-specified or automatically assigned host port. If you specify a container port and not a host port, your container will automatically receive a host port in the ephemeral port range (for more information, see hostPort).

* hostPort (integer) –

The port number on the container instance to reserve for your container. You can specify a non-reserved host port for your container port mapping, or you can omit the hostPort (or set it to 0) while specifying a containerPort and your container will automatically receive a port in the ephemeral port range for your container instance operating system and Docker version.

The default ephemeral port range is 49153 to 65535, and this range is used for Docker versions prior to 1.6.0. For Docker version 1.6.0 and later, the Docker daemon tries to read the ephemeral port range from /proc/sys/net/ipv4/ip_local_port_range; if this kernel parameter is unavailable, the default ephemeral port range is used. You should not attempt to specify a host port in the ephemeral port range, since these are reserved for automatic assignment. In general, ports below 32768 are outside of the ephemeral port range.

The default reserved ports are 22 for SSH, the Docker ports 2375 and 2376, and the Amazon ECS Container Agent port 51678. Any host port that was previously specified in a running task is also reserved while the task is running (once a task stops, the host port is released). The current reserved ports are...
displayed in the `remainingResources` of `DescribeContainerInstances` output, and a container instance may have up to 50 reserved ports at a time, including the default reserved ports (automatically assigned ports do not count toward this limit).

- **protocol** *(string)*
  
  The protocol used for the port mapping. Valid values are `tcp` and `udp`. The default is `tcp`.

- **essential** *(boolean)*
  
  If the `essential` parameter of a container is marked as `true`, the failure of that container will stop the task. If the `essential` parameter of a container is marked as `false`, then its failure will not affect the rest of the containers in a task. If this parameter is omitted, a container is assumed to be essential.

**Note:** All tasks must have at least one essential container.

- **entryPoint** *(list)*

  **Warning:** Early versions of the Amazon ECS container agent do not properly handle `entryPoint` parameters. If you have problems using `entryPoint`, update your container agent or enter your commands and arguments as `command` array items instead.

  The `ENTRYPOINT` that is passed to the container. For more information on the Docker `ENTRYPOINT` parameter, see [https://docs.docker.com/reference/builder/#entrypoint](https://docs.docker.com/reference/builder/#entrypoint).

- **command** *(list)*

  The `CMD` that is passed to the container. For more information on the Docker `CMD` parameter, see [https://docs.docker.com/reference/builder/#cmd](https://docs.docker.com/reference/builder/#cmd).

- **environment** *(list)*

  The environment variables to pass to a container.

  - *(dict)*
    
    A key and value pair object.

  - **name** *(string)*
    
    The name of the key value pair. For environment variables, this is the name of the environment variable.

  - **value** *(string)*
    
    The value of the key value pair. For environment variables, this is the value of the environment variable.

- **mountPoints** *(list)*

  The mount points for data volumes in your container.

  - *(dict)*
    
    Details on a volume mount point that is used in a container definition.
· **sourceVolume** *(string)* –
  The name of the volume to mount.
· **containerPath** *(string)* –
  The path on the container to mount the host volume at.
· **readOnly** *(boolean)* –
  If this value is true, the container has read-only access to the volume. If this value is false, then the container can write to the volume. The default value is false.

* **volumesFrom** *(list)* –
  Data volumes to mount from another container.
  · *(dict)* –
    Details on a data volume from another container.
    · **sourceContainer** *(string)* –
      The name of the container to mount volumes from.
    · **readOnly** *(boolean)* –
      If this value is true, the container has read-only access to the volume. If this value is false, then the container can write to the volume. The default value is false.

· **volumes** *(list)* – A list of volume definitions in JSON format that containers in your task may use.
  · *(dict)* –
    A data volume used in a task definition.
    * **name** *(string)* –
      The name of the volume. This name is referenced in the sourceVolume parameter of container definition mountPoints.
    * **host** *(dict)* –
      The path on the host container instance that is presented to the containers which access the volume. If this parameter is empty, then the Docker daemon assigns a host path for you.
      · **sourcePath** *(string)* –
        The path on the host container instance that is presented to the container. If this parameter is empty, then the Docker daemon has assigned a host path for you.

**Return type** *dict*

**Returns**

Response Structure

* (dict) –
  - taskDefinition (dict) –
    Details of a task definition.
    * taskDefinitionArn (string) –
      The full Amazon Resource Name (ARN) of the of the task defini-

* **containerDefinitions** *(list)* –

A list of container definitions in JSON format that describe the different containers that make up your task. For more information on container definition parameters and defaults, see Amazon ECS Task Definitions in the Amazon EC2 Container Service Developer Guide.

- *(dict)* –

  Container definitions are used in task definitions to describe the different containers that are launched as part of a task.

  - **name** *(string)* –

    The name of a container. If you are linking multiple containers together in a task definition, the name of one container can be entered in the `links` of another container to connect the containers.

  - **image** *(string)* –

    The image used to start a container. This string is passed directly to the Docker daemon. Images in the Docker Hub registry are available by default. Other repositories are specified with `*repository-url* /*image* :*tag*`.

  - **cpu** *(integer)* –

    The number of CPU units reserved for the container. A container instance has 1,024 CPU units for every CPU core. This parameter specifies the minimum amount of CPU to reserve for a container, and containers share unallocated CPU units with other containers on the instance with the same ratio as their allocated amount.

    For example, if you run a single-container task on a single-core instance type with 512 CPU units specified for that container, and that is the only task running on the container instance, that container could use the full 1,024 CPU unit share at any given time. However, if you launched another copy of the same task on that container instance, each task would be guaranteed a minimum of 512 CPU units when needed, and each container could float to higher CPU usage if the other container was not using it, but if both tasks were 100% active all of the time, they would be limited to 512 CPU units.

    The Docker daemon on the container instance uses the CPU value to calculate the relative CPU share ratios for running containers. For more information, see CPU share constraint in the Docker documentation. The minimum valid CPU share value that the Linux kernel will allow is 2; however, the CPU parameter is not required, and you can use CPU values below 2 in your container definitions. For CPU values below 2 (including null), the behavior varies based on your Amazon ECS container agent version:

    - **Agent versions less than or equal to 1.1.0**: Null and zero CPU values are passed to Docker as 0, which Docker then converts to 1,024 CPU shares. CPU values of 1 are passed to Docker as 1, which the Linux kernel converts to 2 CPU.
shares.

- **Agent versions greater than or equal to 1.2.0**: Null, zero, and CPU values of 1 are passed to Docker as 2.

- **memory (integer)** –

  The number of MiB of memory reserved for the container. If your container attempts to exceed the memory allocated here, the container is killed.

- **links (list)** –

  The `link` parameter allows containers to communicate with each other without the need for port mappings, using the `name` parameter. The `name:internalName` construct is analogous to `name:alias` in Docker links. For more information on linking Docker containers, see https://docs.docker.com/userguide/dockerlinks/.

**Warning**: Containers that are collocated on a single container instance may be able to communicate with each other without requiring links or host port mappings. Network isolation is achieved on the container instance using security groups and VPC settings.

- **(string)** –

- **portMappings (list)** –

  The list of port mappings for the container.

- **(dict)** –

  Port mappings allow containers to access ports on the host container instance to send or receive traffic. Port mappings are specified as part of the container definition.

- **containerPort (integer)** –

  The port number on the container that is bound to the user-specified or automatically assigned host port. If you specify a container port and not a host port, your container will automatically receive a host port in the ephemeral port range (for more information, see `hostPort`).

- **hostPort (integer)** –

  The port number on the container instance to reserve for your container. You can specify a non-reserved host port for your container port mapping, or you can omit the `hostPort` (or set it to 0) while specifying a `containerPort` and your container will automatically receive a port in the ephemeral port range for your container instance operating system and Docker version.

The default ephemeral port range is 49153 to 65535, and this range is used for Docker versions prior to 1.6.0. For Docker version 1.6.0 and later, the Docker daemon tries to read the ephemeral port range from `/proc/sys/net/ipv4/ip_local_port_range`; if this kernel parameter is unavailable, the default ephemeral port range is used. You should not attempt to specify a host port in the ephemeral port range, since these are reserved for
automatic assignment. In general, ports below 32768 are outside of the ephemeral port range.

The default reserved ports are 22 for SSH, the Docker ports 2375 and 2376, and the Amazon ECS Container Agent port 51678. Any host port that was previously specified in a running task is also reserved while the task is running (once a task stops, the host port is released). The current reserved ports are displayed in the `remainingResources` of `DescribeContainerInstances` output, and a container instance may have up to 50 reserved ports at a time, including the default reserved ports (automatically assigned ports do not count toward this limit).

- **protocol (string)** –
  
The protocol used for the port mapping. Valid values are `tcp` and `udp`. The default is `tcp`.
- **essential (boolean)** –
  
  If the `essential` parameter of a container is marked as `true`, the failure of that container will stop the task. If the `essential` parameter of a container is marked as `false`, then its failure will not affect the rest of the containers in a task. If this parameter is omitted, a container is assumed to be essential.

**Note:** All tasks must have at least one essential container.

- **entryPoint (list)** –

  **Warning:** Early versions of the Amazon ECS container agent do not properly handle `entryPoint` parameters. If you have problems using `entryPoint`, update your container agent or enter your commands and arguments as `command` array items instead.

  The `ENTRYPOINT` that is passed to the container. For more information on the Docker `ENTRYPOINT` parameter, see https://docs.docker.com/reference/builder/#entrypoint.

  - *(string)* –
  - **command (list)** –

    The `CMD` that is passed to the container. For more information on the Docker `CMD` parameter, see https://docs.docker.com/reference/builder/#cmd.

    - *(string)* –
    - **environment (list)** –

      The environment variables to pass to a container.

      - *(dict)* –

        A key and value pair object.

      - **name (string)** –

        The name of the key value pair. For environment variables, this is the name of the environment variable.

      - **value (string)** –
The value of the key value pair. For environment variables, this is the value of the environment variable.

- **mountPoints (list)** –

  The mount points for data volumes in your container.

- **(dict)** –

  Details on a volume mount point that is used in a container definition.

- **sourceVolume (string)** –

  The name of the volume to mount.

- **containerPath (string)** –

  The path on the container to mount the host volume at.

- **readOnly (boolean)** –

  If this value is true, the container has read-only access to the volume. If this value is false, then the container can write to the volume. The default value is false.

- **volumesFrom (list)** –

  Data volumes to mount from another container.

- **(dict)** –

  Details on a data volume from another container.

- **sourceContainer (string)** –

  The name of the container to mount volumes from.

- **readOnly (boolean)** –

  If this value is true, the container has read-only access to the volume. If this value is false, then the container can write to the volume. The default value is false.

- **family (string)** –

  The family of your task definition. You can think of the family as the name of your task definition.

- **revision (integer)** –

  The revision of the task in a particular family. You can think of the revision as a version number of a task definition in a family. When you register a task definition for the first time, the revision is 1, and each time you register a new revision of a task definition in the same family, the revision value always increases by one (even if you have deregistered previous revisions in this family).

- **volumes (list)** –

  The list of volumes in a task. For more information on volume definition parameters and defaults, see Amazon ECS Task Definitions in the Amazon EC2 Container Service Developer Guide.

- **(dict)** –

  A data volume used in a task definition.

- **name (string)** –

  The name of the volume. This name is referenced in the sourceVolume parameter of container definition mountPoints.

- **host (dict)** –
The path on the host container instance that is presented to the containers which access the volume. If this parameter is empty, then the Docker daemon assigns a host path for you.

- **sourcePath** *(string)*

  The path on the host container instance that is presented to the container. If this parameter is empty, then the Docker daemon has assigned a host path for you.

- **status** *(string)*

  The status of the task definition.

---

### run_task(**kwargs)**

Start a task using random placement and the default Amazon ECS scheduler. If you want to use your own scheduler or place a task on a specific container instance, use `StartTask` instead.

**Warning:** The `count` parameter is limited to 10 tasks per call.

#### Request Syntax

```python
response = client.run_task(
    cluster='string',
    taskDefinition='string',
    overrides={
        'containerOverrides': [
            {
                'name': 'string',
                'command': [
                    'string',
                ],
                'environment': [
                    {
                        'name': 'string',
                        'value': 'string'
                    },
                ],
            }
        ],
        count=123,
        startedBy='string'
    }
)
```

#### Parameters

- **cluster** *(string)* – The short name or full Amazon Resource Name (ARN) of the cluster that you want to run your task on. If you do not specify a cluster, the default cluster is assumed.

- **taskDefinition** *(string)* – [REQUIRED]

  The family and revision *(family:revision)* or full Amazon Resource Name (ARN) of the task definition that you want to run. If a revision is not specified, the latest ACTIVE revision is used.

- **overrides** *(dict)* – A list of container overrides in JSON format that specify the name of a container in the specified task definition and the overrides it should receive. You can override the default command for a container (that is specified in the task definition or Docker image) with a `command` override. You can also override existing environment variables (that are specified in the task definition...
or Docker image) on a container or add new environment variables to it with an environment override.

**Note:** A total of 8192 characters are allowed for overrides. This limit includes the JSON formatting characters of the override structure.

- **containerOverrides** *(list)* –
  
  One or more container overrides sent to a task.

  - *(dict)* –
    
    The overrides that should be sent to a container.
    
    - **name** *(string)* –
      
      The name of the container that receives the override.
    
    - **command** *(list)* –
      
      The command to send to the container that overrides the default command from the Docker image or the task definition.
    
    - *(string)* –
    
    - **environment** *(list)* –
      
      The environment variables to send to the container. You can add new environment variables, which are added to the container at launch, or you can override the existing environment variables from the Docker image or the task definition.
    
    - *(dict)* –
      
      A key and value pair object.
    
    - **name** *(string)* –
      
      The name of the key value pair. For environment variables, this is the name of the environment variable.
    
    - **value** *(string)* –
      
      The value of the key value pair. For environment variables, this is the value of the environment variable.

- **count** *(integer)* – The number of instantiations of the specified task that you would like to place on your cluster.

**Warning:** The **count** parameter is limited to 10 tasks per call.

- **startedBy** *(string)* – An optional tag specified when a task is started. For example if you automatically trigger a task to run a batch process job, you could apply a unique identifier for that job to your task with the **startedBy** parameter. You can then identify which tasks belong to that job by filtering the results of a ListTasks call with the **startedBy** value.

If a task is started by an Amazon ECS service, then the **startedBy** parameter contains the deployment ID of the service that starts it.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'tasks': [
        {
            'taskArn': 'string',
        }
    ]
}
```
'clusterArn': 'string',
'taskDefinitionArn': 'string',
'containerInstanceArn': 'string',
'overrides': {
    'containerOverrides': [
        {
            'name': 'string',
            'command': ['string'],
            'environment': [
                {'name': 'string',
                 'value': 'string'}
            ]
        }
    ],
},
'lastStatus': 'string',
'desiredStatus': 'string',
'containers': [
    {
        'containerArn': 'string',
        'taskArn': 'string',
        'name': 'string',
        'lastStatus': 'string',
        'exitCode': 123,
        'reason': 'string',
        'networkBindings': [
            {'bindIP': 'string',
             'containerPort': 123,
             'hostPort': 123,
             'protocol': 'tcp'|'udp'}
        ],
        'startedBy': 'string'
    }
],
'failures': [
    {'arn': 'string',
     'reason': 'string'}
]
}

**Response Structure**

- *(dict)* –
  - tasks *(list)* –

A full description of the tasks that were run. Each task that was successfully placed on your cluster will be described here.

- *(dict)* –

  Details on a task in a cluster.

3.1. Services 1853
- **taskArn** *(string)* –
  The Amazon Resource Name (ARN) of the task.
- **clusterArn** *(string)* –
  The Amazon Resource Name (ARN) of the cluster that hosts the task.
- **taskDefinitionArn** *(string)* –
  The Amazon Resource Name (ARN) of the task definition that creates the task.
- **containerInstanceArn** *(string)* –
  The Amazon Resource Name (ARN) of the container instances that host the task.
- **overrides** *(dict)* –
  One or more container overrides.
- **containerOverrides** *(list)* –
  One or more container overrides sent to a task.
  - *(dict)* –
    The overrides that should be sent to a container.
    - **name** *(string)* –
      The name of the container that receives the override.
    - **command** *(list)* –
      The command to send to the container that overrides the default command from the Docker image or the task definition.
      - *(string)* –
    - **environment** *(list)* –
      The environment variables to send to the container. You can add new environment variables, which are added to the container at launch, or you can override the existing environment variables from the Docker image or the task definition.
      - *(dict)* –
        A key and value pair object.
        - **name** *(string)* –
          The name of the key value pair. For environment variables, this is the name of the environment variable.
        - **value** *(string)* –
          The value of the key value pair. For environment variables, this is the value of the environment variable.
- **lastStatus** *(string)* –
  The last known status of the task.
- **desiredStatus** *(string)* –
  The desired status of the task.
- **containers** *(list)* –
  The containers associated with the task.
  - *(dict)* –
    A docker container that is part of a task.
containerArn (string) –
The Amazon Resource Name (ARN) of the container.

taskArn (string) –
The Amazon Resource Name (ARN) of the task.

name (string) –
The name of the container.

lastStatus (string) –
The last known status of the container.

exitCode (integer) –
The exit code returned from the container.

reason (string) –
A short (255 max characters) human-readable string to provide additional detail about a running or stopped container.

networkBindings (list) –
The network bindings associated with the container.

(dict) –
Details on the network bindings between a container and its host container instance.

bindIP (string) –
The IP address that the container is bound to on the container instance.

containerPort (integer) –
The port number on the container that is be used with the network binding.

hostPort (integer) –
The port number on the host that is used with the network binding.

protocol (string) –
The protocol used for the network binding.

startedBy (string) –
The tag specified when a task is started. If the task is started by an Amazon ECS service, then the startedBy parameter contains the deployment ID of the service that starts it.

failures (list) –
Any failed tasks from your RunTask action are listed here.

(dict) –
A failed resource.

arn (string) –
The Amazon Resource Name (ARN) of the failed resource.

reason (string) –
The reason for the failure.

start_task (**kwargs)
Starts a new task from the specified task definition on the specified container instance or instances. If you want to use the default Amazon ECS scheduler to place your task, use RunTask instead.
Warning: The list of container instances to start tasks on is limited to 10.

Request Syntax

```python
response = client.start_task(
    cluster='string',
    taskDefinition='string',
    overrides={
        'containerOverrides': [
            {
                'name': 'string',
                'command': [
                    'string',
                ],
                'environment': [
                    {
                        'name': 'string',
                        'value': 'string'
                    },
                ],
            }
        ],
    },
    containerInstances=['string'],
    startedBy='string'
)
```

Parameters

- `cluster (string)` – The short name or full Amazon Resource Name (ARN) of the cluster that you want to start your task on. If you do not specify a cluster, the default cluster is assumed.

- `taskDefinition (string)` – [REQUIRED]

  The family and revision (family:revision) or full Amazon Resource Name (ARN) of the task definition that you want to start. If a revision is not specified, the latest ACTIVE revision is used.

- `overrides (dict)` – A list of container overrides in JSON format that specify the name of a container in the specified task definition and the overrides it should receive. You can override the default command for a container (that is specified in the task definition or Docker image) with a command override. You can also override existing environment variables (that are specified in the task definition or Docker image) on a container or add new environment variables to it with an environment override.

  Note: A total of 8192 characters are allowed for overrides. This limit includes the JSON formatting characters of the override structure.

  - `containerOverrides (list)` –

    One or more container overrides sent to a task.

    - `(dict)` –

      The overrides that should be sent to a container.

      - `name (string)` –
The name of the container that receives the override.

- **command (list)**
  
The command to send to the container that overrides the default command from the Docker image or the task definition.

- **environment (list)**
  
The environment variables to send to the container. You can add new environment variables, which are added to the container at launch, or you can override the existing environment variables from the Docker image or the task definition.

- **name (string)**
  
The name of the key value pair. For environment variables, this is the name of the environment variable.

- **value (string)**
  
The value of the key value pair. For environment variables, this is the value of the environment variable.

- **containerInstances (list)** – [REQUIRED]
  
The container instance UUIDs or full Amazon Resource Name (ARN) entries for the container instances on which you would like to place your task.

  **Warning:** The list of container instances to start tasks on is limited to 10.

- **startedBy (string)**
  
  An optional tag specified when a task is started. For example if you automatically trigger a task to run a batch process job, you could apply a unique identifier for that job to your task with the startedBy parameter. You can then identify which tasks belong to that job by filtering the results of a ListTasks call with the startedBy value.

  If a task is started by an Amazon ECS service, then the startedBy parameter contains the deployment ID of the service that starts it.

**Return type**  
dict

**Returns**

**Response Syntax**

```json
{
    'tasks': [
        {
            'taskArn': 'string',
            'clusterArn': 'string',
            'taskDefinitionArn': 'string',
            'containerInstanceArn': 'string',
            'overrides': {
                'containerOverrides': {
                    'name': 'string',
                    'command': ['string'],
                    'environment': ['string']
                }
            }
        }
    ]
}
```
Response Structure

- *(dict)*
  - **tasks** *(list)*

A full description of the tasks that were started. Each task that was successfully placed on your container instances will be described here.

- *(dict)*

Details on a task in a cluster.

- **taskArn** *(string)*

  The Amazon Resource Name (ARN) of the task.

- **clusterArn** *(string)*

  The Amazon Resource Name (ARN) of the cluster that hosts the task.

- **taskDefinitionArn** *(string)*

  The Amazon Resource Name (ARN) of the task definition that creates the task.

- **containerInstanceArn** *(string)*
The Amazon Resource Name (ARN) of the container instances that host the task.

- **overrides (dict)** –
  One or more container overrides.

- **containerOverrides (list)** –
  One or more container overrides sent to a task.

  - **(dict)** –
    The overrides that should be sent to a container.
    - **name (string)** –
      The name of the container that receives the override.
    - **command (list)** –
      The command to send to the container that overrides the default command from the Docker image or the task definition.

  - **environment (list)** –
    The environment variables to send to the container. You can add new environment variables, which are added to the container at launch, or you can override the existing environment variables from the Docker image or the task definition.

  - **(dict)** –
    A key and value pair object.
    - **name (string)** –
      The name of the key value pair. For environment variables, this is the name of the environment variable.
    - **value (string)** –
      The value of the key value pair. For environment variables, this is the value of the environment variable.

- **lastStatus (string)** –
  The last known status of the task.

- **desiredStatus (string)** –
  The desired status of the task.

- **containers (list)** –
  The containers associated with the task.

  - **(dict)** –
    A docker container that is part of a task.
    - **containerArn (string)** –
      The Amazon Resource Name (ARN) of the container.
    - **taskArn (string)** –
      The Amazon Resource Name (ARN) of the task.
    - **name (string)** –
      The name of the container.
    - **lastStatus (string)** –
      The last known status of the container.

- **exitCode (integer)** –
  The exit code returned from the container.
· **reason** *(string)* —
  A short (255 max characters) human-readable string to provide additional detail about a running or stopped container.

· **networkBindings** *(list)* —
  The network bindings associated with the container.
  
  · *(dict)* —
    Details on the network bindings between a container and its host container instance.
    
    · **bindIP** *(string)* —
      The IP address that the container is bound to on the container instance.
    
    · **containerPort** *(integer)* —
      The port number on the container that is be used with the network binding.
    
    · **hostPort** *(integer)* —
      The port number on the host that is used with the network binding.
    
    · **protocol** *(string)* —
      The protocol used for the network binding.
    
    · **startedBy** *(string)* —
      The tag specified when a task is started. If the task is started by an Amazon ECS service, then the **startedBy** parameter contains the deployment ID of the service that starts it.

· **failures** *(list)* —
  Any failed tasks from your **StartTask** action are listed here.

  · *(dict)* —
    A failed resource.
    
    · **arn** *(string)* —
      The Amazon Resource Name (ARN) of the failed resource.
    
    · **reason** *(string)* —
      The reason for the failure.

**stop_task**( **kwargs)**

Stops a running task.

**Request Syntax**

```python
response = client.stop_task(
    cluster='string',
    task='string'
)
```

**Parameters**

· **cluster** *(string)* – The short name or full Amazon Resource Name (ARN) of the cluster that hosts the task you want to stop. If you do not specify a cluster, the default cluster is assumed.

· **task** *(string)* – [REQUIRED]
  The task UUIDs or full Amazon Resource Name (ARN) entry of the task you would like to stop.
Return type  
dict

Returns

Response Syntax

```json
{
  'task': {
    'taskArn': 'string',
    'clusterArn': 'string',
    'taskDefinitionArn': 'string',
    'containerInstanceArn': 'string',
    'overrides': {
      'containerOverrides': [
        {
          'name': 'string',
          'command': [
            'string',
          ],
          'environment': [
            {
              'name': 'string',
              'value': 'string'
            },
          ],
        },
      ],
      'lastStatus': 'string',
      'desiredStatus': 'string',
      'containers': [
        {
          'containerArn': 'string',
          'taskArn': 'string',
          'name': 'string',
          'lastStatus': 'string',
          'exitCode': 123,
          'reason': 'string',
          'networkBindings': [
            {
              'bindIP': 'string',
              'containerPort': 123,
              'hostPort': 123,
              'protocol': 'tcp'|'udp'
            },
          ],
        },
      ],
      'startedBy': 'string'
    }
  }
}
```

Response Structure

- *(dict)* –
  - **task** *(dict)* –
    
    Details on a task in a cluster.
    
    - **taskArn** *(string)* –
      
      The Amazon Resource Name (ARN) of the task.
* `clusterArn` *(string)* –
  The Amazon Resource Name (ARN) of the cluster that hosts the task.

* `taskDefinitionArn` *(string)* –
  The Amazon Resource Name (ARN) of the task definition that creates the task.

* `containerInstanceArn` *(string)* –
  The Amazon Resource Name (ARN) of the container instances that host the task.

* `overrides` *(dict)* –
  One or more container overrides.
  - `containerOverrides` *(list)* –
    One or more container overrides sent to a task.
    - *(dict)* –
      The overrides that should be sent to a container.
      - `name` *(string)* –
        The name of the container that receives the override.
      - `command` *(list)* –
        The command to send to the container that overrides the default command from the Docker image or the task definition.
      - *(string)* –
      - `environment` *(list)* –
        The environment variables to send to the container. You can add new environment variables, which are added to the container at launch, or you can override the existing environment variables from the Docker image or the task definition.
        - *(dict)* –
          A key and value pair object.
        - `name` *(string)* –
          The name of the key value pair. For environment variables, this is the name of the environment variable.
        - `value` *(string)* –
          The value of the key value pair. For environment variables, this is the value of the environment variable.

* `lastStatus` *(string)* –
  The last known status of the task.

* `desiredStatus` *(string)* –
  The desired status of the task.

* `containers` *(list)* –
  The containers associated with the task.
  - *(dict)* –
    A docker container that is part of a task.
  - `containerArn` *(string)* –
    The Amazon Resource Name (ARN) of the container.
- **taskArn** *(string)*  
The Amazon Resource Name (ARN) of the task.
- **name** *(string)*  
The name of the container.
- **lastStatus** *(string)*  
The last known status of the container.
- **exitCode** *(integer)*  
The exit code returned from the container.
- **reason** *(string)*  
A short (255 max characters) human-readable string to provide additional detail about a running or stopped container.
- **networkBindings** *(list)*  
The network bindings associated with the container.
  - *(dict)*  
Details on the network bindings between a container and its host container instance.
  - **bindIP** *(string)*  
The IP address that the container is bound to on the container instance.
  - **containerPort** *(integer)*  
The port number on the container that is be used with the network binding.
  - **hostPort** *(integer)*  
The port number on the host that is used with the network binding.
  - **protocol** *(string)*  
The protocol used for the network binding.

* **startedBy** *(string)*  
The tag specified when a task is started. If the task is started by an Amazon ECS service, then the `startedBy` parameter contains the deployment ID of the service that starts it.

### submit_container_state_change(**kwargs)**

**Note:** This action is only used by the Amazon EC2 Container Service agent, and it is not intended for use outside of the agent.

Sent to acknowledge that a container changed states.

**Request Syntax**

```python
def response = client.submit_container_state_change(
    cluster='string',
    task='string',
    containerName='string',
    status='string',
    exitCode=123,
    reason='string',
)```

---

### 3.1. Services

1863
networkBindings=[
    {
        'bindIP': 'string',
        'containerPort': 123,
        'hostPort': 123,
        'protocol': 'tcp'|'udp'
    },
]

Parameters

• **cluster** (string) – The short name or full Amazon Resource Name (ARN) of the
  cluster that hosts the container.

• **task** (string) – The task UUID or full Amazon Resource Name (ARN) of the
  task that hosts the container.

• **containerName** (string) – The name of the container.

• **status** (string) – The status of the state change request.

• **exitCode** (integer) – The exit code returned for the state change request.

• **reason** (string) – The reason for the state change request.

• **networkBindings** (list) – The network bindings of the container.
  - (dict) –
    Details on the network bindings between a container and its host container
    instance.
    * **bindIP** (string) –
      The IP address that the container is bound to on the container instance.
    * **containerPort** (integer) –
      The port number on the container that is be used with the network binding.
    * **hostPort** (integer) –
      The port number on the host that is used with the network binding.
    * **protocol** (string) –
      The protocol used for the network binding.

Return type  dict

Returns

Response Syntax

    {
        'acknowledgment': 'string'
    }

Response Structure

• (dict) –
  - **acknowledgment** (string) –
    Acknowledgement of the state change.

submit_task_state_change(**kwargs)

Note: This action is only used by the Amazon EC2 Container Service agent, and it is not intended for use outside of the agent.
Sent to acknowledge that a task changed states.

**Request Syntax**

```python
response = client.submit_task_state_change(
    cluster='string',
    task='string',
    status='string',
    reason='string'
)
```

**Parameters**

- **cluster** (*string*) – The short name or full Amazon Resource Name (ARN) of the cluster that hosts the task.
- **task** (*string*) – The task UUID or full Amazon Resource Name (ARN) of the task in the state change request.
- **status** (*string*) – The status of the state change request.
- **reason** (*string*) – The reason for the state change request.

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'acknowledgment': 'string'
}
```

**Response Structure**

- **(dict)** –
  - **acknowledgment** (*string*) –
    Acknowledgement of the state change.

**update_container_agent(**kwargs)**

Updates the Amazon ECS container agent on a specified container instance. Updating the Amazon ECS container agent does not interrupt running tasks or services on the container instance. The process for updating the agent differs depending on whether your container instance was launched with the Amazon ECS-optimized AMI or another operating system.

**update_container_agent** requires the Amazon ECS-optimized AMI or Amazon Linux with the `ecs-init` service installed and running. For help updating the Amazon ECS container agent on other operating systems, see Manually Updating the Amazon ECS Container Agent in the Amazon EC2 Container Service Developer Guide.

**Request Syntax**

```python
response = client.update_container_agent(
    cluster='string',
    containerInstance='string'
)
```

**Parameters**

- **cluster** (*string*) – The short name or full Amazon Resource Name (ARN) of the cluster that your container instance is running on. If you do not specify a cluster, the default cluster is assumed.
- **containerInstance** (*string*) – [REQUIRED]
The container instance UUID or full Amazon Resource Name (ARN) entries
for the container instance on which you would like to update the Amazon ECS
container agent.

**Return type** dict

**Returns**

**Response Syntax**

```plaintext
{
  'containerInstance': {
    'containerInstanceArn': 'string',
    'ec2InstanceId': 'string',
    'versionInfo': {
      'agentVersion': 'string',
      'agentHash': 'string',
      'dockerVersion': 'string'
    },
    'remainingResources': [
      {
        'name': 'string',
        'type': 'string',
        'doubleValue': 123.0,
        'longValue': 123,
        'integerValue': 123,
        'stringSetValue': [
          'string'
        ]
      }
    ],
    'registeredResources': [

        'doubleValue': 123.0,
        'longValue': 123,
        'integerValue': 123,
        'stringSetValue': [
          'string'
        ]
      }
    ],
    'status': 'string',
    'agentConnected': True|False,
    'runningTasksCount': 123,
    'pendingTasksCount': 123,
    'agentUpdateStatus': 'PENDING'|'STAGING'|'STAGED'|'UPDATING'|'UPDATED'|'FAILED'
  }
}
```

**Response Structure**

- (dict) –
  - containerInstance (dict) –
    - An Amazon EC2 instance that is running the Amazon ECS agent and has
      been registered with a cluster.
    - containerInstanceArn (string) –
      The Amazon Resource Name (ARN) of the container instance. The
      ARN contains the `arn:aws:ecs` namespace, followed by the re-
Region of the container instance, the AWS account ID of the container instance owner, the container-instance namespace, and then the container instance UUID. For example, `arn:aws:ecs:region:aws_account_id:container-instance/container_instance_UUID`.

* `ec2InstanceId (string)` –
  The Amazon EC2 instance ID of the container instance.

* `versionInfo (dict)` –
  The version information for the Amazon ECS container agent and Docker daemon running on the container instance.
  - `agentVersion (string)` –
    The version number of the Amazon ECS container agent.
  - `agentHash (string)` –
    The Git commit hash for the Amazon ECS container agent build on the `amazon-ecs-agent` GitHub repository.
  - `dockerVersion (string)` –
    The Docker version running on the container instance.

* `remainingResources (list)` –
  The remaining resources of the container instance that are available for new tasks.
  - `(dict)` –
    Describes the resources available for a container instance.
  - `name (string)` –
    The name of the resource, such as `CPU`, `MEMORY`, `PORTS`, or a user-defined resource.
  - `type (string)` –
    The type of the resource, such as `INTEGER`, `DOUBLE`, `LONG`, or `STRINGSET`.
  - `doubleValue (float)` –
    When the `doubleValue` type is set, the value of the resource must be a double precision floating-point type.
  - `longValue (integer)` –
    When the `longValue` type is set, the value of the resource must be an extended precision floating-point type.
  - `integerValue (integer)` –
    When the `integerValue` type is set, the value of the resource must be an integer.
  - `stringValue (list)` –
    When the `stringValue` type is set, the value of the resource must be a string type.

* `registeredResources (list)` –
  The registered resources on the container instance that are in use by current tasks.
  - `(dict)` –
    Describes the resources available for a container instance.
· **name (string)** –
  The name of the resource, such as CPU, MEMORY, PORTS, or a user-defined resource.

· **type (string)** –
  The type of the resource, such as INTEGER, DOUBLE, LONG, or STRINGSET.

· **doubleValue (float)** –
  When the `doubleValue` type is set, the value of the resource must be a double precision floating-point type.

· **longValue (integer)** –
  When the `longValue` type is set, the value of the resource must be an extended precision floating-point type.

· **integerValue (integer)** –
  When the `integerValue` type is set, the value of the resource must be an integer.

· **stringSetValue (list)** –
  When the `stringSetValue` type is set, the value of the resource must be a string type.

· **status (string)** –
  The status of the container instance. The valid values are ACTIVE or INACTIVE. ACTIVE indicates that the container instance can accept tasks.

· **agentConnected (boolean)** –
  This parameter returns true if the agent is actually connected to Amazon ECS. Registered instances with an agent that may be unhealthy or stopped will return false, and instances without a connected agent cannot accept placement request.

· **runningTasksCount (integer)** –
  The number of tasks on the container instance that are in the RUNNING status.

· **pendingTasksCount (integer)** –
  The number of tasks on the container instance that are in the PENDING status.

· **agentUpdateStatus (string)** –
  The status of the most recent agent update. If an update has never been requested, this value is NULL.

**update_service(****kwargs**)**

Modify the desired count or task definition used in a service.

You can add to or subtract from the number of instantiations of a task definition in a service by specifying the cluster that the service is running in and a new `desiredCount` parameter.

You can use `UpdateService` to modify your task definition and deploy a new version of your service, one task at a time. If you modify the task definition with `UpdateService`, Amazon ECS spawns a task with the new version of the task definition and then stops an old task after the new version is running. Because `UpdateService` starts a new version of the task before stopping an old version, your cluster must have capacity to support one more instantiation of the task when `UpdateService` is run. If your
cluster cannot support another instantiation of the task used in your service, you can reduce the desired count of your service by one before modifying the task definition.

Request Syntax

```python
response = client.update_service(
cluster='string',
service='string',
desiredCount=123,
taskDefinition='string'
)
```

**Parameters**

- **cluster** *(string)* – The short name or full Amazon Resource Name (ARN) of the cluster that your service is running on. If you do not specify a cluster, the default cluster is assumed.
- **service** *(string)* – [REQUIRED]
  The name of the service that you want to update.
- **desiredCount** *(integer)* – The number of instantiations of the task that you would like to place and keep running in your service.
- **taskDefinition** *(string)* – The family and revision(family:revision) or full Amazon Resource Name (ARN) of the task definition that you want to run in your service. If a revision is not specified, the latest ACTIVE revision is used. If you modify the task definition with UpdateService, Amazon ECS spawns a task with the new version of the task definition and then stops an old task after the new version is running.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
'service': {
'serviceArn': 'string',
'serviceName': 'string',
'clusterArn': 'string',
'loadBalancers': [
{
'loadBalancerName': 'string',
'containerName': 'string',
'containerPort': 123
},
],
'status': 'string',
'desiredCount': 123,
'runningCount': 123,
'pendingCount': 123,
'taskDefinition': 'string',
deployments': [
{
'id': 'string',
'status': 'string',
'taskDefinition': 'string',
'desiredCount': 123,
'pendingCount': 123,
'runningCount': 123,
'createdAt': datetime(2015, 1, 1),
}
}
```
Response Structure

- (dict) – service (dict) –

The full description of your service following the update call.

* serviceArn (string) –

  The Amazon Resource Name (ARN) that identifies the service. The ARN contains the arn:aws:ecs namespace, followed by the region of the service, the AWS account ID of the service owner, the service namespace, and then the service name. For example, arn:aws:ecs:region:012345678910:service/my-service.

* serviceName (string) –

  A user-generated string that you can use to identify your service.

* clusterArn (string) –

  The Amazon Resource Name (ARN) of the of the cluster that hosts the service.

* loadBalancers (list) –

  A list of load balancer objects, containing the load balancer name, the container name (as it appears in a container definition), and the container port to access from the load balancer.

  - (dict) –

    Details on a load balancer that is used with a service.

    * loadBalancerName (string) –

      The name of the load balancer.

    * containerName (string) –

      The name of the container to associate with the load balancer.

    * containerPort (integer) –

      The port on the container to associate with the load balancer. This port must correspond to a containerPort in the service’s task definition. Your container instances must allow ingress traffic on the hostPort of the port mapping.

* status (string) –

  The status of the service. The valid values are ACTIVE, DRAINING, or INACTIVE.

* desiredCount (integer) –

  The desired number of instantiations of the task definition to keep
running on the service. This value is specified when the service is created with CreateService, and it can be modified with UpdateService.

* runningCount (integer) –
  The number of tasks in the cluster that are in the RUNNING state.

* pendingCount (integer) –
  The number of tasks in the cluster that are in the PENDING state.

* taskDefinition (string) –
  The task definition to use for tasks in the service. This value is specified when the service is created with CreateService, and it can be modified with UpdateService.

* deployments (list) –
  The current state of deployments for the service.
    - (dict) –
      The details of an Amazon ECS service deployment.
        - id (string) –
          The ID of the deployment.
        - status (string) –
          The status of the deployment. Valid values are PRIMARY (for the most recent deployment), ACTIVE (for previous deployments that still have tasks running, but are being replaced with the PRIMARY deployment), and INACTIVE (for deployments that have been completely replaced).
        - taskDefinition (string) –
          The most recent task definition that was specified for the service to use.
        - desiredCount (integer) –
          The most recent desired count of tasks that was specified for the service to deploy and/or maintain.
        - pendingCount (integer) –
          The number of tasks in the deployment that are in the PENDING status.
        - runningCount (integer) –
          The number of tasks in the deployment that are in the RUNNING status.
        - createdAt (datetime) –
          The Unix time in seconds and milliseconds when the service was created.
        - updatedAt (datetime) –
          The Unix time in seconds and milliseconds when the service was last updated.
    - roleArn (string) –
      The Amazon Resource Name (ARN) of the IAM role associated with the service that allows the Amazon ECS container agent to register container instances with a load balancer.

* events (list) –
The event stream for your service. A maximum of 100 of the latest events are displayed.

- (dict) –
  Details on an event associated with a service.
  - id (string) –
    The ID string of the event.
  - createdAt (datetime) –
    The Unix time in seconds and milliseconds when the event was triggered.
  - message (string) –
    The event message.

**Paginators**

The available paginators are:

- ECS.Paginator.ListClusters
- ECS.Paginator.ListContainerInstances
- ECS.Paginator.ListServices
- ECS.Paginator.ListTaskDefinitionFamilies
- ECS.Paginator.ListTaskDefinitions
- ECS.Paginator.ListTasks

**class ECS.Paginator.ListClusters**

```
paginator = client.get_paginator('list_clusters')
paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `ECS.Client.list_clusters()`.

**Request Syntax**

```
response_iterator = paginator.paginate(
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }    
)
```

**Parameters**

- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize (integer)** –
    The size of each page.
StartingToken (string) –
A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict

Returns

Response Syntax

```
{  
  'clusterArns': [
    'string',
  ],
  'NextToken': 'string'
}
```

Response Structure

- (dict) –
  - clusterArns (list) –
    The list of full Amazon Resource Name (ARN) entries for each cluster associated with your account.
    - (string) –
  - NextToken (string) –
    A token to resume pagination.

```py
class ECS.Paginator.ListContainerInstances

paginator = client.get_paginator('list_container_instances')

paginate (**kwargs)

Creates an iterator that will paginate through responses from ECS.Client.list_container_instances().
```

Request Syntax

```py
response_iterator = paginator.paginate(
    cluster='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **cluster (string)** – The short name or full Amazon Resource Name (ARN) of the cluster that hosts the container instances you want to list. If you do not specify a cluster, the default cluster is assumed.
- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - MaxItems (integer) –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
- **PageSize** *(integer)* –
  The size of each page.
- **StartingToken** *(string)* –
  A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
  'containerInstanceArns': [
    'string',
  ],
  'NextToken': 'string'
}
```

**Response Structure**

- *(dict)*
  - **containerInstanceArns** *(list)* –
    The list of container instance full Amazon Resource Name (ARN) entries for each container instance associated with the specified cluster.
  - *(string)*
  - **NextToken** *(string)* –
    A token to resume pagination.

```python
class ECS.Paginator.ListServices

paginator = client.get_paginator('list_services')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `ECS.Client.list_services()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    cluster='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **cluster** *(string)* – The short name or full Amazon Resource Name (ARN) of the cluster that hosts the services you want to list. If you do not specify a cluster, the default cluster is assumed.
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* –
The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.

- **PageSize (integer)** –
  The size of each page.
- **StartingToken (string)** –
  A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type**: dict

**Returns**:

**Response Syntax**

```python
{
    'serviceArns': [
        'string',
    ],
    'NextToken': 'string'
}
```

**Response Structure**

- (dict) –
  - **serviceArns (list)** –
    - (string) –
    - **NextToken (string)** –
      - A token to resume pagination.

**class** `ECSPaginator.ListTaskDefinitionFamilies`

```python
paginator = client.get_paginator('list_task_definition_families')
```

**paginate(**kwargs**)

Creates an iterator that will paginate through responses from `ECS.Client.list_task_definition_families()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    familyPrefix='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **familyPrefix (string)** – The `familyPrefix` is a string that is used to filter the results of `ListTaskDefinitionFamilies`. If you specify a `familyPrefix`, only task definition family names that begin with the `familyPrefix` string are returned.
• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  - **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  
  - **PageSize** *(integer)* –
    
    The size of each page.
  
  - **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type**  
dict

**Returns**

**Response Syntax**

```python
{
    'families': [
        'string',
    ],
    'NextToken': 'string'
}
```

**Response Structure**

- *(dict)* –
  
  - **families** *(list)* –
    
    The list of task definition family names that match the ListTaskDefinitionFamilies request.
  
  - **NextToken** *(string)* –
    
    A token to resume pagination.

```python
class ECS.Paginator.ListTaskDefinitions

    paginator = client.get_paginator('list_task_definitions')

paginate(**kwargs)

    Creates an iterator that will paginate through responses from ECS.Client.list_task_definitions().

**Request Syntax**

```python
response_iterator = paginator.paginate(
    familyPrefix='string',
    status='ACTIVE'|'INACTIVE',
    sort='ASC'|'DESC',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    })
```
Parameters

- **familyPrefix** *(string)* – The full family name that you want to filter the `ListTaskDefinitions` results with. Specifying a `familyPrefix` will limit the listed task definitions to task definition revisions that belong to that family.

- **status** *(string)* – The task definition status that you want to filter the `ListTaskDefinitions` results with. By default, only ACTIVE task definitions are listed. By setting this parameter to INACTIVE, you can view task definitions that are INACTIVE as long as an active task or service still references them. If you paginate the resulting output, be sure to keep the `status` value constant in each subsequent request.

- **sort** *(string)* – The order in which to sort the results. Valid values are ASC and DESC. By default (ASC), task definitions are listed lexicographically by family name and in ascending numerical order by revision so that the newest task definitions in a family are listed last. Setting this parameter to DESC reverses the sort order on family name and revision so that the newest task definitions in a family are listed first.

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  - **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.

  - **PageSize** *(integer)* –
    
    The size of each page.

  - **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

Return type  dict

Returns

**Response Syntax**

```{json}
{
    'taskDefinitionArns': [ 
        'string', 
    ], 
    'NextToken': 'string'
}
```

**Response Structure**

- *(dict)* –
  
  - **taskDefinitionArns** *(list)* –
    
    The list of task definition Amazon Resource Name (ARN) entries for the `ListTaskDefinitions` request.

  - *(string)* –
    
    **NextToken** *(string)* –

    A token to resume pagination.

class ECS.Paginator.ListTasks

3.1. Services
paginator = client.get_paginator('list_tasks')

paginate(**kwargs)

Creates an iterator that will paginate through responses from ECS.Client.list_tasks().

Request Syntax

response_iterator = paginator.paginate(
    cluster='string',
    containerInstance='string',
    family='string',
    startedBy='string',
    serviceName='string',
    desiredStatus='RUNNING'|'PENDING'|'STOPPED',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **cluster** *(string)* – The short name or full Amazon Resource Name (ARN) of the cluster that hosts the tasks you want to list. If you do not specify a cluster, the default cluster is assumed.

- **containerInstance** *(string)* – The container instance UUID or full Amazon Resource Name (ARN) of the container instance that you want to filter the ListTasks results with. Specifying a containerInstance will limit the results to tasks that belong to that container instance.

- **family** *(string)* – The name of the family that you want to filter the ListTasks results with. Specifying a family will limit the results to tasks that belong to that family.

- **startedBy** *(string)* – The startedBy value that you want to filter the task results with. Specifying a startedBy value will limit the results to tasks that were started with that value.

- **serviceName** *(string)* – The name of the service that you want to filter the ListTasks results with. Specifying a serviceName will limit the results to tasks that belong to that service.

- **desiredStatus** *(string)* – The task status that you want to filter the ListTasks results with. Specifying a desiredStatus of STOPPED will limit the results to tasks that are in the STOPPED status, which can be useful for debugging tasks that are not starting properly or have died or finished. The default status filter is RUNNING.

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

  - **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

  - **PageSize** *(integer)* –
    
    The size of each page.

  - **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the NextToken
from a previous response.

Return type  dict
Returns

Response Syntax

```python
{
    'taskArns': [
        'string',
    ],
    'NextToken': 'string'
}
```

Response Structure

- (dict) –
  - taskArns (list) –
    The list of task Amazon Resource Name (ARN) entries for the ListTasks request.
  - (string) –
    - NextToken (string) –
      A token to resume pagination.

Waiters

The available waiters are:

- ECS.Waiter.ServicesInactive
- ECS.Waiter.ServicesStable
- ECS.Waiter.TasksRunning
- ECS.Waiter.TasksStopped

class ECS.Waiter.ServicesInactive

```python
waiter = client.get_waiter('services_inactive')

wait(**kwargs)
```

Polls ECS.Client.describe_services() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

```python
waiter.wait(
    cluster='string',
    services=['string'],
)
```

Parameters

- cluster (string) – The name of the cluster that hosts the service you want to describe.
• **services** *(list)* – [REQUIRED]
  A list of services you want to describe.
  
  Returns None

```python
class ECS.Waiter.ServicesStable

waiter = client.get_waiter('services_stable')

wait(**kwargs)
Polls ECS.Client.describe_services() every 15 seconds until a successful state is reached. An error is returned after 40 failed checks.

Request Syntax

waiter.wait(
    cluster='string',
    services=[
        'string',
    ]
)

Parameters

• **cluster** *(string)* – The name of the cluster that hosts the service you want to describe.

• **services** *(list)* – [REQUIRED]
  A list of services you want to describe.
  
  Returns None

```python
class ECS.Waiter.TasksRunning

waiter = client.get_waiter('tasks_running')

wait(**kwargs)
Polls ECS.Client.describe_tasks() every 6 seconds until a successful state is reached. An error is returned after 100 failed checks.

Request Syntax

waiter.wait(
    cluster='string',
    tasks=[
        'string',
    ]
)

Parameters

• **cluster** *(string)* – The short name or full Amazon Resource Name (ARN) of the cluster that hosts the task you want to describe. If you do not specify a cluster, the default cluster is assumed.

• **tasks** *(list)* – [REQUIRED]
  A space-separated list of task UUIDs or full Amazon Resource Name (ARN) entries.
class ECS.Waiter.TasksStopped

waiter = client.get_waiter('tasks_stopped')

wait(**kwargs)

Polls ECS.Client.describe_tasks() every 6 seconds until a successful state is reached. An error is returned after 100 failed checks.

Request Syntax

waiter.wait(
    cluster='string',
    tasks=['string',
           'string',
    ]
)

Parameters

- **cluster** (string) – The short name or full Amazon Resource Name (ARN) of the cluster that hosts the task you want to describe. If you do not specify a cluster, the default cluster is assumed.
- **tasks** (list) – [REQUIRED]
  
  A space-separated list of task UUIDs or full Amazon Resource Name (ARN) entries.

Returns None

---

EFS

Client

class EFS.Client

A low-level client representing Amazon Elastic File System (EFS):

import boto3

client = boto3.client('efs')

These are the available methods:

- can_paginate()
- create_file_system()
- create_mount_target()
- create_tags()
can_paginate(operation_name)

Check if an operation can be paginated.

Parameters operation_name (string) – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs), if the create_foo operation can be paginated, you can use the call client.get_paginator("create_foo").

Returns True if the operation can be paginated, False otherwise.

create_file_system(**kwargs)

Creates a new, empty file system. The operation requires a creation token in the request that Amazon EFS uses to ensure idempotent creation (calling the operation with same creation token has no effect). If a file system does not currently exist that is owned by the caller’s AWS account with the specified creation token, this operation does the following:

• Creates a new, empty file system. The file system will have an Amazon EFS assigned ID, and an initial lifecycle state “creating”.
• Returns with the description of the created file system.

Otherwise, this operation returns a FileSystemAlreadyExists error with the ID of the existing file system.

Note: For basic use cases, you can use a randomly generated UUID for the creation token.

The idempotent operation allows you to retry a CreateFileSystem call without risk of creating an extra file system. This can happen when an initial call fails in a way that leaves it uncertain whether or not a file system was actually created. An example might be that a transport level timeout occurred or your connection was reset. As long as you use the same creation token, if the initial call had succeeded in creating a file system, the client can learn of its existence from the FileSystemAlreadyExists error.

Note: The CreateFileSystem call returns while the file system’s lifecycle state is still “creating”. You can check the file system creation status by calling the DescribeFileSystems API, which among other things returns the file system state.

After the file system is fully created, Amazon EFS sets its lifecycle state to “available”, at which point you can create one or more mount targets for the file system (CreateMountTarget) in your VPC. You mount your Amazon EFS file system on an EC2 instances in your VPC via the mount target. For more information, see Amazon EFS: How it Works

This operation requires permission for the elasticfilesystem:CreateFileSystem action.

Request Syntax

```python
create_file_system(CreationToken='string'
```
Parameters CreationToken (string) – [REQUIRED]

String of up to 64 ASCII characters. Amazon EFS uses this to ensure idempotent creation.

Return type dict

Returns

Response Syntax

```python
{
    'OwnerId': 'string',
    'CreationToken': 'string',
    'FileSystemId': 'string',
    'CreationTime': datetime(2015, 1, 1),
    'LifeCycleState': 'creating'|'available'|'deleting'|'deleted',
    'Name': 'string',
    'NumberOfMountTargets': 123,
    'SizeInBytes': {
        'Value': 123,
        'Timestamp': datetime(2015, 1, 1)
    }
}
```

Response Structure

- (dict) –
  This object provides description of a file system.
  - OwnerId (string) –
    The AWS account that created the file system. If the file system was created by an IAM user, the parent account to which the user belongs is the owner.
  - CreationToken (string) –
    Opaque string specified in the request.
  - FileSystemId (string) –
    The file system ID assigned by Amazon EFS.
  - CreationTime (datetime) –
    The time at which the file system was created, in seconds, since 1970-01-01T00:00:00Z.
  - LifeCycleState (string) –
    A predefined string value that indicates the lifecycle phase of the file system.
  - Name (string) –
    You can add tags to a file system (see CreateTags ) including a “Name” tag. If the file system has a “Name” tag, Amazon EFS returns the value in this field.
  - NumberOfMountTargets (integer) –
    The current number of mount targets (see CreateMountTarget ) the file system has.
  - SizeInBytes (dict) –
This object provides the latest known metered size of data stored in the file system, in bytes, in its `Value` field, and the time at which that size was determined in its `Timestamp` field. The `Timestamp` value is the integer number of seconds since 1970-01-01T00:00:00Z. Note that the value does not represent the size of a consistent snapshot of the file system, but it is eventually consistent when there are no writes to the file system. That is, the value will represent actual size only if the file system is not modified for a period longer than a couple of hours. Otherwise, the value is not the exact size the file system was at any instant in time.

* **Value** (integer) –
  The latest known metered size, in bytes, of data stored in the file system.

* **Timestamp** (datetime) –
  The time at which the size of data, returned in the `Value` field, was determined. The value is the integer number of seconds since 1970-01-01T00:00:00Z.

**create_mount_target (**kwargs**)

Creates a mount target for a file system. You can then mount the file system on EC2 instances via the mount target.

You can create one mount target in each Availability Zone in your VPC. All EC2 instances in a VPC within a given Availability Zone share a single mount target for a given file system. If you have multiple subnets in an Availability Zone, you create a mount target in one of the subnets. EC2 instances do not need to be in the same subnet as the mount target in order to access their file system. For more information, see Amazon EFS: How it Works.

In the request, you also specify a file system ID for which you are creating the mount target and the file system’s lifecycle state must be “available” (see DescribeFileSystems).

In the request, you also provide a subnet ID, which serves several purposes:

• It determines the VPC in which Amazon EFS creates the mount target.
• It determines the Availability Zone in which Amazon EFS creates the mount target.
• It determines the IP address range from which Amazon EFS selects the IP address of the mount target if you don’t specify an IP address in the request.

After creating the mount target, Amazon EFS returns a response that includes, a `MountTargetId` and an `IpAddress`. You use this IP address when mounting the file system in an EC2 instance. You can also use the mount target’s DNS name when mounting the file system. The EC2 instance on which you mount the file system via the mount target can resolve the mount target’s DNS name to its IP address. For more information, see How it Works: Implementation Overview.

Note that you can create mount targets for a file system in only one VPC, and there can be only one mount target per Availability Zone. That is, if the file system already has one or more mount targets created for it, the request to add another mount target must meet the following requirements:

• The subnet specified in the request must belong to the same VPC as the subnets of the existing mount targets.
• The subnet specified in the request must not be in the same Availability Zone as any of the subnets of the existing mount targets.

If the request satisfies the requirements, Amazon EFS does the following:

• Creates a new mount target in the specified subnet.
• Also creates a new network interface in the subnet as follows: * If the request provides an `IpAddress`, Amazon EFS assigns that IP address to the network interface. Otherwise, Amazon EFS assigns a free address in the subnet (in the same way that the Amazon EC2 CreateNetworkInterface call does when a request does not specify a primary private IP address).
• If the request provides SecurityGroups, this network interface is associated with those security groups. Otherwise, it belongs to the default security group for the subnet’s VPC.
• Assigns the description "Mount target *fsmt-id* for file system *fs-id* " where *fsmt-id* is the mount target ID, and *fs-id* is the FileSystemId.
• Sets the requesterManaged property of the network interface to “true”, and the requesterId value to “EFS”.

Each Amazon EFS mount target has one corresponding requestor-managed EC2 network interface. After the network interface is created, Amazon EFS sets the NetworkInterfaceId field in the mount target’s description to the network interface ID, and the IpAddress field to its address. If network interface creation fails, the entire CreateMountTarget operation fails.

**Note:** The CreateMountTarget call returns only after creating the network interface, but while the mount target state is still “creating”. You can check the mount target creation status by calling the DescribeFileSystems API, which among other things returns the mount target state.

We recommend you create a mount target in each of the Availability Zones. There are cost considerations for using a file system in an Availability Zone through a mount target created in another Availability Zone. For more information, go to Amazon EFS product detail page. In addition, by always using a mount target local to the instance’s Availability Zone, you eliminate a partial failure scenario; if the Availability Zone in which your mount target is created goes down, then you won’t be able to access your file system through that mount target.

This operation requires permission for the following action on the file system:

• elasticfilesystem:CreateMountTarget

This operation also requires permission for the following Amazon EC2 actions:

• ec2:DescribeSubnets
• ec2:DescribeNetworkInterfaces
• ec2:CreateNetworkInterface

**Request Syntax**

```python
def create_mount_target:
    response = client.create_mount_target(
        FileSystemId='string',
        SubnetId='string',
        IpAddress='string',
        SecurityGroups=[
            'string',
        ]
    )
```

**Parameters**

• **FileSystemId** *(string)* -- [REQUIRED]
  
  The ID of the file system for which to create the mount target.

• **SubnetId** *(string)* -- [REQUIRED]
  
  The ID of the subnet to add the mount target in.

• **IpAddress** *(string)* -- A valid IPv4 address within the address range of the specified subnet.

• **SecurityGroups** *(list)* -- Up to 5 VPC security group IDs, of the form “sg-xxxxxxxx”. These must be for the same VPC as subnet specified.
  
  - *(string)*

**Return type** dict

**Returns**

**Response Syntax**
Response Structure

- (dict) –

This object provides description of a mount target.

  - **OwnerId** *(string)* –
    The AWS account ID that owns the resource.

  - **MountTargetId** *(string)* –
    The system-assigned mount target ID.

  - **FileSystemId** *(string)* –
    The ID of the file system for which the mount target is intended.

  - **SubnetId** *(string)* –
    The ID of the subnet that the mount target is in.

  - **LifeCycleState** *(string)* –
    The lifecycle state the mount target is in.

  - **IpAddress** *(string)* –
    The address at which the file system may be mounted via the mount target.

  - **NetworkInterfaceId** *(string)* –
    The ID of the network interface that Amazon EFS created when it created the mount target.

create_tags(**kwargs)**

Creates or overwrites tags associated with a file system. Each tag is a key-value pair. If a tag key specified in the request already exists on the file system, this operation overwrites its value with the value provided in the request. If you add the “Name” tag to your file system, Amazon EFS returns it in the response to the DescribeFileSystems API.

This operation requires permission for the elasticfilesystem:CreateTags action.

Request Syntax

```python
response = client.create_tags(
    FileSystemId='string',
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

Parameters

- **FileSystemId** *(string)* – [REQUIRED]
String. The ID of the file system whose tags you want to modify. This operation modifies only the tags and not the file system.

- **Tags (list)** – [REQUIRED]

An array of Tag objects to add. Each Tag object is a key-value pair.

- (dict) –

A tag is a pair of key and value. The allowed characters in keys and values are letters, whitespace, and numbers, representable in UTF-8, and the characters ‘+’, ‘-’, ‘=’, ‘.’, ‘_’, ‘:’, and ‘/’.

- **Key (string)** – [REQUIRED]

Tag key, a string. The key must not start with “aws:”.

- **Value (string)** – [REQUIRED]

Value of the tag key.

Returns None

**delete_file_system(**kwargs)**

Deletes a file system, permanently severing access to its contents. Upon return, the file system no longer exists and you will not be able to access any contents of the deleted file system.

You cannot delete a file system that is in use. That is, if the file system has any mount targets, you must first delete them. For more information, see DescribeMountTargets and DeleteMountTarget.

**Note:** The DeleteFileSystem call returns while the file system state is still “deleting”. You can check the file system deletion status by calling the DescribeFileSystems API, which returns a list of file systems in your account. If you pass file system ID or creation token for the deleted file system, the DescribeFileSystems will return a 404 “FileSystemNotFound” error.

This operation requires permission for the elasticfilesystem:DeleteFileSystem action.

**Request Syntax**

```python
response = client.delete_file_system(
    FileSystemId='string'
)
```

**Parameters** FileSystemId *(string)* – [REQUIRED]

The ID of the file system you want to delete.

**Returns** None

**delete_mount_target(**kwargs)**

Deletes the specified mount target.

This operation forcibly breaks any mounts of the file system via the mount target being deleted, which might disrupt instances or applications using those mounts. To avoid applications getting cut off abruptly, you might consider unmounting any mounts of the mount target, if feasible. The operation also deletes the associated network interface. Uncommitted writes may be lost, but breaking a mount target using this operation does not corrupt the file system itself. The file system you created remains. You can mount an EC2 instance in your VPC using another mount target.

This operation requires permission for the following action on the file system:

- elasticfilesystem:DeleteMountTarget

**Note:** The DeleteMountTarget call returns while the mount target state is still “deleting”. You can check the mount target deletion by calling the DescribeMountTargets API, which returns a list of mount target descriptions for the given file system.
The operation also requires permission for the following Amazon EC2 action on the mount target’s network interface:

• `ec2:DeleteNetworkInterface`

**Request Syntax**

```python
response = client.delete_mount_target(
    MountTargetId='string'
)
```

**Parameters**

- **MountTargetId (string)** – [REQUIRED]
  
  String. The ID of the mount target to delete.

**Returns**

- None

**delete_tags(**kwargs)**

Deletes the specified tags from a file system. If the `DeleteTags` request includes a tag key that does not exist, Amazon EFS ignores it; it is not an error. For more information about tags and related restrictions, go to Tag Restrictions in the AWS Billing and Cost Management User Guide.

This operation requires permission for the `elasticfilesystem:DeleteTags` action.

**Request Syntax**

```python
response = client.delete_tags(
    FileSystemId='string',
    TagKeys=['string',
             'string'],
)
```

**Parameters**

- **FileSystemId (string)** – [REQUIRED]
  
  String. The ID of the file system whose tags you want to delete.

- **TagKeys (list)** – [REQUIRED]
  
  A list of tag keys to delete.

**Returns**

- None

**describe_file_systems(**kwargs)**

Returns the description of a specific Amazon EFS file system if either the file system `CreationToken` or the `FileSystemId` is provided; otherwise, returns descriptions of all file systems owned by the caller’s AWS account in the AWS region of the endpoint that you’re calling.

When retrieving all file system descriptions, you can optionally specify the `MaxItems` parameter to limit the number of descriptions in a response. If more file system descriptions remain, Amazon EFS returns a `NextMarker`, an opaque token, in the response. In this case, you should send a subsequent request with the `Marker` request parameter set to the value of `NextMarker`.

So to retrieve a list of your file system descriptions, the expected usage of this API is an iterative process of first calling `DescribeFileSystems` without the `Marker` and then continuing to call it with the `Marker` parameter set to the value of the `NextMarker` from the previous response until the response has no `NextMarker`.

Note that the implementation may return fewer than `MaxItems` file system descriptions while still including a `NextMarker` value.

The order of file systems returned in the response of one `DescribeFileSystems` call, and the order of file systems returned across the responses of a multi-call iteration, is unspecified.
This operation requires permission for the `elasticfilesystem:DescribeFileSystems` action.

**Request Syntax**

```python
response = client.describe_file_systems(
    MaxItems=123,
    Marker='string',
    CreationToken='string',
    FileSystemId='string'
)
```

**Parameters**

- **MaxItems** *(integer)* – Optional integer. Specifies the maximum number of file systems to return in the response. This parameter value must be greater than 0. The number of items Amazon EFS returns will be the minimum of the `MaxItems` parameter specified in the request and the service's internal maximum number of items per page.
- **Marker** *(string)* – Optional string. Opaque pagination token returned from a previous `DescribeFileSystems` operation. If present, specifies to continue the list from where the returning call had left off.
- **CreationToken** *(string)* – Optional string. Restricts the list to the file system with this creation token (you specify a creation token at the time of creating an Amazon EFS file system).
- **FileSystemId** *(string)* – Optional string. File system ID whose description you want to retrieve.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Marker': 'string',
    'FileSystems': [
        {
            'OwnerId': 'string',
            'CreationToken': 'string',
            'FileSystemId': 'string',
            'CreationTime': datetime(2015, 1, 1),
            'LifeCycleState': 'creating'|'available'|'deleting'|'deleted',
            'Name': 'string',
            'NumberOfMountTargets': 123,
            'SizeInBytes': {
                'Value': 123,
                'Timestamp': datetime(2015, 1, 1)
            }
        }
    ],
    'NextMarker': 'string'
}
```

**Response Structure**

- *(dict)* –
  - **Marker** *(string)* –
    A string, present if provided by caller in the request.
  - **FileSystems** *(list)* –
    An array of file system descriptions.
This object provides description of a file system.

- **OwnerId** *(string)* –
  The AWS account that created the file system. If the file system was created by an IAM user, the parent account to which the user belongs is the owner.

- **CreationToken** *(string)* –
  Opaque string specified in the request.

- **FileSystemId** *(string)* –
  The file system ID assigned by Amazon EFS.

- **CreationTime** *(datetime)* –
  The time at which the file system was created, in seconds, since 1970-01-01T00:00:00Z.

- **LifeCycleState** *(string)* –
  A predefined string value that indicates the lifecycle phase of the file system.

- **Name** *(string)* –
  You can add tags to a file system (see CreateTags) including a “Name” tag. If the file system has a “Name” tag, Amazon EFS returns the value in this field.

- **NumberOfMountTargets** *(integer)* –
  The current number of mount targets (see CreateMountTarget) the file system has.

- **SizeInBytes** *(dict)* –
  This object provides the latest known metered size of data stored in the file system, in bytes, in its **Value** field, and the time at which that size was determined in its **Timestamp** field. The **Timestamp** value is the integer number of seconds since 1970-01-01T00:00:00Z. Note that the value does not represent the size of a consistent snapshot of the file system, but it is eventually consistent when there are no writes to the file system. That is, the value will represent actual size only if the file system is not modified for a period longer than a couple of hours. Otherwise, the value is not the exact size the file system was at any instant in time.

  - **Value** *(integer)* –
    The latest known metered size, in bytes, of data stored in the file system.

  - **Timestamp** *(datetime)* –
    The time at which the size of data, returned in the **Value** field, was determined. The value is the integer number of seconds since 1970-01-01T00:00:00Z.

- **NextMarker** *(string)* –
  A string, present if there are more file systems than returned in the response. You can use the **NextMarker** in the subsequent request to fetch the descriptions.
**describe_mount_target_security_groups(**kwargs)**

Returns the security groups currently in effect for a mount target. This operation requires that the network interface of the mount target has been created and the life cycle state of the mount target is not "deleted".

This operation requires permissions for the following actions:
* elasticfilesystem:DescribeMountTargetSecurityGroups action on the mount target’s file system.
* ec2:DescribeNetworkInterfaceAttribute action on the mount target’s network interface.

Request Syntax

```python
response = client.describe_mount_target_security_groups(
    MountTargetId='string'
)
```

Parameters

- **MountTargetId (string)** – [REQUIRED]
  
  The ID of the mount target whose security groups you want to retrieve.

Return type

dict

Response Syntax

```python
{
    'SecurityGroups': [
        'string',
    ]
}
```

Response Structure

- (dict) –
  - SecurityGroups (list) –
    
    An array of security groups.

**describe_mount_targets(**kwargs)**

Returns the descriptions of all the current mount targets, or a specific mount target, for a file system. When requesting all of the current mount targets, the order of mount targets returned in the response is unspecified.

This operation requires permission for the elasticfilesystem:DescribeMountTargets action, on either the file system id that you specify in FileSystemId, or on the file system of the mount target that you specify in MountTargetId.

Request Syntax

```python
response = client.describe_mount_targets(
    MaxItems=123,
    Marker='string',
    FileSystemId='string',
    MountTargetId='string'
)
```

Parameters

- **MaxItems (integer)** – Optional. Maximum number of mount targets to return in the response. It must be an integer with a value greater than zero.
• **Marker** *(string)* – Optional. String. Opaque pagination token returned from a previous **DescribeMountTargets** operation. If present, it specifies to continue the list from where the previous returning call left off.

• **FileSystemId** *(string)* – Optional. String. The ID of the file system whose mount targets you want to list. It must be included in your request if **MountTargetId** is not included.

• **MountTargetId** *(string)* – Optional. String. The ID of the mount target that you want to have described. It must be included in your request if **FileSystemId** is not included.

Return type  dict
Returns
Response Syntax

```python
{
    'Marker': 'string',
    'MountTargets': [
        {
            'OwnerId': 'string',
            'MountTargetId': 'string',
            'FileSystemId': 'string',
            'SubnetId': 'string',
            'LifeCycleState': 'creating'|'available'|'deleting'|'deleted',
            'IpAddress': 'string',
            'NetworkInterfaceId': 'string'
        },
        
    ]
    'NextMarker': 'string'
}
```

Response Structure

• *(dict)* –
  
  **Marker** *(string)* –
  
  If the request included the **Marker**, the response returns that value in this field.

  **MountTargets** *(list)* –
  
  Returns the file system’s mount targets as an array of **MountTargetDescription** objects.

  • *(dict)* –
    
    This object provides description of a mount target.
    
    **OwnerId** *(string)* –
    
    The AWS account ID that owns the resource.
    
    **MountTargetId** *(string)* –
    
    The system-assigned mount target ID.
    
    **FileSystemId** *(string)* –
    
    The ID of the file system for which the mount target is intended.
    
    **SubnetId** *(string)* –
    
    The ID of the subnet that the mount target is in.

    **LifeCycleState** *(string)* –
    
    The lifecycle state the mount target is in.
- **IpAddress** *(string)* –
  The address at which the file system may be mounted via the mount target.
- **NetworkInterfaceId** *(string)* –
  The ID of the network interface that Amazon EFS created when it created the mount target.
- **NextMarker** *(string)* –
  If a value is present, there are more mount targets to return. In a subsequent request, you can provide `Marker` in your request with this value to retrieve the next set of mount targets.

### `describe_tags(**kwargs)`

Returns the tags associated with a file system. The order of tags returned in the response of one `DescribeTags` call, and the order of tags returned across the responses of a multi-call iteration (when using pagination), is unspecified.

This operation requires permission for the `elasticfilesystem:DescribeTags` action.

#### Request Syntax

```python
response = client.describe_tags(
    MaxItems=123,
    Marker='string',
    FileSystemId='string'
)
```

#### Parameters

- **MaxItems** *(integer)* – Optional. Maximum number of file system tags to return in the response. It must be an integer with a value greater than zero.
- **Marker** *(string)* – Optional. String. Opaque pagination token returned from a previous `DescribeTags` operation. If present, it specifies to continue the list from where the previous call left off.
- **FileSystemId** *(string)* – [REQUIRED]
  The ID of the file system whose tag set you want to retrieve.

#### Return type  `dict`

#### Returns

##### Response Syntax

```python
{
    'Marker': 'string',
    'Tags': [
        {
            'Key': 'string',
            'Value': 'string'
        },
    ],
    'NextMarker': 'string'
}
```

##### Response Structure

- *(dict)* –
  - **Marker** *(string)* –
    If the request included a `Marker`, the response returns that value in this field.
– **Tags** *(list)* –
  Returns tags associated with the file system as an array of Tag objects.
  * *(dict)* –
  A tag is a pair of key and value. The allowed characters in keys and
  values are letters, whitespace, and numbers, representable in UTF-8,
  and the characters `+', '-', '='; ':', and '/'.
  · **Key** *(string)* –
    Tag key, a string. The key must not start with “aws:”.
  · **Value** *(string)* –
    Value of the tag key.

– **NextMarker** *(string)* –
  If a value is present, there are more tags to return. In a subsequent request,
  you can provide the value of **NextMarker** as the value of the **Marker**
  parameter in your next request to retrieve the next set of tags.

**generate_presigned_url** *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*
Generate a presigned url given a client, its method, and arguments

**Parameters**
- **ClientMethod** *(string)* – The client method to presign for
- **Params** *(dict)* – The parameters normally passed to **ClientMethod**.
- **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By
  default it expires in an hour (3600 seconds)
- **HttpMethod** *(string)* – The http method to use on the generated url. By default,
  the http method is whatever is used in the method’s model.

**Returns** The presigned url

**get Paginator** *(operation_name)*
Create a paginator for an operation.

**Parameters** **operation_name** *(string)* – The operation name. This is the same name as
  the method name on the client. For example, if the method name is **create_foo**,
  and you’d normally invoke the operation as **client.create_foo(**kwargs**,)
  if the **create_foo** operation can be paginated, you can use the call
  **client.get Paginator**("**create_foo**")

**Raises** **OperationNotPageableError** Raised if the operation is not pageable. You can use
  the **client.can_paginate** method to check if an operation is pageable.

**Return type** L{botocore.paginate.Paginator}

**Returns** A paginator object.

**get waiter** *(waiter_name)*

**modify_mount_target_security_groups** *(**kwargs**)*
Modifies the set of security groups in effect for a mount target.

When you create a mount target, Amazon EFS also creates a new network interface (see CreateMount-
Target ). This operation replaces the security groups in effect for the network interface associated with
a mount target, with the **SecurityGroups** provided in the request. This operation requires that the
network interface of the mount target has been created and the life cycle state of the mount target is not
“deleted”.

The operation requires permissions for the following actions:
  * **elasticfilesystem:ModifyMountTargetSecurityGroups** action on the mount tar-
    get’s file system.
  * **ec2:ModifyNetworkInterfaceAttribute** action on the mount target’s network inter-
    face.
Request Syntax

```python
response = client.modify_mount_target_security_groups(
    MountTargetId='string',
    SecurityGroups=[
        'string',
    ]
)
```

**Parameters**

- **MountTargetId** *(string)* – [REQUIRED]
  
  The ID of the mount target whose security groups you want to modify.

- **SecurityGroups** *(list)* – An array of up to five VPC security group IDs.
  
  *(string)* –

**Returns** None

ElastiCache

### Table of Contents

- ElastiCache
  - Client
  - Paginators
  - Waiters

Client

```python
class ElastiCache.Client
    A low-level client representing Amazon ElastiCache:

    import boto3

    client = boto3.client('elasticache')
```

These are the available methods:

- `add_tags_to_resource()`
- `authorize_cache_security_group_ingress()`
- `can_paginate()`
- `copy_snapshot()`
- `create_cache_cluster()`
- `create_cache_parameter_group()`
- `create_cache_security_group()`
- `create_cache_subnet_group()`
- `create_replication_group()`
- `create_snapshot()`
- `delete_cache_cluster()`
- `delete_cache_parameter_group()`
- `delete_cache_security_group()`
- `delete_cache_subnet_group()`
- `delete_replication_group()`
- `delete_snapshot()`
The `add_tags_to_resource` action adds up to 10 cost allocation tags to the named resource. A cost allocation tag is a key-value pair where the key and value are case-sensitive. Cost allocation tags can be used to categorize and track your AWS costs.

When you apply tags to your ElastiCache resources, AWS generates a cost allocation report as a comma-separated value (CSV) file with your usage and costs aggregated by your tags. You can apply tags that represent business categories (such as cost centers, application names, or owners) to organize your costs across multiple services. For more information, see Using Cost Allocation Tags in Amazon ElastiCache.

Request Syntax

```python
response = client.add_tags_to_resource(
    ResourceName='string',
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

**Parameters**

- **ResourceName** *(string)* – [REQUIRED]
  
The name of the resource to which the tags are to be added, for example `arn:aws:elasticache:us-west-2:0123456789:cluster:myCluster`

- **Tags** *(list)* – [REQUIRED]
  
  A list of cost allocation tags to be added to this resource. A tag is a key-value pair. A tag key must be accompanied by a tag value.
A cost allocation Tag that can be added to an ElastiCache cluster or replication group. Tags are composed of a Key/Value pair. A tag with a null Value is permitted.

- **Key (string)** –
  The key for the tag.
- **Value (string)** –
  The tag’s value. May not be null.

**Return type**  dict

**Returns**

**Response Syntax**

```
{
    'TagList': [
        {
            'Key': 'string',
            'Value': 'string'
        }
    ]
}
```

**Response Structure**

- **(dict)** –
  Represents the output from the `AddTagsToResource`, `ListTagsOnResource`, and `RemoveTagsFromResource` actions.

  - **TagList (list)** –
    A list of cost allocation tags as key-value pairs.

    - **(dict)** –
      A cost allocation Tag that can be added to an ElastiCache cluster or replication group. Tags are composed of a Key/Value pair. A tag with a null Value is permitted.

        - **Key (string)** –
          The key for the tag.
        - **Value (string)** –
          The tag’s value. May not be null.

**authorize_cache_security_group_ingress(****kwargs)**

The `AuthorizeCacheSecurityGroupIngress` action allows network ingress to a cache security group. Applications using ElastiCache must be running on Amazon EC2, and Amazon EC2 security groups are used as the authorization mechanism.

**Note:** You cannot authorize ingress from an Amazon EC2 security group in one region to an ElastiCache cluster in another region.

**Request Syntax**

```python
response = client.authorize_cache_security_group_ingress(
    CacheSecurityGroupName='string',
    EC2SecurityGroupName='string',
    EC2SecurityGroupOwnerId='string'
)
```
Parameters

- **CacheSecurityGroupName** *(string)* – [REQUIRED]
  
The cache security group which will allow network ingress.

- **EC2SecurityGroupName** *(string)* – [REQUIRED]
  
The Amazon EC2 security group to be authorized for ingress to the cache security group.

- **EC2SecurityGroupOwnerId** *(string)* – [REQUIRED]
  
The AWS account number of the Amazon EC2 security group owner. Note that this is not the same thing as an AWS access key ID - you must provide a valid AWS account number for this parameter.

Return type  
dict

Returns

Response Syntax

```json
{
  'CacheSecurityGroup': {
    'OwnerId': 'string',
    'CacheSecurityGroupName': 'string',
    'Description': 'string',
    'EC2SecurityGroups': [
      {
        'Status': 'string',
        'EC2SecurityGroupName': 'string',
        'EC2SecurityGroupOwnerId': 'string'
      },
    ]
  }
}
```

Response Structure

- *(dict)* –

  Represents the output of one of the following actions:
  - `AuthorizeCacheSecurityGroupIngress`
  - `CreateCacheSecurityGroup`
  - `RevokeCacheSecurityGroupIngress`

- **CacheSecurityGroup** *(dict)* –

  Represents the output of one of the following actions:
  - `AuthorizeCacheSecurityGroupIngress`
  - `CreateCacheSecurityGroup`
  - `RevokeCacheSecurityGroupIngress`

  - **OwnerId** *(string)* –
    
    The AWS account ID of the cache security group owner.

  - **CacheSecurityGroupName** *(string)* –
    
    The name of the cache security group.

  - **Description** *(string)* –
    
    The description of the cache security group.

  - **EC2SecurityGroups** *(list)* –
    
    A list of Amazon EC2 security groups that are associated with this cache security group.
· **dict** –
  Provides ownership and status information for an Amazon
  EC2 security group.
· **Status** *(string)* –
  The status of the Amazon EC2 security group.
· **EC2SecurityGroupName** *(string)* –
  The name of the Amazon EC2 security group.
· **EC2SecurityGroupOwnerId** *(string)* –
  The AWS account ID of the Amazon EC2 security group owner.

can_paginate *(operation_name)*
Check if an operation can be paginated.

**Parameters**

- **operation_name** *(string)* – The operation name. This is the same name as
  the method name on the client. For example, if the method name is create_foo,
  and you’d normally invoke the operation as client.create_foo(**kwargs),
  if the create_foo operation can be paginated, you can use the call
  client.get Paginator("create_foo").

**Returns**

- True if the operation can be paginated, False otherwise.

copy_snapshot (**kwargs)**
The CopySnapshot action makes a copy of an existing snapshot.

**Request Syntax**

```python
response = client.copy_snapshot(
    SourceSnapshotName='string',
    TargetSnapshotName='string'
)
```

**Parameters**

- **SourceSnapshotName** *(string)* – [REQUIRED]
  The name of an existing snapshot from which to copy.
- **TargetSnapshotName** *(string)* – [REQUIRED]
  A name for the copied snapshot.

**Return type**

dict

**Returns**

**Response Syntax**

```json
{
    'Snapshot': {
        'SnapshotName': 'string',
        'CacheClusterId': 'string',
        'SnapshotStatus': 'string',
        'SnapshotSource': 'string',
        'CacheNodeType': 'string',
        'Engine': 'string',
        'EngineVersion': 'string',
        'NumCacheNodes': 123,
        'PreferredAvailabilityZone': 'string',
        'CacheClusterCreateTime': datetime(2015, 1, 1),
        'PreferredMaintenanceWindow': 'string',
        'TopicArn': 'string',
    }
}
```
'Port': 123,
'CacheParameterGroupName': 'string',
'CacheSubnetGroupName': 'string',
'VpcId': 'string',
'AutoMinorVersionUpgrade': True|False,
'SnapshotRetentionLimit': 123,
'SnapshotWindow': 'string',
'NodeSnapshots': [ 
  { 
    'CacheNodeId': 'string',
    'CacheSize': 'string',
    'CacheNodeCreateTime': datetime(2015, 1, 1),
    'SnapshotCreateTime': datetime(2015, 1, 1)
  },
  
  } 
] 

Response Structure
• (dict) –
  Represents a copy of an entire cache cluster as of the time when the snapshot was taken.
  – Snapshot (dict) –
    Represents a copy of an entire cache cluster as of the time when the snapshot was taken.
    * SnapshotName (string) –
      The name of a snapshot. For an automatic snapshot, the name is system-generated; for a manual snapshot, this is the user-provided name.
    * CacheClusterId (string) –
      The user-supplied identifier of the source cache cluster.
    * SnapshotStatus (string) –
      The status of the snapshot. Valid values: creating|available |restoring|copying|deleting.
    * SnapshotSource (string) –
      Indicates whether the snapshot is from an automatic backup (automated) or was created manually (manual).
    * CacheNodeType (string) –
      The name of the compute and memory capacity node type for the source cache cluster.

Valid node types are as follows:
· General purpose: * Current generation: cache.t2.micro , cache.t2.small , cache.t2.medium , cache.m3.medium , cache.m3.large , cache.m3.xlarge , cache.m3.2xlarge
· Previous generation: cache.t1.micro , cache.m1.small , cache.m1.medium , cache.m1.large , cache.m1.xlarge
· Compute optimized: cache.c1.xlarge
· Memory optimized * Current generation: cache.r3.large , cache.r3.xlarge ,
cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge

· Previous generation: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

Notes:
· All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
· Redis backup/restore is not supported for t2 instances.
· Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

* Engine (string) –

The name of the cache engine (memcached or redis) used by the source cache cluster.

* EngineVersion (string) –

The version of the cache engine version that is used by the source cache cluster.

* NumCacheNodes (integer) –

The number of cache nodes in the source cache cluster.

For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.

* PreferredAvailabilityZone (string) –

The name of the Availability Zone in which the source cache cluster is located.

* CacheClusterCreateTime (datetime) –

The date and time when the source cache cluster was created.

* PreferredMaintenanceWindow (string) –

Specifies the weekly time range during which maintenance on the cache cluster is performed. It is specified as a range in the format ddd:hh24:mi-ddd:hh24:mi (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for ddd are:
· sun
· mon
· tue
· wed
· thu
· fri
· sat

Example: sun:05:00-sun:09:00

* TopicArn (string) –

The Amazon Resource Name (ARN) for the topic used by the source cache cluster for publishing notifications.

* Port (integer) –

The port number used by each cache node in the source cache cluster.

* CacheParameterGroupName (string) –
The cache parameter group that is associated with the source cache cluster.

* **CacheSubnetGroupName** *(string)* –
  The name of the cache subnet group associated with the source cache cluster.

* **VpcId** *(string)* –
  The Amazon Virtual Private Cloud identifier (VPC ID) of the cache subnet group for the source cache cluster.

* **AutoMinorVersionUpgrade** *(boolean)* –
  This parameter is currently disabled.

* **SnapshotRetentionLimit** *(integer)* –
  For an automatic snapshot, the number of days for which ElastiCache will retain the snapshot before deleting it.
  For manual snapshots, this field reflects the `SnapshotRetentionLimit` for the source cache cluster when the snapshot was created. This field is otherwise ignored: Manual snapshots do not expire, and can only be deleted using the `DeleteSnapshot` action.

  **Important** If the value of `SnapshotRetentionLimit` is set to zero (0), backups are turned off.

* **SnapshotWindow** *(string)* –
  The daily time range during which ElastiCache takes daily snapshots of the source cache cluster.

* **NodeSnapshots** *(list)* –
  A list of the cache nodes in the source cache cluster.

  · *(dict)* –
    Represents an individual cache node in a snapshot of a cache cluster.

  · **CacheNodeId** *(string)* –
    The cache node identifier for the node in the source cache cluster.

  · **CacheSize** *(string)* –
    The size of the cache on the source cache node.

  · **CacheNodeCreateTime** *(datetime)* –
    The date and time when the cache node was created in the source cache cluster.

  · **SnapshotCreateTime** *(datetime)* –
    The date and time when the source node’s metadata and cache data set was obtained for the snapshot.

**create_cache_cluster(** **kwargs)**

The `CreateCacheCluster` action creates a cache cluster. All nodes in the cache cluster run the same protocol-compliant cache engine software, either Memcached or Redis.

**Request Syntax**

```python
response = client.create_cache_cluster(
    CacheClusterId='string',
    ReplicationGroupId='string',
```

---

1902 Chapter 3. API Reference
Parameters

- **CacheClusterId** (**string**) – [REQUIRED]
  
The node group identifier. This parameter is stored as a lowercase string.
  
  Constraints:
  - A name must contain from 1 to 20 alphanumeric characters or hyphens.
  - The first character must be a letter.
  - A name cannot end with a hyphen or contain two consecutive hyphens.
- **ReplicationGroupId** (**string**) – The ID of the replication group to which this cache cluster should belong. If this parameter is specified, the cache cluster will be added to the specified replication group as a read replica; otherwise, the cache cluster will be a standalone primary that is not part of any replication group.

If the specified replication group is Multi-AZ enabled and the availability zone is not specified, the cache cluster will be created in availability zones that provide the best spread of read replicas across availability zones.

**Note:** This parameter is only valid if the Engine parameter is `redis`.

- **AZMode** (**string**) – Specifies whether the nodes in this Memcached node group are created in a single Availability Zone or created across multiple Availability Zones in the cluster’s region.

This parameter is only supported for Memcached cache clusters.
If the AZMode and PreferredAvailabilityZones are not specified, ElastiCache assumes single-az mode.

- **PreferredAvailabilityZone** *(string)* – The EC2 Availability Zone in which the cache cluster will be created.

  All nodes belonging to this Memcached cache cluster are placed in the preferred Availability Zone. If you want to create your nodes across multiple Availability Zones, use PreferredAvailabilityZones.

  Default: System chosen Availability Zone.

- **PreferredAvailabilityZones** *(list)* – A list of the Availability Zones in which cache nodes will be created. The order of the zones in the list is not important.

  This option is only supported on Memcached.

  **Note:** If you are creating your cache cluster in an Amazon VPC (recommended) you can only locate nodes in Availability Zones that are associated with the subnets in the selected subnet group.

  The number of Availability Zones listed must equal the value of NumCacheNodes.

  If you want all the nodes in the same Availability Zone, use PreferredAvailabilityZone instead, or repeat the Availability Zone multiple times in the list.

  Default: System chosen Availability Zones.

  Example: One Memcached node in each of three different Availability Zones:

  ```
  PreferredAvailabilityZones.member.1=us-west-2a
  PreferredAvailabilityZones.member.2=us-west-2b
  PreferredAvailabilityZones.member.3=us-west-2c
  ```

  Example: All three Memcached nodes in one Availability Zone:

  ```
  PreferredAvailabilityZones.member.1=us-west-2a
  ```

- **NumCacheNodes** *(integer)* – The initial number of cache nodes that the cache cluster will have.

  For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.

  If you need more than 20 nodes for your Memcached cluster, please fill out the ElastiCache Limit Increase Request form at [http://aws.amazon.com/contact-us/elasticache-node-limit-request/](http://aws.amazon.com/contact-us/elasticache-node-limit-request/).

- **CacheNodeType** *(string)* – The compute and memory capacity of the nodes in the node group.

  Valid node types are as follows:

  - General purpose: * Current generation: * cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
    - Previous generation: * cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge
  - Compute optimized: cache.c1.xlarge
  - Memory optimized: * Current generation: * cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
    - Previous generation: * cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

  **Notes:**
All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
Redis backup/restore is not supported for t2 instances.
Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

- **Engine** (string) – The name of the cache engine to be used for this cache cluster.

Valid values for this parameter are:

memcached | redis

- **EngineVersion** (string) – The version number of the cache engine to be used for this cache cluster. To view the supported cache engine versions, use the DescribeCacheEngineVersions action.

- **CacheParameterGroupName** (string) – The name of the parameter group to associate with this cache cluster. If this argument is omitted, the default parameter group for the specified engine is used.

- **CacheSubnetGroupName** (string) – The name of the subnet group to be used for the cache cluster.

Use this parameter only when you are creating a cache cluster in an Amazon Virtual Private Cloud (VPC).

- **CacheSecurityGroupNames** (list) – A list of security group names to associate with this cache cluster.

Use this parameter only when you are creating a cache cluster outside of an Amazon Virtual Private Cloud (VPC).

- **SecurityGroupIds** (list) – One or more VPC security groups associated with the cache cluster.

Use this parameter only when you are creating a cache cluster in an Amazon Virtual Private Cloud (VPC).

- **Tags** (list) – A list of cost allocation tags to be added to this resource. A tag is a key-value pair. A tag key must be accompanied by a tag value.

  - (dict) –

  A cost allocation Tag that can be added to an ElastiCache cluster or replication group. Tags are composed of a Key/Value pair. A tag with a null Value is permitted.

  * **Key** (string) –

  The key for the tag.

  * **Value** (string) –

  The tag’s value. May not be null.

- **SnapshotArns** (list) – A single-element string list containing an Amazon Resource Name (ARN) that uniquely identifies a Redis RDB snapshot file stored in Amazon S3. The snapshot file will be used to populate the node group. The Amazon S3 object name in the ARN cannot contain any commas.

  **Note:** This parameter is only valid if the Engine parameter is redis.

  Example of an Amazon S3 ARN: arn:aws:s3:::my_bucket/snapshot1.rdb

  - (string) –

- **SnapshotName** (string) – The name of a snapshot from which to restore data into the new node group. The snapshot status changes to restoring while the
new node group is being created.

**Note:** This parameter is only valid if the Engine parameter is **redis**.

- **PreferredMaintenanceWindow** *(string)* – Specifies the weekly time range during which maintenance on the cache cluster is performed. It is specified as a range in the format `ddd:hh24:mi-ddd:hh24:mi` (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for `ddd` are:
  - sun
  - mon
  - tue
  - wed
  - thu
  - fri
  - sat

  Example: `sun:05:00-sun:09:00`

- **Port** *(integer)* – The port number on which each of the cache nodes will accept connections.

- **NotificationTopicArn** *(string)* – The Amazon Resource Name (ARN) of the Amazon Simple Notification Service (SNS) topic to which notifications will be sent.

  **Note:** The Amazon SNS topic owner must be the same as the cache cluster owner.

- **AutoMinorVersionUpgrade** *(boolean)* – This parameter is currently disabled.

- **SnapshotRetentionLimit** *(integer)* – The number of days for which ElastiCache will retain automatic snapshots before deleting them. For example, if you set `SnapshotRetentionLimit` to 5, then a snapshot that was taken today will be retained for 5 days before being deleted.

  **Note:** This parameter is only valid if the Engine parameter is **redis**.

  Default: 0 (i.e., automatic backups are disabled for this cache cluster).

- **SnapshotWindow** *(string)* – The daily time range (in UTC) during which ElastiCache will begin taking a daily snapshot of your node group.

  Example: `05:00-09:00`

  If you do not specify this parameter, then ElastiCache will automatically choose an appropriate time range.

  **Note:** This parameter is only valid if the Engine parameter is **redis**.

Return type  **dict**

Returns

**Response Syntax**

```json
{
    'CacheCluster': {
        'CacheClusterId': 'string',
        'ConfigurationEndpoint': {
            'Address': 'string',
            'Port': 123
        },
        'ClientDownloadLandingPage': 'string',
        'CacheNodeType': 'string',
        'Engine': 'string',
        'EngineVersion': 'string'
    }
}
```
Response Structure
• *(dict)* –
Contains all of the attributes of a specific cache cluster.

– **CacheCluster (dict)** –
Contains all of the attributes of a specific cache cluster.

  * **CacheClusterId (string)** –
The user-supplied identifier of the cache cluster. This identifier is a unique key that identifies a cache cluster.

  * **ConfigurationEndpoint (dict)** –
  Represents the information required for client programs to connect to a cache node.
  · **Address (string)** –
    The DNS hostname of the cache node.
  · **Port (integer)** –
    The port number that the cache engine is listening on.

  * **ClientDownloadLandingPage (string)** –
The URL of the web page where you can download the latest ElastiCache client library.

  * **CacheNodeType (string)** –
The name of the compute and memory capacity node type for the cache cluster.

    Valid node types are as follows:

    · General purpose: * Current generation: `cache.t2.micro`, `cache.t2.small`, `cache.t2.medium`, `cache.m3.medium`, `cache.m3.large`, `cache.m3.xlarge`, `cache.m3.2xlarge`
      · Previous generation: `cache.t1.micro`, `cache.m1.small`, `cache.m1.medium`, `cache.m1.large`, `cache.m1.xlarge`
    · Compute optimized: `cache.c1.xlarge`
    · Memory optimized: * Current generation: `cache.r3.large`, `cache.r3.xlarge`, `cache.r3.2xlarge`, `cache.r3.4xlarge`, `cache.r3.8xlarge`
      · Previous generation: `cache.m2.xlarge`, `cache.m2.2xlarge`, `cache.m2.4xlarge`

  Notes:
  · All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
  · Redis backup/restore is not supported for t2 instances.
  · Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

  * **Engine (string)** –
The name of the cache engine (`memcached` or `redis`) to be used for this cache cluster.

  * **EngineVersion (string)** –
The version of the cache engine version that is used in this cache cluster.

* **CacheClusterStatus** *(string)*

The current state of this cache cluster, one of the following values: *available*, *creating*, *deleted*, *deleting*, *incompatible-network*, *modifying*, *rebooting cache cluster nodes*, *restore-failed*, or *snapshotting*.

* **NumCacheNodes** *(integer)*

The number of cache nodes in the cache cluster.

For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.

* **PreferredAvailabilityZone** *(string)*

The name of the Availability Zone in which the cache cluster is located or “Multiple” if the cache nodes are located in different Availability Zones.

* **CacheClusterCreateTime** *(datetime)*

The date and time when the cache cluster was created.

* **PreferredMaintenanceWindow** *(string)*

Specifies the weekly time range during which maintenance on the cache cluster is performed. It is specified as a range in the format ddd:hh24:mi-ddd:hh24:mi (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for ddd are:

- sun
- mon
- tue
- wed
- thu
- fri
- sat

Example: sun:05:00-sun:09:00

* **PendingModifiedValues** *(dict)*

A group of settings that will be applied to the cache cluster in the future, or that are currently being applied.

- **NumCacheNodes** *(integer)*

  The new number of cache nodes for the cache cluster.

  For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.

- **CacheNodeIdsToRemove** *(list)*

  A list of cache node IDs that are being removed (or will be removed) from the cache cluster. A node ID is a numeric identifier (0001, 0002, etc.).

- **EngineVersion** *(string)*

  The new cache engine version that the cache cluster will run.

* **NotificationConfiguration** *(dict)*

Describes a notification topic and its status. Notification topics are used for publishing ElastiCache events to subscribers using Amazon Simple Notification Service (SNS).
· **TopicArn** *(string)* –
  The Amazon Resource Name (ARN) that identifies the topic.
· **TopicStatus** *(string)* –
  The current state of the topic.
* **CacheSecurityGroups** *(list)* –
  A list of cache security group elements, composed of name and status sub-elements.
  · *(dict)* –
    Represents a cache cluster’s status within a particular cache security group.
  · **CacheSecurityGroupName** *(string)* –
    The name of the cache security group.
  · **Status** *(string)* –
    The membership status in the cache security group. The status changes when a cache security group is modified, or when the cache security groups assigned to a cache cluster are modified.
* **CacheParameterGroup** *(dict)* –
  The status of the cache parameter group.
  · **CacheParameterGroupName** *(string)* –
    The name of the cache parameter group.
  · **ParameterApplyStatus** *(string)* –
    The status of parameter updates.
  · **CacheNodeIdsToReboot** *(list)* –
    A list of the cache node IDs which need to be rebooted for parameter changes to be applied. A node ID is a numeric identifier (0001, 0002, etc.).
  · *(string)* –
* **CacheSubnetGroupName** *(string)* –
  The name of the cache subnet group associated with the cache cluster.
* **CacheNodes** *(list)* –
  A list of cache nodes that are members of the cache cluster.
  · *(dict)* –
    Represents an individual cache node within a cache cluster. Each cache node runs its own instance of the cluster’s protocol-compliant caching software - either Memcached or Redis.

Valid node types are as follows:
· **General purpose:** *Current generation:* `cache.t2.micro`, `cache.t2.small`, `cache.t2.medium`, `cache.m3.medium`, `cache.m3.large`, `cache.m3.xlarge`, `cache.m3.2xlarge`  
  · **Previous generation:** `cache.t1.micro`, `cache.m1.small`, `cache.m1.medium`, `cache.m1.large`, `cache.m1.xlarge`  
  · **Compute optimized:** `cache.c1.xlarge`
· Memory optimized * Current generation:
  cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
· Previous generation: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

Notes:
· All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
· Redis backup/restore is not supported for t2 instances.
· Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

· CacheNodeId (string) –
  The cache node identifier. A node ID is a numeric identifier (0001, 0002, etc.). The combination of cluster ID and node ID uniquely identifies every cache node used in a customer’s AWS account.

· CacheNodeStatus (string) –
  The current state of this cache node.

· CacheNodeCreateTime (datetime) –
  The date and time when the cache node was created.

· Endpoint (dict) –
  The hostname for connecting to this cache node.

· Address (string) –
  The DNS hostname of the cache node.

· Port (integer) –
  The port number that the cache engine is listening on.

· ParameterGroupStatus (string) –
  The status of the parameter group applied to this cache node.

· SourceCacheNodeId (string) –
  The ID of the primary node to which this read replica node is synchronized. If this field is empty, then this node is not associated with a primary cache cluster.

· CustomerAvailabilityZone (string) –
  The Availability Zone where this node was created and now resides.

· AutoMinorVersionUpgrade (boolean) –
  This parameter is currently disabled.

· SecurityGroups (list) –
  A list of VPC Security Groups associated with the cache cluster.

· (dict) –
  Represents a single cache security group and its status.

· SecurityGroupId (string) –
The identifier of the cache security group.
· Status (string) –
  The status of the cache security group membership. The status changes whenever a cache security group is modified, or when the cache security groups assigned to a cache cluster are modified.

· ReplicationGroupId (string) –
  The replication group to which this cache cluster belongs. If this field is empty, the cache cluster is not associated with any replication group.

· SnapshotRetentionLimit (integer) –
  The number of days for which ElastiCache will retain automatic cache cluster snapshots before deleting them. For example, if you set SnapshotRetentionLimit to 5, then a snapshot that was taken today will be retained for 5 days before being deleted.

  Important If the value of SnapshotRetentionLimit is set to zero (0), backups are turned off.

· SnapshotWindow (string) –
  The daily time range (in UTC) during which ElastiCache will begin taking a daily snapshot of your cache cluster.

  Example: 05:00–09:00

create_cache_parameter_group(**kwargs)
The CreateCacheParameterGroup action creates a new cache parameter group. A cache parameter group is a collection of parameters that you apply to all of the nodes in a cache cluster.

Request Syntax

response = client.create_cache_parameter_group(
    CacheParameterGroupName='string',
    CacheParameterGroupFamily='string',
    Description='string',
)

Parameters

· CacheParameterGroupName (string) – [REQUIRED]
  A user-specified name for the cache parameter group.

· CacheParameterGroupFamily (string) – [REQUIRED]
  The name of the cache parameter group family the cache parameter group can be used with.

  Valid values are: memcached1.4 | redis2.6 | redis2.8

· Description (string) – [REQUIRED]
  A user-specified description for the cache parameter group.

Return type  dict
Returns

Response Syntax

{  
  'CacheParameterGroupName': 'string',
}
create_cache_security_group(**kwargs)

The `create_cache_security_group` action creates a new cache security group. Use a cache security group to control access to one or more cache clusters.

Cache security groups are only used when you are creating a cache cluster outside of an Amazon Virtual Private Cloud (VPC). If you are creating a cache cluster inside of a VPC, use a cache subnet group instead. For more information, see `create_cache_subnet_group`.

**Request Syntax**

```
response = client.create_cache_security_group(
    CacheSecurityGroupName='string',
    Description='string'
)
```

**Parameters**

- `CacheSecurityGroupName (string) – [REQUIRED]`
  A name for the cache security group. This value is stored as a lowercase string.
  Constraints: Must contain no more than 255 alphanumeric characters. Cannot be the word “Default”.
  Example: `mysecuritygroup`

- `Description (string) – [REQUIRED]`
  A description for the cache security group.

**Return type** `dict`

**Returns**

**Response Syntax**

```
{
    'CacheSecurityGroup': {
        'OwnerId': 'string',
        'CacheSecurityGroupName': 'string',
        'Description': 'string',
        'EC2SecurityGroups': [],
    }
}
```
Response Structure

- (dict) –

  Represents the output of one of the following actions:
  - AuthorizeCacheSecurityGroupIngress
  - CreateCacheSecurityGroup
  - RevokeCacheSecurityGroupIngress

- CacheSecurityGroup (dict) –

  Represents the output of one of the following actions:
  - AuthorizeCacheSecurityGroupIngress
  - CreateCacheSecurityGroup
  - RevokeCacheSecurityGroupIngress

  - OwnerId (string) –
    The AWS account ID of the cache security group owner.
  - CacheSecurityGroupName (string) –
    The name of the cache security group.
  - Description (string) –
    The description of the cache security group.
  - EC2SecurityGroups (list) –
    A list of Amazon EC2 security groups that are associated with this cache security group.

    - (dict) –
      Provides ownership and status information for an Amazon EC2 security group.

    - Status (string) –
      The status of the Amazon EC2 security group.

    - EC2SecurityGroupName (string) –
      The name of the Amazon EC2 security group.

    - EC2SecurityGroupOwnerId (string) –
      The AWS account ID of the Amazon EC2 security group owner.

create_cache_subnet_group(**kwargs)

The CreateCacheSubnetGroup action creates a new cache subnet group.

Use this parameter only when you are creating a cluster in an Amazon Virtual Private Cloud (VPC).

Request Syntax

```python
response = client.create_cache_subnet_group(
    CacheSubnetGroupName='string',
    CacheSubnetGroupDescription='string',
```
SubnetIds=[
    'string',
]

Parameters

- **CacheSubnetGroupName** *(string)* – *[REQUIRED]*
  A name for the cache subnet group. This value is stored as a lowercase string.
  Constraints: Must contain no more than 255 alphanumeric characters or hyphens.
  Example: mysubnetgroup
- **CacheSubnetGroupDescription** *(string)* – *[REQUIRED]*
  A description for the cache subnet group.
- **SubnetIds** *(list)* – *[REQUIRED]*
  A list of VPC subnet IDs for the cache subnet group.
  - *(string)* –

Return type  *dict*

Returns

Response Syntax

```json
{
    'CacheSubnetGroup': {
        'CacheSubnetGroupName': 'string',
        'CacheSubnetGroupDescription': 'string',
        'VpcId': 'string',
        'Subnets': [
            {
                'SubnetIdentifier': 'string',
                'SubnetAvailabilityZone': {
                    'Name': 'string'
                }
            }
        ]
    }
}
```

Response Structure

- *(dict)* –

  Represents the output of one of the following actions:
  - *CreateCacheSubnetGroup*
  - *ModifyCacheSubnetGroup*
  - **CacheSubnetGroup** *(dict)* –

    Represents the output of one of the following actions:
    * *CreateCacheSubnetGroup*
    * *ModifyCacheSubnetGroup*
    * **CacheSubnetGroupName** *(string)* –
      The name of the cache subnet group.
    * **CacheSubnetGroupDescription** *(string)* –
      The description of the cache subnet group.
* VpcId (string) –
The Amazon Virtual Private Cloud identifier (VPC ID) of the cache subnet group.

* Subnets (list) –
A list of subnets associated with the cache subnet group.
  · (dict) –
    Represents the subnet associated with a cache cluster. This parameter refers to subnets defined in Amazon Virtual Private Cloud (Amazon VPC) and used with ElastiCache.
  · SubnetIdentifier (string) –
    The unique identifier for the subnet.
  · SubnetAvailabilityZone (dict) –
    The Availability Zone associated with the subnet.
  · Name (string) –
    The name of the Availability Zone.

create_replication_group(**kwargs)

The CreateReplicationGroup action creates a replication group. A replication group is a collection of cache clusters, where one of the cache clusters is a read/write primary and the others are read-only replicas. Writes to the primary are automatically propagated to the replicas.

When you create a replication group, you must specify an existing cache cluster that is in the primary role. When the replication group has been successfully created, you can add one or more read replica replicas to it, up to a total of five read replicas.

**Note:** This action is valid only for Redis.

**Request Syntax**

```python
response = client.create_replication_group(
    ReplicationGroupId='string',
    ReplicationGroupDescription='string',
    PrimaryClusterId='string',
    AutomaticFailoverEnabled=True|False,
    NumCacheClusters=123,
    PreferredCacheClusterAZs=[
        'string',
    ],
    CacheNodeType='string',
    Engine='string',
    EngineVersion='string',
    CacheParameterGroupName='string',
    CacheSubnetGroupName='string',
    CacheSecurityGroupNames=[
        'string',
    ],
    SecurityGroupIds=[
        'string',
    ],
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ],
)```
SnapshotArns=[
    'string',
],
SnapshotName='string',
PreferredMaintenanceWindow='string',
Port=123,
NotificationTopicArn='string',
AutoMinorVersionUpgrade=True|False,
SnapshotRetentionLimit=123,
SnapshotWindow='string'
)

Parameters

- **ReplicationGroupId** *(string) – [REQUIRED]*
  
The replication group identifier. This parameter is stored as a lowercase string.

  Constraints:
  - A name must contain from 1 to 20 alphanumeric characters or hyphens.
  - The first character must be a letter.
  - A name cannot end with a hyphen or contain two consecutive hyphens.

- **ReplicationGroupDescription** *(string) – [REQUIRED]*
  
  A user-created description for the replication group.

- **PrimaryClusterId** *(string)*
  
  The identifier of the cache cluster that will serve as the primary for this replication group. This cache cluster must already exist and have a status of available.

  This parameter is not required if **NumCacheClusters** is specified.

- **AutomaticFailoverEnabled** *(boolean)*
  
  Specifies whether a read-only replica will be automatically promoted to read/write primary if the existing primary fails.

  If **true**, Multi-AZ is enabled for this replication group. If **false**, Multi-AZ is disabled for this replication group.

  Default: false

  **Note:** ElastiCache Multi-AZ replication groups is not supported on:
  - Redis versions earlier than 2.8.6.
  - T1 and T2 cache node types.

- **NumCacheClusters** *(integer)*
  
  The number of cache clusters this replication group will initially have.

  If **Multi-AZ** is enabled, the value of this parameter must be at least 2.

  The maximum permitted value for **NumCacheClusters** is 6 (primary plus 5 replicas). If you need to exceed this limit, please fill out the ElastiCache Limit Increase Request form at http://aws.amazon.com/contact-us/elasticache-node-limit-request.

- **PreferredCacheClusterAZs** *(list)*
  
  A list of EC2 availability zones in which the replication group’s cache clusters will be created. The order of the availability zones in the list is not important.

  **Note:** If you are creating your replication group in an Amazon VPC (recommended), you can only locate cache clusters in availability zones associated with the subnets in the selected subnet group.

  The number of availability zones listed must equal the value of **NumCacheClus-
Default: system chosen availability zones.

Example: One Redis cache cluster in each of three availability zones.

PreferredAvailabilityZones.member.1=us-west-2a
PreferredAvailabilityZones.member.2=us-west-2c
PreferredAvailabilityZones.member.3=us-west-2c

• **CacheNodeType** *(string)* – The compute and memory capacity of the nodes in the node group.

Valid node types are as follows:

- **General purpose**: *Current generation*: cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
- **Previous generation**: cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge
- **Compute optimized**: cache.c1.xlarge
- **Memory optimized**: *Current generation*: cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
- **Previous generation**: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

**Notes:**
- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

• **Engine** *(string)* – The name of the cache engine to be used for the cache clusters in this replication group.

Default: redis

• **EngineVersion** *(string)* – The version number of the cache engine to be used for the cache clusters in this replication group. To view the supported cache engine versions, use the `DescribeCacheEngineVersions` action.

• **CacheParameterGroupName** *(string)* – The name of the parameter group to associate with this replication group. If this argument is omitted, the default cache parameter group for the specified engine is used.

• **CacheSubnetGroupName** *(string)* – The name of the cache subnet group to be used for the replication group.

• **CacheSecurityGroupNames** *(list)* – A list of cache security group names to associate with this replication group.

• **SecurityGroupIds** *(list)* – One or more Amazon VPC security groups associated with this replication group.

Use this parameter only when you are creating a replication group in an Amazon Virtual Private Cloud (VPC).

• **Tags** *(list)* – A list of cost allocation tags to be added to this resource. A tag is a key-value pair. A tag key must be accompanied by a tag value.

  - *(dict)* –
A cost allocation Tag that can be added to an ElastiCache cluster or replication group. Tags are composed of a Key/Value pair. A tag with a null Value is permitted.

* **Key** *(string)* – The key for the tag.

* **Value** *(string)* – The tag’s value. May not be null.

- **SnapshotArns** *(list)* – A single-element string list containing an Amazon Resource Name (ARN) that uniquely identifies a Redis RDB snapshot file stored in Amazon S3. The snapshot file will be used to populate the node group. The Amazon S3 object name in the ARN cannot contain any commas.

  **Note:** This parameter is only valid if the **Engine** parameter is `redis`.

  Example of an Amazon S3 ARN: `arn:aws:s3:::my_bucket/snapshot1.rdb`

- **SnapshotName** *(string)* – The name of a snapshot from which to restore data into the new node group. The snapshot status changes to restoring while the new node group is being created.

  **Note:** This parameter is only valid if the **Engine** parameter is `redis`.

- **PreferredMaintenanceWindow** *(string)* – Specifies the weekly time range during which maintenance on the cache cluster is performed. It is specified as a range in the format `ddd:hh24:mi-ddd:hh24:mi` (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for `ddd` are:
  - sun
  - mon
  - tue
  - wed
  - thu
  - fri
  - sat

  Example: `sun:05:00-sun:09:00`

- **Port** *(integer)* – The port number on which each member of the replication group will accept connections.

- **NotificationTopicArn** *(string)* – The Amazon Resource Name (ARN) of the Amazon Simple Notification Service (SNS) topic to which notifications will be sent.

  **Note:** The Amazon SNS topic owner must be the same as the cache cluster owner.

- **AutoMinorVersionUpgrade** *(boolean)* – This parameter is currently disabled.

- **SnapshotRetentionLimit** *(integer)* – The number of days for which ElastiCache will retain automatic snapshots before deleting them. For example, if you set **SnapshotRetentionLimit** to 5, then a snapshot that was taken today will be retained for 5 days before being deleted.

  **Note:** This parameter is only valid if the **Engine** parameter is `redis`.

  Default: 0 (i.e., automatic backups are disabled for this cache cluster).

- **SnapshotWindow** *(string)* – The daily time range (in UTC) during which ElastiCache will begin taking a daily snapshot of your node group.

  Example: `05:00-09:00`
If you do not specify this parameter, then ElastiCache will automatically choose an appropriate time range.

**Note:** This parameter is only valid if the `Engine` parameter is `redis`.

**Return type**  
dict

**Returns**

**Response Syntax**

```
{
    'ReplicationGroup': {
        'ReplicationGroupId': 'string',
        'Description': 'string',
        'Status': 'string',

                        },
                        'PreferredAvailabilityZone': 'string',
                        'CurrentRole': 'string'
                    }
                ],
            }
        ],
        'SnapshottingClusterId': 'string',
        'AutomaticFailover': 'enabled'|'disabled'|'enabling'|'disabling'
    }
}
```

**Response Structure**

- `(dict)` – Contains all of the attributes of a specific replication group.
  - **ReplicationGroup** `(dict)` – Contains all of the attributes of a specific replication group.
    - **ReplicationGroupId** `(string)` – The identifier for the replication group.
    - **Description** `(string)` –
The description of the replication group.

* **Status (string)** –

The current state of this replication group - *creating, available, etc.*

* **PendingModifiedValues (dict)** –

A group of settings to be applied to the replication group, either immediately or during the next maintenance window.

  - **PrimaryClusterId (string)** –
    
    The primary cluster ID which will be applied immediately (if --apply-immediately was specified), or during the next maintenance window.

  - **AutomaticFailoverStatus (string)** –
    
    Indicates the status of Multi-AZ for this replication group.

    **Note:** ElastiCache Multi-AZ replication groups are not supported on:
    
    - Redis versions earlier than 2.8.6.
    - T1 and T2 cache node types.

* **MemberClusters (list)** –

The names of all the cache clusters that are part of this replication group.

  - **(string)** –

* **NodeGroups (list)** –

A single element list with information about the nodes in the replication group.

  - **(dict)** –

    Represents a collection of cache nodes in a replication group.

    - **NodeGroupId (string)** –
      
      The identifier for the node group. A replication group contains only one node group; therefore, the node group ID is 0001.

    - **Status (string)** –
      
      The current state of this replication group - *creating, available, etc.*

    - **PrimaryEndpoint (dict)** –
      
      Represents the information required for client programs to connect to a cache node.

      - **Address (string)** –
        
        The DNS hostname of the cache node.

      - **Port (integer)** –
        
        The port number that the cache engine is listening on.

      - **NodeGroupMembers (list)** –
        
        A list containing information about individual nodes within the node group.

        - **(dict)** –

          Represents a single node within a node group.

        - **CacheClusterId (string)** –
The ID of the cache cluster to which the node belongs.

- **CacheNodeId**: (string)
  - The ID of the node within its cache cluster. A node ID is a numeric identifier (0001, 0002, etc.).

- **ReadEndpoint**: (dict)
  - Represents the information required for client programs to connect to a cache node.
    - **Address**: (string)
      - The DNS hostname of the cache node.
    - **Port**: (integer)
      - The port number that the cache engine is listening on.
    - **PreferredAvailabilityZone**: (string)
      - The name of the Availability Zone in which the node is located.
    - **CurrentRole**: (string)
      - The role that is currently assigned to the node - *primary* or *replica*.

- **SnapshottingClusterId**: (string)
  - The cache cluster ID that is used as the daily snapshot source for the replication group.

- **AutomaticFailover**: (string)
  - Indicates the status of Multi-AZ for this replication group.

**Note:** ElastiCache Multi-AZ replication groups are not supported on:
- Redis versions earlier than 2.8.6.
- T1 and T2 cache node types.

### create_snapshot(**kwargs)**

The `CreateSnapshot` action creates a copy of an entire cache cluster at a specific moment in time.

#### Request Syntax

```python
response = client.create_snapshot(
    CacheClusterId='string',
    SnapshotName='string'
)
```

#### Parameters

- **CacheClusterId**: (string) – [REQUIRED]
  - The identifier of an existing cache cluster. The snapshot will be created from this cache cluster.
- **SnapshotName**: (string) – [REQUIRED]
  - A name for the snapshot being created.

#### Return type
dict

#### Returns

Response Syntax
Response Structure

- **(dict)** –
  Represents a copy of an entire cache cluster as of the time when the snapshot was taken.

  - **Snapshot (dict)** –
    Represents a copy of an entire cache cluster as of the time when the snapshot was taken.

      - **SnapshotName (string)** –
        The name of a snapshot. For an automatic snapshot, the name is system-generated; for a manual snapshot, this is the user-provided name.
      - **CacheClusterId (string)** –
        The user-supplied identifier of the source cache cluster.
      - **SnapshotStatus (string)** –
        The status of the snapshot. Valid values: creating | available | restoring | copying | deleting.
      - **SnapshotSource (string)** –
        Indicates whether the snapshot is from an automatic backup (automated) or was created manually (manual).
      - **CacheNodeType (string)** –
        The name of the compute and memory capacity node type for the
source cache cluster.

Valid node types are as follows:

- **General purpose:**
  - *Current generation:* cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
  - *Previous generation:* cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge

- **Compute optimized:** cache.c1.xlarge

- **Memory optimized**
  - *Current generation:* cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
  - *Previous generation:* cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

**Notes:**

- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon Elasticache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

* **Engine** *(string)* --
  The name of the cache engine (*memcached* or *redis*) used by the source cache cluster.

* **EngineVersion** *(string)* --
  The version of the cache engine version that is used by the source cache cluster.

* **NumCacheNodes** *(integer)* --
  The number of cache nodes in the source cache cluster.

  For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.

* **PreferredAvailabilityZone** *(string)* --
  The name of the Availability Zone in which the source cache cluster is located.

* **CacheClusterCreateTime** *(datetime)* --
  The date and time when the source cache cluster was created.

* **PreferredMaintenanceWindow** *(string)* --
  Specifies the weekly time range during which maintenance on the cache cluster is performed. It is specified as a range in the format ddd:hh24:mi-ddd:hh24:mi (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for ddd are:
  - sun
  - mon
  - tue
  - wed
Example: sun:05:00-sun:09:00

* **TopicArn** *(string)* –
  The Amazon Resource Name (ARN) for the topic used by the source cache cluster for publishing notifications.

* **Port** *(integer)* –
  The port number used by each cache nodes in the source cache cluster.

* **CacheParameterGroupName** *(string)* –
  The cache parameter group that is associated with the source cache cluster.

* **CacheSubnetGroupName** *(string)* –
  The name of the cache subnet group associated with the source cache cluster.

* **VpcId** *(string)* –
  The Amazon Virtual Private Cloud identifier (VPC ID) of the cache subnet group for the source cache cluster.

* **AutoMinorVersionUpgrade** *(boolean)* –
  This parameter is currently disabled.

* **SnapshotRetentionLimit** *(integer)* –
  For an automatic snapshot, the number of days for which ElastiCache will retain the snapshot before deleting it.
  For manual snapshots, this field reflects the `SnapshotRetentionLimit` for the source cache cluster when the snapshot was created. This field is otherwise ignored: Manual snapshots do not expire, and can only be deleted using the `DeleteSnapshot` action.

**Important** If the value of `SnapshotRetentionLimit` is set to zero (0), backups are turned off.

* **SnapshotWindow** *(string)* –
  The daily time range during which ElastiCache takes daily snapshots of the source cache cluster.

* **NodeSnapshots** *(list)* –
  A list of the cache nodes in the source cache cluster.
  
  · **(dict)** –
    Represents an individual cache node in a snapshot of a cache cluster.

  · **CacheNodeId** *(string)* –
    The cache node identifier for the node in the source cache cluster.

  · **CacheSize** *(string)* –
    The size of the cache on the source cache node.

  · **CacheNodeCreateTime** *(datetime)* –
    The date and time when the cache node was created in the source cache cluster.
- **SnapshotCreateTime** *(datetime)* –
  The date and time when the source node’s metadata and cache data set was obtained for the snapshot.

**delete_cache_cluster(**kwargs**)**

The *DeleteCacheCluster* action deletes a previously provisioned cache cluster. *DeleteCacheCluster* deletes all associated cache nodes, node endpoints and the cache cluster itself. When you receive a successful response from this action, Amazon ElastiCache immediately begins deleting the cache cluster; you cannot cancel or revert this action.

This API cannot be used to delete a cache cluster that is the last read replica of a replication group that has Multi-AZ mode enabled.

**Request Syntax**

```python
response = client.delete_cache_cluster(
    CacheClusterId='string',
    FinalSnapshotIdentifier='string'
)
```

**Parameters**

- **CacheClusterId** *(string)* – [REQUIRED]
  The cache cluster identifier for the cluster to be deleted. This parameter is not case sensitive.

- **FinalSnapshotIdentifier** *(string)* – The user-supplied name of a final cache cluster snapshot. This is the unique name that identifies the snapshot. ElastiCache creates the snapshot, and then deletes the cache cluster immediately afterward.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'CacheCluster': {
        'CacheClusterId': 'string',
        'ConfigurationEndpoint': {
            'Address': 'string',
            'Port': 123
        },
        'ClientDownloadLandingPage': 'string',
        'CacheNodeType': 'string',

'SnapshotRetentionLimit': 123,
'SnapshotWindow': 'string'
}

Response Structure

- *(dict)* –
  Contains all of the attributes of a specific cache cluster.
  - **CacheCluster**(dict) –
    Contains all of the attributes of a specific cache cluster.
      * **CacheClusterId**(string) –
        The user-supplied identifier of the cache cluster. This identifier is a unique key that identifies a cache cluster.
      * **ConfigurationEndpoint**(dict) –
        Represents the information required for client programs to connect to a cache node.
          * **Address**(string) –
The DNS hostname of the cache node.

- **Port (integer)** –

  The port number that the cache engine is listening on.

- **ClientDownloadLandingPage (string)** –

  The URL of the web page where you can download the latest ElastiCache client library.

- **CacheNodeType (string)** –

  The name of the compute and memory capacity node type for the cache cluster.

Valid node types are as follows:

- **General purpose:** *Current generation*: cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
- **Previous generation**: cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge
- **Compute optimized**: cache.c1.xlarge
- **Memory optimized:** *Current generation*: cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
- **Previous generation**: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

**Notes:**

- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

- **Engine (string)** –

  The name of the cache engine (memcached or redis) to be used for this cache cluster.

- **EngineVersion (string)** –

  The version of the cache engine version that is used in this cache cluster.

- **CacheClusterStatus (string)** –

  The current state of this cache cluster, one of the following values: available, creating, deleted, deleting, incompatible-network, modifying, rebooting cache cluster nodes, restore-failed, or snapshotting.

- **NumCacheNodes (integer)** –

  The number of cache nodes in the cache cluster.

  For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.
* **PreferredAvailabilityZone** *(string)* –

The name of the Availability Zone in which the cache cluster is located or “Multiple” if the cache nodes are located in different Availability Zones.

* **CacheClusterCreateTime** *(datetime)* –

The date and time when the cache cluster was created.

* **PreferredMaintenanceWindow** *(string)* –

Specifies the weekly time range during which maintenance on the cache cluster is performed. It is specified as a range in the format `ddd:hh24:mi-ddd:hh24:mi` (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for `ddd` are:

- sun
- mon
- tue
- wed
- thu
- fri
- sat

Example: `sun:05:00-sun:09:00`

* **PendingModifiedValues** *(dict)* –

A group of settings that will be applied to the cache cluster in the future, or that are currently being applied.

- **NumCacheNodes** *(integer)* –

  The new number of cache nodes for the cache cluster.

  For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.

- **CacheNodeIdsToRemove** *(list)* –

  A list of cache node IDs that are being removed (or will be removed) from the cache cluster. A node ID is a numeric identifier (0001, 0002, etc.).

- **EngineVersion** *(string)* –

  The new cache engine version that the cache cluster will run.

* **NotificationConfiguration** *(dict)* –

Describes a notification topic and its status. Notification topics are used for publishing ElastiCache events to subscribers using Amazon Simple Notification Service (SNS).

- **TopicArn** *(string)* –

  The Amazon Resource Name (ARN) that identifies the topic.

- **TopicStatus** *(string)* –

  The current state of the topic.

* **CacheSecurityGroups** *(list)* –

A list of cache security group elements, composed of name and status sub-elements.

- *(dict)* –

  Represents a cache cluster’s status within a particular cache security group.
· **CacheSecurityGroupName** *(string)* –
  The name of the cache security group.
· **Status** *(string)* –
  The membership status in the cache security group. The status changes when a cache security group is modified, or when the cache security groups assigned to a cache cluster are modified.

* **CacheParameterGroup** *(dict)* –
  The status of the cache parameter group.
  · **CacheParameterGroupName** *(string)* –
    The name of the cache parameter group.
  · **ParameterApplyStatus** *(string)* –
    The status of parameter updates.
  · **CacheNodeIdsToReboot** *(list)* –
    A list of the cache node IDs which need to be rebooted for parameter changes to be applied. A node ID is a numeric identifier (0001, 0002, etc.).
  · *(string)* –

* **CacheSubnetGroupName** *(string)* –
  The name of the cache subnet group associated with the cache cluster.

* **CacheNodes** *(list)* –
  A list of cache nodes that are members of the cache cluster.
  · *(dict)* –
    Represents an individual cache node within a cache cluster. Each cache node runs its own instance of the cluster’s protocol-compliant caching software - either Memcached or Redis.

Valid node types are as follows:
· **General purpose**: *Current generation*: cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
  · **Previous generation**: cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge
· **Compute optimized**: cache.c1.xlarge
· **Memory optimized**: *Current generation*: cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
  · **Previous generation**: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

**Notes**:  
· All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
· Redis backup/restore is not supported for t2 instances.
· Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.
For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

- **CacheNodeId (string)** –
  The cache node identifier. A node ID is a numeric identifier (0001, 0002, etc.). The combination of cluster ID and node ID uniquely identifies every cache node used in a customer’s AWS account.

- **CacheNodeStatus (string)** –
  The current state of this cache node.

- **CacheNodeCreateTime (datetime)** –
  The date and time when the cache node was created.

- **Endpoint (dict)** –
  The hostname for connecting to this cache node.

  - **Address (string)** –
    The DNS hostname of the cache node.

  - **Port (integer)** –
    The port number that the cache engine is listening on.

- **ParameterGroupStatus (string)** –
  The status of the parameter group applied to this cache node.

- **SourceCacheNodeId (string)** –
  The ID of the primary node to which this read replica node is synchronized. If this field is empty, then this node is not associated with a primary cache cluster.

- **CustomerAvailabilityZone (string)** –
  The Availability Zone where this node was created and now resides.

- **AutoMinorVersionUpgrade (boolean)** –
  This parameter is currently disabled.

- **SecurityGroups (list)** –
  A list of VPC Security Groups associated with the cache cluster.

  - (dict) –
    Represents a single cache security group and its status.

  - **SecurityGroupId (string)** –
    The identifier of the cache security group.

  - **Status (string)** –
    The status of the cache security group membership. The status changes whenever a cache security group is modified, or when the cache security groups assigned to a cache cluster are modified.

- **ReplicationGroupId (string)** –
  The replication group to which this cache cluster belongs. If this field is empty, the cache cluster is not associated with any replication group.
* **SnapshotRetentionLimit** *(integer)* –

The number of days for which ElastiCache will retain automatic cache cluster snapshots before deleting them. For example, if you set `SnapshotRetentionLimit` to 5, then a snapshot that was taken today will be retained for 5 days before being deleted.

**Important** If the value of `SnapshotRetentionLimit` is set to zero (0), backups are turned off.

* **SnapshotWindow** *(string)* –

The daily time range (in UTC) during which ElastiCache will begin taking a daily snapshot of your cache cluster.

Example: 05:00–09:00

```python
delete_cache_parameter_group(**kwargs)
```

The `DeleteCacheParameterGroup` action deletes the specified cache parameter group. You cannot delete a cache parameter group if it is associated with any cache clusters.

**Request Syntax**

```python
response = client.delete_cache_parameter_group(
    CacheParameterGroupName='string'
)
```

**Parameters**

- **CacheParameterGroupName** *(string)* – [REQUIRED]

  The name of the cache parameter group to delete.

**Note:** The specified cache security group must not be associated with any cache clusters.

**Returns** None

```python
delete_cache_security_group(**kwargs)
```

The `DeleteCacheSecurityGroup` action deletes a cache security group.

**Note:** You cannot delete a cache security group if it is associated with any cache clusters.

**Request Syntax**

```python
response = client.delete_cache_security_group(
    CacheSecurityGroupName='string'
)
```

**Parameters**

- **CacheSecurityGroupName** *(string)* – [REQUIRED]

  The name of the cache security group to delete.

  **Note:** You cannot delete the default security group.

**Returns** None

```python
delete_cache_subnet_group(**kwargs)
```

The `DeleteCacheSubnetGroup` action deletes a cache subnet group.

**Note:** You cannot delete a cache subnet group if it is associated with any cache clusters.

**Request Syntax**
response = client.delete_cache_subnet_group(
    CacheSubnetGroupName='string'
)

**Parameters**  **CacheSubnetGroupName** *(string)* – [REQUIRED]

The name of the cache subnet group to delete.

Constraints: Must contain no more than 255 alphanumeric characters or hyphens.

**Returns**  None

```python
delete_replication_group(**kwargs)
```

The `DeleteReplicationGroup` action deletes an existing replication group. By default, this action deletes the entire replication group, including the primary cluster and all of the read replicas. You can optionally delete only the read replicas, while retaining the primary cluster.

When you receive a successful response from this action, Amazon ElastiCache immediately begins deleting the selected resources; you cannot cancel or revert this action.

**Request Syntax**

```python
response = client.delete_replication_group(
    ReplicationGroupId='string',
    RetainPrimaryCluster=True|False,
    FinalSnapshotIdentifier='string'
)
```

**Parameters**

- **ReplicationGroupId** *(string)* – [REQUIRED]
  
  The identifier for the cluster to be deleted. This parameter is not case sensitive.

- **RetainPrimaryCluster** *(boolean)* – If set to `true`, all of the read replicas will be deleted, but the primary node will be retained.

- **FinalSnapshotIdentifier** *(string)* – The name of a final node group snapshot. ElastiCache creates the snapshot from the primary node in the cluster, rather than one of the replicas; this is to ensure that it captures the freshest data. After the final snapshot is taken, the cluster is immediately deleted.

**Return type**  **dict**

**Returns**

**Response Syntax**

```python
{
    'ReplicationGroup': {
        'ReplicationGroupId': 'string',
        'Description': 'string',
        'Status': 'string',
        'PendingModifiedValues': {
            'PrimaryClusterId': 'string',
            'AutomaticFailoverStatus': 'enabled'|'disabled'
        },
        'MemberClusters': [
            'string',
        ],
        'NodeGroups': [
            {
                'NodeGroupId': 'string',
                'Status': 'string',
            }
        ]
    }
}
```
Response Structure

- *(dict)* –
  Contains all of the attributes of a specific replication group.

  - **ReplicationGroup**(dict) –
    Contains all of the attributes of a specific replication group.
    
    - **ReplicationGroupId**(string) –
      The identifier for the replication group.
    
    - **Description**(string) –
      The description of the replication group.
    
    - **Status**(string) –
      The current state of this replication group - *creating*, *available*, etc.
    
    - **PendingModifiedValues**(dict) –
      A group of settings to be applied to the replication group, either immediately or during the next maintenance window.
    
      - **PrimaryClusterId**(string) –
        The primary cluster ID which will be applied immediately (if *--apply-immediately* was specified), or during the next maintenance window.
      
      - **AutomaticFailoverStatus**(string) –
        Indicates the status of Multi-AZ for this replication group.

  Note: ElastiCache Multi-AZ replication groups are not supported on:
  
  - Redis versions earlier than 2.8.6.
  - T1 and T2 cache node types.

- **MemberClusters**(list) –
  The names of all the cache clusters that are part of this replication group.
- (string) –
  - **NodeGroups** (list) –
    A single element list with information about the nodes in the replication group.
    - (dict) –
      Represents a collection of cache nodes in a replication group.
      - **NodeGroupId** (string) –
        The identifier for the node group. A replication group contains only one node group; therefore, the node group ID is 0001.
      - **Status** (string) –
        The current state of this replication group - creating, available, etc.
      - **PrimaryEndpoint** (dict) –
        Represents the information required for client programs to connect to a cache node.
        - **Address** (string) –
          The DNS hostname of the cache node.
        - **Port** (integer) –
          The port number that the cache engine is listening on.
      - **NodeGroupMembers** (list) –
        A list containing information about individual nodes within the node group.
        - (dict) –
          Represents a single node within a node group.
          - **CacheClusterId** (string) –
            The ID of the cache cluster to which the node belongs.
          - **CacheNodeId** (string) –
            The ID of the node within its cache cluster. A node ID is a numeric identifier (0001, 0002, etc.).
          - **ReadEndpoint** (dict) –
            Represents the information required for client programs to connect to a cache node.
            - **Address** (string) –
              The DNS hostname of the cache node.
            - **Port** (integer) –
              The port number that the cache engine is listening on.
          - **PreferredAvailabilityZone** (string) –
            The name of the Availability Zone in which the node is located.
          - **CurrentRole** (string) –
            The role that is currently assigned to the node - primary or replica.
      - **SnapshottlngClusterId** (string) –
The cache cluster ID that is used as the daily snapshot source for the replication group.

* **AutomaticFailover** *(string)* –

Indicates the status of Multi-AZ for this replication group.

**Note:** ElastiCache Multi-AZ replication groups are not supported on:

- Redis versions earlier than 2.8.6.
- T1 and T2 cache node types.

### delete_snapshot(**kwargs**)

The *DeleteSnapshot* action deletes an existing snapshot. When you receive a successful response from this action, ElastiCache immediately begins deleting the snapshot; you cannot cancel or revert this action.

**Request Syntax**

```python
response = client.delete_snapshot(
    SnapshotName='string'
)
```

**Parameters**

**SnapshotName** *(string)* – [REQUIRED]

The name of the snapshot to be deleted.

**Return type**

**dict**

**Returns**

**Response Syntax**

```json
{
    'Snapshot': {

        ]
    }
}
```
Response Structure

- **(dict)** –
  Represents a copy of an entire cache cluster as of the time when the snapshot was taken.

- **Snapshot (dict)** –
  Represents a copy of an entire cache cluster as of the time when the snapshot was taken.

* **SnapshotName (string)** –
  The name of a snapshot. For an automatic snapshot, the name is system-generated; for a manual snapshot, this is the user-provided name.

* **CacheClusterId (string)** –
  The user-supplied identifier of the source cache cluster.

* **SnapshotStatus (string)** –
  The status of the snapshot. Valid values: creating | available | restoring | copying | deleting.

* **SnapshotSource (string)** –
  Indicates whether the snapshot is from an automatic backup (automated) or was created manually (manual).

* **CacheNodeType (string)** –
  The name of the compute and memory capacity node type for the source cache cluster.

Valid node types are as follows:

- **General purpose:**
  - Current generation: `cache.t2.micro`, `cache.t2.small`, `cache.t2.medium`, `cache.m3.medium`, `cache.m3.large`, `cache.m3.xlarge`, `cache.m3.2xlarge`
  - Previous generation: `cache.t1.micro`, `cache.m1.small`, `cache.m1.medium`, `cache.m1.large`, `cache.m1.xlarge`

- **Compute optimized:** `cache.c1.xlarge`

- **Memory optimized:**
  - Current generation: `cache.r3.large`, `cache.r3.xlarge`, `cache.r3.2xlarge`, `cache.r3.4xlarge`, `cache.r3.8xlarge`
  - Previous generation: `cache.m2.xlarge`, `cache.m2.2xlarge`, `cache.m2.4xlarge`

Notes:

- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.
* **Engine** *(string)* –
  The name of the cache engine *(memcached or redis)* used by the source cache cluster.

* **EngineVersion** *(string)* –
  The version of the cache engine version that is used by the source cache cluster.

* **NumCacheNodes** *(integer)* –
  The number of cache nodes in the source cache cluster.
  For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.

* **PreferredAvailabilityZone** *(string)* –
  The name of the Availability Zone in which the source cache cluster is located.

* **CacheClusterCreateTime** *(datetime)* –
  The date and time when the source cache cluster was created.

* **PreferredMaintenanceWindow** *(string)* –
  Specifies the weekly time range during which maintenance on the cache cluster is performed. It is specified as a range in the format ddd:hh24:mi-ddd:hh24:mi (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for ddd are:
  - sun
  - mon
  - tue
  - wed
  - thu
  - fri
  - sat
  Example: sun:05:00-sun:09:00

* **TopicArn** *(string)* –
  The Amazon Resource Name (ARN) for the topic used by the source cache cluster for publishing notifications.

* **Port** *(integer)* –
  The port number used by each cache nodes in the source cache cluster.

* **CacheParameterGroupName** *(string)* –
  The cache parameter group that is associated with the source cache cluster.

* **CacheSubnetGroupName** *(string)* –
  The name of the cache subnet group associated with the source cache cluster.

* **VpcId** *(string)* –
  The Amazon Virtual Private Cloud identifier (VPC ID) of the cache subnet group for the source cache cluster.

* **AutoMinorVersionUpgrade** *(boolean)* –
  This parameter is currently disabled.

* **SnapshotRetentionLimit** *(integer)* –
For an automatic snapshot, the number of days for which Elasti-
Cache will retain the snapshot before deleting it.

For manual snapshots, this field reflects the SnapshotRetentionLimit
for the source cache cluster when the snapshot was created. This
field is otherwise ignored: Manual snapshots do not expire, and can
only be deleted using the DeleteSnapshot action.

**Important** If the value of SnapshotRetentionLimit is set to zero (0),
backups are turned off.

* **SnapshotWindow** *(string)* –
  The daily time range during which ElastiCache takes daily snap-
  shots of the source cache cluster.

* **NodeSnapshots** *(list)* –
  A list of the cache nodes in the source cache cluster.
    
    · *(dict)* –
      Represents an individual cache node in a snapshot of a cache
      cluster.
      · **CacheNodeId** *(string)* –
        The cache node identifier for the node in the source cache
        cluster.
      · **CacheSize** *(string)* –
        The size of the cache on the source cache node.
      · **CacheNodeCreateTime** *(datetime)* –
        The date and time when the cache node was created in the
        source cache cluster.
      · **SnapshotCreateTime** *(datetime)* –
        The date and time when the source node’s metadata and cache
        data set was obtained for the snapshot.

**describe_cache_clusters**( **kwargs)

The DescribeCacheClusters action returns information about all provisioned cache clusters if no cache
cluster identifier is specified, or about a specific cache cluster if a cache cluster identifier is supplied.

By default, abbreviated information about the cache clusters(s) will be returned. You can use the optional
ShowDetails flag to retrieve detailed information about the cache nodes associated with the cache clusters.
These details include the DNS address and port for the cache node endpoint.

If the cluster is in the CREATING state, only cluster level information will be displayed until all of the
nodes are successfully provisioned.

If the cluster is in the DELETING state, only cluster level information will be displayed.

If cache nodes are currently being added to the cache cluster, node endpoint information and creation
time for the additional nodes will not be displayed until they are completely provisioned. When the cache
cluster state is available, the cluster is ready for use.

If cache nodes are currently being removed from the cache cluster, no endpoint information for the re-
moved nodes is displayed.

**Request Syntax**

```python
response = client.describe_cache_clusters(
    CacheClusterId='string',
    MaxRecords=123,
```

Parameters

- **CacheClusterId** *(string)* – The user-supplied cluster identifier. If this parameter is specified, only information about that specific cache cluster is returned. This parameter isn’t case sensitive.
- **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a marker is included in the response so that the remaining results can be retrieved.

Default: 100
Constraints: minimum 20; maximum 100.
- **Marker** *(string)* – An optional marker returned from a prior request. Use this marker for pagination of results from this action. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.
- **ShowCacheNodeInfo** *(boolean)* – An optional flag that can be included in the DescribeCacheCluster request to retrieve information about the individual cache nodes.

Return type  dict

Returns

Response Syntax

```python
{
    'Marker': 'string',
    'CacheClusters': [
        {
            'CacheClusterId': 'string',
            'ConfigurationEndpoint': {
                'Address': 'string',
                'Port': 123
            },
            'ClientDownloadLandingPage': 'string',
            'CacheNodeType': 'string',
            'Engine': 'string',
            'EngineVersion': 'string',
            'CacheClusterStatus': 'string',
            'NumCacheNodes': 123,
            'PreferredAvailabilityZone': 'string',
            'CacheClusterCreateTime': datetime(2015, 1, 1),
            'PreferredMaintenanceWindow': 'string',
            'PendingModifiedValues': {
                'NumCacheNodes': 123,
                'CacheNodeIdsToRemove': ['string'],
            },
            'EngineVersion': 'string',
            'NotificationConfiguration': {
                'TopicArn': 'string',
                'TopicStatus': 'string'
            },
            'CacheSecurityGroups': ['string']
        }
    ]
}
```
Response Structure

- *(dict)* –

  Represents the output of a `DescribeCacheClusters` action.

  - **Marker (string)** –

    Provides an identifier to allow retrieval of paginated results.

  - **CacheClusters (list)** –

    A list of cache clusters. Each item in the list contains detailed information about one cache cluster.

    - *(dict)* –

      Contains all of the attributes of a specific cache cluster.

      - **CacheClusterId (string)** –

        The user-supplied identifier of the cache cluster. This identifier is a unique key that identifies a cache cluster.

      - **ConfigurationEndpoint (dict)** –

Represents the information required for client programs to connect to a cache node.

- **Address (string)** –
  The DNS hostname of the cache node.

- **Port (integer)** –
  The port number that the cache engine is listening on.

- **ClientDownloadLandingPage (string)** –
  The URL of the web page where you can download the latest ElastiCache client library.

- **CacheNodeType (string)** –
  The name of the compute and memory capacity node type for the cache cluster.

Validity node types are as follows:

- **General purpose**: *Current generation:* cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
  *Previous generation:* cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge

- **Compute optimized**: cache.c1.xlarge

- **Memory optimized**: *Current generation:* cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
  *Previous generation:* cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

**Notes:**

- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see [Amazon ElastiCache Product Features and Details](#) and [Cache Node Type-Specific Parameters for Memcached](#) or [Cache Node Type-Specific Parameters for Redis](#).

- **Engine (string)** –
  The name of the cache engine (memcached or redis) to be used for this cache cluster.

- **EngineVersion (string)** –
  The version of the cache engine version that is used in this cache cluster.

- **CacheClusterStatus (string)** –
  The current state of this cache cluster, one of the following values: available, creating, deleted, deleting, incompatible-network, modifying, rebooting cache cluster nodes, restore-failed, or snapshotting.

- **NumCacheNodes (integer)** –
The number of cache nodes in the cache cluster.

For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.

- **PreferredAvailabilityZone** *(string)* –
  
The name of the Availability Zone in which the cache cluster is located or “Multiple” if the cache nodes are located in different Availability Zones.

- **CacheClusterCreateTime** *(datetime)* –
  
The date and time when the cache cluster was created.

- **PreferredMaintenanceWindow** *(string)* –
  
Specifies the weekly time range during which maintenance on the cache cluster is performed. It is specified as a range in the format ddd:hh24:mi-ddd:hh24:mi (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for **ddd** are:
  - sun
  - mon
  - tue
  - wed
  - thu
  - fri
  - sat

Example: **sun:05:00-sun:09:00**

- **PendingModifiedValues** *(dict)* –
  
A group of settings that will be applied to the cache cluster in the future, or that are currently being applied.

- **NumCacheNodes** *(integer)* –
  
The new number of cache nodes for the cache cluster.

For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.

- **CacheNodeIdsToRemove** *(list)* –
  
A list of cache node IDs that are being removed (or will be removed) from the cache cluster. A node ID is a numeric identifier (0001, 0002, etc.).

- **EngineVersion** *(string)* –
  
The new cache engine version that the cache cluster will run.

- **NotificationConfiguration** *(dict)* –
  
Describes a notification topic and its status. Notification topics are used for publishing ElastiCache events to subscribers using Amazon Simple Notification Service (SNS).

- **TopicArn** *(string)* –
  
The Amazon Resource Name (ARN) that identifies the topic.

- **TopicStatus** *(string)* –
  
The current state of the topic.

- **CacheSecurityGroups** *(list)* –
A list of cache security group elements, composed of name and status sub-elements.

- (dict) –
  Represents a cache cluster's status within a particular cache security group.

- CacheSecurityGroupName (string) –
  The name of the cache security group.

- Status (string) –
  The membership status in the cache security group. The status changes when a cache security group is modified, or when the cache security groups assigned to a cache cluster are modified.

- CacheParameterGroup (dict) –
  The status of the cache parameter group.

- CacheParameterGroupName (string) –
  The name of the cache parameter group.

- ParameterApplyStatus (string) –
  The status of parameter updates.

- CacheNodeIdsToReboot (list) –
  A list of the cache node IDs which need to be rebooted for parameter changes to be applied. A node ID is a numeric identifier (0001, 0002, etc.).

- (string) –
- CacheSubnetGroupName (string) –
  The name of the cache subnet group associated with the cache cluster.

- CacheNodes (list) –
  A list of cache nodes that are members of the cache cluster.

- (dict) –
  Represents an individual cache node within a cache cluster. Each cache node runs its own instance of the cluster's protocol-compliant caching software - either Memcached or Redis.

  Valid node types are as follows:

  · General purpose: * Current generation: cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
    · Previous generation: cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge
  · Compute optimized: cache.c1.xlarge
  · Memory optimized: * Current generation: cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
    · Previous generation: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge
Notes:
- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

- **CacheNodeId (string)** –
  The cache node identifier. A node ID is a numeric identifier (0001, 0002, etc.). The combination of cluster ID and node ID uniquely identifies every cache node used in a customer's AWS account.

- **CacheNodeStatus (string)** –
  The current state of this cache node.

- **CacheNodeCreateTime (datetime)** –
  The date and time when the cache node was created.

- **Endpoint (dict)** –
  The hostname for connecting to this cache node.

  - **Address (string)** –
    The DNS hostname of the cache node.

  - **Port (integer)** –
    The port number that the cache engine is listening on.

- **ParameterGroupStatus (string)** –
  The status of the parameter group applied to this cache node.

- **SourceCacheNodeId (string)** –
  The ID of the primary node to which this read replica node is synchronized. If this field is empty, then this node is not associated with a primary cache cluster.

- **CustomerAvailabilityZone (string)** –
  The Availability Zone where this node was created and now resides.

- **AutoMinorVersionUpgrade (boolean)** –
  This parameter is currently disabled.

- **SecurityGroups (list)** –
  A list of VPC Security Groups associated with the cache cluster.

  - **(dict)** –
    Represents a single cache security group and its status.

  - **SecurityGroupId (string)** –
    The identifier of the cache security group.

  - **Status (string)** –
    The status of the cache security group membership. The status changes whenever a cache security group is modified, or
when the cache security groups assigned to a cache cluster are modified.

- **ReplicationGroupId (string)** –
  The replication group to which this cache cluster belongs. If this field is empty, the cache cluster is not associated with any replication group.

- **SnapshotRetentionLimit (integer)** –
  The number of days for which ElastiCache will retain automatic cache cluster snapshots before deleting them. For example, if you set `SnapshotRetentionLimit` to 5, then a snapshot that was taken today will be retained for 5 days before being deleted.

  **Important** If the value of `SnapshotRetentionLimit` is set to zero (0), backups are turned off.

- **SnapshotWindow (string)** –
  The daily time range (in UTC) during which ElastiCache will begin taking a daily snapshot of your cache cluster.

  Example: 05:00–09:00

**describe_cache_engine_versions (**kwargs**)

The `DescribeCacheEngineVersions` action returns a list of the available cache engines and their versions.

**Request Syntax**

```python
response = client.describe_cache_engine_versions(
    Engine='string',
    EngineVersion='string',
    CacheParameterGroupFamily='string',
    MaxRecords=123,
    Marker='string',
    DefaultOnly=True|False
)
```

**Parameters**

- **Engine (string)** – The cache engine to return. Valid values: `memcached` | `redis`

- **EngineVersion (string)** – The cache engine version to return.

  Example: 1.4.14

- **CacheParameterGroupFamily (string)** – The name of a specific cache parameter group family to return details for.

  Constraints:
  - Must be 1 to 255 alphanumeric characters
  - First character must be a letter
  - Cannot end with a hyphen or contain two consecutive hyphens

- **MaxRecords (integer)** – The maximum number of records to include in the response. If more records exist than the specified `MaxRecords` value, a marker is included in the response so that the remaining results can be retrieved.

  Default: 100

  Constraints: minimum 20; maximum 100.

- **Marker (string)** – An optional marker returned from a prior request. Use this marker for pagination of results from this action. If this parameter is specified,
the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

- **DefaultOnly** *(boolean)* – If true, specifies that only the default version of the specified engine or engine and major version combination is to be returned.

**Return type** `dict`

**Returns**

**Response Syntax**

```
{
  'Marker': 'string',
  'CacheEngineVersions': [
    {
      'Engine': 'string',
      'EngineVersion': 'string',
      'CacheParameterGroupFamily': 'string',
      'CacheEngineDescription': 'string',
      'CacheEngineVersionDescription': 'string'
    },
  ]
}
```

**Response Structure**

- *(dict)* – Represents the output of a DescribeCacheEngineVersions action.
  - **Marker** *(string)* – Provides an identifier to allow retrieval of paginated results.
  - **CacheEngineVersions** *(list)* – A list of cache engine version details. Each element in the list contains detailed information about one cache engine version.
    * *(dict)* – Provides all of the details about a particular cache engine version.
      - **Engine** *(string)* – The name of the cache engine.
      - **EngineVersion** *(string)* – The version number of the cache engine.
      - **CacheParameterGroupFamily** *(string)* – The name of the cache parameter group family associated with this cache engine.
      - **CacheEngineDescription** *(string)* – The description of the cache engine.
      - **CacheEngineVersionDescription** *(string)* – The description of the cache engine version.

**describe_cache_parameter_groups** *(**kwargs)*

The DescribeCacheParameterGroups action returns a list of cache parameter group descriptions. If a cache parameter group name is specified, the list will contain only the descriptions for that group.

**Request Syntax**
response = client.describe_cache_parameter_groups(
    CacheParameterGroupName='string',
    MaxRecords=123,
    Marker='string'
)

Parameters

- **CacheParameterGroupName** *(string)* – The name of a specific cache parameter group to return details for.
- **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a marker is included in the response so that the remaining results can be retrieved.

  Default: 100

  Constraints: minimum 20; maximum 100.
- **Marker** *(string)* – An optional marker returned from a prior request. Use this marker for pagination of results from this action. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

Return type  dict

Returns

**Response Syntax**

```python
{
    'Marker': 'string',
    'CacheParameterGroups': [
        {
            'CacheParameterGroupName': 'string',
            'CacheParameterGroupFamily': 'string',
            'Description': 'string'
        },
    ]
}
```

**Response Structure**

- *(dict)* – Represents the output of a DescribeCacheParameterGroups action.
  - **Marker** *(string)* – Provides an identifier to allow retrieval of paginated results.
  - **CacheParameterGroups** *(list)* – A list of cache parameter groups. Each element in the list contains detailed information about one cache parameter group.
    - *(dict)* – Represents the output of a CreateCacheParameterGroup action.
      - **CacheParameterGroupName** *(string)* – The name of the cache parameter group.
      - **CacheParameterGroupFamily** *(string)* – The name of the cache parameter group family that this cache parameter group is compatible with.
      - **Description** *(string)* – The description for this cache parameter group.
describe_cache_parameters(**kwargs)

The DescribeCacheParameters action returns the detailed parameter list for a particular cache parameter group.

Request Syntax

```python
response = client.describe_cache_parameters(
    CacheParameterGroupName='string',
    Source='string',
    MaxRecords=123,
    Marker='string'
)
```

Parameters

- **CacheParameterGroupName** (*string*) – [REQUIRED]
  
The name of a specific cache parameter group to return details for.
- **Source** (*string*) – The parameter types to return.
  
  Valid values: user | system | engine-default
- **MaxRecords** (*integer*) – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a marker is included in the response so that the remaining results can be retrieved.
  
  Default: 100

  Constraints: minimum 20; maximum 100.
- **Marker** (*string*) – An optional marker returned from a prior request. Use this marker for pagination of results from this action. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords .

Return type  dict

Returns

Response Syntax

```python
{
    'Marker': 'string',
    'Parameters': [
        {
            'ParameterName': 'string',
            'ParameterValue': 'string',
            'Description': 'string',
            'Source': 'string',
            'DataType': 'string',
            'AllowedValues': 'string',
            'IsModifiable': True|False,
            'MinimumEngineVersion': 'string'
        },
    ],
    'CacheNodeTypeSpecificParameters': [
        {
            'ParameterName': 'string',
            'Description': 'string',
            'Source': 'string',
            'DataType': 'string',
            'AllowedValues': 'string',
            'IsModifiable': True|False,
            'MinimumEngineVersion': 'string',
        },
    ]
}
```
Response Structure

* (dict) –

- Description

  Represents the output of a DescribeCacheParameters action.

  - Marker (string) –

  Provides an identifier to allow retrieval of paginated results.

  - Parameters (list) –

    A list of Parameter instances.

      * (dict) –

      Describes an individual setting that controls some aspect of ElastiCache behavior.

        - ParameterName (string) –

          The name of the parameter.

        - ParameterValue (string) –

          The value of the parameter.

        - Description (string) –

          A description of the parameter.

        - Source (string) –

          The source of the parameter.

        - DataType (string) –

          The valid data type for the parameter.

        - AllowedValues (string) –

          The valid range of values for the parameter.

        - IsModifiable (boolean) –

          Indicates whether (true) or not (false) the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.

        - MinimumEngineVersion (string) –

          The earliest cache engine version to which the parameter can apply.

  - CacheNodeTypeSpecificParameters (list) –

    A list of parameters specific to a particular cache node type. Each element in the list contains detailed information about one parameter.

      * (dict) –

      A parameter that has a different value for each cache node type it is applied to. For example, in a Redis cache cluster, a cache.m1.large cache node type would have a larger maxmemory value than a cache.m1.small type.
- **ParameterName** *(string)* – The name of the parameter.
- **Description** *(string)* – A description of the parameter.
- **Source** *(string)* – The source of the parameter value.
- **DataType** *(string)* – The valid data type for the parameter.
- **AllowedValues** *(string)* – The valid range of values for the parameter.
- **IsModifiable** *(boolean)* – Indicates whether *(true)* or not *(false)* the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.
- **MinimumEngineVersion** *(string)* – The earliest cache engine version to which the parameter can apply.
- **CacheNodeTypeSpecificValues** *(list)* – A list of cache node types and their corresponding values for this parameter.
- **CacheNodeType** *(string)* – The cache node type for which this value applies.
- **Value** *(string)* – The value for the cache node type.

**describe_cache_security_groups**( **kwargs** )

The `DescribeCacheSecurityGroups` action returns a list of cache security group descriptions. If a cache security group name is specified, the list will contain only the description of that group.

**Request Syntax**

```python
response = client.describe_cache_security_groups(
    CacheSecurityGroupName='string',
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**

- **CacheSecurityGroupName** *(string)* – The name of the cache security group to return details for.
- **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a marker is included in the response so that the remaining results can be retrieved.
  
  Default: 100
  
  Constraints: minimum 20; maximum 100.
- **Marker** *(string)* – An optional marker returned from a prior request. Use this marker for pagination of results from this action. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

**Return type**  `dict`

**Returns**

**Response Syntax**

```
{
    'Marker': 'string',
    'CacheSecurityGroups': [
        {
            'OwnerId': 'string',
            'CacheSecurityGroupName': 'string',
            'Description': 'string',
            'EC2SecurityGroups': [
                {
                    'Status': 'string',
                    'EC2SecurityGroupName': 'string',
                    'EC2SecurityGroupOwnerId': 'string'
                }
            ]
        }
    ]
}
```

**Response Structure**

- *(dict)* – Represents the output of a `DescribeCacheSecurityGroups` action.
  - **Marker** *(string)* – Provides an identifier to allow retrieval of paginated results.
  - **CacheSecurityGroups** *(list)* – A list of cache security groups. Each element in the list contains detailed information about one group.
    - *(dict)* – Represents the output of one of the following actions:
      - `AuthorizeCacheSecurityGroupIngress`
      - `CreateCacheSecurityGroup`
      - `RevokeCacheSecurityGroupIngress`
    - **OwnerId** *(string)* – The AWS account ID of the cache security group owner.
    - **CacheSecurityGroupName** *(string)* – The name of the cache security group.
    - **Description** *(string)* – The description of the cache security group.
    - **EC2SecurityGroups** *(list)* – A list of Amazon EC2 security groups that are associated with this cache security group.
      - *(dict)* –
Provides ownership and status information for an Amazon EC2 security group.

- **Status (string)** –
  The status of the Amazon EC2 security group.

- **EC2SecurityGroupName (string)** –
  The name of the Amazon EC2 security group.

- **EC2SecurityGroupOwnerId (string)** –
  The AWS account ID of the Amazon EC2 security group owner.

**describe_cache_subnet_groups(**kwargs)**

The `DescribeCacheSubnetGroups` action returns a list of cache subnet group descriptions. If a subnet group name is specified, the list will contain only the description of that group.

**Request Syntax**

```python
response = client.describe_cache_subnet_groups(
    CacheSubnetGroupName='string',
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**

- **CacheSubnetGroupName (string)** – The name of the cache subnet group to return details for.

- **MaxRecords (integer)** – The maximum number of records to include in the response. If more records exist than the specified `MaxRecords` value, a marker is included in the response so that the remaining results can be retrieved.

  Default: 100

  Constraints: minimum 20; maximum 100.

- **Marker (string)** – An optional marker returned from a prior request. Use this marker for pagination of results from this action. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

**Return type** `dict`

**Returns**

**Response Syntax**

```json
{
    'Marker': 'string',
    'CacheSubnetGroups': [
        {
            'CacheSubnetGroupName': 'string',
            'CacheSubnetGroupDescription': 'string',
            'VpcId': 'string',
            'Subnets': [
                {
                    'SubnetIdentifier': 'string',
                    'SubnetAvailabilityZone': {
                        'Name': 'string'
                    }
                }
            ]
        }
    ]
}
```
Response Structure

- (dict) – Represents the output of a DescribeCacheSubnetGroups action.
  
  - Marker (string) – Provides an identifier to allow retrieval of paginated results.
  
  - CacheSubnetGroups (list) – A list of cache subnet groups. Each element in the list contains detailed information about one group.

  * (dict) – Represents the output of one of the following actions:

  - CreateCacheSubnetGroup
  - ModifyCacheSubnetGroup

    - CacheSubnetGroupName (string) – The name of the cache subnet group.

    - CacheSubnetGroupDescription (string) – The description of the cache subnet group.

    - VpcId (string) – The Amazon Virtual Private Cloud identifier (VPC ID) of the cache subnet group.

    - Subnets (list) – A list of subnets associated with the cache subnet group.

      * (dict) – Represents the subnet associated with a cache cluster. This parameter refers to subnets defined in Amazon Virtual Private Cloud (Amazon VPC) and used with ElastiCache.

      - SubnetIdentifier (string) – The unique identifier for the subnet.

      - SubnetAvailabilityZone (dict) – The Availability Zone associated with the subnet.

      - Name (string) – The name of the Availability Zone.

describe_engine_default_parameters (**kwargs)

The DescribeEngineDefaultParameters action returns the default engine and system parameter information for the specified cache engine.

Request Syntax

```python
response = client.describe_engine_default_parameters(
    CacheParameterGroupFamily='string',
    MaxRecords=123,
    Marker='string'
)
```

Parameters
• **CacheParameterGroupFamily** *(string)* – [REQUIRED]

The name of the cache parameter group family. Valid values are: memcached1.4 | redis2.6 | redis2.8

• **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a marker is included in the response so that the remaining results can be retrieved.

Default: 100

Constraints: minimum 20; maximum 100.

• **Marker** *(string)* – An optional marker returned from a prior request. Use this marker for pagination of results from this action. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

Return type: dict

Returns

Response Syntax

```
{
    'EngineDefaults': {
        'CacheParameterGroupFamily': 'string',
        'Marker': 'string',
        'Parameters': [
            {
                'ParameterName': 'string',
                'ParameterValue': 'string',
                'Description': 'string',
                'Source': 'string',
                'DataType': 'string',
                'AllowedValues': 'string',
                'IsModifiable': True|False,
                'MinimumEngineVersion': 'string'
            }
        ],
    },
    'CacheNodeTypeSpecificParameters': [
        {
            'ParameterName': 'string',
            'Description': 'string',
            'Source': 'string',
            'DataType': 'string',
            'AllowedValues': 'string',
            'IsModifiable': True|False,
            'MinimumEngineVersion': 'string',
            'CacheNodeTypeSpecificValues': [
                {
                    'CacheNodeType': 'string',
                    'Value': 'string'
                }
            ]
        }
    ]
}
```

Response Structure

• *(dict)* –
Represents the output of a `DescribeEngineDefaultParameters` action.

- **EngineDefaults** *(dict)* –

  Represents the output of a `DescribeEngineDefaultParameters` action.

  * **CacheParameterGroupFamily** *(string)* –
    
    Specifies the name of the cache parameter group family to which the engine default parameters apply.

  * **Marker** *(string)* –
    
    Provides an identifier to allow retrieval of paginated results.

  * **Parameters** *(list)* –
    
    Contains a list of engine default parameters.

      * *(dict)* –
        
        Describes an individual setting that controls some aspect of ElastiCache behavior.

          * **ParameterName** *(string)* –
            
            The name of the parameter.

          * **ParameterValue** *(string)* –
            
            The value of the parameter.

          * **Description** *(string)* –
            
            A description of the parameter.

          * **Source** *(string)* –
            
            The source of the parameter.

          * **DataType** *(string)* –
            
            The valid data type for the parameter.

          * **AllowedValues** *(string)* –
            
            The valid range of values for the parameter.

          * **IsModifiable** *(boolean)* –
            
            Indicates whether (true) or not (false) the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.

          * **MinimumEngineVersion** *(string)* –
            
            The earliest cache engine version to which the parameter can apply.

  * **CacheNodeTypeSpecificParameters** *(list)* –
    
    A list of parameters specific to a particular cache node type. Each element in the list contains detailed information about one parameter.

      * *(dict)* –
        
        A parameter that has a different value for each cache node type it is applied to. For example, in a Redis cache cluster, a `cache.m1.large` cache node type would have a larger `maxmemory` value than a `cache.m1.small` type.

        * **ParameterName** *(string)* –
          
          The name of the parameter.

        * **Description** *(string)* –
          
          A description of the parameter.
· **Source** *(string)* –
  The source of the parameter value.

· **DataType** *(string)* –
  The valid data type for the parameter.

· **AllowedValues** *(string)* –
  The valid range of values for the parameter.

· **IsModifiable** *(boolean)* –
  Indicates whether *(true)* or not *(false)* the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.

· **MinimumEngineVersion** *(string)* –
  The earliest cache engine version to which the parameter can apply.

· **CacheNodeTypeSpecificValues** *(list)* –
  A list of cache node types and their corresponding values for this parameter.

· *(dict)* –
  A value that applies only to a certain cache node type.

· **CacheNodeType** *(string)* –
  The cache node type for which this value applies.

· **Value** *(string)* –
  The value for the cache node type.

**describe_events** (**kwargs**)

The `DescribeEvents` action returns events related to cache clusters, cache security groups, and cache parameter groups. You can obtain events specific to a particular cache cluster, cache security group, or cache parameter group by providing the name as a parameter.

By default, only the events occurring within the last hour are returned; however, you can retrieve up to 14 days’ worth of events if necessary.

**Request Syntax**

```python
response = client.describe_events(
    SourceIdentifier='string',
    SourceType='cache-cluster'|'cache-parameter-group'|'cache-security-group'|'cache-subnet-group',
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    Duration=123,
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**

- **SourceIdentifier** *(string)* – The identifier of the event source for which events will be returned. If not specified, then all sources are included in the response.
- **SourceType** *(string)* – The event source to retrieve events for. If no value is specified, all events are returned.

Valid values are: `cache-cluster` | `cache-parameter-group` | `cache-security-group` | `cache-subnet-group`
• **StartTime** (*datetime*) – The beginning of the time interval to retrieve events for, specified in ISO 8601 format.

• **EndTime** (*datetime*) – The end of the time interval for which to retrieve events, specified in ISO 8601 format.

• **Duration** (*integer*) – The number of minutes’ worth of events to retrieve.

• **MaxRecords** (*integer*) – The maximum number of records to include in the response. If more records exist than the specified `MaxRecords` value, a marker is included in the response so that the remaining results can be retrieved.

  Default: 100

  Constraints: minimum 20; maximum 100.

• **Marker** (*string*) – An optional marker returned from a prior request. Use this marker for pagination of results from this action. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'Marker': 'string',
    'Events': [
        {
            'SourceIdentifier': 'string',
            'SourceType': 'cache-cluster'|'cache-parameter-group'|'cache-security-group'|'cache-subnet-group',
            'Message': 'string',
            'Date': datetime(2015, 1, 1)
        },
    ],
}
```

**Response Structure**

• *(dict)* –

  Represents the output of a `DescribeEvents` action.

  – **Marker** (*string*) –

    Provides an identifier to allow retrieval of paginated results.

  – **Events** (*list*) –

    A list of events. Each element in the list contains detailed information about one event.

    * *(dict)* –

      Represents a single occurrence of something interesting within the system. Some examples of events are creating a cache cluster, adding or removing a cache node, or rebooting a node.

      – **SourceIdentifier** (*string*) –

        The identifier for the source of the event. For example, if the event occurred at the cache cluster level, the identifier would be the name of the cache cluster.

      – **SourceType** (*string*) –

        Specifies the origin of this event - a cache cluster, a parameter group, a security group, etc.
- **Message** *(string)* –
  The text of the event.
- **Date** *(datetime)* –
  The date and time when the event occurred.

**describe_replication_groups(****kwargs)**

The `DescribeReplicationGroups` action returns information about a particular replication group. If no identifier is specified, `DescribeReplicationGroups` returns information about all replication groups.

**Request Syntax**

```python
response = client.describe_replication_groups(
    ReplicationGroupId='string',
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**

- **ReplicationGroupId** *(string)* – The identifier for the replication group to be described. This parameter is not case sensitive.
  
  If you do not specify this parameter, information about all replication groups is returned.

- **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified `MaxRecords` value, a marker is included in the response so that the remaining results can be retrieved.
  
  Default: 100
  
  Constraints: minimum 20; maximum 100.

- **Marker** *(string)* – An optional marker returned from a prior request. Use this marker for pagination of results from this action. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

**Return type**  `dict`

**Returns**

**Response Syntax**

```python
{
    'Marker': 'string',
    'ReplicationGroups': [ {
        'ReplicationGroupId': 'string',
        'Description': 'string',
        'Status': 'string',
        'PendingModifiedValues': { 'PrimaryClusterId': 'string',
                                    'AutomaticFailoverStatus': 'enabled'|'disabled' },
        'MemberClusters': [ 'string', ],
        'NodeGroups': [ { 'NodeGroupId': 'string',
                          'Status': 'string',
                          'PrimaryEndpoint': {...}
                          } ]
    } ]
}
```
'Address': 'string',
'Port': 123
},
'NodeGroupMembers': [
{
 'CacheClusterId': 'string',
 'CacheNodeId': 'string',
 'ReadEndpoint': {
 'Address': 'string',
 'Port': 123
 },
 'PreferredAvailabilityZone': 'string',
 'CurrentRole': 'string'
 },
]
],
'SnapshottingClusterId': 'string',
'AutomaticFailover': 'enabled'|'disabled'|'enabling'|'disabling'
}

Response Structure
• (dict) –

Represents the output of a DescribeReplicationGroups action.
  – Marker (string) –

Provides an identifier to allow retrieval of paginated results.
  – ReplicationGroups (list) –

A list of replication groups. Each item in the list contains detailed information about one replication group.
  * (dict) –

Contains all of the attributes of a specific replication group.
  · ReplicationGroupId (string) –

The identifier for the replication group.
  · Description (string) –

The description of the replication group.
  · Status (string) –

The current state of this replication group - creating, available, etc.
  · PendingModifiedValues (dict) –

A group of settings to be applied to the replication group, either immediately or during the next maintenance window.
  · PrimaryClusterId (string) –

The primary cluster ID which will be applied immediately (if --apply-immediately was specified), or during the next maintenance window.
  · AutomaticFailoverStatus (string) –

Indicates the status of Multi-AZ for this replication group.
Note: ElastiCache Multi-AZ replication groups are not supported on:
- Redis versions earlier than 2.8.6.
- T1 and T2 cache node types.

- **MemberClusters (list)** –
  The names of all the cache clusters that are part of this replication group.
  - (string)

- **NodeGroups (list)** –
  A single element list with information about the nodes in the replication group.
  - (dict)

  Represents a collection of cache nodes in a replication group.

- **NodeGroupId (string)** –
  The identifier for the node group. A replication group contains only one node group; therefore, the node group ID is 0001.

- **Status (string)** –
  The current state of this replication group - creating, available, etc.

- **PrimaryEndpoint (dict)** –
  Represents the information required for client programs to connect to a cache node.
  - **Address (string)** –
    The DNS hostname of the cache node.
  - **Port (integer)** –
    The port number that the cache engine is listening on.

- **NodeGroupMembers (list)** –
  A list containing information about individual nodes within the node group.
  - (dict)

  Represents a single node within a node group.

- **CacheClusterId (string)** –
  The ID of the cache cluster to which the node belongs.

- **CacheNodeId (string)** –
  The ID of the node within its cache cluster. A node ID is a numeric identifier (0001, 0002, etc.).

- **ReadEndpoint (dict)** –
  Represents the information required for client programs to connect to a cache node.
  - **Address (string)** –
    The DNS hostname of the cache node.
  - **Port (integer)** –
    The port number that the cache engine is listening on.

- **PreferredAvailabilityZone (string)** –
The name of the Availability Zone in which the node is located.

- **CurrentRole (string)**
  
  The role that is currently assigned to the node - *primary* or *replica*.

- **SnapshottingClusterId (string)**
  
  The cache cluster ID that is used as the daily snapshot source for the replication group.

- **AutomaticFailover (string)**
  
  Indicates the status of Multi-AZ for this replication group.

**Note:** ElastiCache Multi-AZ replication groups are not supported on:

- Redis versions earlier than 2.8.6.
- T1 and T2 cache node types.

### describe_reserved_cache_nodes(**kwargs)

The *DescribeReservedCacheNodes* action returns information about reserved cache nodes for this account, or about a specified reserved cache node.

**Request Syntax**

```python
response = client.describe_reserved_cache_nodes(
    ReservedCacheNodeId='string',
    ReservedCacheNodesOfferingId='string',
    CacheNodeType='string',
    Duration='string',
    ProductDescription='string',
    OfferingType='string',
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**

- **ReservedCacheNodeId (string)** – The reserved cache node identifier filter value. Use this parameter to show only the reservation that matches the specified reservation ID.

- **ReservedCacheNodesOfferingId (string)** – The offering identifier filter value. Use this parameter to show only purchased reservations matching the specified offering identifier.

- **CacheNodeType (string)** – The cache node type filter value. Use this parameter to show only those reservations matching the specified cache node type.

Valid node types are as follows:

- **General purpose**:
  - *Current generation*: `cache.t2.micro`, `cache.t2.small`, `cache.t2.medium`, `cache.m3.medium`, `cache.m3.large`, `cache.m3.xlarge`, `cache.m3.2xlarge`
  - *Previous generation*: `cache.t1.micro`, `cache.m1.small`, `cache.m1.medium`, `cache.m1.large`, `cache.m1.xlarge`

- **Compute optimized**: `cache.c1.xlarge`

- **Memory optimized**:
  - *Current generation*: `cache.r3.large`, `cache.r3.xlarge`, `cache.r3.2xlarge`, `cache.r3.4xlarge`, `cache.r3.8xlarge`
  - *Previous generation*: `cache.m2.xlarge`, `cache.m2.2xlarge`, `cache.m2.4xlarge`
Notes:
- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon Elasticache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

- **Duration (string)** – The duration filter value, specified in years or seconds. Use this parameter to show only reservations for this duration.
  
  Valid Values: 1 | 3 | 31536000 | 94608000

- **ProductDescription (string)** – The product description filter value. Use this parameter to show only those reservations matching the specified product description.

- **OfferingType (string)** – The offering type filter value. Use this parameter to show only the available offerings matching the specified offering type.
  
  Valid values: "Light Utilization"|"Medium Utilization"|"Heavy Utilization"

- **MaxRecords (integer)** – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a marker is included in the response so that the remaining results can be retrieved.
  
  Default: 100
  Constraints: minimum 20; maximum 100.

- **Marker (string)** – An optional marker returned from a prior request. Use this marker for pagination of results from this action. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

Return type  dict

Returns

Response Syntax

```python
{
    'Marker': 'string',
    'ReservedCacheNodes': [
        {
            'ReservedCacheNodeId': 'string',
            'ReservedCacheNodesOfferingId': 'string',
            'CacheNodeType': 'string',
            'StartTime': datetime(2015, 1, 1),
            'Duration': 123,
            'FixedPrice': 123.0,
            'UsagePrice': 123.0,
            'CacheNodeCount': 123,
            'ProductDescription': 'string',
            'OfferingType': 'string',
            'State': 'string',
            'RecurringCharges': [
                {
                    'RecurringChargeAmount': 123.0,
                    'RecurringChargeFrequency': 'string'
                },
            ],
        },
    ],
}
```
Response Structure

- (dict) – Represents the output of a DescribeReservedCacheNodes action.
  - Marker (string) – Provides an identifier to allow retrieval of paginated results.
  - ReservedCacheNodes (list) – A list of reserved cache nodes. Each element in the list contains detailed information about one node.
    * (dict) – Represents the output of a PurchaseReservedCacheNodesOffering action.
      - ReservedCacheNodeId (string) – The unique identifier for the reservation.
      - ReservedCacheNodesOfferingId (string) – The offering identifier.
      - CacheNodeType (string) – The cache node type for the reserved cache nodes.

Valid node types are as follows:

- General purpose: * Current generation: cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
  - Previous generation: cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge
- Compute optimized: cache.c1.xlarge
- Memory optimized: * Current generation: cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
  - Previous generation: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

Notes:

- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

- StartTime (datetime) – The time the reservation started.
- Duration (integer) – The duration of the reservation in seconds.
· **FixedPrice** *(float)* –
  The fixed price charged for this reserved cache node.
· **UsagePrice** *(float)* –
  The hourly price charged for this reserved cache node.
· **CacheNodeCount** *(integer)* –
  The number of cache nodes that have been reserved.
· **ProductDescription** *(string)* –
  The description of the reserved cache node.
· **OfferingType** *(string)* –
  The offering type of this reserved cache node.
· **State** *(string)* –
  The state of the reserved cache node.
· **RecurringCharges** *(list)* –
  The recurring price charged to run this reserved cache node.
  *(dict)* –
  Contains the specific price and frequency of a recurring charge for a reserved cache node, or for a reserved cache node offering.
· **RecurringChargeAmount** *(float)* –
  The monetary amount of the recurring charge.
· **RecurringChargeFrequency** *(string)* –
  The frequency of the recurring charge.

**describe_reserved_cache_nodes_offerings**( **kwargs)
The *DescribeReservedCacheNodesOfferings* action lists available reserved cache node offerings.

**Request Syntax**

```python
response = client.describe_reserved_cache_nodes_offerings(
    ReservedCacheNodesOfferingId='string',
    CacheNodeType='string',
    Duration='string',
    ProductDescription='string',
    OfferingType='string',
    MaxRecords=123,
    Marker='string'
)
```

**Parameters**

- **ReservedCacheNodesOfferingId** *(string)* – The offering identifier filter value. Use this parameter to show only the available offering that matches the specified reservation identifier.
  Example: 438012d3-4052-4cc7-b2e3-8d3372e0e706
- **CacheNodeType** *(string)* – The cache node type filter value. Use this parameter to show only the available offerings matching the specified cache node type.

Valid node types are as follows:

- General purpose: * Current generation: cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
– Previous generation: cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge
– Compute optimized: cache.cl.xlarge
– Memory optimized

Current generation: cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
– Previous generation: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

Notes:
– All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
– Redis backup/restore is not supported for t2 instances.
– Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon Elasticache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

• **Duration** (string) – Duration filter value, specified in years or seconds. Use this parameter to show only reservations for a given duration.

  Valid Values: 1 | 3 | 31536000 | 94608000

• **ProductDescription** (string) – The product description filter value. Use this parameter to show only the available offerings matching the specified product description.

• **OfferingType** (string) – The offering type filter value. Use this parameter to show only the available offerings matching the specified offering type.

  Valid Values: "Light Utilization" | "Medium Utilization" | "Heavy Utilization"

• **MaxRecords** (integer) – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a marker is included in the response so that the remaining results can be retrieved.

  Default: 100

  Constraints: minimum 20; maximum 100.

• **Marker** (string) – An optional marker returned from a prior request. Use this marker for pagination of results from this action. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

Return type dict

Returns

Response Syntax

```json
{
  'Marker': 'string',
  'ReservedCacheNodesOfferings': [
    {
      'ReservedCacheNodesOfferingId': 'string',
      'CacheNodeType': 'string',
      'Duration': 123,
      'FixedPrice': 123.0,
      'UsagePrice': 123.0,
      'ProductDescription': 'string',
      'OfferingType': 'string',
      'RecurringCharges': [
        {
          'RecurringCharges': 'string'
        }
      ]
    }
  ]
}
```
Response Structure

- (dict) – Represents the output of a `DescribeReservedCacheNodesOfferings` action.
  - Marker (string) – Provides an identifier to allow retrieval of paginated results.
  - ReservedCacheNodesOfferings (list) – A list of reserved cache node offerings. Each element in the list contains detailed information about one offering.
    - (dict) – Describes all of the attributes of a reserved cache node offering.
      - ReservedCacheNodesOfferingId (string) – A unique identifier for the reserved cache node offering.
      - CacheNodeType (string) – The cache node type for the reserved cache node.

Valid node types are as follows:
- General purpose: * Current generation: `cache.t2.micro`, `cache.t2.small`, `cache.t2.medium`, `cache.m3.medium`, `cache.m3.large`, `cache.m3.xlarge`, `cache.m3.2xlarge`  
  - Previous generation: `cache.t1.micro`, `cache.m1.small`, `cache.m1.medium`, `cache.m1.large`, `cache.m1.xlarge`  
- Compute optimized: `cache.c1.xlarge`  
- Memory optimized * Current generation: `cache.r3.large`, `cache.r3.xlarge`, `cache.r3.2xlarge`, `cache.r3.4xlarge`, `cache.r3.8xlarge`  
  - Previous generation: `cache.m2.xlarge`, `cache.m2.2xlarge`, `cache.m2.4xlarge`  

Notes:
- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).  
- Redis backup/restore is not supported for t2 instances.  
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.  
  For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis .
- Duration (integer) – The duration of the offering, in seconds.
- FixedPrice (float) –
The fixed price charged for this offering.

- **UsagePrice** (*float*)
  The hourly price charged for this offering.

- **ProductDescription** (*string*)
  The cache engine used by the offering.

- **OfferingType** (*string*)
  The offering type.

- **RecurringCharges** (*list*)
  The recurring price charged to run this reserved cache node.
  
  - (dict)
    Contains the specific price and frequency of a recurring charges for a reserved cache node, or for a reserved cache node offering.

- **RecurringChargeAmount** (*float*)
  The monetary amount of the recurring charge.

- **RecurringChargeFrequency** (*string*)
  The frequency of the recurring charge.

---

### describe_snapshots (**kwargs**)

The *DescribeSnapshots* action returns information about cache cluster snapshots. By default, *DescribeSnapshots* lists all of your snapshots; it can optionally describe a single snapshot, or just the snapshots associated with a particular cache cluster.

**Request Syntax**

```python
response = client.describe_snapshots(
    CacheClusterId='string',
    SnapshotName='string',
    SnapshotSource='string',
    Marker='string',
    MaxRecords=123
)
```

**Parameters**

- **CacheClusterId** (*string*) – A user-supplied cluster identifier. If this parameter is specified, only snapshots associated with that specific cache cluster will be described.

- **SnapshotName** (*string*) – A user-supplied name of the snapshot. If this parameter is specified, only this snapshot will be described.

- **SnapshotSource** (*string*) – If set to `system`, the output shows snapshots that were automatically created by ElastiCache. If set to `user` the output shows snapshots that were manually created. If omitted, the output shows both automatically and manually created snapshots.

- **Marker** (*string*) – An optional marker returned from a prior request. Use this marker for pagination of results from this action. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

- **MaxRecords** (*integer*) – The maximum number of records to include in the response. If more records exist than the specified `MaxRecords` value, a marker is included in the response so that the remaining results can be retrieved.

Default: 50
Return type: `dict`

**Returns**

**Response Syntax**

```json
{
    'Marker': 'string',
    'Snapshots': [
        {
            'SnapshotName': 'string',
            'CacheClusterId': 'string',
            'SnapshotStatus': 'string',
            'SnapshotSource': 'string',
            'CacheNodeType': 'string',
            'Engine': 'string',
            'EngineVersion': 'string',
            'NumCacheNodes': 123,
            'PreferredAvailabilityZone': 'string',
            'CacheClusterCreateTime': datetime(2015, 1, 1),
            'PreferredMaintenanceWindow': 'string',
            'TopicArn': 'string',
            'Port': 123,
            'CacheParameterGroupName': 'string',
            'CacheSubnetGroupName': 'string',
            'VpcId': 'string',
            'AutoMinorVersionUpgrade': True|False,
            'SnapshotRetentionLimit': 123,
            'SnapshotWindow': 'string',
            'NodeSnapshots': [
                {
                    'CacheNodeId': 'string',
                    'CacheSize': 'string',
                    'CacheNodeCreateTime': datetime(2015, 1, 1),
                    'SnapshotCreateTime': datetime(2015, 1, 1)
                }
            ]
        }
    ]
}
```

**Response Structure**

- `(dict)` –

  Represents the output of a `DescribeSnapshots` action.

  - **Marker** (string) –

    An optional marker returned from a prior request. Use this marker for pagination of results from this action. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by `MaxRecords`.

  - **Snapshots** (list) –

    A list of snapshots. Each item in the list contains detailed information about one snapshot.

      * `(dict)` –

        Represents a copy of an entire cache cluster as of the time when the snapshot was taken.
- **SnapshotName** *(string)*
  The name of a snapshot. For an automatic snapshot, the name is system-generated; for a manual snapshot, this is the user-provided name.

- **CacheClusterId** *(string)*
  The user-supplied identifier of the source cache cluster.

- **SnapshotStatus** *(string)*
  The status of the snapshot. Valid values: creating | available | restoring | copying | deleting.

- **SnapshotSource** *(string)*
  Indicates whether the snapshot is from an automatic backup *(automated)* or was created manually *(manual)*.

- **CacheNodeType** *(string)*
  The name of the compute and memory capacity node type for the source cache cluster.

Valid node types are as follows:
- **General purpose**: *
  *Current generation*: cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
  *Previous generation*: cache.t1.micro, cache.ml.small, cache.ml.medium, cache.ml.large, cache.ml.xlarge
  - **Compute optimized**: cache.c1.xlarge

- **Memory optimized**: *
  *Current generation*: cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
  *Previous generation*: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

**Notes:**
- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

- **Engine** *(string)*
  The name of the cache engine *(memcached or redis)* used by the source cache cluster.

- **EngineVersion** *(string)*
  The version of the cache engine version that is used by the source cache cluster.

- **NumCacheNodes** *(integer)*
  The number of cache nodes in the source cache cluster.
For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.

- **PreferredAvailabilityZone** *(string)* –
  The name of the Availability Zone in which the source cache cluster is located.

- **CacheClusterCreateTime** *(datetime)* –
  The date and time when the source cache cluster was created.

- **PreferredMaintenanceWindow** *(string)* –
  Specifies the weekly time range during which maintenance on the cache cluster is performed. It is specified as a range in the format ddd:hh24:mi-ddd:hh24:mi (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for ddd are:
  - sun
  - mon
  - tue
  - wed
  - thu
  - fri
  - sat
  Example: sun:05:00–sun:09:00

- **TopicArn** *(string)* –
  The Amazon Resource Name (ARN) for the topic used by the source cache cluster for publishing notifications.

- **Port** *(integer)* –
  The port number used by each cache nodes in the source cache cluster.

- **CacheParameterGroupName** *(string)* –
  The cache parameter group that is associated with the source cache cluster.

- **CacheSubnetGroupName** *(string)* –
  The name of the cache subnet group associated with the source cache cluster.

- **VpcId** *(string)* –
  The Amazon Virtual Private Cloud identifier (VPC ID) of the cache subnet group for the source cache cluster.

- **AutoMinorVersionUpgrade** *(boolean)* –
  This parameter is currently disabled.

- **SnapshotRetentionLimit** *(integer)* –
  For an automatic snapshot, the number of days for which ElastiCache will retain the snapshot before deleting it.
  For manual snapshots, this field reflects the `SnapshotRetentionLimit` for the source cache cluster when the snapshot was created. This field is otherwise ignored: Manual snapshots do not expire, and can only be deleted using the `DeleteSnapshot` action.

**Important** If the value of SnapshotRetentionLimit is set to zero (0), backups are turned off.
- **SnapshotWindow** *(string)* –
  The daily time range during which ElastiCache takes daily snapshots of the source cache cluster.

- **NodeSnapshots** *(list)* –
  A list of the cache nodes in the source cache cluster.
  
  - *(dict)* –
    Represents an individual cache node in a snapshot of a cache cluster.

- **CacheNodeId** *(string)* –
  The cache node identifier for the node in the source cache cluster.

- **CacheSize** *(string)* –
  The size of the cache on the source cache node.

- **CacheNodeCreateTime** *(datetime)* –
  The date and time when the cache node was created in the source cache cluster.

- **SnapshotCreateTime** *(datetime)* –
  The date and time when the source node’s metadata and cache data set was obtained for the snapshot.

generate_presigned_url *(ClientMethod, Params=None, ExpiresIn=3600, HttpMethod=None)*
 Generate a presigned url given a client, its method, and arguments

  **Parameters**
  
  - **ClientMethod** *(string)* – The client method to presign for
  
  - **Params** *(dict)* – The parameters normally passed to ClientMethod.
  
  - **ExpiresIn** *(int)* – The number of seconds the presigned url is valid for. By default it expires in an hour (3600 seconds)
  
  - **HttpMethod** *(string)* – The http method to use on the generated url. By default, the http method is whatever is used in the method’s model.

  **Returns** The presigned url

get Paginator *(operation_name)*
 Create a paginator for an operation.

  **Parameters operation_name** *(string)* – The operation name. This is the same name as the method name on the client. For example, if the method name is create_foo, and you’d normally invoke the operation as client.create_foo(**kwargs),
  
  if the create_foo operation can be paginated, you can use the call client.get Paginator("create_foo").

  **Raises** OperationNotPageableError Raised if the operation is not pageable. You can use
  
  the client.canPaginate method to check if an operation is pageable.

  **Return type** L{botocore.paginate.Paginator}

  **Returns** A paginator object.

get_waiter *(waiter_name)*

list_tags_for_resource *(**kwargs)*
 The ListTagsForResource action lists all cost allocation tags currently on the named resource. A cost allocation tag is a key-value pair where the key is case-sensitive and the value is optional. Cost allocation tags can be used to categorize and track your AWS costs.

You can have a maximum of 10 cost allocation tags on an ElastiCache resource. For more information, see Using Cost Allocation Tags in Amazon ElastiCache.
Request Syntax

```python
response = client.list_tags_for_resource(
    ResourceName='string'
)
```

**Parameters**  
**ResourceName** *(string)* – [REQUIRED]

The name of the resource for which you want the list of tags, for example `arn:aws:elasticache:us-west-2:0123456789:cluster:myCluster`.

**Return type**  
dict

Returns

Response Syntax

```python
{
    'TagList': [
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
}
```

**Response Structure**

- *(dict)* – Represents the output from the `AddTagsToResource`, `ListTagsOnResource`, and `RemoveTagsFromResource` actions.
  - **TagList** *(list)* – A list of cost allocation tags as key-value pairs.
    - *(dict)* – A cost allocation Tag that can be added to an ElastiCache cluster or replication group. Tags are composed of a Key/Value pair. A tag with a null Value is permitted.
      - **Key** *(string)* – The key for the tag.
      - **Value** *(string)* – The tag’s value. May not be null.

modify_cache_cluster(**kwargs)**

The `ModifyCacheCluster` action modifies the settings for a cache cluster. You can use this action to change one or more cluster configuration parameters by specifying the parameters and the new values.

Request Syntax

```python
response = client.modify_cache_cluster(
    CacheClusterId='string',
    NumCacheNodes=123,
    CacheNodeIdsToRemove=[
        'string',
    ],
    AZMode='single-az'|'cross-az',
    NewAvailabilityZones=[
        'string',
    ],
    **kwargs)
```
Parameters

- **CacheClusterId** *(string)* – [REQUIRED]

  The cache cluster identifier. This value is stored as a lowercase string.

- **NumCacheNodes** *(integer)* – The number of cache nodes that the cache cluster should have. If the value for NumCacheNodes is greater than the sum of the number of current cache nodes and the number of cache nodes pending creation (which may be zero), then more nodes will be added. If the value is less than the number of existing cache nodes, then nodes will be removed. If the value is equal to the number of current cache nodes, then any pending add or remove requests are canceled.

  If you are removing cache nodes, you must use the CacheNodeIdsToRemove parameter to provide the IDs of the specific cache nodes to remove.

  For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.

  **Note:** Adding or removing Memcached cache nodes can be applied immediately or as a pending action. See ApplyImmediately. A pending action to modify the number of cache nodes in a cluster during its maintenance window, whether by adding or removing nodes in accordance with the scale out architecture, is not queued. The customer’s latest request to add or remove nodes to the cluster overrides any previous pending actions to modify the number of cache nodes in the cluster. For example, a request to remove 2 nodes would override a previous pending action to remove 3 nodes. Similarly, a request to add 2 nodes would override a previous pending action to remove 3 nodes and vice versa. As Memcached cache nodes may now be provisioned in different Availability Zones with flexible cache node placement, a request to add nodes does not automatically override a previous pending action to add nodes. The customer can modify the previous pending action to add more nodes or explicitly cancel the pending request and retry the new request. To cancel pending actions to modify the number of cache nodes in a cluster, use the ModifyCacheCluster request and set NumCacheNodes equal to the number of cache nodes currently in the cache cluster.

- **CacheNodeIdsToRemove** *(list)* – A list of cache node IDs to be removed. A node ID is a numeric identifier (0001, 0002, etc.). This parameter is only valid when NumCacheNodes is less than the existing number of cache nodes. The
number of cache node IDs supplied in this parameter must match the difference between the existing number of cache nodes in the cluster or pending cache nodes, whichever is greater, and the value of NumCacheNodes in the request.

For example: If you have 3 active cache nodes, 7 pending cache nodes, and the number of cache nodes in this ModifyCacheCluster call is 5, you must list 2 (7 - 5) cache node IDs to remove.

– (string) –

• AZMode (string) – Specifies whether the new nodes in this Memcached cache cluster are all created in a single Availability Zone or created across multiple Availability Zones.

Valid values: single-az|cross-az.

This option is only supported for Memcached cache clusters.

Note: You cannot specify single-az if the Memcached cache cluster already has cache nodes in different Availability Zones. If cross-az is specified, existing Memcached nodes remain in their current Availability Zone.

Only newly created nodes will be located in different Availability Zones. For instructions on how to move existing Memcached nodes to different Availability Zones, see the Availability Zone Considerations section of Cache Node Considerations for Memcached.

• NewAvailabilityZones (list) – The list of Availability Zones where the new Memcached cache nodes will be created.

This parameter is only valid when NumCacheNodes in the request is greater than the sum of the number of active cache nodes and the number of cache nodes pending creation (which may be zero). The number of Availability Zones supplied in this list must match the cache nodes being added in this request.

This option is only supported on Memcached clusters.

Scenarios:

– Scenario 1: You have 3 active nodes and wish to add 2 nodes. Specify NumCacheNodes=5 (3 + 2) and optionally specify two Availability Zones for the two new nodes.

– Scenario 2: You have 3 active nodes and 2 nodes pending creation (from the scenario 1 call) and want to add 1 more node. Specify NumCacheNodes=6 ((3 + 2) + 1)

and optionally specify an Availability Zone for the new node. * Scenario 3: You want to cancel all pending actions. Specify NumCacheNodes=3 to cancel all pending actions.

The Availability Zone placement of nodes pending creation cannot be modified. If you wish to cancel any nodes pending creation, add 0 nodes by setting NumCacheNodes to the number of current nodes.

If cross-az is specified, existing Memcached nodes remain in their current Availability Zone. Only newly created nodes can be located in different Availability Zones. For guidance on how to move existing Memcached nodes to different Availability Zones, see the Availability Zone Considerations section of Cache Node Considerations for Memcached.

Impact of new add/remove requests upon pending requests

Scenarios Pending action New Request Results Scenario-1 Delete Delete The new delete, pending or immediate, replaces the pend-
ing delete. Scenario-2 Delete Create The new create, pending or immediate, replaces the pending delete. Scenario-3 Create Delete The new delete, pending or immediate, replaces the pending create. Scenario-4 Create Create The new create is added to the pending create.

**Important:** If the new create request is **Apply Immediately - Yes**, all creates are performed immediately. If the new create request is **Apply Immediately - No**, all creates are pending.

Example: NewAvailabilityZones.member.1=us-west-2aNewAvailabilityZones.member.2=us-west-2bNewAvailabilityZones.member.3=us-west-2c

- **CacheSecurityGroupNames (list)** – A list of cache security group names to authorize on this cache cluster. This change is asynchronously applied as soon as possible.

  This parameter can be used only with clusters that are created outside of an Amazon Virtual Private Cloud (VPC).

  Constraints: Must contain no more than 255 alphanumeric characters. Must not be “Default”.
  - (string)

- **SecurityGroupIds (list)** – Specifies the VPC Security Groups associated with the cache cluster.

  This parameter can be used only with clusters that are created in an Amazon Virtual Private Cloud (VPC).

  - (string)

- **PreferredMaintenanceWindow (string)** – Specifies the weekly time range during which maintenance on the cache cluster is performed. It is specified as a range in the format ddd:hh24:mi-ddd:hh24:mi (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for ddd are:
  - sun
  - mon
  - tue
  - wed
  - thu
  - fri
  - sat

  Example: sun:05:00-sun:09:00

- **NotificationTopicArn (string)** – The Amazon Resource Name (ARN) of the Amazon SNS topic to which notifications will be sent.

  Note: The Amazon SNS topic owner must be same as the cache cluster owner.

- **CacheParameterGroupName (string)** – The name of the cache parameter group to apply to this cache cluster. This change is asynchronously applied as soon as possible for parameters when the **ApplyImmediately** parameter is specified as **true** for this request.

- **NotificationTopicStatus (string)** – The status of the Amazon SNS notification topic. Notifications are sent only if the status is **active**.

  Valid values: active | inactive

- **ApplyImmediately (boolean)** – If **true**, this parameter causes the modifications in this request and any pending modifications to be applied, asynchronously and as soon as possible, regardless of the **PreferredMaintenanceWindow** setting for the cache cluster.

  If **false**, then changes to the cache cluster are applied on the next maintenance reboot, or the next failure reboot, whichever occurs first.
Warning: If you perform a ModifyCacheCluster before a pending modification is applied, the pending modification is replaced by the newer modification.

Valid values: true | false

Default: false

• **EngineVersion** *(string)* – The upgraded version of the cache engine to be run on the cache nodes.

• **AutoMinorVersionUpgrade** *(boolean)* – This parameter is currently disabled.

• **SnapshotRetentionLimit** *(integer)* – The number of days for which ElastiCache will retain automatic cache cluster snapshots before deleting them. For example, if you set **SnapshotRetentionLimit** to 5, then a snapshot that was taken today will be retained for 5 days before being deleted.

**Important** If the value of **SnapshotRetentionLimit** is set to zero (0), backups are turned off.

• **SnapshotWindow** *(string)* – The daily time range (in UTC) during which ElastiCache will begin taking a daily snapshot of your cache cluster.

Return type: dict

Returns

Response Syntax

```
{
    'CacheCluster': {
        'CacheClusterId': 'string',
        'ConfigurationEndpoint': {
            'Address': 'string',
            'Port': 123
        },
        'ClientDownloadLandingPage': 'string',
        'CacheNodeType': 'string',

```
Response Structure

- (dict) –
  Contains all of the attributes of a specific cache cluster.
  - **CacheCluster** (dict) –
    Contains all of the attributes of a specific cache cluster.
    - **CacheClusterId** (string) –
      The user-supplied identifier of the cache cluster. This identifier is a unique key that identifies a cache cluster.
    - **ConfigurationEndpoint** (dict) –
      Represents the information required for client programs to connect to a cache node.
      - **Address** (string) –
        The DNS hostname of the cache node.
      - **Port** (integer) –
        The port number that the cache engine is listening on.
    - **ClientDownloadLandingPage** (string) –
      The URL of the web page where you can download the latest ElastiCache client library.
* CacheNodeType *(string)* –

The name of the compute and memory capacity node type for the cache cluster.

Valid node types are as follows:

- **General purpose**:
  - *Current generation*: cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
  - *Previous generation*: cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge

- **Compute optimized**: cache.c1.xlarge

- **Memory optimized**:
  - *Current generation*: cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
  - *Previous generation*: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

Notes:

- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

* Engine *(string)* –

The name of the cache engine (memcached or redis) to be used for this cache cluster.

* EngineVersion *(string)* –

The version of the cache engine version that is used in this cache cluster.

* CacheClusterStatus *(string)* –

The current state of this cache cluster, one of the following values: available, creating, deleted, deleting, incompatible-network, modifying, rebooting cache cluster nodes, restore-failed, or snapshotting.

* NumCacheNodes *(integer)* –

The number of cache nodes in the cache cluster.

For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.

* PreferredAvailabilityZone *(string)* –

The name of the Availability Zone in which the cache cluster is located or “Multiple” if the cache nodes are located in different Availability Zones.

* CacheClusterCreateTime *(datetime)* –

The date and time when the cache cluster was created.
* PreferredMaintenanceWindow *(string)* –

Specifies the weekly time range during which maintenance on the cache cluster is performed. It is specified as a range in the format ddd:hh24:mi-ddd:hh24:mi (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for ddd are:

- sun
- mon
- tue
- wed
- thu
- fri
- sat

Example: sun:05:00-sun:09:00

* PendingModifiedValues *(dict)* –

A group of settings that will be applied to the cache cluster in the future, or that are currently being applied.

- NumCacheNodes *(integer)* –

  The new number of cache nodes for the cache cluster.

  For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.

- CacheNodeIdsToRemove *(list)* –

  A list of cache node IDs that are being removed (or will be removed) from the cache cluster. A node ID is a numeric identifier (0001, 0002, etc.).

- EngineVersion *(string)* –

  The new cache engine version that the cache cluster will run.

* NotificationConfiguration *(dict)* –

Describes a notification topic and its status. Notification topics are used for publishing ElastiCache events to subscribers using Amazon Simple Notification Service (SNS).

- TopicArn *(string)* –

  The Amazon Resource Name (ARN) that identifies the topic.

- TopicStatus *(string)* –

  The current state of the topic.

* CacheSecurityGroups *(list)* –

A list of cache security group elements, composed of name and status sub-elements.

- *(dict)* –

  Represents a cache cluster’s status within a particular cache security group.

- CacheSecurityGroupName *(string)* –

  The name of the cache security group.

- Status *(string)* –

  The membership status in the cache security group. The status changes when a cache security group is modified, or when
the cache security groups assigned to a cache cluster are modified.

* CacheParameterGroup *(dict)* –

The status of the cache parameter group.

- **CacheParameterGroupName** *(string)* –
  The name of the cache parameter group.

- **ParameterApplyStatus** *(string)* –
  The status of parameter updates.

- **CacheNodeIdsToReboot** *(list)* –
  A list of the cache node IDs which need to be rebooted for parameter changes to be applied. A node ID is a numeric identifier (0001, 0002, etc.).

* **CacheSubnetGroupName** *(string)* –

The name of the cache subnet group associated with the cache cluster.

* **CacheNodes** *(list)* –

A list of cache nodes that are members of the cache cluster.

- *(dict)* –

  Represents an individual cache node within a cache cluster. Each cache node runs its own instance of the cluster’s protocol-compliant caching software - either Memcached or Redis.

Valid node types are as follows:

- General purpose: * Current generation: cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
  * Previous generation: cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge
- Compute optimized: cache.c1.xlarge
- Memory optimized * Current generation: cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
  * Previous generation: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

Notes:

- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.
For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

* **CacheNodeId** *(string)* –
The cache node identifier. A node ID is a numeric identifier (0001, 0002, etc.). The combination of cluster ID and node ID uniquely identifies every cache node used in a customer’s AWS account.

- **CacheNodeStatus** *(string)* –
  
  The current state of this cache node.

- **CacheNodeCreateTime** *(datetime)* –
  
  The date and time when the cache node was created.

- **Endpoint** *(dict)* –
  
  The hostname for connecting to this cache node.
  - **Address** *(string)* –
    
    The DNS hostname of the cache node.
  - **Port** *(integer)* –
    
    The port number that the cache engine is listening on.

- **ParameterGroupStatus** *(string)* –
  
  The status of the parameter group applied to this cache node.

- **SourceCacheNodeId** *(string)* –
  
  The ID of the primary node to which this read replica node is synchronized. If this field is empty, then this node is not associated with a primary cache cluster.

- **CustomerAvailabilityZone** *(string)* –
  
  The Availability Zone where this node was created and now resides.

- **AutoMinorVersionUpgrade** *(boolean)* –
  
  This parameter is currently disabled.

- **SecurityGroups** *(list)* –
  
  A list of VPC Security Groups associated with the cache cluster.
    - *(dict)* –
      
      Represents a single cache security group and its status.
      - **SecurityGroupId** *(string)* –
        
        The identifier of the cache security group.
      - **Status** *(string)* –
        
        The status of the cache security group membership. The status changes whenever a cache security group is modified, or when the cache security groups assigned to a cache cluster are modified.

- **ReplicationGroupId** *(string)* –
  
  The replication group to which this cache cluster belongs. If this field is empty, the cache cluster is not associated with any replication group.

- **SnapshotRetentionLimit** *(integer)* –
  
  The number of days for which ElastiCache will retain automatic cache cluster snapshots before deleting them. For example, if you set `SnapshotRetentionLimit` to 5, then a snapshot that was taken today will be retained for 5 days before being deleted.
**Important** If the value of SnapshotRetentionLimit is set to zero (0),
backups are turned off.

* **SnapshotWindow (string)** –

The daily time range (in UTC) during which ElastiCache will begin
taking a daily snapshot of your cache cluster.

Example: 05:00-09:00

**modify_cache_parameter_group (**kwargs**)

The *ModifyCacheParameterGroup* action modifies the parameters of a cache parameter group. You can
modify up to 20 parameters in a single request by submitting a list parameter name and value pairs.

**Request Syntax**

```python
response = client.modify_cache_parameter_group(
    CacheParameterGroupName='string',
    ParameterNameValues=[
        {
            'ParameterName': 'string',
            'ParameterValue': 'string'
        },
    ]
)
```

**Parameters**

- **CacheParameterGroupName (string)** – [REQUIRED]
  The name of the cache parameter group to modify.
- **ParameterNameValues (list)** – [REQUIRED]
  An array of parameter names and values for the parameter update. You must sup-
  ply at least one parameter name and value; subsequent arguments are optional.
  A maximum of 20 parameters may be modified per request.
  - (dict) –
    
    Describes a name-value pair that is used to update the value of a parameter.
    * **ParameterName (string)** –
      
      The name of the parameter.
    * **ParameterValue (string)** –
      
      The value of the parameter.

**Return type**  dict  
**Returns**

**Response Syntax**

```python
{}
```

**Response Structure**

- (dict) –

  Represents the output of one of the following actions:
  - *ModifyCacheParameterGroup*
  - *ResetCacheParameterGroup*
  - **CacheParameterGroupName (string)** –
    
    The name of the cache parameter group.
**modify_cache_subnet_group(**kwargs)**

The `ModifyCacheSubnetGroup` action modifies an existing cache subnet group.

**Request Syntax**

```python
response = client.modify_cache_subnet_group(
    CacheSubnetGroupName='string',
    CacheSubnetGroupDescription='string',
    SubnetIds=['string'],
)
```

**Parameters**

- **CacheSubnetGroupName** *(string)* – [REQUIRED]
  The name for the cache subnet group. This value is stored as a lowercase string.
  Constraints: Must contain no more than 255 alphanumeric characters or hyphens.
  Example: `mysubnetgroup`

- **CacheSubnetGroupDescription** *(string)* – A description for the cache subnet group.

- **SubnetIds** *(list)* – The EC2 subnet IDs for the cache subnet group.
  - *(string)* –

**Return type** *dict*

**Returns**

**Response Syntax**

```python
{
    'CacheSubnetGroup': {
        'CacheSubnetGroupName': 'string',
        'CacheSubnetGroupDescription': 'string',
        'VpcId': 'string',
        'Subnets': [
            {'SubnetIdentifier': 'string',
             'SubnetAvailabilityZone': {'Name': 'string'},
            },
        ],
    }
}
```

**Response Structure**

- *(dict)* –
  Represents the output of one of the following actions:
  - `CreateCacheSubnetGroup`
  - `ModifyCacheSubnetGroup`

- **CacheSubnetGroup** *(dict)* –
  Represents the output of one of the following actions:
  - `CreateCacheSubnetGroup`
  - `ModifyCacheSubnetGroup`
* CacheSubnetGroupName *(string)* –
  The name of the cache subnet group.
* CacheSubnetGroupDescription *(string)* –
  The description of the cache subnet group.
* VpcId *(string)* –
  The Amazon Virtual Private Cloud identifier (VPC ID) of the cache subnet group.
* Subnets *(list)* –
  A list of subnets associated with the cache subnet group.
    · *(dict)* –
      Represents the subnet associated with a cache cluster. This parameter refers to subnets defined in Amazon Virtual Private Cloud (Amazon VPC) and used with ElastiCache.
    · SubnetIdentifier *(string)* –
      The unique identifier for the subnet.
    · SubnetAvailabilityZone *(dict)* –
      The Availability Zone associated with the subnet.
    · Name *(string)* –
      The name of the Availability Zone.

**modify_replication_group**( **kwargs)

The *ModifyReplicationGroup* action modifies the settings for a replication group.

**Request Syntax**

```python
response = client.modify_replication_group(
    ReplicationGroupId='string',
    ReplicationGroupDescription='string',
    PrimaryClusterId='string',
    SnapshottingClusterId='string',
    AutomaticFailoverEnabled=True|False,
    CacheSecurityGroupNames=['string'],
    SecurityGroupIds=['string'],
    PreferredMaintenanceWindow='string',
    NotificationTopicArn='string',
    CacheParameterGroupName='string',
    NotificationTopicStatus='string',
    ApplyImmediately=True|False,
    EngineVersion='string',
    AutoMinorVersionUpgrade=True|False,
    SnapshotRetentionLimit=123,
    SnapshotWindow='string'
)
```

**Parameters**

- **ReplicationGroupId**(string) – [REQUIRED]
  The identifier of the replication group to modify.
• **ReplicationGroupDescription** *(string)* – A description for the replication group. Maximum length is 255 characters.

• **PrimaryClusterId** *(string)* – If this parameter is specified, ElastiCache will promote each of the cache clusters in the specified replication group to the primary role. The nodes of all other cache clusters in the replication group will be read replicas.

• **SnapshottingClusterId** *(string)* – The cache cluster ID that will be used as the daily snapshot source for the replication group.

• **AutomaticFailoverEnabled** *(boolean)* – Whether a read replica will be automatically promoted to read/write primary if the existing primary encounters a failure.

  Valid values: `true` | `false`

  **Note:** ElastiCache Multi-AZ replication groups are not supported on:
  – Redis versions earlier than 2.8.6.
  – T1 and T2 cache node types.

• **CacheSecurityGroupNames** *(list)* – A list of cache security group names to authorize for the clusters in this replication group. This change is asynchronously applied as soon as possible.

  This parameter can be used only with replication group containing cache clusters running outside of an Amazon Virtual Private Cloud (VPC).

  Constraints: Must contain no more than 255 alphanumeric characters. Must not be “Default”.

  – *(string)* –

• **SecurityGroupIds** *(list)* – Specifies the VPC Security Groups associated with the cache clusters in the replication group.

  This parameter can be used only with replication group containing cache clusters running in an Amazon Virtual Private Cloud (VPC).

  – *(string)* –

• **PreferredMaintenanceWindow** *(string)* – Specifies the weekly time range during which maintenance on the cache cluster is performed. It is specified as a range in the format `ddd:hh24:mi-ddd:hh24:mi` (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for `ddd` are:

  – `sun`
  – `mon`
  – `tue`
  – `wed`
  – `thu`
  – `fri`
  – `sat`

  Example: `sun:05:00-sun:09:00`

• **NotificationTopicArn** *(string)* – The Amazon Resource Name (ARN) of the Amazon SNS topic to which notifications will be sent.

  **Note:** The Amazon SNS topic owner must be same as the replication group owner.

• **CacheParameterGroupName** *(string)* – The name of the cache parameter group to apply to all of the clusters in this replication group. This change is asynchronously applied as soon as possible for parameters when the `ApplyImmediately` parameter is specified as `true` for this request.

• **NotificationTopicStatus** *(string)* – The status of the Amazon SNS notification...
Valid values: active | inactive

- **ApplyImmediately** (boolean) – If true, this parameter causes the modifications in this request and any pending modifications to be applied, asynchronously and as soon as possible, regardless of the PreferredMaintenanceWindow setting for the replication group.

If false, then changes to the nodes in the replication group are applied on the next maintenance reboot, or the next failure reboot, whichever occurs first.

Valid values: true | false

Default: false

- **EngineVersion** (string) – The upgraded version of the cache engine to be run on the cache clusters in the replication group.

- **AutoMinorVersionUpgrade** (boolean) – This parameter is currently disabled.

- **SnapshotRetentionLimit** (integer) – The number of days for which ElastiCache will retain automatic node group snapshots before deleting them. For example, if you set SnapshotRetentionLimit to 5, then a snapshot that was taken today will be retained for 5 days before being deleted.

  **Important** If the value of SnapshotRetentionLimit is set to zero (0), backups are turned off.

- **SnapshotWindow** (string) – The daily time range (in UTC) during which ElastiCache will begin taking a daily snapshot of the node group specified by SnapshottingClusterId.

  Example: 05:00–09:00

  If you do not specify this parameter, then ElastiCache will automatically choose an appropriate time range.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'ReplicationGroup': {
        'ReplicationGroupId': 'string',
        'Description': 'string',
        'Status': 'string',
        'PendingModifiedValues': {
            'PrimaryClusterId': 'string',
            'AutomaticFailoverStatus': 'enabled' | 'disabled'
        },
        'MemberClusters': [
            'string',
        ],
        'NodeGroups': [
            {
                'NodeGroupId': 'string',
                'Status': 'string',
                'PrimaryEndpoint': {
                    'Address': 'string',
                    'Port': 123
                },
                'NodeGroupMembers': [
                    {
                
```
'CacheClusterId': 'string',
'CacheNodeId': 'string',
'ReadEndpoint': {
    'Address': 'string',
    'Port': 123
},
'PreferredAvailabilityZone': 'string',
'CurrentRole': 'string'
],
},
},
],
'SnapshottingClusterId': 'string',
'AutomaticFailover': 'enabled'|'disabled'|'enabling'|'disabling'
}
}

Response Structure

• *(dict)* –

Contains all of the attributes of a specific replication group.

• **ReplicationGroup** *(dict)* –

Contains all of the attributes of a specific replication group.

* **ReplicationGroupId** *(string)* –

The identifier for the replication group.

* **Description** *(string)* –

The description of the replication group.

* **Status** *(string)* –

The current state of this replication group - creating, available, etc.

* **PendingModifiedValues** *(dict)* –

A group of settings to be applied to the replication group, either immediately or during the next maintenance window.

  • **PrimaryClusterId** *(string)* –

    The primary cluster ID which will be applied immediately (if --apply-immediately was specified), or during the next maintenance window.

  • **AutomaticFailoverStatus** *(string)* –

    Indicates the status of Multi-AZ for this replication group.

  • **MemberClusters** *(list)* –

    The names of all the cache clusters that are part of this replication group.

  • *(string)* –

* **NodeGroups** *(list)* –

A single element list with information about the nodes in the replication group.

  • *(dict)* –

**Note:** ElastiCache Multi-AZ replication groups are not supported on:

• Redis versions earlier than 2.8.6.
• T1 and T2 cache node types.
Represents a collection of cache nodes in a replication group.

- **NodeGroupId** *(string)*
  
The identifier for the node group. A replication group contains only one node group; therefore, the node group ID is 0001.

- **Status** *(string)*
  
The current state of this replication group - *creating*, *available*, etc.

- **PrimaryEndpoint** *(dict)*
  
  Represents the information required for client programs to connect to a cache node.

  - **Address** *(string)*
    
The DNS hostname of the cache node.

  - **Port** *(integer)*
    
The port number that the cache engine is listening on.

- **NodeGroupMembers** *(list)*
  
  A list containing information about individual nodes within the node group.

- **SnapshottingClusterId** *(string)*
  
The cache cluster ID that is used as the daily snapshot source for the replication group.

- **AutomaticFailover** *(string)*
  
  Indicates the status of Multi-AZ for this replication group.

**Note:** ElastiCache Multi-AZ replication groups are not supported on:
Redis versions earlier than 2.8.6.
· T1 and T2 cache node types.

**purchase_reserved_cache_nodes_offering(**kwargs)**

The `PurchaseReservedCacheNodesOffering` action allows you to purchase a reserved cache node offering.

**Request Syntax**

```python
response = client.purchase_reserved_cache_nodes_offering(
    ReservedCacheNodesOfferingId='string',
    ReservedCacheNodeId='string',
    CacheNodeCount=123
)
```

**Parameters**

- **ReservedCacheNodesOfferingId** *(string)* – [REQUIRED]
  
  The ID of the reserved cache node offering to purchase.
  
  Example: 438012d3-4052-4cc7-b2e3-8d3372e0e706

- **ReservedCacheNodeId** *(string)* – A customer-specified identifier to track this reservation.
  
  Example: myreservationID

- **CacheNodeCount** *(integer)* – The number of cache node instances to reserve.
  
  Default: 1

**Return type**  dict

**Returns**

**Response Syntax**

```python
{
    'ReservedCacheNode': {
        'ReservedCacheNodeId': 'string',
        'ReservedCacheNodesOfferingId': 'string',
        'CacheNodeType': 'string',
        'StartTime': datetime(2015, 1, 1),
        'Duration': 123,
        'FixedPrice': 123.0,
        'UsagePrice': 123.0,
        'CacheNodeCount': 123,
        'ProductDescription': 'string',
        'OfferingType': 'string',
        'State': 'string',
        'RecurringCharges': [
            {
                'RecurringChargeAmount': 123.0,
                'RecurringChargeFrequency': 'string'
            }
        ]
    }
}
```

**Response Structure**

- *(dict)* –

  Represents the output of a `PurchaseReservedCacheNodesOffering` action.

    - **ReservedCacheNode** *(dict)* –
Represents the output of a `PurchaseReservedCacheNodesOffering` action.

* **ReservedCacheNodeId** *(string)* –
  
  The unique identifier for the reservation.

* **ReservedCacheNodesOfferingId** *(string)* –

  The offering identifier.

* **CacheNodeType** *(string)* –

  The cache node type for the reserved cache nodes.

Valid node types are as follows:

- **General purpose**:
  - *Current generation*: `cache.t2.micro`, `cache.t2.small`, `cache.t2.medium`, `cache.m3.medium`, `cache.m3.large`, `cache.m3.xlarge`, `cache.m3.2xlarge`
  - *Previous generation*: `cache.t1.micro`, `cache.m1.small`, `cache.m1.medium`, `cache.m1.large`, `cache.m1.xlarge`
- **Compute optimized**: `cache.c1.xlarge`
- **Memory optimized**:
  - *Current generation*: `cache.r3.large`, `cache.r3.xlarge`, `cache.r3.2xlarge`, `cache.r3.4xlarge`, `cache.r3.8xlarge`
  - *Previous generation*: `cache.m2.xlarge`, `cache.m2.2xlarge`, `cache.m2.4xlarge`

**Notes:**

- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

* **StartTime** *(datetime)* –

  The time the reservation started.

* **Duration** *(integer)* –

  The duration of the reservation in seconds.

* **FixedPrice** *(float)* –

  The fixed price charged for this reserved cache node.

* **UsagePrice** *(float)* –

  The hourly price charged for this reserved cache node.

* **CacheNodeCount** *(integer)* –

  The number of cache nodes that have been reserved.

* **ProductDescription** *(string)* –

  The description of the reserved cache node.

* **OfferingType** *(string)* –

  The offering type of this reserved cache node.

* **State** *(string)* –

  The state of the reserved cache node.
RecurringCharges (list) –

The recurring price charged to run this reserved cache node.

· (dict) –

Contains the specific price and frequency of a recurring charges for a reserved cache node, or for a reserved cache node offering.

· RecurringChargeAmount (float) –

The monetary amount of the recurring charge.

· RecurringChargeFrequency (string) –

The frequency of the recurring charge.

reboot_cache_cluster (**kwargs)

The RebootCacheCluster action reboots some, or all, of the cache nodes within a provisioned cache cluster. This API will apply any modified cache parameter groups to the cache cluster. The reboot action takes place as soon as possible, and results in a momentary outage to the cache cluster. During the reboot, the cache cluster status is set to REBOOTING.

The reboot causes the contents of the cache (for each cache node being rebooted) to be lost.

When the reboot is complete, a cache cluster event is created.

Request Syntax

response = client.reboot_cache_cluster(
    CacheClusterId='string',
    CacheNodeIdsToReboot=[
        'string',
    ],
)

Parameters

· CacheClusterId (string) – [REQUIRED]

The cache cluster identifier. This parameter is stored as a lowercase string.

· CacheNodeIdsToReboot (list) – [REQUIRED]

A list of cache node IDs to reboot. A node ID is a numeric identifier (0001, 0002, etc.). To reboot an entire cache cluster, specify all of the cache node IDs.

Return type  dict

Returns

Response Structure

- (dict) –

Contains all of the attributes of a specific cache cluster.
-- CacheCluster (dict) --

Contains all of the attributes of a specific cache cluster.

* CacheClusterId (string) --

The user-supplied identifier of the cache cluster. This identifier is a unique key that identifies a cache cluster.

* ConfigurationEndpoint (dict) --

Represents the information required for client programs to connect to a cache node.

  · Address (string) --

    The DNS hostname of the cache node.

  · Port (integer) --

    The port number that the cache engine is listening on.

* ClientDownloadLandingPage (string) --

The URL of the web page where you can download the latest ElastiCache client library.

* CacheNodeType (string) --

The name of the compute and memory capacity node type for the cache cluster.

Valid node types are as follows:

  · General purpose: * Current generation: cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
  · Previous generation: cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge
  · Compute optimized: cache.c1.xlarge
  · Memory optimized * Current generation: cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
  · Previous generation: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

Notes:

  · All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
  · Redis backup/restore is not supported for t2 instances.
  · Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

* Engine (string) --

The name of the cache engine (memcached or redis) to be used for this cache cluster.

* EngineVersion (string) --

The version of the cache engine version that is used in this cache cluster.
* CacheClusterStatus (string) –
  The current state of this cache cluster, one of the following values: available, creating, deleted, deleting, incompatible-network, modifying, rebooting cache cluster nodes, restore-failed, or snapshooting.

* NumCacheNodes (integer) –
  The number of cache nodes in the cache cluster.
  For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.

* PreferredAvailabilityZone (string) –
  The name of the Availability Zone in which the cache cluster is located or “Multiple” if the cache nodes are located in different Availability Zones.

* CacheClusterCreateTime (datetime) –
  The date and time when the cache cluster was created.

* PreferredMaintenanceWindow (string) –
  Specifies the weekly time range during which maintenance on the cache cluster is performed. It is specified as a range in the format ddd:hh24:mi-ddd:hh24:mi (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for ddd are:
  - sun
  - mon
  - tue
  - wed
  - thu
  - fri
  - sat
  Example: sun:05:00-sun:09:00

* PendingModifiedValues (dict) –
  A group of settings that will be applied to the cache cluster in the future, or that are currently being applied.
  - NumCacheNodes (integer) –
    The new number of cache nodes for the cache cluster.
    For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.
  - CacheNodeIdsToRemove (list) –
    A list of cache node IDs that are being removed (or will be removed) from the cache cluster. A node ID is a numeric identifier (0001, 0002, etc.).
    - (string) –
    - EngineVersion (string) –
      The new cache engine version that the cache cluster will run.

* NotificationConfiguration (dict) –
  Describes a notification topic and its status. Notification topics are used for publishing ElastiCache events to subscribers using Amazon Simple Notification Service (SNS).
  - TopicArn (string) –
The Amazon Resource Name (ARN) that identifies the topic.

- **TopicStatus (string)** –

  The current state of the topic.

* **CacheSecurityGroups (list)** –

  A list of cache security group elements, composed of name and status sub-elements.

  - (dict) –

    Represents a cache cluster’s status within a particular cache security group.

    - **CacheSecurityGroupName (string)** –

      The name of the cache security group.

    - **Status (string)** –

      The membership status in the cache security group. The status changes when a cache security group is modified, or when the cache security groups assigned to a cache cluster are modified.

* **CacheParameterGroup (dict)** –

  The status of the cache parameter group.

  - **CacheParameterGroupName (string)** –

    The name of the cache parameter group.

  - **ParameterApplyStatus (string)** –

    The status of parameter updates.

  - **CacheNodeIdsToReboot (list)** –

    A list of the cache node IDs which need to be rebooted for parameter changes to be applied. A node ID is a numeric identifier (0001, 0002, etc.).

  - (string) –

* **CacheSubnetGroupName (string)** –

  The name of the cache subnet group associated with the cache cluster.

* **CacheNodes (list)** –

  A list of cache nodes that are members of the cache cluster.

  - (dict) –

    Represents an individual cache node within a cache cluster. Each cache node runs its own instance of the cluster’s protocol-compliant caching software - either Memcached or Redis.

    Valid node types are as follows:

    - **General purpose:** 
      - *Current generation:* cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
      - *Previous generation:* cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge
      - *Compute optimized:* cache.c1.xlarge
Memory optimized

Current generation:
cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge

Previous generation:
cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

Notes:

- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

- **CacheNodeId (string)** –
  
  The cache node identifier. A node ID is a numeric identifier (0001, 0002, etc.). The combination of cluster ID and node ID uniquely identifies every cache node used in a customer's AWS account.

- **CacheNodeStatus (string)** –
  
  The current state of this cache node.

- **CacheNodeCreateTime (datetime)** –
  
  The date and time when the cache node was created.

- **Endpoint (dict)** –
  
  The hostname for connecting to this cache node.

- **Address (string)** –
  
  The DNS hostname of the cache node.

- **Port (integer)** –
  
  The port number that the cache engine is listening on.

- **ParameterGroupStatus (string)** –
  
  The status of the parameter group applied to this cache node.

- **SourceCacheNodeId (string)** –
  
  The ID of the primary node to which this read replica node is synchronized. If this field is empty, then this node is not associated with a primary cache cluster.

- **CustomerAvailabilityZone (string)** –
  
  The Availability Zone where this node was created and now resides.

- **AutoMinorVersionUpgrade (boolean)** –
  
  This parameter is currently disabled.

- **SecurityGroups (list)** –
  
  A list of VPC Security Groups associated with the cache cluster.

  - (dict) –
    
    Represents a single cache security group and its status.

  - **SecurityGroupId (string)** –
The identifier of the cache security group.

- **Status** *(string)*

The status of the cache security group membership. The status changes whenever a cache security group is modified, or when the cache security groups assigned to a cache cluster are modified.

- **ReplicationGroupId** *(string)*

The replication group to which this cache cluster belongs. If this field is empty, the cache cluster is not associated with any replication group.

- **SnapshotRetentionLimit** *(integer)*

The number of days for which ElastiCache will retain automatic cache cluster snapshots before deleting them. For example, if you set `SnapshotRetentionLimit` to 5, then a snapshot that was taken today will be retained for 5 days before being deleted.

**Important** If the value of `SnapshotRetentionLimit` is set to zero (0), backups are turned off.

- **SnapshotWindow** *(string)*

The daily time range (in UTC) during which ElastiCache will begin taking a daily snapshot of your cache cluster.

Example: `05:00-09:00`

### remove_tags_from_resource(**kwargs)**

The `remove_tags_from_resource` action removes the tags identified by the `TagKeys` list from the named resource.

#### Request Syntax

```python
response = client.remove_tags_from_resource(
    ResourceName='string',
    TagKeys=[
        'string',
    ]
)
```

#### Parameters

- **ResourceName** *(string)* – [REQUIRED]

  The name of the ElastiCache resource from which you want the listed tags removed, for example `arn:aws:elasticache:us-west-2:0123456789:cluster:myCluster`.

- **TagKeys** *(list)* – [REQUIRED]

  A list of `TagKeys` identifying the tags you want removed from the named resource. For example, `TagKeys.member.1=Region` removes the cost allocation tag with the key name `Region` from the resource named by the `ResourceName` parameter.

- **TagKeys** *(string)* –

  **Return type** `dict`

  **Returns**

  **Response Syntax**
\{
   'TagList': [
      {
         'Key': 'string',
         'Value': 'string'
      },
      {
         'Key': 'string',
         'Value': 'string'
      }
   ]
\}

**Response Structure**

- (dict) – Represents the output from the `AddTagsToResource`, `ListTagsOnResource`, and `RemoveTagsFromResource` actions.
  - TagList (list) – A list of cost allocation tags as key-value pairs.
    * (dict) – A cost allocation Tag that can be added to an ElastiCache cluster or replication group. Tags are composed of a Key/Value pair. A tag with a null Value is permitted.
      - **Key (string)** – The key for the tag.
      - **Value (string)** – The tag’s value. May not be null.

**reset_cache_parameter_group (**kwargs)**

The `ResetCacheParameterGroup` action modifies the parameters of a cache parameter group to the engine or system default value. You can reset specific parameters by submitting a list of parameter names. To reset the entire cache parameter group, specify the `ResetAllParameters` and `CacheParameterGroupName` parameters.

**Request Syntax**

```python
response = client.reset_cache_parameter_group(
    CacheParameterGroupName='string',
    ResetAllParameters=True|False,
    ParameterNameValues=[
        {
            'ParameterName': 'string',
            'ParameterValue': 'string'
        },
        {
            'ParameterName': 'string',
            'ParameterValue': 'string'
        }
    ]
)
```

**Parameters**

- **CacheParameterGroupName (string) – [REQUIRED]**
  The name of the cache parameter group to reset.
- **ResetAllParameters (boolean) – [REQUIRED]**
  If true, all parameters in the cache parameter group will be reset to default values. If false, no such action occurs.
  Valid values: true | false
- **ParameterNameValues (list) – [REQUIRED]**
  An array of parameter names to be reset. If you are not resetting the entire cache parameter group, you must specify at least one parameter name.
Describes a name-value pair that is used to update the value of a parameter.

- **ParameterName** *(string)* –
  The name of the parameter.

- **ParameterValue** *(string)* –
  The value of the parameter.

**Return type**  dict

**Returns**

**Response Syntax**

```
{ 'CacheParameterGroupName': 'string'
}
```

**Response Structure**

- **(dict)** –
  Represents the output of one of the following actions:
  - `ModifyCacheParameterGroup`
  - `ResetCacheParameterGroup`

- **CacheParameterGroupName** *(string)* –
  The name of the cache parameter group.

---

**revoke_cache_security_group_ingress(**kwargs)**

The `revoke_cache_security_group_ingress` action revokes ingress from a cache security group. Use this action to disallow access from an Amazon EC2 security group that had been previously authorized.

**Request Syntax**

```python
response = client.revoke_cache_security_group_ingress(
    CacheSecurityGroupName='string',
    EC2SecurityGroupName='string',
    EC2SecurityGroupOwnerId='string'
)
```

**Parameters**

- **CacheSecurityGroupName** *(string)* – [REQUIRED]
  The name of the cache security group to revoke ingress from.

- **EC2SecurityGroupName** *(string)* – [REQUIRED]
  The name of the Amazon EC2 security group to revoke access from.

- **EC2SecurityGroupOwnerId** *(string)* – [REQUIRED]
  The AWS account number of the Amazon EC2 security group owner. Note that this is not the same thing as an AWS access key ID - you must provide a valid AWS account number for this parameter.

**Return type**  dict

**Returns**

**Response Syntax**

```python
{
    'CacheSecurityGroup': {
        'OwnerId': 'string',
    }
}
```
Response Structure

- (dict) – Represents the output of one of the following actions:
  - AuthorizeCacheSecurityGroupIngress
  - CreateCacheSecurityGroup
  - RevokeCacheSecurityGroupIngress

- CacheSecurityGroup (dict) – Represents the output of one of the following actions:
  - AuthorizeCacheSecurityGroupIngress
  - CreateCacheSecurityGroup
  - RevokeCacheSecurityGroupIngress

  - OwnerId (string) – The AWS account ID of the cache security group owner.
  - CacheSecurityGroupName (string) – The name of the cache security group.
  - Description (string) – The description of the cache security group.
  - EC2SecurityGroups (list) – A list of Amazon EC2 security groups that are associated with this cache security group.
    - (dict) – Provides ownership and status information for an Amazon EC2 security group.
      - Status (string) – The status of the Amazon EC2 security group.
      - EC2SecurityGroupName (string) – The name of the Amazon EC2 security group.
      - EC2SecurityGroupOwnerId (string) – The AWS account ID of the Amazon EC2 security group owner.

Paginators

The available paginators are:

- ElastiCache.Paginator.DescribeCacheClusters
class ElastiCache.Paginator.DescribeCacheClusters

Paginator = client.get_paginator('describe_cache_clusters')

paginate(**kwargs)

Creates an iterator that will paginate through responses from
ElastiCache.Client.describe_cache_clusters().

Request Syntax

response_iterator = Paginator.paginate(
    CacheClusterId='string',
    ShowCacheNodeInfo=True|False,
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

- **CacheClusterId (string)** – The user-supplied cluster identifier. If this parameter is specified, only information about that specific cache cluster is returned. This parameter isn’t case sensitive.
- **ShowCacheNodeInfo (boolean)** – An optional flag that can be included in the DescribeCacheCluster request to retrieve information about the individual cache nodes.
- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize (integer)** –
    The size of each page.
– **StartingToken** *(string)* –  
A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`  
**Returns**

**Response Syntax**

```json
{
    'CacheClusters': [
        {
            'CacheClusterId': 'string',
            'ConfigurationEndpoint': {
                'Address': 'string',
                'Port': 123
            },
            'ClientDownloadLandingPage': 'string',
            'CacheNodeType': 'string',
            'Engine': 'string',
            'EngineVersion': 'string',
            'CacheClusterStatus': 'string',
            'NumCacheNodes': 123,
            'PreferredAvailabilityZone': 'string',
            'CacheClusterCreateTime': datetime(2015, 1, 1),
            'PreferredMaintenanceWindow': 'string',
            'PendingModifiedValues': {
                'NumCacheNodes': 123,
                'CacheNodeIdsToRemove': [ 'string', ],
                'EngineVersion': 'string'
            },
            'NotificationConfiguration': {
                'TopicArn': 'string',
                'TopicStatus': 'string'
            },
            'CacheSecurityGroups': [
                {
                    'CacheSecurityGroupName': 'string',
                    'Status': 'string'
                },
            ],
            'CacheParameterGroup': {
                'CacheParameterGroupName': 'string',
                'ParameterApplyStatus': 'string',
                'CacheNodeIdsToReboot': [ 'string', ]
            },
            'CacheSubnetGroupName': 'string',
            'CacheNodes': [
                {
                    'CacheNodeId': 'string',
                    'CacheNodeStatus': 'string',
                    'CacheNodeCreateTime': datetime(2015, 1, 1),
                    'Endpoint': {
                        'Address': 'string',
                        'Port': 123
                    }
                }
            ]
        }
    ]
}
```
Response Structure

- (dict) – Represents the output of a DescribeCacheClusters action.
  
  - CacheClusters (list) – A list of cache clusters. Each item in the list contains detailed information about one cache cluster.
    
    * (dict) – Contains all of the attributes of a specific cache cluster.
      
      - CacheClusterId (string) – The user-supplied identifier of the cache cluster. This identifier is a unique key that identifies a cache cluster.
      
      - ConfigurationEndpoint (dict) – Represents the information required for client programs to connect to a cache node.
        
        - Address (string) – The DNS hostname of the cache node.
        
        - Port (integer) – The port number that the cache engine is listening on.
        
        - ClientDownloadLandingPage (string) – The URL of the web page where you can download the latest ElastiCache client library.
        
        - CacheNodeType (string) – The name of the compute and memory capacity node type for the cache cluster.

Valid node types are as follows:

- General purpose: * Current generation: cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
- Previous generation: cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge
- Current generation: cache.c1.xlarge
- Compute optimized: cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
- Previous generation: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

Notes:
- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

- **Engine** *(string)* –
  The name of the cache engine (memcached or redis) to be used for this cache cluster.

- **EngineVersion** *(string)* –
  The version of the cache engine version that is used in this cache cluster.

- **CacheClusterStatus** *(string)* –
  The current state of this cache cluster, one of the following values: available, creating, deleted, deleting, incompatible-network, modifying, rebooting cache cluster nodes, restore-failed, or snapshotting.

- **NumCacheNodes** *(integer)* –
  The number of cache nodes in the cache cluster.

  For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.

- **PreferredAvailabilityZone** *(string)* –
  The name of the Availability Zone in which the cache cluster is located or “Multiple” if the cache nodes are located in different Availability Zones.

- **CacheClusterCreateTime** *(datetime)* –
  The date and time when the cache cluster was created.

- **PreferredMaintenanceWindow** *(string)* –
  Specifies the weekly time range during which maintenance on the cache cluster is performed. It is specified as a range in the format ddd:hh24:mi-ddd:hh24:mi (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for ddd are:
  - sun
  - mon
  - tue
Example: sun:05:00-sun:09:00

- **PendingModifiedValues** *(dict)* —
  A group of settings that will be applied to the cache cluster in the future, or that are currently being applied.

- **NumCacheNodes** *(integer)* —
  The new number of cache nodes for the cache cluster.

For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.

- **CacheNodeIdsToRemove** *(list)* —
  A list of cache node IDs that are being removed (or will be removed) from the cache cluster. A node ID is a numeric identifier (0001, 0002, etc.).

- **EngineVersion** *(string)* —
  The new cache engine version that the cache cluster will run.

- **NotificationConfiguration** *(dict)* —
  Describes a notification topic and its status. Notification topics are used for publishing ElastiCache events to subscribers using Amazon Simple Notification Service (SNS).

- **TopicArn** *(string)* —
  The Amazon Resource Name (ARN) that identifies the topic.

- **TopicStatus** *(string)* —
  The current state of the topic.

- **CacheSecurityGroups** *(list)* —
  A list of cache security group elements, composed of name and status sub-elements.

- **CacheSecurityGroupName** *(string)* —
  The name of the cache security group.

- **Status** *(string)* —
  The membership status in the cache security group. The status changes when a cache security group is modified, or when the cache security groups assigned to a cache cluster are modified.

- **CacheParameterGroup** *(dict)* —
  The status of the cache parameter group.

- **CacheParameterGroupName** *(string)* —
  The name of the cache parameter group.

- **ParameterApplyStatus** *(string)* —
  The status of parameter updates.
**CacheNodeIdsToReboot (list)** –
A list of the cache node IDs which need to be rebooted for parameter changes to be applied. A node ID is a numeric identifier (0001, 0002, etc.).

**CacheSubnetGroupName (string)** –
The name of the cache subnet group associated with the cache cluster.

**CacheNodes (list)** –
A list of cache nodes that are members of the cache cluster.

**CacheNodeId (string)** –
The cache node identifier. A node ID is a numeric identifier (0001, 0002, etc.). The combination of cluster ID and node ID uniquely identifies every cache node used in a customer’s AWS account.

**CacheNodeStatus (string)** –
The current state of this cache node.

**CacheNodeCreate Time (datetime)** –
The date and time when the cache node was created.

**Notes:**
- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

**Valid node types are as follows:**
- **General purpose:**
  - *Current generation:* cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
  - *Previous generation:* cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge
- **Compute optimized:** cache.c1.xlarge
- **Memory optimized**
  - *Current generation:* cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
  - *Previous generation:* cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

- **Endpoint (dict)** –
The hostname for connecting to this cache node.

- **Address** *(string)* –

  The DNS hostname of the cache node.

- **Port** *(integer)* –

  The port number that the cache engine is listening on.

- **ParameterGroupStatus** *(string)* –

  The status of the parameter group applied to this cache node.

- **SourceCacheNodeId** *(string)* –

  The ID of the primary node to which this read replica node is synchronized. If this field is empty, then this node is not associated with a primary cache cluster.

- **CustomerAvailabilityZone** *(string)* –

  The Availability Zone where this node was created and now resides.

- **AutoMinorVersionUpgrade** *(boolean)* –

  This parameter is currently disabled.

- **SecurityGroups** *(list)* –

  A list of VPC Security Groups associated with the cache cluster.

  - *(dict)* –

    Represents a single cache security group and its status.

    - **SecurityGroupId** *(string)* –

      The identifier of the cache security group.

    - **Status** *(string)* –

      The status of the cache security group membership. The status changes whenever a cache security group is modified, or when the cache security groups assigned to a cache cluster are modified.

    - **ReplicationGroupId** *(string)* –

      The replication group to which this cache cluster belongs. If this field is empty, the cache cluster is not associated with any replication group.

    - **SnapshotRetentionLimit** *(integer)* –

      The number of days for which ElastiCache will retain automatic cache cluster snapshots before deleting them. For example, if you set `SnapshotRetentionLimit` to 5, then a snapshot that was taken today will be retained for 5 days before being deleted.

      **Important** If the value of `SnapshotRetentionLimit` is set to zero (0), backups are turned off.

    - **SnapshotWindow** *(string)* –

      The daily time range (in UTC) during which ElastiCache will begin taking a daily snapshot of your cache cluster.

      Example: 05:00–09:00

    - **NextToken** *(string)* –

      A token to resume pagination.
class ElastiCache.Paginator.DescribeCacheEngineVersions

paginator = client.get_paginator('describe_cache_engine_versions')

paginate(**kwargs)
Creates an iterator that will paginate through responses from
ElastiCache.Client.describe_cache_engine_versions().

Request Syntax

response_iterator = paginator.paginate(
    Engine='string',
    EngineVersion='string',
    CacheParameterGroupFamily='string',
    DefaultOnly=True|False,
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

• **Engine** *(string)* – The cache engine to return. Valid values: memcached | redis
• **EngineVersion** *(string)* – The cache engine version to return.
  Example: 1.4.14
• **CacheParameterGroupFamily** *(string)* – The name of a specific cache parameter group family to return details for.
  Constraints:
  – Must be 1 to 255 alphanumeric characters
  – First character must be a letter
  – Cannot end with a hyphen or contain two consecutive hyphens
• **DefaultOnly** *(boolean)* – If true, specifies that only the default version of the specified engine or engine and major version combination is to be returned.
• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  – **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  – **PageSize** *(integer)* –
    The size of each page.
  – **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  dict
Returns

Response Syntax
```python
{
    'CacheEngineVersions': [
        {
            'Engine': 'string',
            'EngineVersion': 'string',
            'CacheParameterGroupFamily': 'string',
            'CacheEngineDescription': 'string',
            'CacheEngineVersionDescription': 'string'
        },
    ],
    'NextToken': 'string'
}
```

**Response Structure**

- *(dict)* – Represents the output of a DescribeCacheEngineVersions action.
  - **CacheEngineVersions (list)** – A list of cache engine version details. Each element in the list contains detailed information about one cache engine version.
    - *(dict)* – Provides all of the details about a particular cache engine version.
      - **Engine (string)** – The name of the cache engine.
      - **EngineVersion (string)** – The version number of the cache engine.
      - **CacheParameterGroupFamily (string)** – The name of the cache parameter group family associated with this cache engine.
      - **CacheEngineDescription (string)** – The description of the cache engine.
      - **CacheEngineVersionDescription (string)** – The description of the cache engine version.
  - **NextToken (string)** – A token to resume pagination.

class ElastiCache.Paginator.DescribeCacheParameterGroups

```python
paginator = client.get_paginator('describe_cache_parameter_groups')
paginate(**kwargs)
```

**Request Syntax**

```python
response_iterator = paginator.paginate(
    CacheParameterGroupName='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
    })
```

2010 Chapter 3. API Reference
Parameters

- **CacheParameterGroupName** *(string)* – The name of a specific cache parameter group to return details for.
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –
    The size of each page.
  - **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the NextToken from a previous response.

Return type  **dict**

Returns

Response Syntax

```python
{
  'CacheParameterGroups': [
    {
      'CacheParameterGroupName': 'string',
      'CacheParameterGroupFamily': 'string',
      'Description': 'string'
    },
  ],
  'NextToken': 'string'
}
```

Response Structure

- *(dict)* – Represents the output of a DescribeCacheParameterGroups action.
  - **CacheParameterGroups** *(list)* –
    A list of cache parameter groups. Each element in the list contains detailed information about one cache parameter group.
      - *(dict)* – Represents the output of a CreateCacheParameterGroup action.
        - **CacheParameterGroupName** *(string)* –
          The name of the cache parameter group.
        - **CacheParameterGroupFamily** *(string)* –
          The name of the cache parameter group family that this cache parameter group is compatible with.
        - **Description** *(string)* –
          The description for this cache parameter group.
- **NextToken (string)** –
  A token to resume pagination.

```python
class ElastiCache.Paginator.DescribeCacheParameters

paginator = client.get_paginator('describe_cache_parameters')
paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `ElastiCache.Client.describe_cache_parameters()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    CacheParameterGroupName='string',
    Source='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **CacheParameterGroupName (string)** – [REQUIRED]
  The name of a specific cache parameter group to return details for.

- **Source (string)** – The parameter types to return.
  Valid values: user | system | engine-default

- **PaginationConfig (dict)** – A dictionary that provides parameters to control pagination.
  - **MaxItems (integer)** –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  - **PageSize (integer)** –
    The size of each page.
  - **StartingToken (string)** –
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type**  dict

**Returns**

**Response Syntax**

```python
{}
'Parameters': [
    {}
    'ParameterName': 'string',
    'ParameterValue': 'string',
    'Description': 'string',
    'Source': 'string',
    'DataType': 'string',
    'AllowedValues': 'string','
```
'IsModifiable': True|False,
'MinimumEngineVersion': 'string'
},

'CacheNodeTypeSpecificParameters': [
  {
    'ParameterName': 'string',
    'Description': 'string',
    'Source': 'string',
    'DataType': 'string',
    'AllowedValues': 'string',
    'IsModifiable': True|False,
    'MinimumEngineVersion': 'string',
    'CacheNodeTypeSpecificValues': [
      {
        'CacheNodeType': 'string',
        'Value': 'string'
      }
    ]
  },
],

'NextToken': 'string'

Response Structure
• (dict) –

Represents the output of a DescribeCacheParameters action.
– Parameters (list) –

A list of Parameter instances.
  • (dict) –

  Describes an individual setting that controls some aspect of Elasti-
Cache behavior.
    • ParameterName (string) –
      The name of the parameter.
    • ParameterValue (string) –
      The value of the parameter.
    • Description (string) –
      A description of the parameter.
    • Source (string) –
      The source of the parameter.
    • DataType (string) –
      The valid data type for the parameter.
    • AllowedValues (string) –
      The valid range of values for the parameter.
    • IsModifiable (boolean) –
      Indicates whether (true) or not (false) the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.
    • MinimumEngineVersion (string) –
The earliest cache engine version to which the parameter can apply.

- **CacheNodeTypeSpecificParameters** *(list)* –

  A list of parameters specific to a particular cache node type. Each element in the list contains detailed information about one parameter.

  * *(dict)* –

    A parameter that has a different value for each cache node type it is applied to. For example, in a Redis cache cluster, a `cache.m1.large` cache node type would have a larger `maxmemory` value than a `cache.m1.small` type.

    - **ParameterName** *(string)* –

      The name of the parameter.

    - **Description** *(string)* –

      A description of the parameter.

    - **Source** *(string)* –

      The source of the parameter value.

    - **DataType** *(string)* –

      The valid data type for the parameter.

    - **AllowedValues** *(string)* –

      The valid range of values for the parameter.

    - **IsModifiable** *(boolean)* –

      Indicates whether *(true)* or not *(false)* the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.

    - **MinimumEngineVersion** *(string)* –

      The earliest cache engine version to which the parameter can apply.

- **CacheNodeTypeSpecificValues** *(list)* –

  A list of cache node types and their corresponding values for this parameter.

  * *(dict)* –

    A value that applies only to a certain cache node type.

    - **CacheNodeType** *(string)* –

      The cache node type for which this value applies.

    - **Value** *(string)* –

      The value for the cache node type.

- **NextToken** *(string)* –

  A token to resume pagination.

```python
class ElastiCache.Paginator.DescribeCacheSecurityGroups

paginator = client.get_paginator('describe_cache_security_groups')

paginate(**kwargs)

Creates an iterator that will paginate through responses from
ElastiCache.Client.describe_cache_security_groups().
```
Request Syntax

```python
response_iterator = paginator.paginate(
    CacheSecurityGroupName='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **CacheSecurityGroupName** *(string)* – The name of the cache security group to return details for.
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* – The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* – The size of each page.
  - **StartingToken** *(string)* – A token to specify where to start paginating. This is the NextToken from a previous response.

Return type **dict**

Returns

Response Syntax

```json
{
    'CacheSecurityGroups': [
        {
            'OwnerId': 'string',
            'CacheSecurityGroupName': 'string',
            'Description': 'string',
            'EC2SecurityGroups': [
                {
                    'Status': 'string',
                    'EC2SecurityGroupName': 'string',
                    'EC2SecurityGroupOwnerId': 'string'
                }
            ],
            'NextToken': 'string'
        }
    ]
}
```

Response Structure

- **(dict)** – Represents the output of a DescribeCacheSecurityGroups action.
  - **CacheSecurityGroups** *(list)* – A list of cache security groups. Each element in the list contains detailed information about one group.
* (dict) –

Represents the output of one of the following actions:

- `AuthorizeCacheSecurityGroupIngress`
- `CreateCacheSecurityGroup`
- `RevokeCacheSecurityGroupIngress`

- **OwnerId** *(string)* –

  The AWS account ID of the cache security group owner.

- **CacheSecurityGroupName** *(string)* –

  The name of the cache security group.

- **Description** *(string)* –

  The description of the cache security group.

- **EC2SecurityGroups** *(list)* –

  A list of Amazon EC2 security groups that are associated with
  this cache security group.

  (dict) –

  Provides ownership and status information for an Amazon
  EC2 security group.

  - **Status** *(string)* –

    The status of the Amazon EC2 security group.

  - **EC2SecurityGroupName** *(string)* –

    The name of the Amazon EC2 security group.

  - **EC2SecurityGroupOwnerId** *(string)* –

    The AWS account ID of the Amazon EC2 security group
    owner.

- **NextToken** *(string)* –

  A token to resume pagination.

```python
class ElastiCache.Paginator.DescribeCacheSubnetGroups

paginator = client.get_paginator('describe_cache_subnet_groups')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from
ElastiCache.Client.describe_cache_subnet_groups().

**Request Syntax**

```python
response_iterator = paginator.paginate(
    CacheSubnetGroupName='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **CacheSubnetGroupName** *(string)* – The name of the cache subnet group to
  return details for.
• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  – **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  
  – **PageSize** *(integer)* –
    
    The size of each page.
  
  – **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type**  
`dict`

**Returns**

**Response Syntax**

```python
{
    'CacheSubnetGroups': [
        {
            'CacheSubnetGroupName': 'string',
            'CacheSubnetGroupDescription': 'string',
            'VpcId': 'string',
            'Subnets': [
                {
                    'SubnetIdentifier': 'string',
                    'SubnetAvailabilityZone': {
                        'Name': 'string'
                    }
                },
                {
                }
            ],
            'NextToken': 'string'
        }
    ]
}
```

**Response Structure**

• *(dict)* –

    Represents the output of a `DescribeCacheSubnetGroups` action.

  – **CacheSubnetGroups** *(list)* –

    A list of cache subnet groups. Each element in the list contains detailed information about one group.

    • *(dict)* –

      Represents the output of one of the following actions:

      • `CreateCacheSubnetGroup`
      • `ModifyCacheSubnetGroup`

      • **CacheSubnetGroupName** *(string)* –

        The name of the cache subnet group.

      • **CacheSubnetGroupDescription** *(string)* –

        The description of the cache subnet group.

      • **VpcId** *(string)* –
The Amazon Virtual Private Cloud identifier (VPC ID) of the cache subnet group.

- **Subnets** *(list)* –
  A list of subnets associated with the cache subnet group.

- **(dict)** –
  Represents the subnet associated with a cache cluster. This parameter refers to subnets defined in Amazon Virtual Private Cloud (Amazon VPC) and used with ElastiCache.

- **SubnetIdentifier** *(string)* –
  The unique identifier for the subnet.

- **SubnetAvailabilityZone** *(dict)* –
  The Availability Zone associated with the subnet.

- **Name** *(string)* –
  The name of the Availability Zone.

- **NextToken** *(string)* –
  A token to resume pagination.

class ElastiCache.Paginator.DescribeEngineDefaultParameters

```python
paginator = client.get_paginator('describe_engine_default_parameters')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `ElastiCache.Client.describe_engine_default_parameters()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    CacheParameterGroupFamily='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **CacheParameterGroupFamily** *(string)* – [REQUIRED]
  The name of the cache parameter group family. Valid values are: `memcached1.4` | `redis2.6` | `redis2.8`

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* –
    The size of each page.
- **StartingToken** *(string)*

A token to specify where to start paginating. This is the `NextToken` from a previous response.

**Return type** `dict`

**Returns**

**Response Syntax**

```python
{
    'EngineDefaults': {
        'CacheParameterGroupFamily': 'string',
        'Marker': 'string',
        'Parameters': [
            {
                'ParameterName': 'string',
                'ParameterValue': 'string',
                'Description': 'string',
                'Source': 'string',
                'DataType': 'string',
                'AllowedValues': 'string',
                'IsModifiable': True|False,
                'MinimumEngineVersion': 'string'
            },
        ],
        'CacheNodeTypeSpecificParameters': [
            {
                'ParameterName': 'string',
                'Description': 'string',
                'Source': 'string',
                'DataType': 'string',
                'AllowedValues': 'string',
                'IsModifiable': True|False,
                'MinimumEngineVersion': 'string',
                'CacheNodeTypeSpecificValues': [
                    {
                        'CacheNodeType': 'string',
                        'Value': 'string'
                    }]
            },
        ],
        'NextToken': 'string'
    }
}
```

**Response Structure**

- *(dict)* – Represents the output of a `DescribeEngineDefaultParameters` action.
  
  **EngineDefaults** *(dict)* – Represents the output of a `DescribeEngineDefaultParameters` action.

  - **CacheParameterGroupFamily** *(string)* – Specifies the name of the cache parameter group family to which the engine default parameters apply.
  
  - **Marker** *(string)* – Provides an identifier to allow retrieval of paginated results.
* **Parameters** *(list)*

  Contains a list of engine default parameters.
  
  - *(dict)*
    
    Describes an individual setting that controls some aspect of ElastiCache behavior.
    
    - **ParameterName** *(string)*
      
      The name of the parameter.
    
    - **ParameterValue** *(string)*
      
      The value of the parameter.
    
    - **Description** *(string)*
      
      A description of the parameter.
    
    - **Source** *(string)*
      
      The source of the parameter.
    
    - **DataType** *(string)*
      
      The valid data type for the parameter.
    
    - **AllowedValues** *(string)*
      
      The valid range of values for the parameter.
    
    - **IsModifiable** *(boolean)*
      
      Indicates whether *(true)* or not *(false)* the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.
    
    - **MinimumEngineVersion** *(string)*
      
      The earliest cache engine version to which the parameter can apply.

* **CacheNodeTypeSpecificParameters** *(list)*

  A list of parameters specific to a particular cache node type. Each element in the list contains detailed information about one parameter.
  
  - *(dict)*
    
    A parameter that has a different value for each cache node type it is applied to. For example, in a Redis cache cluster, a `cache.m1.large` cache node type would have a larger `maxmemory` value than a `cache.m1.small` type.
    
    - **ParameterName** *(string)*
      
      The name of the parameter.
    
    - **Description** *(string)*
      
      A description of the parameter.
    
    - **Source** *(string)*
      
      The source of the parameter value.
    
    - **DataType** *(string)*
      
      The valid data type for the parameter.
    
    - **AllowedValues** *(string)*
      
      The valid range of values for the parameter.
    
    - **IsModifiable** *(boolean)*
Indicates whether (true) or not (false) the parameter can be modified. Some parameters have security or operational implications that prevent them from being changed.

- **MinimumEngineVersion (string)** –
  The earliest cache engine version to which the parameter can apply.
- **CacheNodeTypeSpecificValues (list)** –
  A list of cache node types and their corresponding values for this parameter.
  - **(dict)** –
    A value that applies only to a certain cache node type.
  - **CacheNodeType (string)** –
    The cache node type for which this value applies.
  - **Value (string)** –
    The value for the cache node type.

- **NextToken (string)** –
  A token to resume pagination.

```python
class ElastiCache.Paginator.DescribeEvents

paginator = client.get_paginator('describe_events')

paginate(**kwargs)
```

Creates an iterator that will paginate through responses from `ElastiCache.Client.describe_events()`.

**Request Syntax**

```python
response_iterator = paginator.paginate(
    SourceIdentifier='string',
    SourceType='cache-cluster'|'cache-parameter-group'|'cache-security-group'|'cache-subnet-group',
    StartTime=datetime(2015, 1, 1),
    EndTime=datetime(2015, 1, 1),
    Duration=123,
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **SourceIdentifier (string)** – The identifier of the event source for which events will be returned. If not specified, then all sources are included in the response.
- **SourceType (string)** – The event source to retrieve events for. If no value is specified, all events are returned.

  Valid values are: cache-cluster | cache-parameter-group | cache-security-group | cache-subnet-group
- **StartTime (datetime)** – The beginning of the time interval to retrieve events for, specified in ISO 8601 format.
- **EndTime (datetime)** – The end of the time interval for which to retrieve events, specified in ISO 8601 format.
• **Duration** (*integer*) – The number of minutes’ worth of events to retrieve.

• **PaginationConfig** (*dict*) – A dictionary that provides parameters to control pagination.
  
  – **MaxItems** (*integer*) –
  
  The total number of items to return. If the total number of items available is more than the value specified in max-items then a `NextToken` will be provided in the output that you can use to resume pagination.
  
  – **PageSize** (*integer*) –
  
  The size of each page.
  
  – **StartingToken** (*string*) –
  
  A token to specify where to start paginating. This is the `NextToken` from a previous response.

Return type: `dict`

Returns

Response Syntax

```python
{
    'Events': [
        {
            'SourceIdentifier': 'string',
            'SourceType': 'cache-cluster'|'cache-parameter-group'|'cache-security-group'|'cache-subnet-group',
            'Message': 'string',
            'Date': datetime(2015, 1, 1)
        },
    ],
    'NextToken': 'string'
}
```

Response Structure

• (*dict*) –

  Represents the output of a `DescribeEvents` action.

  – **Events** (*list*) –

    A list of events. Each element in the list contains detailed information about one event.

    • (*dict*) –

      Represents a single occurrence of something interesting within the system. Some examples of events are creating a cache cluster, adding or removing a cache node, or rebooting a node.

      • **SourceIdentifier** (*string*) –

        The identifier for the source of the event. For example, if the event occurred at the cache cluster level, the identifier would be the name of the cache cluster.

      • **SourceType** (*string*) –

        Specifies the origin of this event - a cache cluster, a parameter group, a security group, etc.

      • **Message** (*string*) –

        The text of the event.

      • **Date** (*datetime*) –

        The date and time when the event occurred.
– NextToken (string) –
A token to resume pagination.

class ElastiCache.Paginator.DescribeReplicationGroups

paginator = client.get_paginator('describe_replication_groups')

paginate(**kwargs)
Creates an iterator that will paginate through responses from
ElastiCache.Client.describe_replication_groups().

Request Syntax

response_iterator = paginator.paginate(
    ReplicationGroupId='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)

Parameters

• ReplicationGroupId (string) – The identifier for the replication group to be
described. This parameter is not case sensitive.

If you do not specify this parameter, information about all replication groups is
returned.

• PaginationConfig (dict) – A dictionary that provides parameters to control pag-
ination.
  – MaxItems (integer) –
    The total number of items to return. If the total number of items available
    is more than the value specified in max-items then a NextToken will be
    provided in the output that you can use to resume pagination.
  – PageSize (integer) –
    The size of each page.
  – StartingToken (string) –
    A token to specify where to start paginating. This is the NextToken
    from a previous response.

Return type  dict

Returns

Response Syntax

{
    'ReplicationGroups': [
        {
            'ReplicationGroupId': 'string',
            'Description': 'string',
            'Status': 'string',
            'PendingModifiedValues': {
                'PrimaryClusterId': 'string',
                'AutomaticFailoverStatus': 'enabled'|'disabled'
            }
        }
    ]
}
'MemberClusters': [
    'string',
],
'NodeGroups': [
    {
        'NodeGroupId': 'string',
        'Status': 'string',
        'PrimaryEndpoint': {
            'Address': 'string',
            'Port': 123
        },
        'NodeGroupMembers': [
            {
                'CacheClusterId': 'string',
                'CacheNodeId': 'string',
                'ReadEndpoint': {
                    'Address': 'string',
                    'Port': 123
                },
                'PreferredAvailabilityZone': 'string',
                'CurrentRole': 'string'
            }
        ],
    },
    'SnapshottingClusterId': 'string',
    'AutomaticFailover': 'enabled'|'disabled'|'enabling'|'disabling'
],
'NextToken': 'string'
}

Response Structure
- (dict) –
  Represents the output of a `DescribeReplicationGroups` action.

  - ReplicationGroups (list) –
    A list of replication groups. Each item in the list contains detailed information about one replication group.
    * (dict) –
      Contains all of the attributes of a specific replication group.
      - ReplicationGroupId (string) –
        The identifier for the replication group.
      - Description (string) –
        The description of the replication group.
      - Status (string) –
        The current state of this replication group - creating, available, etc.
      - PendingModifiedValues (dict) –
        A group of settings to be applied to the replication group, either immediately or during the next maintenance window.
      - PrimaryClusterId (string) –
        The primary cluster ID which will be applied immediately.
(if --apply-immediately was specified), or during the next maintenance window.

- **AutomaticFailoverStatus (string)**

  Indicates the status of Multi-AZ for this replication group.

---

**Note:** ElastiCache Multi-AZ replication groups are not supported on:

- Redis versions earlier than 2.8.6.
- T1 and T2 cache node types.

- **MemberClusters (list)**

  The names of all the cache clusters that are part of this replication group.

  - **(string)**

- **NodeGroups (list)**

  A single element list with information about the nodes in the replication group.

  - **(dict)**

    Represents a collection of cache nodes in a replication group.

- **NodeGroupId (string)**

  The identifier for the node group. A replication group contains only one node group; therefore, the node group ID is 0001.

- **Status (string)**

  The current state of this replication group - creating, available, etc.

- **PrimaryEndpoint (dict)**

  Represents the information required for client programs to connect to a cache node.

  - **Address (string)**

    The DNS hostname of the cache node.

  - **Port (integer)**

    The port number that the cache engine is listening on.

- **NodeGroupMembers (list)**

  A list containing information about individual nodes within the node group.

  - **(dict)**

    Represents a single node within a node group.

- **CacheClusterId (string)**

  The ID of the cache cluster to which the node belongs.

- **CacheNodeId (string)**

  The ID of the node within its cache cluster. A node ID is a numeric identifier (0001, 0002, etc.).

- **ReadEndpoint (dict)**

  Represents the information required for client programs to connect to a cache node.

  - **Address (string)**

---

3.1. Services
The DNS hostname of the cache node.

- **Port (integer)** –

  The port number that the cache engine is listening on.

- **PreferredAvailabilityZone (string)** –

  The name of the Availability Zone in which the node is located.

- **CurrentRole (string)** –

  The role that is currently assigned to the node - primary or replica.

- **SnapshottingClusterId (string)** –

  The cache cluster ID that is used as the daily snapshot source for the replication group.

- **AutomaticFailover (string)** –

  Indicates the status of Multi-AZ for this replication group.

---

**Note:** ElastiCache Multi-AZ replication groups are not supported on:

- Redis versions earlier than 2.8.6.
- T1 and T2 cache node types.

- **NextToken (string)** –

  A token to resume pagination.

```python
class ElastiCache.Paginator.DescribeReservedCacheNodes

paginator = client.get_paginator('describe_reserved_cache_nodes')

paginate(**kwargs)

Creates an iterator that will paginate through responses from
ElastiCache.Client.describe_reserved_cache_nodes().

Request Syntax

response_iterator = paginator.paginate(
    ReservedCacheNodeId='string',
    ReservedCacheNodesOfferingId='string',
    CacheNodeType='string',
    Duration='string',
    ProductDescription='string',
    OfferingType='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

**Parameters**

- **ReservedCacheNodeId (string)** – The reserved cache node identifier filter value. Use this parameter to show only the reservation that matches the specified reservation ID.
• **ReservedCacheNodesOfferingId** *(string)* – The offering identifier filter value. Use this parameter to show only purchased reservations matching the specified offering identifier.

• **CacheNodeType** *(string)* – The cache node type filter value. Use this parameter to show only those reservations matching the specified cache node type.

Valid node types are as follows:

- General purpose: * Current generation: cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m1.large, cache.m1.xlarge, cache.m3.2xlarge
- Previous generation: cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge
- Compute optimized: cache.cl.xlarge
- Memory optimized * Current generation: cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
- Previous generation: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

**Notes:**

- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

• **Duration** *(string)* – The duration filter value, specified in years or seconds. Use this parameter to show only reservations for this duration.

Valid Values: 1 | 3 | 31536000 | 94608000

• **ProductDescription** *(string)* – The product description filter value. Use this parameter to show only those reservations matching the specified product description.

• **OfferingType** *(string)* – The offering type filter value. Use this parameter to show only the available offerings matching the specified offering type.

Valid values: "Light Utilization"|"Medium Utilization"|"Heavy Utilization"

• **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.

  - **MaxItems** *(integer)* –
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.

  - **PageSize** *(integer)* –
    The size of each page.

  - **StartingToken** *(string)* –
    A token to specify where to start paginating. This is the NextToken from a previous response.

**Return type** dict

**Returns**

**Response Syntax**
Response Structure

* (dict) –

Represents the output of a `DescribeReservedCacheNodes` action.

* ReservedCacheNodes (list) –

A list of reserved cache nodes. Each element in the list contains detailed information about one node.

* (dict) –

Represents the output of a `PurchaseReservedCacheNodesOffering` action.

* ReservedCacheNodeId (string) –

The unique identifier for the reservation.

* ReservedCacheNodesOfferingId (string) –

The offering identifier.

* CacheNodeType (string) –

The cache node type for the reserved cache nodes.

Valid node types are as follows:

* General purpose: * Current generation: cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge

* Previous generation: cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge

* Compute optimized: cache.c1.xlarge

* Memory optimized * Current generation: cache.r3.large, cache.r3.xlarge,
Notes:

- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

- **StartTime** (`datetime`)
  
The time the reservation started.

- **Duration** (`integer`)
  
The duration of the reservation in seconds.

- **FixedPrice** (`float`)
  
The fixed price charged for this reserved cache node.

- **UsagePrice** (`float`)
  
The hourly price charged for this reserved cache node.

- **CacheNodeCount** (`integer`)
  
The number of cache nodes that have been reserved.

- **ProductDescription** (`string`)
  
The description of the reserved cache node.

- **OfferingType** (`string`)
  
The offering type of this reserved cache node.

- **State** (`string`)
  
The state of the reserved cache node.

- **RecurringCharges** (`list`)
  
The recurring price charged to run this reserved cache node.

- **RecurringChargeAmount** (`float`)
  
The monetary amount of the recurring charge.

- **RecurringChargeFrequency** (`string`)
  
The frequency of the recurring charge.

- **NextToken** (`string`)
  
A token to resume pagination.

class ElastiCachePaginator.DescribeReservedCacheNodesOfferings

    paginator = client.get_paginator('describe_reserved_cache_nodes_offerings')
paginate(**kwargs)

Creates an iterator that will paginate through responses from
ElastiCache.Client.describe_reserved_cache_nodes_offerings().

Request Syntax

```python
response_iterator = paginator.paginate(
    ReservedCacheNodesOfferingId='string',
    CacheNodeType='string',
    Duration='string',
    ProductDescription='string',
    OfferingType='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **ReservedCacheNodesOfferingId** *(string)* – The offering identifier filter value. Use this parameter to show only the available offering that matches the specified reservation identifier.

  Example: 438012d3-4052-4cc7-b2e3-8d3372e0e706

- **CacheNodeType** *(string)* – The cache node type filter value. Use this parameter to show only the available offerings matching the specified cache node type.

  Valid node types are as follows:
  
  - General purpose: * Current generation: cache.t2.micro , cache.t2.small , cache.t2.medium , cache.m3.medium , cache.m3.large , cache.m3.xlarge , cache.m3.2xlarge
  - Previous generation: cache.t1.micro , cache.m1.small , cache.m1.medium , cache.m1.large , cache.m1.xlarge
  - Compute optimized: cache.c1.xlarge
  - Memory optimized * Current generation: cache.r3.large , cache.r3.xlarge , cache.r3.2xlarge , cache.r3.4xlarge , cache.r3.8xlarge
  - Previous generation: cache.m2.xlarge , cache.m2.2xlarge , cache.m2.4xlarge

- **Duration** *(string)* – Duration filter value, specified in years or seconds. Use this parameter to show only reservations for a given duration.

  Valid Values: 1 | 3 | 31536000 | 94608000

- **ProductDescription** *(string)* – The product description filter value. Use this parameter to show only the available offerings matching the specified product description.

- **OfferingType** *(string)* – The offering type filter value. Use this parameter to show only the available offerings matching the specified offering type.

  Notes:
  
  - All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
  - Redis backup/restore is not supported for t2 instances.
  - Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon Elasticache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

- **Duration** *(string)* – Duration filter value, specified in years or seconds. Use this parameter to show only reservations for a given duration.

  Valid Values: 1 | 3 | 31536000 | 94608000

- **ProductDescription** *(string)* – The product description filter value. Use this parameter to show only the available offerings matching the specified product description.

- **OfferingType** *(string)* – The offering type filter value. Use this parameter to show only the available offerings matching the specified offering type.
Valid Values: "Light Utilization" | "Medium Utilization" | "Heavy Utilization"

- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  
  - **MaxItems** *(integer)* –
    
    The total number of items to return. If the total number of items available is more than the value specified in max-items then a **NextToken** will be provided in the output that you can use to resume pagination.
  
  - **PageSize** *(integer)* –
    
    The size of each page.
  
  - **StartingToken** *(string)* –
    
    A token to specify where to start paginating. This is the **NextToken** from a previous response.

Return type  *dict*

Returns

**Response Syntax**

```python
{
    'ReservedCacheNodesOfferings': [
        {
            'ReservedCacheNodesOfferingId': 'string',
            'CacheNodeType': 'string',
            'Duration': 123,
            'FixedPrice': 123.0,
            'UsagePrice': 123.0,
            'ProductDescription': 'string',
            'OfferingType': 'string',
            'RecurringCharges': [
                {
                    'RecurringChargeAmount': 123.0,
                    'RecurringChargeFrequency': 'string'
                }
            ],
            'RecurringChargeFrequency': 'string',
            'NextToken': 'string'
        }
    ]
}
```

**Response Structure**

- *(dict)* –
  
  Represents the output of a **DescribeReservedCacheNodesOfferings** action.
  
  - **ReservedCacheNodesOfferings** *(list)* –
    
    A list of reserved cache node offerings. Each element in the list contains detailed information about one offering.
    
    - *(dict)* –
      
      Describes all of the attributes of a reserved cache node offering.
      
      - **ReservedCacheNodesOfferingId** *(string)* –
        
        A unique identifier for the reserved cache node offering.
      
      - **CacheNodeType** *(string)* –
        
        The cache node type for the reserved cache node.

Valid node types are as follows:
· General purpose: * Current generation: cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
  · Previous generation: cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large,cache.m1.xlarge
· Compute optimized: cache.c1.xlarge
· Memory optimized * Current generation: cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
  · Previous generation: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

Notes:
· All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
· Redis backup/restore is not supported for t2 instances.
· Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

· Duration (integer) – The duration of the offering, in seconds.
· FixedPrice (float) – The fixed price charged for this offering.
· UsagePrice (float) – The hourly price charged for this offering.
· ProductDescription (string) – The cache engine used by the offering.
· OfferingType (string) – The offering type.
· RecurringCharges (list) – The recurring price charged to run this reserved cache node.
· (dict) – Contains the specific price and frequency of a recurring charges for a reserved cache node, or for a reserved cache node offering.
· RecurringChargeAmount (float) – The monetary amount of the recurring charge.
· RecurringChargeFrequency (string) – The frequency of the recurring charge.

– NextToken (string) – A token to resume pagination.

class ElastiCache.Paginator.DescribeSnapshots
paginator = client.get_paginator('describe_snapshots')

paginate(**kwargs)

Creates an iterator that will paginate through responses from ElastiCache.Client.describe_snapshots().

Request Syntax

```
response_iterator = paginator.paginate(
    CacheClusterId='string',
    SnapshotName='string',
    SnapshotSource='string',
    PaginationConfig={
        'MaxItems': 123,
        'PageSize': 123,
        'StartingToken': 'string'
    }
)
```

Parameters

- **CacheClusterId** *(string)* – A user-supplied cluster identifier. If this parameter is specified, only snapshots associated with that specific cache cluster will be described.
- **SnapshotName** *(string)* – A user-supplied name of the snapshot. If this parameter is specified, only this snapshot will be described.
- **SnapshotSource** *(string)* – If set to *system*, the output shows snapshots that were automatically created by ElastiCache. If set to *user* the output shows snapshots that were manually created. If omitted, the output shows both automatically and manually created snapshots.
- **PaginationConfig** *(dict)* – A dictionary that provides parameters to control pagination.
  - **MaxItems** *(integer)* – The total number of items to return. If the total number of items available is more than the value specified in max-items then a NextToken will be provided in the output that you can use to resume pagination.
  - **PageSize** *(integer)* – The size of each page.
  - **StartingToken** *(string)* – A token to specify where to start paginating. This is the NextToken from a previous response.

Return type **dict**

Response Syntax

```
{
    'Snapshots': [
        {
            'SnapshotName': 'string',
            'CacheClusterId': 'string',
            'SnapshotStatus': 'string',
            'SnapshotSource': 'string',
            'CacheNodeType': 'string',
            'Engine': 'string',
        }
    ]
}
```
'EngineVersion': 'string',
'NumCacheNodes': 123,
'PreferredAvailabilityZone': 'string',
'CacheClusterCreateTime': datetime(2015, 1, 1),
'PreferredMaintenanceWindow': 'string',
'TopicArn': 'string',
'Port': 123,
'CacheParameterGroupName': 'string',
'CacheSubnetGroupName': 'string',
'VpcId': 'string',
'AutoMinorVersionUpgrade': True|False,
'SnapshotRetentionLimit': 123,
'SnapshotWindow': 'string',
'NodeSnapshots': [
{
    'CacheNodeId': 'string',
    'CacheSize': 'string',
    'CacheNodeCreateTime': datetime(2015, 1, 1),
    'SnapshotCreateTime': datetime(2015, 1, 1)
  },
],
],
'NextToken': 'string'
}

Response Structure

- *(dict)* –

  Represents the output of a DescribeSnapshots action.

    - **Snapshots** *(list)* –

      A list of snapshots. Each item in the list contains detailed information about one snapshot.

      - *(dict)* –

        Represents a copy of an entire cache cluster as of the time when the snapshot was taken.

        - **SnapshotName** *(string)* –

          The name of a snapshot. For an automatic snapshot, the name is system-generated; for a manual snapshot, this is the user-provided name.

        - **CacheClusterId** *(string)* –

          The user-supplied identifier of the source cache cluster.

        - **SnapshotStatus** *(string)* –

          The status of the snapshot. Valid values: creating | available | restoring | copying | deleting.

        - **SnapshotSource** *(string)* –

          Indicates whether the snapshot is from an automatic backup (automated) or was created manually (manual).

        - **CacheNodeType** *(string)* –

          The name of the compute and memory capacity node type for the source cache cluster.

        Valid node types are as follows:
- General purpose: *Current generation:* cache.t2.micro, cache.t2.small, cache.t2.medium, cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
  - *Previous generation:* cache.t1.micro, cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge
- Compute optimized: cache.c1.xlarge
- Memory optimized: *Current generation:* cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge
  - *Previous generation:* cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

Notes:
- All t2 instances are created in an Amazon Virtual Private Cloud (VPC).
- Redis backup/restore is not supported for t2 instances.
- Redis Append-only files (AOF) functionality is not supported for t1 or t2 instances.

For a complete listing of cache node types and specifications, see Amazon ElastiCache Product Features and Details and Cache Node Type-Specific Parameters for Memcached or Cache Node Type-Specific Parameters for Redis.

- **Engine** *(string)* –
  - The name of the cache engine *(memcached or redis)* used by the source cache cluster.
- **EngineVersion** *(string)* –
  - The version of the cache engine version that is used by the source cache cluster.
- **NumCacheNodes** *(integer)* –
  - The number of cache nodes in the source cache cluster.
    - For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.
- **PreferredAvailabilityZone** *(string)* –
  - The name of the Availability Zone in which the source cache cluster is located.
- **CacheClusterCreateTime** *(datetime)* –
  - The date and time when the source cache cluster was created.
- **PreferredMaintenanceWindow** *(string)* –
  - Specifies the weekly time range during which maintenance on the cache cluster is performed. It is specified as a range in the format ddd:hh24:mi-ddd:hh24:mi (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for ddd are:
    - sun
    - mon
    - tue
    - wed
    - thu
· fri
· sat
Example: sun:05:00–sun:09:00
· TopicArn (string) –
The Amazon Resource Name (ARN) for the topic used by the
source cache cluster for publishing notifications.
· Port (integer) –
The port number used by each cache nodes in the source cache
cluster.
· CacheParameterGroupName (string) –
The cache parameter group that is associated with the source
cluster.
· CacheSubnetGroupName (string) –
The name of the cache subnet group associated with the
source cache cluster.
· VpcId (string) –
The Amazon Virtual Private Cloud identifier (VPC ID) of the
cache subnet group for the source cache cluster.
· AutoMinorVersionUpgrade (boolean) –
This parameter is currently disabled.
· SnapshotRetentionLimit (integer) –
For an automatic snapshot, the number of days for which
ElastiCache will retain the snapshot before deleting it.
For manual snapshots, this field reflects the SnapshotReten-
tionLimit for the source cache cluster when the snapshot was
created. This field is otherwise ignored: Manual snapshots do
not expire, and can only be deleted using the DeleteSnapshot
action.
Important If the value of SnapshotRetentionLimit is set to
zero (0), backups are turned off.
· SnapshotWindow (string) –
The daily time range during which ElastiCache takes daily
snapshots of the source cache cluster.
· NodeSnapshots (list) –
A list of the cache nodes in the source cache cluster.
· (dict) –
Represents an individual cache node in a snapshot of a cache
cluster.
· CacheNodeId (string) –
The cache node identifier for the node in the source cache
cluster.
· CacheSize (string) –
The size of the cache on the source cache node.
· CacheNodeCreateTime (datetime) –
The date and time when the cache node was created in the
source cache cluster.
- **SnapshotCreateTime** *(datetime)* –
  The date and time when the source node’s metadata and cache data set was obtained for the snapshot.

- **NextToken** *(string)* –
  A token to resume pagination.

**Waiters**

The available waiters are:

- `ElastiCache.Waiter.CacheClusterAvailable`
- `ElastiCache.Waiter.CacheClusterDeleted`
- `ElastiCache.Waiter.ReplicationGroupAvailable`
- `ElastiCache.Waiter.ReplicationGroupDeleted`

```python
class ElastiCache.Waiter.CacheClusterAvailable

waiter = client.get_waiter('cache_cluster_available')
wait(**kwargs)

Polls `ElastiCache.Client.describe_cache_clusters()` every 30 seconds until a successful state is reached. An error is returned after 60 failed checks.
```

**Request Syntax**

```python
waiter.wait({
    CacheClusterId='string',
    MaxRecords=123,
    Marker='string',
    ShowCacheNodeInfo=True|False
})
```

**Parameters**

- **CacheClusterId** *(string)* – The user-supplied cluster identifier. If this parameter is specified, only information about that specific cache cluster is returned. This parameter isn’t case sensitive.
- **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a marker is included in the response so that the remaining results can be retrieved.
  Default: 100
  Constraints: minimum 20; maximum 100.
- **Marker** *(string)* – An optional marker returned from a prior request. Use this marker for pagination of results from this action. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.
- **ShowCacheNodeInfo** *(boolean)* – An optional flag that can be included in the `DescribeCacheCluster` request to retrieve information about the individual cache nodes.

**Returns** None

3.1. Services
class ElastiCache.Waiter.CacheClusterDeleted

waiter = client.get_waiter('cache_cluster_deleted')

wait(**kwargs)
    Polls ElastiCache.Client.describe_cache_clusters() every 30 seconds until a successful state is reached. An error is returned after 60 failed checks.

Request Syntax

waiter.wait(
    CacheClusterId='string',
    MaxRecords=123,
    Marker='string',
    ShowCacheNodeInfo=True|False
)

Parameters

- **CacheClusterId** *(string)* – The user-supplied cluster identifier. If this parameter is specified, only information about that specific cache cluster is returned. This parameter isn’t case sensitive.
- **MaxRecords** *(integer)* – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a marker is included in the response so that the remaining results can be retrieved.

    Default: 100

    Constraints: minimum 20; maximum 100.
- **Marker** *(string)* – An optional marker returned from a prior request. Use this marker for pagination of results from this action. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.
- **ShowCacheNodeInfo** *(boolean)* – An optional flag that can be included in the DescribeCacheCluster request to retrieve information about the individual cache nodes.

Returns None

class ElastiCache.Waiter.ReplicationGroupAvailable

waiter = client.get_waiter('replication_group_available')

wait(**kwargs)
    Polls ElastiCache.Client.describe_replication_groups() every 30 seconds until a successful state is reached. An error is returned after 60 failed checks.

Request Syntax

waiter.wait(
    ReplicationGroupId='string',
    MaxRecords=123,
    Marker='string'
)

Parameters

- **ReplicationGroupId** *(string)* – The user-supplied replication group identifier. If this parameter is specified, only information about that specific replication group is returned. This parameter isn’t case sensitive.
• **ReplicationGroupId** (*string*) – The identifier for the replication group to be described. This parameter is not case sensitive.

  If you do not specify this parameter, information about all replication groups is returned.

• **MaxRecords** (*integer*) – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a marker is included in the response so that the remaining results can be retrieved.

  Default: 100

  Constraints: minimum 20; maximum 100.

• **Marker** (*string*) – An optional marker returned from a prior request. Use this marker for pagination of results from this action. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

  Returns  None

```python
class ElastiCache.Waiter.ReplicationGroupDeleted

waiter = client.get_waiter('replication_group_deleted')

wait(**kwargs)
  Polls ElastiCache.Client.describe_replication_groups() every 30 seconds until a successful state is reached. An error is returned after 60 failed checks.

Request Syntax

```python
waiter.wait{
  ReplicationGroupId='string',
  MaxRecords=123,
  Marker='string'
}
```

Parameters

• **ReplicationGroupId** (*string*) – The identifier for the replication group to be described. This parameter is not case sensitive.

  If you do not specify this parameter, information about all replication groups is returned.

• **MaxRecords** (*integer*) – The maximum number of records to include in the response. If more records exist than the specified MaxRecords value, a marker is included in the response so that the remaining results can be retrieved.

  Default: 100

  Constraints: minimum 20; maximum 100.

• **Marker** (*string*) – An optional marker returned from a prior request. Use this marker for pagination of results from this action. If this parameter is specified, the response includes only records beyond the marker, up to the value specified by MaxRecords.

  Returns  None

ElasticBeanstalk

3.1. Services
Boto3 Documentation, Release 1.1.4

Table of Contents

- ElasticBeanstalk
  - Client
  - Paginators

Client

class ElasticBeanstalk.Client

A low-level client representing AWS Elastic Beanstalk:

```python
import boto3

client = boto3.client('elasticbeanstalk')
```

These are the available methods:

- `abort_environment_update()`
- `can_paginate()`
- `check_dns_availability()`
- `create_application()`
- `create_application_version()`
- `create_configuration_template()`
- `create_environment()`
- `create_storage_location()`
- `delete_application()`
- `delete_application_version()`
- `delete_configuration_template()`
- `delete_environment_configuration()`
- `describe_application_versions()`
- `describe_applications()`
- `describe_configuration_options()`
- `describe_configuration_settings()`
- `describe_environment_health()`
- `describe_environment_resources()`
- `describe_environments()`
- `describe_events()`
- `describe_instances_health()`
- `generate_presigned_url()`
- `get_paginator()`
- `get_waiter()`
- `list_available_solution_stacks()`
- `rebuild_environment()`
- `request_environment_info()`
- `restart_app_server()`
- `retrieve_environment_info()`
- `swap_environment_cnames()`
- `terminate_environment()`
- `update_application()`
- `update_application_version()`
- `update_configuration_template()`
- `update_environment()`
- `validate_configuration_settings()`
**abort_environment_update(**kwargs)**

Cancels in-progress environment configuration update or application version deployment.

**Request Syntax**

```python
def abort_environment_update(kwargs)
    response = client.abort_environment_update(
        EnvironmentId='string',
        EnvironmentName='string'
    )
```

**Parameters**

- **EnvironmentId** (*string*)
  - This specifies the ID of the environment with the in-progress update that you want to cancel.

- **EnvironmentName** (*string*)
  - This specifies the name of the environment with the in-progress update that you want to cancel.

**Returns**

None

**can_paginate(operation_name)**

Check if an operation can be paginated.

**Parameters**

- **operation_name** (*string*)
  - The operation name. This is the same name as the method name on the client. For example, if the method name is `create_foo`, and you'd normally invoke the operation as `client.create_foo(**kwargs)`, if the `create_foo` operation can be paginated, you can use the call `client.get_paginators('create_foo')`.

**Returns**

`True` if the operation can be paginated, `False` otherwise.

**check_dns_availability(**kwargs)**

Checks if the specified CNAME is available.

**Request Syntax**

```python
def check_dns_availability(kwargs)
    response = client.check_dns_availability(
        CNAMEPrefix='string'
    )
```

**Parameters**

- **CNAMEPrefix** (*string*) – [REQUIRED]
  - The prefix used when this CNAME is reserved.

**Return type**

`dict`

**Returns**

**Response Syntax**

```python
{
    'Available': True|False,
    'FullyQualifiedCNAME': 'string'
}
```

**Response Structure**

- **(dict)**
  - Indicates if the specified CNAME is available.
    - **Available** (*boolean*)
      - Indicates if the specified CNAME is available:
        - `true`: The CNAME is available.
        - `false`: The CNAME is not available.
        - `true`: The CNAME is available.
false: The CNAME is not available.

- FullyQualifiedCNAME (string)
  The fully qualified CNAME to reserve when CreateEnvironment is called with the provided prefix.

create_application(**kwargs)
Creates an application that has one configuration template named default and no application versions.

Request Syntax

response = client.create_application(
  ApplicationName='string',
  Description='string'
)

Parameters

- ApplicationName (string) – [REQUIRED]
  The name of the application.
  
  Constraint: This name must be unique within your account. If the specified name already exists, the action returns an InvalidParameterValue error.

- Description (string) – Describes the application.

Returns

dict

Response Syntax

{
  'Application': {
    'ApplicationName': 'string',
    'Description': 'string',
    'DateCreated': datetime(2015, 1, 1),
    'DateUpdated': datetime(2015, 1, 1),
    'Versions': [{
      'string',
    },
    'ConfigurationTemplates': [{
      'string',
    }]
  }
}

Response Structure

- (dict) – Result message containing a single description of an application.

  - Application (dict) – The ApplicationDescription of the application.
    - ApplicationName (string) – The name of the application.
    - Description (string) – User-defined description of the application.
    - DateCreated (datetime) – The date when the application was created.
create_application_version(**kwargs)

Creates an application version for the specified application.

**Note:** Once you create an application version with a specified Amazon S3 bucket and key location, you cannot change that Amazon S3 location. If you change the Amazon S3 location, you receive an exception when you attempt to launch an environment from the application version.

**Request Syntax**

```python
response = client.create_application_version(
    ApplicationName='string',
    VersionLabel='string',
    Description='string',
    SourceBundle={
        'S3Bucket': 'string',
        'S3Key': 'string'
    },
    AutoCreateApplication=True|False
)
```

**Parameters**

- **ApplicationName (string) – [REQUIRED]**
  
  The name of the application. If no application is found with this name, and AutoCreateApplication is false, returns an InvalidParameterValue error.

- **VersionLabel (string) – [REQUIRED]**
  
  A label identifying this version.
  
  Constraint: Must be unique per application. If an application version already exists with this label for the specified application, AWS Elastic Beanstalk returns an InvalidParameterValue error.

- **Description (string) –**
  
  Describes this version.

- **SourceBundle (dict) –**
  
  The Amazon S3 bucket and key that identify the location of the source bundle for this version.
  
  If data found at the Amazon S3 location exceeds the maximum allowed source bundle size, AWS Elastic Beanstalk returns an InvalidParameterValue error. The maximum size allowed is 512 MB.
  
  Default: If not specified, AWS Elastic Beanstalk uses a sample application. If only partially specified (for example, a bucket is provided but not the key) or if no data is found at the Amazon S3 location, AWS Elastic Beanstalk returns an InvalidParameterCombination error.
- **S3Bucket** *(string)* –
  The Amazon S3 bucket where the data is located.

- **S3Key** *(string)* –
  The Amazon S3 key where the data is located.

**AutoCreateApplication** *(boolean)* – Determines how the system behaves if the specified application for this version does not already exist:

  - **true**: Automatically creates the specified application for this version if it does not already exist.
  
    - **false**: Throws an `InvalidParameterValue` if the specified application for this version does not already exist.

  - **true**: Automatically creates the specified application for this release if it does not already exist.
  
    - **false**: Returns an `InvalidParameterValue` if the specified application for this release does not already exist.

  Default: **false**

  Valid Values: **true | false**

**Return type**  
`dict`

**Returns**

**Response Syntax**

```json
{
  "ApplicationVersion": {
    "ApplicationName": 'string',
    "Description": 'string',
    "VersionLabel": 'string',
    "SourceBundle": {
      "S3Bucket": 'string',
      "S3Key": 'string'
    },
    "DateCreated": datetime(2015, 1, 1),
    "DateUpdated": datetime(2015, 1, 1)
  }
}
```

**Response Structure**

- **(dict)** –
  Result message wrapping a single description of an application version.

  - **ApplicationVersion** *(dict)* –
    The ApplicationVersionDescription of the application version.

      - **ApplicationName** *(string)* –
        The name of the application associated with this release.

      - **Description** *(string)* –
        The description of this application version.

      - **VersionLabel** *(string)* –
        A label uniquely identifying the version for the associated application.

      - **SourceBundle** *(dict)* –
        The location where the source bundle is located for this version.
create_configuration_template(**kwargs)

Creates a configuration template. Templates are associated with a specific application and are used to deploy different versions of the application with the same configuration settings.

**Related Topics**
- DescribeConfigurationOptions
- DescribeConfigurationSettings
- ListAvailableSolutionStacks

**Request Syntax**

```python
response = client.create_configuration_template(
    ApplicationName='string',
   TemplateName='string',
    SolutionStackName='string',
    SourceConfiguration={
        'ApplicationName': 'string',
        'TemplateName': 'string',
    },
    EnvironmentId='string',
    Description='string',
    OptionSettings=[
        {
            'ResourceName': 'string',
            'Namespace': 'string',
            'OptionName': 'string',
            'Value': 'string',
        },
    ],
)
```

**Parameters**

- **ApplicationName (string) – [REQUIRED]**
  
The name of the application to associate with this configuration template. If no application is found with this name, AWS Elastic Beanstalk returns an InvalidParameterValue error.

- **TemplateName (string) – [REQUIRED]**
  
The name of the configuration template.

  Constraint: This name must be unique per application.

  Default: If a configuration template already exists with this name, AWS Elastic Beanstalk returns an InvalidParameterValue error.

- **SolutionStackName (string) –**
  
The name of the solution stack used by this configuration. The solution stack specifies the operating system, architecture, and application server for a configuration template. It determines the set of configuration options as well as the possible and default values.
Use ListAvailableSolutionStacks to obtain a list of available solution stacks.

A solution stack name or a source configuration parameter must be specified, otherwise AWS Elastic Beanstalk returns an InvalidParameterValue error.

If a solution stack name is not specified and the source configuration parameter is specified, AWS Elastic Beanstalk uses the same solution stack as the source configuration template.

- **SourceConfiguration** (dict) – If specified, AWS Elastic Beanstalk uses the configuration values from the specified configuration template to create a new configuration.

Values specified in the OptionSettings parameter of this call overrides any values obtained from the SourceConfiguration.

If no configuration template is found, returns an InvalidParameterValue error.

Constraint: If both the solution stack name parameter and the source configuration parameters are specified, the solution stack of the source configuration template must match the specified solution stack name or else AWS Elastic Beanstalk returns an InvalidParameterCombination error.

- **ApplicationName** (string) – The name of the application associated with the configuration.
- **TemplateName** (string) – The name of the configuration template.
- **EnvironmentId** (string) – The ID of the environment used with this configuration template.
- **Description** (string) – Describes this configuration.
- **OptionSettings** (list) – If specified, AWS Elastic Beanstalk sets the specified configuration option to the requested value. The new value overrides the value obtained from the solution stack or the source configuration template.

  - (dict) – A specification identifying an individual configuration option along with its current value. For a list of possible option values, go to Option Values in the AWS Elastic Beanstalk Developer Guide.

    - **ResourceName** (string) – A unique resource name for a time-based scaling configuration option.
    - **Namespace** (string) – A unique namespace identifying the option’s associated AWS resource.
    - **OptionName** (string) – The name of the configuration option.
    - **Value** (string) – The current value for the configuration option.

**Return type** dict

**Returns**

**Response Syntax**

```json
{
    'SolutionStackName': 'string',
    'ApplicationName': 'string',
    'TemplateName': 'string',
    'Description': 'string',
    'EnvironmentName': 'string',
    'DeploymentStatus': 'deployed'|'pending'|'failed',
    'DateCreated': datetime(2015, 1, 1),
    'DateUpdated': datetime(2015, 1, 1),
    'OptionSettings': [
        {
            'ResourceName': 'string',
            'Namespace': 'string',
            'OptionName': 'string',
            'Value': 'string'
        },
    ],
}
```
